## Preface

This book belongs to a series of online books summarizing the recent state Topological Geometrodynamics (TGD) and its applications. TGD can be regarded as a unified theory of fundamental interactions but is not the kind of unified theory as so called GUTs constructed by graduate students at seventies and eighties using detailed recipes for how to reduce everything to group theory. Nowadays this activity has been completely computerized and it probably takes only a few hours to print out the predictions of this kind of unified theory as an article in the desired format. TGD is something different and I am not ashamed to confess that I have devoted the last 32 years of my life to this enterprise and am still unable to write The Rules.

I got the basic idea of Topological Geometrodynamics (TGD) during autumn 1978, perhaps it was October. What I realized was that the representability of physical space-times as 4-dimensional surfaces of some higher-dimensional space-time obtained by replacing the points of Minkowski space with some very small compact internal space could resolve the conceptual difficulties of general relativity related to the definition of the notion of energy. This belief was too optimistic and only with the advent of what I call zero energy ontology the understanding of the notion of Poincare invariance has become satisfactory.

It soon became clear that the approach leads to a generalization of the notion of space-time with particles being represented by space-time surfaces with finite size so that TGD could be also seen as a generalization of the string model. Much later it became clear that this generalization is consistent with conformal invariance only if space-time is 4-dimensional and the Minkowski space factor of imbedding space is 4-dimensional.

It took some time to discover that also the geometrization of also gauge interactions and elementary particle quantum numbers could be possible in this framework: it took two years to find the unique internal space providing this geometrization involving also the realization that family replication phenomenon for fermions has a natural topological explanation in TGD framework and that the symmetries of the standard model symmetries are much more profound than pragmatic TOE builders have believed them to be. If TGD is correct, main stream particle physics chose the wrong track leading to the recent deep crisis when people decided that quarks and leptons belong to same multiplet of the gauge group implying instability of proton.

There have been also longstanding problems.

- Gravitational energy is well-defined in cosmological models but is not conserved. Hence the conservation of the inertial energy does not seem to be consistent with the Equivalence Principle. Furthermore, the imbeddings of Robertson-Walker cosmologies turned out to be vacuum extremals with respect to the inertial energy. About 25 years was needed to realize that the sign of the inertial energy can be also negative and in cosmological scales the density of inertial energy vanishes: physically acceptable universes are creatable from vacuum. Eventually this led to the notion of zero energy ontology which deviates dramatically from the standard ontology being however consistent with the crossing symmetry of quantum field theories. In this framework the quantum numbers are assigned with zero energy states located at the boundaries of so called causal diamonds defined as intersections of future and past directed light-cones. The notion of energy-momentum becomes length scale dependent since one has a scale hierarchy for causal diamonds. This allows to understand the non-conservation of energy as apparent. Equivalence Principle generalizes and has a formulation in terms of coset representations of Super-Virasoro algebras providing also a justification for p-adic thermodynamics.
- From the beginning it was clear that the theory predicts the presence of long ranged classical electro-weak and color gauge fields and that these fields necessarily accompany classical electromagnetic fields. It took about 26 years to gain the maturity to admit the obvious: these fields are classical correlates for long range color and weak interactions assignable to dark matter. The only possible conclusion is that TGD physics is a fractal consisting of an entire hierarchy of fractal copies of standard model physics. Also the understanding of electro-weak massivation and screening of weak charges has been a long standing problem, and 32 years was needed to discover that what I call weak form of electric-magnetic duality gives a satisfactory solution of the problem and provides also surprisingly powerful insights to the mathematical structure of quantum TGD.

I started the serious attempts to construct quantum TGD after my thesis around 1982. The original optimistic hope was that path integral formalism or canonical quantization might be enough to construct the quantum theory but the first discovery made already during first year of TGD was that these formalisms might be useless due to the extreme non-linearity and enormous vacuum degeneracy of the theory. This turned out to be the case.

- It took some years to discover that the only working approach is based on the generalization of Einstein's program. Quantum physics involves the geometrization of the infinite-dimensional "world of classical worlds" (WCW) identified as 3-dimensional surfaces. Still few years had to pass before I understood that general coordinate invariance leads to a more or less unique solution of the problem and implies that space-time surfaces are analogous to Bohr orbits. Still a couple of years and I discovered that quantum states of the Universe can be identified as classical spinor fields in WCW. Only quantum jump remains the genuinely quantal aspect of quantum physics.
- During these years TGD led to a rather profound generalization of the space-time concept. Quite general properties of the theory led to the notion of many-sheeted space-time with sheets representing physical subsystems of various sizes. At the beginning of 90s I became dimly aware of the importance of p-adic number fields and soon ended up with the idea that p-adic thermodynamics for a conformally invariant system allows to understand elementary particle massivation with amazingly few input assumptions. The attempts to understand p-adicity from basic principles led gradually to the vision about physics as a generalized number theory as an approach complementary to the physics as an infinite-dimensional spinor geometry of WCW approach. One of its elements was a generalization of the number concept obtained by fusing real numbers and various p-adic numbers along common rationals. The number theoretical trinity involves besides p-adic number fields also quaternions and octonions and the notion of infinite prime.
- TGD inspired theory of consciousness entered the scheme after 1995 as I started to write a book about consciousness. Gradually it became difficult to say where physics ends and consciousness theory begins since consciousness theory could be seen as a generalization of quantum measurement theory by identifying quantum jump as a moment of consciousness and by replacing the observer with the notion of self identified as a system which is conscious as long as it can avoid entanglement with environment. "Everything is conscious and consciousness can be only lost" summarizes the basic philosophy neatly. The idea about p-adic physics as physics of cognition and intentionality emerged also rather naturally and implies perhaps the most dramatic generalization of the space-time concept in which most points of p-adic space-time sheets are infinite in real sense and the projection to the real imbedding space consists of discrete set of points. One of the most fascinating outcomes was the observation that the entropy based on p-adic norm can be negative. This observation led to the vision that life can be regarded as something in the intersection of real and p-adic worlds. Negentropic entanglement has interpretation as a correlate for various positively colored aspects of conscious experience and means also the possibility of strongly correlated states stable under state function reduction and different from the conventional bound states and perhaps playing key role in the energy metabolism of living matter.
- One of the latest threads in the evolution of ideas is only slightly more than six years old. Learning about the paper of Laurent Nottale about the possibility to identify planetary orbits as Bohr orbits with a gigantic value of gravitational Planck constant made once again possible to see the obvious. Dynamical quantized Planck constant is strongly suggested by quantum classical correspondence and the fact that space-time sheets identifiable as quantum coherence regions can have arbitrarily large sizes. During summer 2010 several new insights about the mathematical structure and interpretation of TGD emerged. One of these insights was the realization that the postulated hierarchy of Planck constants might follow from the basic structure of quantum TGD. The point is that due to the extreme non-linearity of the classical action principle the correspondence between canonical momentum densities and time derivatives of the imbedding space coordinates is one-to-many and the natural description of the situation is in terms of local singular covering spaces of the imbedding space. One could speak about effective value of Planck

constant coming as a multiple of its minimal value. The implications of the hierarchy of Planck constants are extremely far reaching so that the significance of the reduction of this hierarchy to the basic mathematical structure distinguishing between TGD and competing theories cannot be under-estimated.

From the point of view of particle physics the ultimate goal is of course a practical construction recipe for the S-matrix of the theory. I have myself regarded this dream as quite too ambitious taking into account how far reaching re-structuring and generalization of the basic mathematical structure of quantum physics is required. It has indeed turned out that the dream about explicit formula is unrealistic before one has understood what happens in quantum jump. Symmetries and general physical principles have turned out to be the proper guide line here. To give some impressions about what is required some highlights are in order.

- With the emergence of zero energy ontology the notion of S-matrix was replaced with M-matrix which can be interpreted as a complex square root of density matrix representable as a diagonal and positive square root of density matrix and unitary S-matrix so that quantum theory in zero energy ontology can be said to define a square root of thermodynamics at least formally.
- A decisive step was the strengthening of the General Coordinate Invariance to the requirement that the formulations of the theory in terms of light-like 3-surfaces identified as 3-surfaces at which the induced metric of space-time surfaces changes its signature and in terms of space-like 3-surfaces are equivalent. This means effective 2-dimensionality in the sense that partonic 2-surfaces defined as intersections of these two kinds of surfaces plus 4-D tangent space data at partonic 2-surfaces code for the physics. Quantum classical correspondence requires the coding of the quantum numbers characterizing quantum states assigned to the partonic 2-surfaces to the geometry of space-time surface. This is achieved by adding to the modified Dirac action a measurement interaction term assigned with light-like 3-surfaces.
- The replacement of strings with light-like 3-surfaces equivalent to space-like 3-surfaces means enormous generalization of the super conformal symmetries of string models. A further generalization of these symmetries to non-local Yangian symmetries generalizing the recently discovered Yangian symmetry of  $\mathcal{N} = 4$  supersymmetric Yang-Mills theories is highly suggestive. Here the replacement of point like particles with partonic 2-surfaces means the replacement of conformal symmetry of Minkowski space with infinite-dimensional super-conformal algebras. Yangian symmetry provides also a further refinement to the notion of conserved quantum numbers allowing to define them for bound states using non-local energy conserved currents.
- A further attractive idea is that quantum TGD reduces to almost topological quantum field theory. This is possible if the Kähler action for the preferred extremals defining WCW Kähler function reduces to a 3-D boundary term. This takes place if the conserved currents are so called Beltrami fields with the defining property that the coordinates associated with flow lines extend to single global coordinate variable. This ansatz together with the weak form of electric-magnetic duality reduces the Kähler action to Chern-Simons term with the condition that the 3-surfaces are extremals of Chern-Simons action subject to the constraint force defined by the weak form of electric magnetic duality. It is the latter constraint which prevents the trivialization of the theory to a topological quantum field theory. Also the identification of the Kähler function of WCW as Dirac determinant finds support as well as the description of the scattering amplitudes in terms of braids with interpretation in terms of finite measurement resolution coded to the basic structure of the solutions of field equations.
- In standard QFT Feynman diagrams provide the description of scattering amplitudes. The beauty of Feynman diagrams is that they realize unitarity automatically via the so called Cutkosky rules. In contrast to Feynman's original beliefs, Feynman diagrams and virtual particles are taken only as a convenient mathematical tool in quantum field theories. QFT approach is however plagued by UV and IR divergences and one must keep mind open for the possibility that a genuine progress might mean opening of the black box of the virtual particle.

In TGD framework this generalization of Feynman diagrams indeed emerges unavoidably. Light-like 3-surfaces replace the lines of Feynman diagrams and vertices are replaced by 2-D partonic

2-surfaces. Zero energy ontology and the interpretation of parton orbits as light-like "wormhole throats" suggests that virtual particles do not differ from on mass shell particles only in that the four- and three- momenta of wormhole throats fail to be parallel. The two throats of the wormhole defining virtual particle would contact carry on mass shell quantum numbers but for virtual particles the four-momenta need not be parallel and can also have opposite signs of energy. Modified Dirac equation suggests a number theoretical quantization of the masses of the virtual particles. The kinematic constraints on the virtual momenta are extremely restrictive and reduce the dimension of the sub-space of virtual momenta and if massless particles are not allowed (IR cutoff provided by zero energy ontology naturally), the number of Feynman diagrams contributing to a particular kind of scattering amplitude is finite and manifestly UV and IR finite and satisfies unitarity constraint in terms of Cutkosky rules. What is remarkable that fermionic propagators are massless propagators but for on mass shell four-momenta. This gives a connection with the twistor approach and inspires the generalization of the Yangian symmetry to infinite-dimensional super-conformal algebras.

What I have said above is strongly biased view about the recent situation in quantum TGD and I have left all about applications to the introductions of the books whose purpose is to provide a bird's eye view about TGD as it is now. This vision is single man's view and doomed to contain unrealistic elements as I know from experience. My dream is that young critical readers could take this vision seriously enough to try to demonstrate that some of its basic premises are wrong or to develop an alternative based on these or better premises. I must be however honest and tell that 32 years of TGD is a really vast bundle of thoughts and quite a challenge for anyone who is not able to cheat himself by taking the attitude of a blind believer or a light-hearted debunker trusting on the power of easy rhetoric tricks.

## Acknowledgements

Neither TGD nor these books would exist without the help and encouragement of many people. The friendship with Heikki and Raija Haila and their family have kept me in contact with the everyday world and without this friendship I would not have survived through these lonely 32 years most of which I have remained unemployed as a scientific dissident. I am happy that my children have understood my difficult position and like my friends have believed that what I am doing is something valuable although I have not received any official recognition for it.

During last decade Tapio Tammi has helped me quite concretely by providing the necessary computer facilities and being one of the few persons in Finland with whom to discuss about my work. I have had also stimulating discussions with Samuli Penttinen who has also helped to get through the economical situations in which there seemed to be no hope. The continual updating of fifteen online books means quite a heavy bureaucracy at the level of bits and without a systemization one ends up with endless copying and pasting and internal consistency is soon lost. Pekka Rapinoja has offered his help in this respect and I am especially grateful for him for my Python skills. Also Matti Vallinkoski has helped me in computer related problems.

The collaboration with Lian Sidoroff was extremely fruitful and she also helped me to survive economically through the hardest years. The participation to CASYS conferences in Liege has been an important window to the academic world and I am grateful for Daniel Dubois and Peter Marcer for making this participation possible. The discussions and collaboration with Eduardo de Luna and Istvan Dienes stimulated the hope that the communication of new vision might not be a mission impossible after all. Also blog discussions have been very useful. During these years I have received innumerable email contacts from people around the world. In particular, I am grateful for Mark McWilliams and Ulla Matfolk for providing links to possibly interesting web sites and articles. These contacts have helped me to avoid the depressive feeling of being some kind of Don Quixote of Science and helped me to widen my views: I am grateful for all these people.

In the situation in which the conventional scientific communication channels are strictly closed it is important to have some loop hole through which the information about the work done can at

---

least in principle leak to the publicity through the iron wall of the academic censorship. Without any exaggeration I can say that without the world wide web I would not have survived as a scientist nor as individual. Homepage and blog are however not enough since only the formally published result is a result in recent day science. Publishing is however impossible without a direct support from power holders- even in archives like arXiv.org.

Situation changed for five years ago as Andrew Adamatsky proposed the writing of a book about TGD when I had already got used to the thought that my work would not be published during my life time. The Prespacetime Journal and two other journals related to quantum biology and consciousness - all of them founded by Huping Hu - have provided this kind of loop holes. In particular, Dainis Zeps, Phil Gibbs, and Arkadiusz Jadczyk deserve my gratitude for their kind help in the preparation of an article series about TGD catalyzing a considerable progress in the understanding of quantum TGD. Also the viXra archive founded by Phil Gibbs and its predecessor Archive Freedom have been of great help: Victor Christianto deserves special thanks for doing the hard work needed to run Archive Freedom. Also the Neuroquantology Journal founded by Sultan Tarlaci deserves a special mention for its publication policy. And last but not least: there are people who experience as a fascinating intellectual challenge to spoil the practical working conditions of a person working with something which might be called unified theory: I am grateful for the people who have helped me to survive through the virus attacks, an activity which has taken roughly one month per year during the last half decade and given a strong hue of grey to my hair.

For a person approaching his sixty year birthday it is somewhat easier to overcome the hard feelings due to the loss of academic human rights than for an inpatient youngster. Unfortunately the economic situation has become increasingly difficult during the twenty years after the economic depression in Finland which in practice meant that Finland ceased to be a constitutional state in the strong sense of the word. It became possible to depose people like me from the society without fear about public reactions and the classification as dropout became a convenient tool of ridicule to circumvent the ethical issues. During last few years when the right wing has held the political power this trend has been steadily strengthening. In this kind of situation the concrete help from individuals has been and will be of utmost importance. Against this background it becomes obvious that this kind of work is not possible without the support from outside and I apologize for not being able to mention all the people who have helped me during these years.

<b>1</b>	<b>Introduction</b>	<b>1</b>
1.1	Background . . . . .	1
1.2	Basic Ideas of TGD . . . . .	2
1.2.1	TGD as a Poincare invariant theory of gravitation . . . . .	2
1.2.2	TGD as a generalization of the hadronic string model . . . . .	2
1.2.3	Fusion of the two approaches via a generalization of the space-time concept . . . . .	2
1.3	The threads in the development of quantum TGD . . . . .	3
1.3.1	Quantum TGD as spinor geometry of World of Classical Worlds . . . . .	3
1.3.2	TGD as a generalized number theory . . . . .	5
1.3.3	Hierarchy of Planck constants and dark matter hierarchy . . . . .	8
1.3.4	TGD as a generalization of physics to a theory consciousness . . . . .	9
1.4	Bird's eye of view about the topics of the book . . . . .	14
1.5	The contents of the book . . . . .	17
1.5.1	Part I: General Theory . . . . .	17
1.5.2	Part II: Twistors, Bosonic Emergence, Space-time Supersymmetry . . . . .	26
1.5.3	Part III: Hyper-Finite Factors of Type II and Hierarchy of Planck Constants . . . . .	30
<b>I</b>	<b>GENERAL THEORY</b>	<b>49</b>
<b>2</b>	<b>Basic Extremals of the Kähler Action</b>	<b>51</b>
2.1	Introduction . . . . .	51
2.1.1	General considerations . . . . .	51
2.1.2	In what sense field equations mimic dissipative dynamics? . . . . .	52
2.1.3	The dimension of $CP_2$ projection as classifier for the fundamental phases of matter . . . . .	52
2.1.4	Specific extremals of Kähler action . . . . .	53
2.1.5	The weak form of electric-magnetic duality and modification of Kähler action . . . . .	53
2.2	General considerations . . . . .	54
2.2.1	Number theoretical compactification and $M^8 - H$ duality . . . . .	54
2.2.2	The exponent of Kähler function as Dirac determinant for the modified Dirac action . . . . .	56
2.2.3	Preferred extremal property as classical correlate for quantum criticality, holography, and quantum classical correspondence . . . . .	57
2.2.4	Can one determine experimentally the shape of the space-time surface? . . . . .	59
2.3	General view about field equations . . . . .	61
2.3.1	Field equations . . . . .	61
2.3.2	Topologization and light-likeness of the Kähler current as alternative manners to guarantee vanishing of Lorentz 4-force . . . . .	62
2.3.3	How to satisfy field equations? . . . . .	67
2.3.4	$D_{CP_2} = 3$ phase allows infinite number of topological charges characterizing the linking of magnetic field lines . . . . .	77
2.3.5	Preferred extremal property and the topologization/light-likeness of Kähler current? . . . . .	78
2.3.6	Generalized Beltrami fields and biological systems . . . . .	79
2.3.7	About small perturbations of field equations . . . . .	83

2.4	Vacuum extremals . . . . .	86
2.4.1	$CP_2$ type extremals . . . . .	86
2.4.2	Vacuum extremals with vanishing Kähler field . . . . .	90
2.5	Non-vacuum extremals . . . . .	91
2.5.1	Cosmic strings . . . . .	91
2.5.2	Massless extremals . . . . .	91
2.5.3	Generalization of the solution ansatz defining massless extremals (MEs) . . . . .	92
2.5.4	Maxwell phase . . . . .	96
2.5.5	Stationary, spherically symmetric extremals . . . . .	97
2.5.6	Maxwell hydrodynamics as a toy model for TGD . . . . .	104
2.6	Weak form electric-magnetic duality and its implications . . . . .	107
2.6.1	Could a weak form of electric-magnetic duality hold true? . . . . .	109
2.6.2	Magnetic confinement, the short range of weak forces, and color confinement . . . . .	113
2.6.3	Could Quantum TGD reduce to almost topological QFT? . . . . .	117
2.6.4	Kähler action for Euclidian regions as Kähler function and Kähler action for Minkowskian regions as Morse function? . . . . .	119
2.6.5	A general solution ansatz based on almost topological QFT property . . . . .	121
2.6.6	Hydrodynamic picture in fermionic sector . . . . .	124
2.6.7	Possible role of Beltrami flows and symplectic invariance in the description of gauge and gravitational interactions . . . . .	130
2.7	How to define Dirac determinant? . . . . .	132
2.7.1	Dirac determinant when the number of eigenvalues is infinite . . . . .	132
2.7.2	Hyper-octonionic primes . . . . .	134
2.7.3	Three basic options for the pseudo-momentum spectrum . . . . .	135
2.7.4	Expression for the Dirac determinant for various options . . . . .	137
2.8	An attempt to understand preferred extremals of Kähler action . . . . .	145
2.8.1	Basic ideas about preferred extremals . . . . .	146
2.8.2	What could be the construction recipe for the preferred extremals assuming $CP_2 = CP_2^{mod}$ identification? . . . . .	150
2.8.3	Could octonion analyticity solve the field equations? . . . . .	153
2.9	In what sense TGD could be an integrable theory? . . . . .	160
2.9.1	What integrable theories are? . . . . .	160
2.9.2	Why TGD could be integrable theory in some sense? . . . . .	163
2.9.3	Questions . . . . .	164
2.9.4	Could TGD be an integrable theory? . . . . .	164
<b>3</b>	<b>Construction of Quantum Theory: Symmetries</b> . . . . .	<b>187</b>
3.1	Introduction . . . . .	187
3.1.1	Physics as infinite-dimensional Kähler geometry . . . . .	187
3.1.2	p-Adic physics as physics of cognition and intentionality . . . . .	188
3.1.3	Hierarchy of Planck constants and dark matter hierarchy . . . . .	189
3.1.4	Number theoretical symmetries . . . . .	189
3.2	Symmetries . . . . .	190
3.2.1	General Coordinate Invariance and generalized quantum gravitational holography . . . . .	190
3.2.2	Light like 3-D causal determinants and effective 2-dimensionality . . . . .	191
3.2.3	Magic properties of light cone boundary and isometries of configuration space . . . . .	191
3.2.4	Symplectic transformations of $\delta M_+^4 \times CP_2$ as isometries of configuration space . . . . .	192
3.2.5	Does the symmetric space property reduce to coset construction for Super Virasoro algebras? . . . . .	193
3.2.6	What effective 2-dimensionality and holography really mean? . . . . .	193
3.2.7	About the relationship between super-symplectic and super Kac-Moody algebras . . . . .	194
3.2.8	Comparison of TGD and stringy views about super-conformal symmetries . . . . .	196
3.3	Number theoretic compactification and $M^8 - H$ duality . . . . .	199
3.3.1	Basic idea behind $M^8 - M^4 \times CP_2$ duality . . . . .	199
3.3.2	Hyper-octonionic Pauli "matrices" and modified definition of hyper-quaternionicity . . . . .	200
3.3.3	Minimal form of $M^8 - H$ duality . . . . .	201
3.3.4	Strong form of $M^8 - H$ duality . . . . .	202

3.3.5	$M^8 - H$ duality and low energy hadron physics . . . . .	208
3.3.6	The notion of number theoretical braid . . . . .	208
3.3.7	Connection with string model and Equivalence Principle at space-time level . . . . .	210
3.4	Does modified Dirac action define the fundamental action principle? . . . . .	213
3.4.1	What are the basic equations of quantum TGD? . . . . .	213
3.4.2	Quantum criticality and modified Dirac action . . . . .	214
3.4.3	Handful of problems with a common resolution . . . . .	220
3.4.4	Generalized eigenvalues of $D_{C-S}$ and General Coordinate Invariance . . . . .	229
3.5	Super-conformal symmetries at space-time and configuration space level . . . . .	229
3.5.1	Configuration space as a union of symmetric spaces . . . . .	229
3.5.2	Isometries of configuration space geometry as symplectic transformations of $\delta M_+^4 \times CP_2$ . . . . .	230
3.5.3	SUSY algebra defined by the anticommutation relations of fermionic oscillator operators and WCW local Clifford algebra elements as chiral super-fields . . . . .	232
3.5.4	Identification of Kac-Moody symmetries . . . . .	234
3.5.5	Coset space structure for configuration space as a symmetric space . . . . .	239
3.5.6	The relationship between super-symplectic and Super Kac-Moody algebras, Equivalence Principle, and justification of p-adic thermodynamics . . . . .	240
3.6	Trying to understand $N = 4$ super-conformal symmetry . . . . .	243
3.6.1	Large $N = 4$ SCA . . . . .	243
3.6.2	Overall view about how different $N = 4$ SCAs could emerge in TGD framework . . . . .	245
3.6.3	How large $N = 4$ SCA could emerge in quantum TGD? . . . . .	247
3.6.4	Relationship to super string models, M theory and WZW model . . . . .	249
3.6.5	The interpretation of the critical dimension $D = 4$ and the objection related to the signature of the space-time metric . . . . .	251
3.6.6	How could exotic Kac-Moody algebras emerge from Jones inclusions? . . . . .	253
3.6.7	Are both quark and lepton like chiralities needed/possible? . . . . .	253
3.7	Generalization of the notion of imbedding space . . . . .	257
3.7.1	Generalization of the notion of imbedding space . . . . .	257
3.7.2	Phase transitions changing the value of Planck constant . . . . .	260
3.7.3	Could the dynamics of Kähler action predict the hierarchy of Planck constants? . . . . .	260
<b>4</b>	<b>Construction of Quantum Theory: <math>M</math>-matrix</b> . . . . .	<b>283</b>
4.1	Introduction . . . . .	283
4.1.1	The recent progress in Quantum TGD and identification of $M$ -matrix . . . . .	283
4.1.2	Various inputs to the construction of $M$ -matrix . . . . .	288
4.1.3	Topics of the chapter . . . . .	292
4.2	Basic philosophical ideas . . . . .	293
4.2.1	Zero energy ontology . . . . .	293
4.2.2	The anatomy of the quantum jump . . . . .	299
4.3	Zero energy ontology and conformal invariance . . . . .	302
4.3.1	$M$ -matrix as characterizer of time-like entanglement between positive and negative energy components of zero energy state . . . . .	303
4.3.2	Feynman rules in configuration space degrees of freedom . . . . .	305
4.3.3	Rational conformal field theories and stringy scattering amplitudes . . . . .	307
4.3.4	Objection against zero energy ontology and quantum classical correspondence . . . . .	312
4.3.5	Issues related to Lorentz symmetry . . . . .	312
4.4	Are both symplectic and conformal field theories needed? . . . . .	315
4.4.1	Symplectic QFT at sphere . . . . .	315
4.4.2	Symplectic QFT with spontaneous breaking of rotational and reflection symmetries . . . . .	316
4.4.3	Generalization to quantum TGD . . . . .	317
4.5	Weak form of electric-magnetic duality and fermionic propagator . . . . .	320
4.5.1	Could Quantum TGD reduce to almost topological QFT? . . . . .	320
4.5.2	A general solution ansatz based on almost topological QFT property . . . . .	323
4.5.3	Hydrodynamic picture in fermionic sector . . . . .	326

## II TWISTORS, BOSONIC EMERGENCE, SPACE-TIME SUPERSYMMETRY 413

<b>6</b>	<b>Twistors, <math>N = 4</math> Super-Conformal Symmetry, and Quantum TGD</b>	<b>415</b>
6.1	Introduction . . . . .	415
6.1.1	Twistors and classical TGD . . . . .	416
6.1.2	Twistors and Feynman diagrams . . . . .	417
6.1.3	Massive particles and the generalization of twistors to 8-D case . . . . .	417
6.1.4	Twistors and electric-magnetic duality . . . . .	418
6.2	Could the target space be identified in terms of twistors? . . . . .	418
6.2.1	General remarks . . . . .	419
6.2.2	What twistor Fourier transform could mean in TGD framework? . . . . .	419
6.2.3	Could one define the phase factor of the twistor uniquely? . . . . .	421

6.3	Could one regard space-time surfaces as surfaces in twistor space? . . . . .	422
6.3.1	How $M^4 \times CP_2$ emerges in twistor context? . . . . .	422
6.3.2	How to identify twistorial surfaces in $PT \times CP_2$ and how to map them to $M^4 \times CP_2$ ? . . . . .	423
6.3.3	How to code the basic parameters of preferred extremals in terms of twistors? . . . . .	424
6.3.4	Hyper-quaternionic and co-hyper-quaternionic surfaces and twistor duality . . . . .	425
6.4	Could one lift Feynman diagrams to twistor space? . . . . .	425
6.4.1	The treatment of massive case in terms of twistors . . . . .	425
6.4.2	Purely twistorial formulation of Feynman graphs . . . . .	426
6.4.3	What could be the propagator in twistor space? . . . . .	428
6.4.4	What to do with the perturbation theory? . . . . .	429
6.5	Could one generalize the notion of twistor to 8-D case? . . . . .	430
6.5.1	Octo-twistors defined in terms of ordinary spinors . . . . .	430
6.5.2	Could right handed neutrino spinor modes define octo-twistors? . . . . .	431
6.5.3	Octo-twistors and modified Dirac equation . . . . .	432
6.5.4	What one really means with a virtual particle? . . . . .	438
6.6	Does weak form of electric-magnetic duality lead to a twistorial description? . . . . .	444
6.6.1	The simplest vision about how twistors might emerge from TGD . . . . .	444
6.6.2	Generalized eigen modes for the modified Chern-Simons Dirac equation and hydrodynamical picture . . . . .	446
6.6.3	Generalized Feynman diagrams at fermionic and momentum space level . . . . .	446
6.6.4	Hyper-octonionic primes . . . . .	453
6.6.5	Generalized Feynman diagrams at fermionic and momentum space level . . . . .	454
6.6.6	Three basic options for the pseudo-momentum spectrum . . . . .	457
<b>7</b>	<b>Yangian Symmetry, Twistors, and TGD</b> . . . . .	<b>481</b>
7.1	Introduction . . . . .	481
7.1.1	Background . . . . .	481
7.1.2	Yangian symmetry . . . . .	482
7.2	How to generalize Yangian symmetry in TGD framework? . . . . .	483
7.2.1	Is there any hope about description in terms of Grassmannians? . . . . .	484
7.2.2	Could zero energy ontology make possible full Yangian symmetry? . . . . .	486
7.2.3	Could Yangian symmetry provide a new view about conserved quantum numbers? . . . . .	486
7.2.4	What about the selection of preferred $M^2 \subset M^4$ ? . . . . .	487
7.2.5	Does $M^8 - H$ duality generalize the duality between twistor and momentum twistor descriptions? . . . . .	488
7.3	Some mathematical details about Grassmannian formalism . . . . .	490
7.3.1	Yangian algebra and its super counterpart . . . . .	491
7.3.2	Twistors and momentum twistors and super-symmetrization . . . . .	494
7.3.3	Brief summary of the work of Arkani-Hamed and collaborators . . . . .	497
7.3.4	The general form of Grassmannian integrals . . . . .	498
7.3.5	Canonical operations for Yangian invariants . . . . .	500
7.3.6	Explicit formula for the recursion relation . . . . .	503
7.4	Could the Grassmannian program be realized in TGD framework? . . . . .	504
7.4.1	What Yangian symmetry could mean in TGD framework? . . . . .	504
7.4.2	How to achieve Yangian invariance without trivial scattering amplitudes? . . . . .	506
7.4.3	Number theoretical constraints on the pseudo-momenta . . . . .	507
7.4.4	Could recursion formula allow interpretation in terms of zero energy ontology? . . . . .	508
7.4.5	What about unitarity? . . . . .	510
7.5	Could TGD allow formulation in terms of twistors . . . . .	511
7.5.1	$M^4 \times CP_2$ from twistor approach . . . . .	511
7.5.2	Does twistor string theory generalize to TGD? . . . . .	512
7.5.3	What is the relationship of TGD to M-theory and F-theory? . . . . .	514
7.5.4	What could the field equations be in twistorial formulation? . . . . .	515
7.6	Comparing twistor revolution with TGD revolution . . . . .	522
7.6.1	The declaration of revolution by Nima from TGD point of view . . . . .	522
7.6.2	Basic results of twistor approach from TGD point of view . . . . .	524
7.6.3	Could planar diagrams be enough in the theory transcending $\mathcal{N} = 4$ SUSY? . . . . .	526

7.6.4	Motives and twistors . . . . .	526
7.6.5	Reducing non-planar diagrams to planar ones by a generalization of algorithm for calculating knot invariants? . . . . .	527
7.6.6	Langlands duality, electric-magnetic duality, S-duality, finite measurement resolution, and quantum Yangian symmetry . . . . .	528
7.6.7	About the structure of the Yangian algebra . . . . .	530
7.7	Does the exponent of Chern-Simons action reduce to the exponent of the area of minimal surfaces? . . . . .	534
7.7.1	Why Chern-Simons action should reduce to area for minimal surfaces? . . . . .	534
7.7.2	IR cutoff and connection with p-adic physics . . . . .	535
7.7.3	Could Kähler action reduce to Kähler magnetic flux over string world sheets and partonic 2-surfaces? . . . . .	536
7.7.4	What is the interpretation of Yangian duality in TGD framework? . . . . .	537
<b>8</b>	<b>Quantum Field Theory Limit of TGD from Bosonic Emergence</b>	<b>555</b>
8.1	Introduction . . . . .	555
8.1.1	The dream . . . . .	555
8.1.2	Improved dream . . . . .	556
8.1.3	SUSY improved dream . . . . .	557
8.1.4	ZEO improved dream . . . . .	558
8.1.5	What can one conclude? . . . . .	558
8.2	Bootstrap approach to obtain a unitary S-matrix . . . . .	559
8.2.1	Quantitative realization of UV finiteness in terms of p-adic length scale hypothesis and finite measurement resolution . . . . .	559
8.2.2	A more detailed summary of Feynman diagrammatics . . . . .	566
8.2.3	Could quantum criticality fix hyperbolic cutoff uniquely? . . . . .	574
8.3	Calculation of the bosonic propagator . . . . .	575
8.3.1	The basic integrals . . . . .	575
8.3.2	How to avoid generation of mass term? . . . . .	576
8.3.3	Explicit form of the integrals . . . . .	577
8.3.4	k-integration for the principal value parts of the integrals . . . . .	579
8.3.5	Numerical calculation of the integrals over the hyperbolic angle . . . . .	582
8.3.6	The evolution of $1/\alpha_{em}(p)$ for given IR cutoff for loop momenta . . . . .	592
8.4	How quantum criticality could predict the evolution of hyperbolic cutoff? . . . . .	595
8.4.1	Summary about how ideas about quantum criticality have evolved . . . . .	595
8.4.2	Searching for the solutions of criticality conditions . . . . .	597
8.4.3	Could p-adic fractality solve the problems? . . . . .	604
8.5	Further progress . . . . .	612
8.5.1	Could supersymmetry make momentum cutoffs un-necessary? . . . . .	612
8.5.2	Generalized Feynman diagrams at fermionic and momentum space level . . . . .	615
<b>9</b>	<b>Does the QFT Limit of TGD Have Space-Time Super-Symmetry?</b>	<b>637</b>
9.1	Introduction . . . . .	637
9.2	SUSY briefly . . . . .	640
9.2.1	Weyl fermions . . . . .	641
9.2.2	SUSY algebras . . . . .	641
9.2.3	Super-space . . . . .	643
9.2.4	Non-renormalization theorems . . . . .	646
9.3	Does TGD allow the counterpart of space-time super-symmetry? . . . . .	647
9.3.1	Basic data bits . . . . .	647
9.3.2	Could one generalize super-symmetry? . . . . .	648
9.3.3	Modified Dirac equation briefly . . . . .	648
9.3.4	TGD counterpart of space-time super-symmetry . . . . .	649
9.3.5	Experimental indication for space-time super-symmetry . . . . .	650
9.4	Octo-twistors and modified Dirac equation . . . . .	651
9.4.1	The replacement of $SO(7,1)$ with $G_2$ . . . . .	653
9.4.2	Octonionic counterpart of the modified Dirac equation . . . . .	655

9.4.3	Could the notion of octo-twistor make sense? . . . . .	658
9.5	SUSY algebra of fermionic oscillator operators and WCW local Clifford algebra elements as super-fields . . . . .	659
9.5.1	Super-algebra associated with the modified gamma matrices . . . . .	660
9.5.2	Super-fields associated with WCW Clifford algebra . . . . .	661
9.6	SUSY algebra at QFT limit . . . . .	662
9.6.1	Minimum information about space-time sheet and particle quantum numbers needed to formulate SUSY algebra . . . . .	663
9.6.2	The physical picture behind the realization of SUSY algebra at point like limit . . . . .	663
9.6.3	Explicit form of the SUSY algebra at QFT limit . . . . .	665
9.6.4	How the representations of SUSY in TGD differ from the standard representations? . . . . .	666
9.7	Super-symmetric QFT limit of TGD . . . . .	667
9.7.1	Basic concepts and ideas . . . . .	667
9.7.2	About super-field formalism in $\mathcal{N} = 2$ case . . . . .	670
9.7.3	Electric magnetic duality, monopole condensation and confinement from TGD point view . . . . .	671
9.7.4	Interpretation of Kähler potential and super-potential terms in TGD framework . . . . .	673
9.7.5	Generalization of bosonic emergence . . . . .	673
9.7.6	Is $\mathcal{N} > 8$ super-symmetry internally consistent? . . . . .	673
9.7.7	Super-fields in TGD framework . . . . .	674
9.7.8	Could QFT limit be finite? . . . . .	678
9.7.9	Can one understand p-adic coupling constant evolution as a prediction of QFT limit? . . . . .	679
9.7.10	Is the QFT type description of gravitational interactions possible? . . . . .	681
9.8	A more detailed summary of Feynman diagrammatics for emergence . . . . .	685
9.8.1	Emergence in absence of super-symmetry . . . . .	686
9.8.2	Some differences from standard Feynman diagrammatics . . . . .	686
9.8.3	Generalization of the formalism to the super-symmetric case . . . . .	687
<b>10</b>	<b>Generalized Feynman Graphs as Generalized Braids</b> . . . . .	<b>709</b>

### III HYPER-FINITE FACTORS AND HIERARCHY OF PLANCK CONSTANTS 773

<b>11 Was von Neumann Right After All?</b>	<b>775</b>
11.1 Introduction . . . . .	775
11.1.1 Philosophical ideas behind von Neumann algebras . . . . .	775
11.1.2 Von Neumann, Dirac, and Feynman . . . . .	776
11.1.3 Hyper-finite factors in quantum TGD . . . . .	776
11.1.4 Hyper-finite factors and M-matrix . . . . .	777
11.1.5 Connes tensor product as a realization of finite measurement resolution . . . . .	777
11.1.6 Quantum spinors and fuzzy quantum mechanics . . . . .	778
11.2 Von Neumann algebras . . . . .	778
11.2.1 Basic definitions . . . . .	778
11.2.2 Basic classification of von Neumann algebras . . . . .	779
11.2.3 Non-commutative measure theory and non-commutative topologies and geometries	779
11.2.4 Modular automorphisms . . . . .	780
11.2.5 Joint modular structure and sectors . . . . .	781
11.2.6 Basic facts about hyper-finite factors of type III . . . . .	781
11.3 Braid group, von Neumann algebras, quantum TGD, and formation of bound states . . . . .	783
11.3.1 Factors of von Neumann algebras . . . . .	783
11.3.2 Sub-factors . . . . .	784
11.3.3 $II_1$ factors and the spinor structure of infinite-dimensional configuration space of 3-surfaces . . . . .	784
11.3.4 About possible space-time correlates for the hierarchy of $II_1$ sub-factors . . . . .	786
11.3.5 Could binding energy spectra reflect the hierarchy of effective tensor factor dimensions? . . . . .	787
11.3.6 Four-color problem, $II_1$ factors, and anyons . . . . .	788
11.4 Inclusions of $II_1$ and $III_1$ factors . . . . .	789
11.4.1 Basic findings about inclusions . . . . .	789
11.4.2 The fundamental construction and Temperley-Lieb algebras . . . . .	790
11.4.3 Connection with Dynkin diagrams . . . . .	791
11.4.4 Indices for the inclusions of type $III_1$ factors . . . . .	792
11.5 TGD and hyper-finite factors of type $II_1$ : ideas and questions . . . . .	792
11.5.1 What kind of hyper-finite factors one can imagine in TGD? . . . . .	792
11.5.2 Direct sum of HFFs of type $II_1$ as a minimal option . . . . .	794
11.5.3 Bott periodicity, its generalization, and dimension $D = 8$ as an inherent property of the hyper-finite $II_1$ factor . . . . .	795
11.5.4 The interpretation of Jones inclusions in TGD framework . . . . .	796
11.5.5 Configuration space, space-time, and imbedding space and hyper-finite type $II_1$ factors . . . . .	798
11.5.6 Quaternions, octonions, and hyper-finite type $II_1$ factors . . . . .	800
11.5.7 Does the hierarchy of infinite primes relate to the hierarchy of $II_1$ factors? . . . . .	803
11.6 Could HFFs of type $III$ have application in TGD framework? . . . . .	804
11.6.1 Problems associated with the physical interpretation of $III_1$ factors . . . . .	804
11.6.2 Quantum measurement theory and HFFs of type III . . . . .	805
11.6.3 What could one say about $II_1$ automorphism associated with the $II_\infty$ automorphism defining factor of type III? . . . . .	807
11.6.4 What could be the physical interpretation of two kinds of invariants associated with HFFs type III? . . . . .	807
11.6.5 Does the time parameter $t$ represent time translation or scaling? . . . . .	808
11.6.6 Could HFFs of type $III$ be associated with the dynamics in $M_\pm^4$ degrees of freedom? . . . . .	809
11.6.7 Could the continuation of braidings to homotopies involve $\Delta^{it}$ automorphisms . . . . .	810
11.6.8 HFFs of type $III$ as super-structures providing additional uniqueness? . . . . .	810
11.7 The latest vision about the role of HFFs in TGD . . . . .	810
11.7.1 Basic facts about factors . . . . .	811
11.7.2 Inclusions and Connes tensor product . . . . .	814

11.7.3	Factors in quantum field theory and thermodynamics . . . . .	816
11.7.4	TGD and factors . . . . .	816
11.7.5	Can one identify $M$ -matrix from physical arguments? . . . . .	821
11.7.6	Finite measurement resolution and HFFs . . . . .	825
11.7.7	Questions about quantum measurement theory in zero energy ontology . . . . .	830
11.7.8	How p-adic coupling constant evolution and p-adic length scale hypothesis emerge from quantum TGD proper? . . . . .	832
11.7.9	Planar algebras and generalized Feynman diagrams . . . . .	834
11.7.10	Miscellaneous . . . . .	836
11.8	Jones inclusions and cognitive consciousness . . . . .	837
11.8.1	Does one have a hierarchy of $U$ - and $M$ -matrices? . . . . .	837
11.8.2	Feynman diagrams as higher level particles and their scattering as dynamics of self consciousness . . . . .	838
11.8.3	Logic, beliefs, and spinor fields in the world of classical worlds . . . . .	841
11.8.4	Jones inclusions for hyperfinite factors of type $II_1$ as a model for symbolic and cognitive representations . . . . .	842
11.8.5	Intentional comparison of beliefs by topological quantum computation? . . . . .	844
11.8.6	The stability of fuzzy qbits and quantum computation . . . . .	845
11.8.7	Fuzzy quantum logic and possible anomalies in the experimental data for the EPR-Bohm experiment . . . . .	845
11.8.8	Category theoretic formulation for quantum measurement theory with finite measurement resolution? . . . . .	847
11.9	Appendix: Inclusions of hyper-finite factors of type $II_1$ . . . . .	849
11.9.1	Jones inclusions . . . . .	850
11.9.2	Wassermann's inclusion . . . . .	850
11.9.3	Generalization from $SU(2)$ to arbitrary compact group . . . . .	851
<b>12</b>	<b>Does TGD Predict a Spectrum of Planck Constants?</b> . . . . .	<b>875</b>
12.1	Introduction . . . . .	875
12.1.1	The evolution of mathematical ideas . . . . .	875
12.1.2	The evolution of physical ideas . . . . .	878
12.1.3	Brief summary about the generalization of the imbedding space concept . . . . .	878

# Chapter 1

## Introduction

### 1.1 Background

*T(opological) G(eometro)D(ynamics)* is one of the many attempts to find a unified description of basic interactions. The development of the basic ideas of TGD to a relatively stable form took time of about half decade [1]. The great challenge is to construct a mathematical theory around these physically very attractive ideas and I have devoted the last twenty-three years for the realization of this dream and this has resulted in seven online books about TGD and eight online books about TGD inspired theory of consciousness and of quantum biology.

Quantum T(opological) G(eometro)D(ynamics) as a classical spinor geometry for infinite-dimensional configuration space, p-adic numbers and quantum TGD, and TGD inspired theory of consciousness and of quantum biology have been for last decade of the second millenium the basic three strongly interacting threads in the tapestry of quantum TGD.

For few years ago the discussions with Tony Smith initiated a fourth thread which deserves the name 'TGD as a generalized number theory'. The basic observation was that classical number fields might allow a deeper formulation of quantum TGD. The work with Riemann hypothesis made time ripe for realization that the notion of infinite primes could provide, not only a reformulation, but a deep generalization of quantum TGD. This led to a thorough and extremely fruitful revision of the basic views about what the final form and physical content of quantum TGD might be. Together with the vision about the fusion of p-adic and real physics to a larger coherent structure these sub-threads fused to the "physics as generalized number theory" th

A further thread emerged from the realization that by quantum classical correspondence TGD predicts an infinite hierarchy of macroscopic quantum systems with increasing sizes, that it is not at all clear whether standard quantum mechanics can accommodate this hierarchy, and that a dynamical quantized Planck constant might be necessary and certainly possible in TGD framework. The identification of hierarchy of Planck constants whose values TGD "predicts" in terms of dark matter hierarchy would be natural. This also led to a solution of a long standing puzzle: what is the proper interpretation of the predicted fractal hierarchy of long ranged classical electro-weak and color gauge fields. Quantum classical correspondences allows only single answer: there is infinite hierarchy of p-adically scaled up variants of standard model physics and for each of them also dark hierarchy. Thus TGD Universe would be fractal in very abstract and deep sense.

Every updating of the books makes me frustrated as I see how badly the structure of the representation reflects my bird's eye of view as it is at the moment of updating. At this time I realized that the chronology based identification of the threads is quite natural but not logical and it is much more logical to see p-adic physics, the ideas related to classical number fields, and infinite primes as sub-threads of a thread which might be called "physics as a generalized number theory". In the following I adopt this view. This reduces the number of threads to four! I am not even sure about the number of threads! Be patient!

TGD forces the generalization of physics to a quantum theory of consciousness, and represent TGD as a generalized number theory vision leads naturally to the emergence of p-adic physics as physics of cognitive representations. The seven online books [79, 60, 54, 48, 61, 69, 67] about TGD and eight online books about TGD inspired theory of consciousness and of quantum biology [73, 10, 58, 9, 34,

39, 42, 66] are warmly recommended to the interested reader.

## 1.2 Basic Ideas of TGD

The basic physical picture behind TGD was formed as a fusion of two rather disparate approaches: namely TGD is as a Poincare invariant theory of gravitation and TGD as a generalization of the old-fashioned string model.

### 1.2.1 TGD as a Poincare invariant theory of gravitation

The first approach was born as an attempt to construct a Poincare invariant theory of gravitation. Space-time, rather than being an abstract manifold endowed with a pseudo-Riemannian structure, is regarded as a surface in the 8-dimensional space  $H = M^4 \times CP_2$ , where  $M^4$  denotes Minkowski space and  $CP_2 = SU(3)/U(2)$  is the complex projective space of two complex dimensions [119, 84, 103, 79].

The identification of the space-time as a submanifold [72, 117] of  $M^4 \times CP_2$  leads to an exact Poincare invariance and solves the conceptual difficulties related to the definition of the energy-momentum in General Relativity.

It soon however turned out that submanifold geometry, being considerably richer in structure than the abstract manifold geometry, leads to a geometrization of all basic interactions. First, the geometrization of the elementary particle quantum numbers is achieved. The geometry of  $CP_2$  explains electro-weak and color quantum numbers. The different H-chiralities of  $H$ -spinors correspond to the conserved baryon and lepton numbers. Secondly, the geometrization of the field concept results. The projections of the  $CP_2$  spinor connection, Killing vector fields of  $CP_2$  and of  $H$ -metric to four-surface define classical electro-weak, color gauge fields and metric in  $X^4$ .

### 1.2.2 TGD as a generalization of the hadronic string model

The second approach was based on the generalization of the mesonic string model describing mesons as strings with quarks attached to the ends of the string. In the 3-dimensional generalization 3-surfaces correspond to free particles and the boundaries of the 3- surface correspond to partons in the sense that the quantum numbers of the elementary particles reside on the boundaries. Various boundary topologies (number of handles) correspond to various fermion families so that one obtains an explanation for the known elementary particle quantum numbers. This approach leads also to a natural topological description of the particle reactions as topology changes: for instance, two-particle decay corresponds to a decay of a 3-surface to two disjoint 3-surfaces.

This decay vertex does not however correspond to a direct generalization of trouser vertex of string models. Indeed, the important difference between TGD and string models is that the analogs of string world sheet diagrams do not describe particle decays but the propagation of particles via different routes. Particle reactions are described by generalized Feynman diagrams for which 3-D light-like surface describing particle propagating join along their ends at vertices. As 4-manifolds the space-time surfaces are therefore singular like Feynman diagrams as 1-manifolds.

### 1.2.3 Fusion of the two approaches via a generalization of the space-time concept

The problem is that the two approaches to TGD seem to be mutually exclusive since the orbit of a particle like 3-surface defines 4-dimensional surface, which differs drastically from the topologically trivial macroscopic space-time of General Relativity. The unification of these approaches forces a considerable generalization of the conventional space-time concept. First, the topologically trivial 3-space of General Relativity is replaced with a "topological condensate" containing matter as particle like 3-surfaces "glued" to the topologically trivial background 3-space by connected sum operation. Secondly, the assumption about connectedness of the 3-space is given up. Besides the "topological condensate" there could be "vapor phase" that is a "gas" of particle like 3-surfaces (counterpart of the "baby universes" of GRT) and the nonconservation of energy in GRT corresponds to the transfer of energy between the topological condensate and vapor phase.

What one obtains is what I have christened as many-sheeted space-time. One particular aspect is topological field quantization meaning that various classical fields assignable to a physical system correspond to space-time sheets representing the classical fields to that particular system. One can speak of the field body of a particular physical system. Field body consists of topological light rays, and electric and magnetic flux quanta. In Maxwell's theory system does not possess this kind of field identity. The notion of magnetic body is one of the key players in TGD inspired theory of consciousness and quantum biology.

This picture became more detailed with the advent of zero energy ontology (ZEO). The basic notion of ZEO is causal diamond ( $CD$ ) identified as the Cartesian product of  $CP_2$  and of the intersection of future and past directed light-cones and having scale coming as an integer multiple of  $CP_2$  size is fundamental.  $CD$ s form a fractal hierarchy and zero energy states decompose to products of positive and negative energy parts assignable to the opposite boundaries of  $CD$  defining the ends of the space-time surface. The counterpart of zero energy state in positive energy ontology is in terms of initial and final states of a physical event, say particle reaction.

General Coordinate Invariance allows to identify the basic dynamical objects as space-like 3-surfaces at the ends of space-time surface at boundaries of  $CD$ : this means that space-time surface is analogous to Bohr orbit. An alternative identification is as light-like 3-surfaces at which the signature of the induced metric changes from Minkowskian to Euclidian and interpreted as lines of generalized Feynman diagrams. Also the Euclidian 4-D regions would have similar interpretation. The requirement that the two interpretations are equivalent, leads to a strong form of General Coordinate Invariance. The outcome is effective 2-dimensionality stating that the partonic 2-surfaces identified as intersections of the space-like ends of space-time surface and light-like wormhole throats are the fundamental objects. That only effective 2-dimensionality is in question is due to the effects caused by the failure of strict determinism of Kähler action. In finite length scale resolution these effects can be neglected below UV cutoff and above IR cutoff. One can also speak about strong form of holography.

There is a further generalization of the space-time concept inspired by p-adic physics forcing a generalization of the number concept through the fusion of real numbers and various p-adic number fields. Also the hierarchy of Planck constants forces a generalization of the notion of space-time.

A very concise manner to express how TGD differs from Special and General Relativities could be following. Relativity Principle (Poincare Invariance), General Coordinate Invariance, and Equivalence Principle remain true. What is new is the notion of sub-manifold geometry: this allows to realize Poincare Invariance and geometrize gravitation simultaneously. This notion also allows a geometrization of known fundamental interactions and is an essential element of all applications of TGD ranging from Planck length to cosmological scales. Sub-manifold geometry is also crucial in the applications of TGD to biology and consciousness theory.

## 1.3 The threads in the development of quantum TGD

The development of TGD has involved several strongly interacting threads: physics as infinite-dimensional geometry; TGD as a generalized number theory, the hierarchy of Planck constants interpreted in terms of dark matter hierarchy, and TGD inspired theory of consciousness. In the following these threads are briefly described.

### 1.3.1 Quantum TGD as spinor geometry of World of Classical Worlds

A turning point in the attempts to formulate a mathematical theory was reached after seven years from the birth of TGD. The great insight was "Do not quantize". The basic ingredients to the new approach have served as the basic philosophy for the attempt to construct Quantum TGD since then and have been the following ones:

1. Quantum theory for extended particles is free(!), classical(!) field theory for a generalized Schrödinger amplitude in the configuration space  $CH$  consisting of all possible 3-surfaces in  $H$ . "All possible" means that surfaces with arbitrary many disjoint components and with arbitrary internal topology and also singular surfaces topologically intermediate between two different manifold topologies are included. Particle reactions are identified as topology changes [99, 123, 125]. For instance, the decay of a 3-surface to two 3-surfaces corresponds to the decay  $A \rightarrow B + C$ . Classically this corresponds to a path of configuration space leading from 1-particle

sector to 2-particle sector. At quantum level this corresponds to the dispersion of the generalized Schrödinger amplitude localized to 1-particle sector to two-particle sector. All coupling constants should result as predictions of the theory since no nonlinearities are introduced.

2. During years this naive and very rough vision has of course developed a lot and is not anymore quite equivalent with the original insight. In particular, the space-time correlates of Feynman graphs have emerged from theory as Euclidian space-time regions and the strong form of General Coordinate Invariance has led to a rather detailed and in many respects un-expected visions. This picture forces to give up the idea about smooth space-time surfaces and replace space-time surface with a generalization of Feynman diagram in which vertices represent the failure of manifold property. I have also started introduced the word "world of classical worlds" (WCW) instead of rather formal "configuration space". I hope that "WCW" does not induce despair in the reader having tendency to think about the technicalities involved!
3. WCW is endowed with metric and spinor structure so that one can define various metric related differential operators, say Dirac operator, appearing in the field equations of the theory. The most ambitious dream is that zero energy states correspond to a complete solution basis for the Dirac operator of WCW so that this classical free field theory would dictate M-matrices which form orthonormal rows of what I call U-matrix. Given M-matrix in turn would decompose to a product of a hermitian density matrix and unitary S-matrix.

M-matrix would define time-like entanglement coefficients between positive and negative energy parts of zero energy states (all net quantum numbers vanish for them) and can be regarded as a hermitian square root of density matrix multiplied by a unitary S-matrix. Quantum theory would be in well-defined sense a square root of thermodynamics. The orthogonality and hermiticity of the complex square roots of density matrices commuting with S-matrix means that they span infinite-dimensional Lie algebra acting as symmetries of the S-matrix. Therefore quantum TGD would reduce to group theory in well-defined sense: its own symmetries would define the symmetries of the theory. In fact the Lie algebra of Hermitian M-matrices extends to Kac-Moody type algebra obtained by multiplying hermitian square roots of density matrices with powers of the S-matrix. Also the analog of Yangian algebra involving only non-negative powers of S-matrix is possible.

4. By quantum classical correspondence the construction of WCW spinor structure reduces to the second quantization of the induced spinor fields at space-time surface. The basic action is so called modified Dirac action in which gamma matrices are replaced with the modified gamma matrices defined as contractions of the canonical momentum currents with the imbedding space gamma matrices. In this manner one achieves super-conformal symmetry and conservation of fermionic currents among other things and consistent Dirac equation. This modified gamma matrices define as anticommutators effective metric, which might provide geometrization for some basic observables of condensed matter physics. The conjecture is that Dirac determinant for the modified Dirac action gives the exponent of Kähler action for a preferred extremal as vacuum functional so that one might talk about bosonic emergence in accordance with the prediction that the gauge bosons and graviton are expressible in terms of bound states of fermion and antifermion.

The evolution of these basic ideas has been rather slow but has gradually led to a rather beautiful vision. One of the key problems has been the definition of Kähler function. Kähler function is Kähler action for a preferred extremal assignable to a given 3-surface but what this preferred extremal is? The obvious first guess was as absolute minimum of Kähler action but could not be proven to be right or wrong. One big step in the progress was boosted by the idea that TGD should reduce to almost topological QFT in which braids would replace 3-surfaces in finite measurement resolution, which could be inherent property of the theory itself and imply discretization at partonic 2-surfaces with discrete points carrying fermion number.

1. TGD as almost topological QFT vision suggests that Kähler action for preferred extremals reduces to Chern-Simons term assigned with space-like 3-surfaces at the ends of space-time (recall the notion of causal diamond (*CD*)) and with the light-like 3-surfaces at which the signature of the induced metric changes from Minkowskian to Euclidian. Minkowskian and

Euclidian regions would give at wormhole throats the same contribution apart from coefficients and in Minkowskian regions the  $\sqrt{g_4}$  factor would be imaginary so that one would obtain sum of real term identifiable as Kähler function and imaginary term identifiable as the ordinary action giving rise to interference effects and stationary phase approximation central in both classical and quantum field theory. Imaginary contribution - the presence of which I realized only after 33 years of TGD - could also have topological interpretation as a Morse function. On physical side the emergence of Euclidian space-time regions is something completely new and leads to a dramatic modification of the ideas about black hole interior.

2. The manner to achieve the reduction to Chern-Simons terms is simple. The vanishing of Coulombic contribution to Kähler action is required and is true for all known extremals if one makes a general ansatz about the form of classical conserved currents. The so called weak form of electric-magnetic duality defines a boundary condition reducing the resulting 3-D terms to Chern-Simons terms. In this manner almost topological QFT results. But only "almost" since the Lagrange multiplier term forcing electric-magnetic duality implies that Chern-Simons action for preferred extremals depends on metric.
3. A further quite recent hypothesis inspired by effective 2-dimensionality is that Chern-Simons terms reduce to a sum of two 2-dimensional terms. An imaginary term proportional to the total area of Minkowskian string world sheets and a real term proportional to the total area of partonic 2-surfaces or equivalently strings world sheets in Euclidian space-time regions. Also the equality of the total areas of strings world sheets and partonic 2-surfaces is highly suggestive and would realize a duality between these two kinds of objects. String world sheets indeed emerge naturally for the proposed ansatz defining preferred extremals. Therefore Kähler action would have very stringy character apart from effects due to the failure of the strict determinism meaning that radiative corrections break the effective 2-dimensionality.

### 1.3.2 TGD as a generalized number theory

Quantum T(opological)D(ynamics) as a classical spinor geometry for infinite-dimensional configuration space, p-adic numbers and quantum TGD, and TGD inspired theory of consciousness, have been for last ten years the basic three strongly interacting threads in the tapestry of quantum TGD. The fourth thread deserves the name 'TGD as a generalized number theory'. It involves three separate threads: the fusion of real and various p-adic physics to a single coherent whole by requiring number theoretic universality discussed already, the formulation of quantum TGD in terms of hyper-counterparts of classical number fields identified as sub-spaces of complexified classical number fields with Minkowskian signature of the metric defined by the complexified inner product, and the notion of infinite prime.

#### **p-Adic TGD and fusion of real and p-adic physics to single coherent whole**

The p-adic thread emerged for roughly ten years ago as a dim hunch that p-adic numbers might be important for TGD. Experimentation with p-adic numbers led to the notion of canonical identification mapping reals to p-adics and vice versa. The breakthrough came with the successful p-adic mass calculations using p-adic thermodynamics for Super-Virasoro representations with the super-Kac-Moody algebra associated with a Lie-group containing standard model gauge group. Although the details of the calculations have varied from year to year, it was clear that p-adic physics reduces not only the ratio of proton and Planck mass, the great mystery number of physics, but all elementary particle mass scales, to number theory if one assumes that primes near prime powers of two are in a physically favored position. Why this is the case, became one of the key puzzles and led to a number of arguments with a common gist: evolution is present already at the elementary particle level and the primes allowed by the p-adic length scale hypothesis are the fittest ones.

It became very soon clear that p-adic topology is not something emerging in Planck length scale as often believed, but that there is an infinite hierarchy of p-adic physics characterized by p-adic length scales varying to even cosmological length scales. The idea about the connection of p-adics with cognition motivated already the first attempts to understand the role of the p-adics and inspired 'Universe as Computer' vision but time was not ripe to develop this idea to anything concrete (p-adic numbers are however in a central role in TGD inspired theory of consciousness). It became however

obvious that the p-adic length scale hierarchy somehow corresponds to a hierarchy of intelligences and that p-adic prime serves as a kind of intelligence quotient. Ironically, the almost obvious idea about p-adic regions as cognitive regions of space-time providing cognitive representations for real regions had to wait for almost a decade for the access into my consciousness.

There were many interpretational and technical questions crying for a definite answer.

1. What is the relationship of p-adic non-determinism to the classical non-determinism of the basic field equations of TGD? Are the p-adic space-time region genuinely p-adic or does p-adic topology only serve as an effective topology? If p-adic physics is direct image of real physics, how the mapping relating them is constructed so that it respects various symmetries? Is the basic physics p-adic or real (also real TGD seems to be free of divergences) or both? If it is both, how should one glue the physics in different number field together to get *The Physics*? Should one perform p-adicization also at the level of the configuration space of 3-surfaces? Certainly the p-adicization at the level of super-conformal representation is necessary for the p-adic mass calculations.
2. Perhaps the most basic and most irritating technical problem was how to precisely define p-adic definite integral which is a crucial element of any variational principle based formulation of the field equations. Here the frustration was not due to the lack of solution but due to the too large number of solutions to the problem, a clear symptom for the sad fact that clever inventions rather than real discoveries might be in question. Quite recently I however learned that the problem of making sense about p-adic integration has been for decades central problem in the frontier of mathematics and a lot of profound work has been done along same intuitive lines as I have proceeded in TGD framework. The basic idea is certainly the notion of algebraic continuation from the world of rationals belonging to the intersection of real world and various p-adic worlds.

Despite these frustrating uncertainties, the number of the applications of the poorly defined p-adic physics grew steadily and the applications turned out to be relatively stable so that it was clear that the solution to these problems must exist. It became only gradually clear that the solution of the problems might require going down to a deeper level than that represented by reals and p-adics.

The key challenge is to fuse various p-adic physics and real physics to single larger structures. This has inspired a proposal for a generalization of the notion of number field by fusing real numbers and various p-adic number fields and their extensions along rationals and possible common algebraic numbers. This leads to a generalization of the notions of imbedding space and space-time concept and one can speak about real and p-adic space-time sheets. The quantum dynamics should be such that it allows quantum transitions transforming space-time sheets belonging to different number fields to each other. The space-time sheets in the intersection of real and p-adic worlds are of special interest and the hypothesis is that living matter resides in this intersection. This leads to surprisingly detailed predictions and far reaching conjectures. For instance, the number theoretic generalization of entropy concept allows negentropic entanglement central for the applications to living matter.

The basic principle is number theoretic universality stating roughly that the physics in various number fields can be obtained as completion of rational number based physics to various number fields. Rational number based physics would in turn describe physics in finite measurement resolution and cognitive resolution. The notion of finite measurement resolution has become one of the basic principles of quantum TGD and leads to the notions of braids as representatives of 3-surfaces and inclusions of hyper-finite factors as a representation for finite measurement resolution.

### The role of classical number fields

The vision about the physical role of the classical number fields relies on the notion of number theoretic compactification stating that space-time surfaces can be regarded as surfaces of either  $M^8$  or  $M^4 \times CP_2$ . As surfaces of  $M^8$  identifiable as space of hyper-octonions they are hyper-quaternionic or co-hyper-quaternionic- and thus maximally associative or co-associative. This means that their tangent space is either hyper-quaternionic plane of  $M^8$  or an orthogonal complement of such a plane. These surface can be mapped in natural manner to surfaces in  $M^4 \times CP_2$  [72] provided one can assign to each point of tangent space a hyper-complex plane  $M^2(x) \subset M^4$ . One can also speak about  $M^8 - H$  duality.

This vision has very strong predictive power. It predicts that the extremals of Kähler action correspond to either hyper-quaternionic or co-hyper-quaternionic surfaces such that one can assign to tangent space at each point of space-time surface a hyper-complex plane  $M^2(x) \subset M^4$ . As a consequence, the  $M^4$  projection of space-time surface at each point contains  $M^2(x)$  and its orthogonal complement. These distributions are integrable implying that space-time surface allows dual slicings defined by string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$ . The existence of this kind of slicing was earlier deduced from the study of extremals of Kähler action and christened as Hamilton-Jacobi structure. The physical interpretation of  $M^2(x)$  is as the space of non-physical polarizations and the plane of local 4-momentum.

One can fairly say, that number theoretical compactification is responsible for most of the understanding of quantum TGD that has emerged during last years. This includes the realization of Equivalence Principle at space-time level, dual formulations of TGD as Minkowskian and Euclidian string model type theories, the precise identification of preferred extremals of Kähler action as extremals for which second variation vanishes (at least for deformations representing dynamical symmetries) and thus providing space-time correlate for quantum criticality, the notion of number theoretic braid implied by the basic dynamics of Kähler action and crucial for precise construction of quantum TGD as almost-topological QFT, the construction of configuration space metric and spinor structure in terms of second quantized induced spinor fields with modified Dirac action defined by Kähler action realizing automatically the notion of finite measurement resolution and a connection with inclusions of hyper-finite factors of type  $II_1$  about which Clifford algebra of configuration space represents an example.

The two most important number theoretic conjectures relate to the preferred extremals of Kähler action. The general idea is that classical dynamics for the preferred extremals of Kähler action should reduce to number theory: space-time surfaces should be either associative or co-associative in some sense.

1. The first meaning for associativity (co-associativity) would be that tangent (normal) spaces of space-time surfaces are quaternionic in some sense and thus associative. This can be formulated in terms of octonionic representation of the imbedding space gamma matrices possible in dimension  $D = 8$  and states that induced gamma matrices generate quaternionic sub-algebra at each space-time point. It seems that induced rather than modified gamma matrices must be in question.
2. Second meaning for associative (co-associativity) would be following. In the case of complex numbers the vanishing of the real part of real-analytic function defines a 1-D curve. In octonionic case one can decompose octonion to sum of quaternion and quaternion multiplied by an octonionic imaginary unit. Quaternionicity could mean that space-time surfaces correspond to the vanishing of the imaginary part of the octonion real-analytic function. Co-quaternionicity would be defined in an obvious manner. Octonionic real analytic functions form a function field closed also with respect to the composition of functions. Space-time surfaces would form the analog of function field with the composition of functions with all operations realized as algebraic operations for space-time surfaces. Co-associativity could be perhaps seen as an additional feature making the algebra in question also co-algebra.
3. The third conjecture is that these conjectures are equivalent.

### Infinite primes

The discovery of the hierarchy of infinite primes and their correspondence with a hierarchy defined by a repeatedly second quantized arithmetic quantum field theory gave a further boost for the speculations about TGD as a generalized number theory. The work with Riemann hypothesis led to further ideas.

After the realization that infinite primes can be mapped to polynomials representable as surfaces geometrically, it was clear how TGD might be formulated as a generalized number theory with infinite primes forming the bridge between classical and quantum such that real numbers, p-adic numbers, and various generalizations of p-adics emerge dynamically from algebraic physics as various completions of the algebraic extensions of rational (hyper-)quaternions and (hyper-)octonions. Complete algebraic, topological and dimensional democracy would characterize the theory.

What is especially satisfying is that p-adic and real regions of the space-time surface could emerge automatically as solutions of the field equations. In the space-time regions where the solutions of field equations give rise to in-admissible complex values of the imbedding space coordinates, p-adic solution can exist for some values of the p-adic prime. The characteristic non-determinism of the p-adic differential equations suggests strongly that p-adic regions correspond to 'mind stuff', the regions of space-time where cognitive representations reside. This interpretation implies that p-adic physics is physics of cognition. Since Nature is probably an extremely brilliant simulator of Nature, the natural idea is to study the p-adic physics of the cognitive representations to derive information about the real physics. This view encouraged by TGD inspired theory of consciousness clarifies difficult interpretational issues and provides a clear interpretation for the predictions of p-adic physics.

### 1.3.3 Hierarchy of Planck constants and dark matter hierarchy

By quantum classical correspondence space-time sheets can be identified as quantum coherence regions. Hence the fact that they have all possible size scales more or less unavoidably implies that Planck constant must be quantized and have arbitrarily large values. If one accepts this then also the idea about dark matter as a macroscopic quantum phase characterized by an arbitrarily large value of Planck constant emerges naturally as does also the interpretation for the long ranged classical electro-weak and color fields predicted by TGD. Rather seldom the evolution of ideas follows simple linear logic, and this was the case also now. In any case, this vision represents the fifth, relatively new thread in the evolution of TGD and the ideas involved are still evolving.

#### Dark matter as large $\hbar$ phase

D. Da Rocha and Laurent Nottale [10] have proposed that Schrödinger equation with Planck constant  $\hbar$  replaced with what might be called gravitational Planck constant  $\hbar_{gr} = \frac{GmM}{v_0}$  ( $\hbar = c = 1$ ).  $v_0$  is a velocity parameter having the value  $v_0 = 144.7 \pm .7$  km/s giving  $v_0/c = 4.6 \times 10^{-4}$ . This is rather near to the peak orbital velocity of stars in galactic halos. Also subharmonics and harmonics of  $v_0$  seem to appear. The support for the hypothesis coming from empirical data is impressive.

Nottale and Da Rocha believe that their Schrödinger equation results from a fractal hydrodynamics. Many-sheeted space-time however suggests astrophysical systems are not only quantum systems at larger space-time sheets but correspond to a gigantic value of gravitational Planck constant. The gravitational (ordinary) Schrödinger equation would provide a solution of the black hole collapse (IR catastrophe) problem encountered at the classical level. The resolution of the problem inspired by TGD inspired theory of living matter is that it is the dark matter at larger space-time sheets which is quantum coherent in the required time scale [64].

TGD predicts correctly the value of the parameter  $v_0$  assuming that cosmic strings and their decay remnants are responsible for the dark matter. The harmonics of  $v_0$  can be understood as corresponding to perturbations replacing cosmic strings with their n-branched coverings so that tension becomes  $n^2$ -fold: much like the replacement of a closed orbit with an orbit closing only after  $n$  turns.  $1/n$ -sub-harmonic would result when a magnetic flux tube split into  $n$  disjoint magnetic flux tubes. Also a model for the formation of planetary system as a condensation of ordinary matter around quantum coherent dark matter emerges [64].

The values of Planck constants postulated by Nottale are gigantic and it is natural to assign them to the space-time sheets mediating gravitational interaction and identifiable as magnetic flux tubes (quanta). The magnetic energy of these flux quanta would correspond to dark energy and magnetic tension would give rise to negative "pressure" forcing accelerate cosmological expansion. This leads to a rather detailed vision about the evolution of stars and galaxies identified as bubbles of ordinary and dark matter inside magnetic flux tubes identifiable as dark energy.

#### Hierarchy of Planck constants from the anomalies of neuroscience biology

The quantal effects of ELF em fields on vertebrate brain have been known since seventies. ELF em fields at frequencies identifiable as cyclotron frequencies in magnetic field whose intensity is about 2/5 times that of Earth for biologically important ions have physiological effects and affect also behavior. What is intriguing that the effects are found only in vertebrates (to my best knowledge). The energies for the photons of ELF em fields are extremely low - about  $10^{-10}$  times lower than thermal energy

at physiological temperatures- so that quantal effects are impossible in the framework of standard quantum theory. The values of Planck constant would be in these situations large but not gigantic.

This inspired the hypothesis that these photons correspond to so large value of Planck constant that the energy of photons is above the thermal energy. The proposed interpretation was as dark photons and the general hypothesis was that dark matter corresponds to ordinary matter with non-standard value of Planck constant. If only particles with the same value of Planck constant can appear in the same vertex of Feynman diagram, the phases with different value of Planck constant are dark relative to each other. The phase transitions changing Planck constant can however make possible interactions between phases with different Planck constant but these interactions do not manifest themselves in particle physics. Also the interactions mediated by classical fields should be possible. Dark matter would not be so dark as we have used to believe.

Also the anomalies of biology support the view that dark matter might be a key player in living matter.

### **Does the hierarchy of Planck constants reduce to the vacuum degeneracy of Kähler action?**

This starting point led gradually to the recent picture in which the hierarchy of Planck constants is postulated to come as integer multiples of the standard value of Planck constant. Given integer multiple  $\hbar = n\hbar_0$  of the ordinary Planck constant  $\hbar_0$  is assigned with a multiple singular covering of the imbedding space [27]. One ends up to an identification of dark matter as phases with non-standard value of Planck constant having geometric interpretation in terms of these coverings providing generalized imbedding space with a book like structure with pages labelled by Planck constants or integers characterizing Planck constant. The phase transitions changing the value of Planck constant would correspond to leakage between different sectors of the extended imbedding space. The question is whether these coverings must be postulated separately or whether they are only a convenient auxiliary tool.

The simplest option is that the hierarchy of coverings of imbedding space is only effective. Many-sheeted coverings of the imbedding space indeed emerge naturally in TGD framework. The huge vacuum degeneracy of Kähler action implies that the relationship between gradients of the imbedding space coordinates and canonical momentum currents is many-to-one: this was the very fact forcing to give up all the standard quantization recipes and leading to the idea about physics as geometry of the "world of classical worlds". If one allows space-time surfaces for which all sheets corresponding to the same values of the canonical momentum currents are present, one obtains effectively many-sheeted covering of the imbedding space and the contributions from sheets to the Kähler action are identical. If all sheets are treated effectively as one and the same sheet, the value of Planck constant is an integer multiple of the ordinary one. A natural boundary condition would be that at the ends of space-time at future and past boundaries of causal diamond containing the space-time surface, various branches co-incide. This would raise the ends of space-time surface in special physical role.

### **Dark matter as a source of long ranged weak and color fields**

Long ranged classical electro-weak and color gauge fields are unavoidable in TGD framework. The smallness of the parity breaking effects in hadronic, nuclear, and atomic length scales does not however seem to allow long ranged electro-weak gauge fields. The problem disappears if long range classical electro-weak gauge fields are identified as space-time correlates for massless gauge fields created by dark matter. Also scaled up variants of ordinary electro-weak particle spectra are possible. The identification explains chiral selection in living matter and unbroken  $U(2)_{ew}$  invariance and free color in bio length scales become characteristics of living matter and of bio-chemistry and bio-nuclear physics. A possible solution of the matter antimatter asymmetry is based on the identification of also antimatter as dark matter.

#### **1.3.4 TGD as a generalization of physics to a theory consciousness**

General coordinate invariance forces the identification of quantum jump as quantum jump between entire deterministic quantum histories rather than time=constant snapshots of single history. The new view about quantum jump forces a generalization of quantum measurement theory such that

observer becomes part of the physical system. Thus a general theory of consciousness is unavoidable outcome. This theory is developed in detail in the books [73, 10, 58, 9, 34, 39, 42, 66] .

### Quantum jump as a moment of consciousness

The identification of quantum jump between deterministic quantum histories (configuration space spinor fields) as a moment of consciousness defines microscopic theory of consciousness. Quantum jump involves the steps

$$\Psi_i \rightarrow U\Psi_i \rightarrow \Psi_f ,$$

where  $U$  is informational "time development" operator, which is unitary like the S-matrix characterizing the unitary time evolution of quantum mechanics.  $U$  is however only formally analogous to Schrödinger time evolution of infinite duration although there is *no* real time evolution involved. It is not however clear whether one should regard U-matrix and S-matrix as two different things or not:  $U$ -matrix is a completely universal object characterizing the dynamics of evolution by self-organization whereas S-matrix is a highly context dependent concept in wave mechanics and in quantum field theories where it at least formally represents unitary time translation operator at the limit of an infinitely long interaction time. The S-matrix understood in the spirit of superstring models is however something very different and could correspond to U-matrix.

The requirement that quantum jump corresponds to a measurement in the sense of quantum field theories implies that each quantum jump involves localization in zero modes which parameterize also the possible choices of the quantization axes. Thus the selection of the quantization axes performed by the Cartesian outsider becomes now a part of quantum theory. Together these requirements imply that the final states of quantum jump correspond to quantum superpositions of space-time surfaces which are macroscopically equivalent. Hence the world of conscious experience looks classical. At least formally quantum jump can be interpreted also as a quantum computation in which matrix  $U$  represents unitary quantum computation which is however not identifiable as unitary translation in time direction and cannot be 'engineered'.

### The notion of self

The concept of self is absolutely essential for the understanding of the macroscopic and macro-temporal aspects of consciousness. Self corresponds to a subsystem able to remain un-entangled under the sequential informational 'time evolutions'  $U$ . Exactly vanishing entanglement is practically impossible in ordinary quantum mechanics and it might be that 'vanishing entanglement' in the condition for self-property should be replaced with 'subcritical entanglement'. On the other hand, if space-time decomposes into p-adic and real regions, and if entanglement between regions representing physics in different number fields vanishes, space-time indeed decomposes into selves in a natural manner.

It is assumed that the experiences of the self after the last 'wake-up' sum up to single average experience. This means that subjective memory is identifiable as conscious, immediate short term memory. Selves form an infinite hierarchy with the entire Universe at the top. Self can be also interpreted as mental images: our mental images are selves having mental images and also we represent mental images of a higher level self. A natural hypothesis is that self  $S$  experiences the experiences of its subselves as kind of abstracted experience: the experiences of subselves  $S_i$  are not experienced as such but represent kind of averages  $\langle S_{ij} \rangle$  of sub-subselves  $S_{ij}$ . Entanglement between selves, most naturally realized by the formation of join along boundaries bonds between cognitive or material space-time sheets, provides a possible a mechanism for the fusion of selves to larger selves (for instance, the fusion of the mental images representing separate right and left visual fields to single visual field) and forms wholes from parts at the level of mental images.

An attractive possibility suggested by zero energy ontology is that the notions of self and quantum jump reduce to each other and that a fractal hierarchy of quantum jumps within quantum jumps is enough.  $CD$ s would serve as imbedding space correlates of selves and quantum jumps would be followed by cascades of state function reductions beginning from given  $CD$  and proceeding downwards to the smaller scales (smaller  $CD$ s). State function reduction cascades could also take place in parallel branches of the quantum state. One ends up with concrete ideas about how the arrow of geometric time is induced from that of subjective time defined by the experiences induced by the sequences of quantum jumps for sub-selves of self. One ends also ends up with concrete ideas about how the

localization of the contents of sensory experience and cognition to the upper boundaries of  $CD$  could take place.

### Relationship to quantum measurement theory

The third basic element relates TGD inspired theory of consciousness to quantum measurement theory. The assumption that localization occurs in zero modes in each quantum jump implies that the world of conscious experience looks classical. It also implies the state function reduction of the standard quantum measurement theory as the following arguments demonstrate (it took incredibly long time to realize this almost obvious fact!).

1. The standard quantum measurement theory a la von Neumann involves the interaction of brain with the measurement apparatus. If this interaction corresponds to entanglement between microscopic degrees of freedom  $m$  with the macroscopic effectively classical degrees of freedom  $M$  characterizing the reading of the measurement apparatus coded to brain state, then the reduction of this entanglement in quantum jump reproduces standard quantum measurement theory provide the unitary time evolution operator  $U$  acts as flow in zero mode degrees of freedom and correlates completely some orthonormal basis of configuration space spinor fields in non-zero modes with the values of the zero modes. The flow property guarantees that the localization is consistent with unitarity: it also means 1-1 mapping of quantum state basis to classical variables (say, spin direction of the electron to its orbit in the external magnetic field).
2. Since zero modes represent classical information about the geometry of space-time surface (shape, size, classical Kähler field,...), they have interpretation as effectively classical degrees of freedom and are the TGD counterpart of the degrees of freedom  $M$  representing the reading of the measurement apparatus. The entanglement between quantum fluctuating non-zero modes and zero modes is the TGD counterpart for the  $m - M$  entanglement. Therefore the localization in zero modes is equivalent with a quantum jump leading to a final state where the measurement apparatus gives a definite reading.

This simple prediction is of utmost theoretical importance since the black box of the quantum measurement theory is reduced to a fundamental quantum theory. This reduction is implied by the replacement of the notion of a point like particle with particle as a 3-surface. Also the infinite-dimensionality of the zero mode sector of the configuration space of 3-surfaces is absolutely essential. Therefore the reduction is a triumph for quantum TGD and favors TGD against string models.

Standard quantum measurement theory involves also the notion of state preparation which reduces to the notion of self measurement. Each localization in zero modes is followed by a cascade of self measurements leading to a product state. This process is obviously equivalent with the state preparation process. Self measurement is governed by the so called Negentropy Maximization Principle (NMP) stating that the information content of conscious experience is maximized. In the self measurement the density matrix of some subsystem of a given self localized in zero modes (after ordinary quantum measurement) is measured. The self measurement takes place for that subsystem of self for which the reduction of the entanglement entropy is maximal in the measurement. In p-adic context NMP can be regarded as the variational principle defining the dynamics of cognition. In real context self measurement could be seen as a repair mechanism allowing the system to fight against quantum thermalization by reducing the entanglement for the subsystem for which it is largest (fill the largest hole first in a leaking boat).

### Selves self-organize

The fourth basic element is quantum theory of self-organization based on the identification of quantum jump as the basic step of self-organization [62]. Quantum entanglement gives rise to the generation of long range order and the emergence of longer p-adic length scales corresponds to the emergence of larger and larger coherent dynamical units and generation of a slaving hierarchy. Energy (and quantum entanglement) feed implying entropy feed is a necessary prerequisite for quantum self-organization. Zero modes represent fundamental order parameters and localization in zero modes implies that the sequence of quantum jumps can be regarded as hopping in the zero modes so that Haken's classical theory of self organization applies almost as such. Spin glass analogy is a further important element:

self-organization of self leads to some characteristic pattern selected by dissipation as some valley of the "energy" landscape.

Dissipation can be regarded as the ultimate Darwinian selector of both memes and genes. The mathematically ugly irreversible dissipative dynamics obtained by adding phenomenological dissipation terms to the reversible fundamental dynamical equations derivable from an action principle can be understood as a phenomenological description replacing in a well defined sense the series of reversible quantum histories with its envelope.

### Classical non-determinism of Kähler action

The fifth basic element are the concepts of association sequence and cognitive space-time sheet. The huge vacuum degeneracy of the Kähler action suggests strongly that the absolute minimum space-time is not always unique. For instance, a sequence of bifurcations can occur so that a given space-time branch can be fixed only by selecting a finite number of 3-surfaces with time like(!) separations on the orbit of 3-surface. Quantum classical correspondence suggest an alternative formulation. Space-time surface decomposes into maximal deterministic regions and their temporal sequences have interpretation a space-time correlate for a sequence of quantum states defined by the initial (or final) states of quantum jumps. This is consistent with the fact that the variational principle selects preferred extremals of Kähler action as generalized Bohr orbits.

In the case that non-determinism is located to a finite time interval and is microscopic, this sequence of 3-surfaces has interpretation as a simulation of a classical history, a geometric correlate for contents of consciousness. When non-determinism has long lasting and macroscopic effect one can identify it as volitional non-determinism associated with our choices. Association sequences relate closely with the cognitive space-time sheets defined as space-time sheets having finite time duration and psychological time can be identified as a temporal center of mass coordinate of the cognitive space-time sheet. The gradual drift of the cognitive space-time sheets to the direction of future force by the geometry of the future light cone explains the arrow of psychological time.

### p-Adic physics as physics of cognition and intentionality

The sixth basic element adds a physical theory of cognition to this vision. TGD space-time decomposes into regions obeying real and p-adic topologies labelled by primes  $p = 2, 3, 5, \dots$ . p-Adic regions obey the same field equations as the real regions but are characterized by p-adic non-determinism since the functions having vanishing p-adic derivative are pseudo constants which are piecewise constant functions. Pseudo constants depend on a finite number of positive binary digits of arguments just like numerical predictions of any theory always involve decimal cutoff. This means that p-adic space-time regions are obtained by gluing together regions for which integration constants are genuine constants. The natural interpretation of the p-adic regions is as cognitive representations of real physics. The freedom of imagination is due to the p-adic non-determinism. p-Adic regions perform mimicry and make possible for the Universe to form cognitive representations about itself. p-Adic physics space-time sheets serve also as correlates for intentional action.

A more more precise formulation of this vision requires a generalization of the number concept obtained by fusing reals and p-adic number fields along common rationals (in the case of algebraic extensions among common algebraic numbers). This picture is discussed in [71]. The application this notion at the level of the imbedding space implies that imbedding space has a book like structure with various variants of the imbedding space glued together along common rationals (algebraics). The implication is that genuinely p-adic numbers (non-rationals) are strictly infinite as real numbers so that most points of p-adic space-time sheets are at real infinity, outside the cosmos, and that the projection to the real imbedding space is discrete set of rationals (algebraics). Hence cognition and intentionality are almost completely outside the real cosmos and touch it at a discrete set of points only.

This view implies also that purely local p-adic physics codes for the p-adic fractality characterizing long range real physics and provides an explanation for p-adic length scale hypothesis stating that the primes  $p \simeq 2^k$ ,  $k$  integer are especially interesting. It also explains the long range correlations and short term chaos characterizing intentional behavior and explains why the physical realizations of cognition are always discrete (say in the case of numerical computations). Furthermore, a concrete quantum model for how intentions are transformed to actions emerges.

The discrete real projections of p-adic space-time sheets serve also space-time correlate for a logical thought. It is very natural to assign to p-adic pinary digits a  $p$ -valued logic but as such this kind of logic does not have any reasonable identification. p-Adic length scale hypothesis suggest that the  $p = 2^k - n$  pinary digits represent a Boolean logic  $B^k$  with  $k$  elementary statements (the points of the  $k$ -element set in the set theoretic realization) with  $n$  taboos which are constrained to be identically true.

### p-Adic and dark matter hierarchies and hierarchy of moments of consciousness

Dark matter hierarchy assigned to a spectrum of Planck constant having arbitrarily large values brings additional elements to the TGD inspired theory of consciousness.

1. Macroscopic quantum coherence can be understood since a particle with a given mass can in principle appear as arbitrarily large scaled up copies (Compton length scales as  $\hbar$ ). The phase transition to this kind of phase implies that space-time sheets of particles overlap and this makes possible macroscopic quantum coherence.
2. The space-time sheets with large Planck constant can be in thermal equilibrium with ordinary ones without the loss of quantum coherence. For instance, the cyclotron energy scale associated with EEG turns out to be above thermal energy at room temperature for the level of dark matter hierarchy corresponding to magnetic flux quanta of the Earth's magnetic field with the size scale of Earth and a successful quantitative model for EEG results [24] .

Dark matter hierarchy leads to detailed quantitative view about quantum biology with several testable predictions [24] . The general prediction is that Universe is a kind of inverted Mandelbrot fractal for which each bird's eye of view reveals new structures in long length and time scales representing scaled down copies of standard physics and their dark variants. These structures would correspond to higher levels in self hierarchy. This prediction is consistent with the belief that 75 per cent of matter in the universe is dark.

#### 1. *Living matter and dark matter*

Living matter as ordinary matter quantum controlled by the dark matter hierarchy has turned out to be a particularly successful idea. The hypothesis has led to models for EEG predicting correctly the band structure and even individual resonance bands and also generalizing the notion of EEG [24] . Also a generalization of the notion of genetic code emerges resolving the paradoxes related to the standard dogma [40, 24] . A particularly fascinating implication is the possibility to identify great leaps in evolution as phase transitions in which new higher level of dark matter emerges [24] .

It seems safe to conclude that the dark matter hierarchy with levels labelled by the values of Planck constants explains the macroscopic and macro-temporal quantum coherence naturally. That this explanation is consistent with the explanation based on spin glass degeneracy is suggested by following observations. First, the argument supporting spin glass degeneracy as an explanation of the macro-temporal quantum coherence does not involve the value of  $\hbar$  at all. Secondly, the failure of the perturbation theory assumed to lead to the increase of Planck constant and formation of macroscopic quantum phases could be precisely due to the emergence of a large number of new degrees of freedom due to spin glass degeneracy. Thirdly, the phase transition increasing Planck constant has concrete topological interpretation in terms of many-sheeted space-time consistent with the spin glass degeneracy.

#### 2. *Dark matter hierarchy and the notion of self*

The vision about dark matter hierarchy leads to a more refined view about self hierarchy and hierarchy of moments of consciousness [23, 24] . The larger the value of Planck constant, the longer the subjectively experienced duration and the average geometric duration  $T(k) \propto \hbar$  of the quantum jump.

Quantum jumps form also a hierarchy with respect to p-adic and dark hierarchies and the geometric durations of quantum jumps scale like  $\hbar$ . Dark matter hierarchy suggests also a slight modification of the notion of self. Each self involves a hierarchy of dark matter levels, and one is led to ask whether the highest level in this hierarchy corresponds to single quantum jump rather than a sequence of quantum jumps. The averaging of conscious experience over quantum jumps would occur only for

sub-selves at lower levels of dark matter hierarchy and these mental images would be ordered, and single moment of consciousness would be experienced as a history of events. The quantum parallel dissipation at the lower levels would give rise to the experience of flow of time. For instance, hadron as a macro-temporal quantum system in the characteristic time scale of hadron is a dissipating system at quark and gluon level corresponding to shorter p-adic time scales. One can ask whether even entire life cycle could be regarded as a single quantum jump at the highest level so that consciousness would not be completely lost even during deep sleep. This would allow to understand why we seem to know directly that this biological body of mine existed yesterday.

The fact that we can remember phone numbers with 5 to 9 digits supports the view that self corresponds at the highest dark matter level to single moment of consciousness. Self would experience the average over the sequence of moments of consciousness associated with each sub-self but there would be no averaging over the separate mental images of this kind, be their parallel or serial. These mental images correspond to sub-selves having shorter wake-up periods than self and would be experienced as being time ordered. Hence the digits in the phone number are experienced as separate mental images and ordered with respect to experienced time.

### *3. The time span of long term memories as signature for the level of dark matter hierarchy*

The basic question is what time scale can one assign to the geometric duration of quantum jump measured naturally as the size scale of the space-time region about which quantum jump gives conscious information. This scale is naturally the size scale in which the non-determinism of quantum jump is localized. During years I have made several guesses about this time scales but zero energy ontology and the vision about fractal hierarchy of quantum jumps within quantum jumps leads to a unique identification.

Causal diamond as an imbedding space correlate of self defines the time scale  $\tau$  for the space-time region about which the consciousness experience is about. The temporal distances between the tips of  $CD$  as come as integer multiples of  $CP_2$  length scales and for prime multiples correspond to what I have christened as secondary p-adic time scales. A reasonable guess is that secondary p-adic time scales are selected during evolution and the primes near powers of two are especially favored. For electron, which corresponds to Mersenne prime  $M_{127} = 2^{127} - 1$  this scale corresponds to .1 seconds defining the fundamental time scale of living matter via 10 Hz biorhythm (alpha rhythm). The unexpected prediction is that all elementary particles correspond to time scales possibly relevant to living matter.

Dark matter hierarchy brings additional finesse. For the higher levels of dark matter hierarchy  $\tau$  is scaled up by  $\hbar/\hbar_0$ . One could understand evolutionary leaps as the emergence of higher levels at the level of individual organism making possible intentionality and memory in the time scale defined  $\tau$ .

Higher levels of dark matter hierarchy provide a neat quantitative view about self hierarchy and its evolution. Various levels of dark matter hierarchy would naturally correspond to higher levels in the hierarchy of consciousness and the typical duration of life cycle would give an idea about the level in question. The level would determine also the time span of long term memories as discussed in [24]. The emergence of these levels must have meant evolutionary leap since long term memory is also accompanied by ability to anticipate future in the same time scale. This picture would suggest that the basic difference between us and our cousins is not at the level of genome as it is usually understood but at the level of the hierarchy of magnetic bodies [40, 24]. In fact, higher levels of dark matter hierarchy motivate the introduction of the notions of super-genome and hyper-genome. The genomes of entire organ can join to form super-genome expressing genes coherently. Hyper-genomes would result from the fusion of genomes of different organisms and collective levels of consciousness would express themselves via hyper-genome and make possible social rules and moral.

## 1.4 Bird's eye of view about the topics of the book

This book is devoted to a detailed representation of what quantum TGD in its recent form. Quantum TGD relies on two different views about physics: physics as an infinite-dimensional spinor geometry and physics as a generalized number theory. The most important guiding principle is quantum classical correspondence whose most profound implications follow almost trivially from the basic structure of the classical theory forming an exact part of quantum theory. A further mathematical guideline is

the mathematics associated with hyper-finite factors of type  $II_1$  about which the spinors of the world of classical worlds represent a canonical example.

### 1. *Quantum classical correspondence*

Quantum classical correspondence has turned out to be the most important guiding principle concerning the interpretation of the theory.

1. Quantum classical correspondence and the properties of the simplest extremals of Kähler action have served as the basic guideline in the attempts to understand the new physics predicted by TGD. The most dramatic predictions follow without even considering field equations in detail by using quantum classical correspondence and form the backbone of TGD and TGD inspired theory of living matter in particular.

The notions of many-sheeted space-time, topological field quantization and the notion of field/magnetic body, follow from simple topological considerations. The observation that space-time sheets can have arbitrarily large sizes and their interpretation as quantum coherence regions forces to conclude that in TGD Universe macroscopic and macro-temporal quantum coherence are possible in arbitrarily long scales.

2. Also long ranged classical color and electro-weak fields are an unavoidable prediction. It however took a considerable time to make the obvious conclusion: TGD Universe is fractal containing fractal copies of standard model physics at various space-time sheets and labeled by the collection of p-adic primes assignable to elementary particles and by the level of dark matter hierarchy characterized partially by the value of Planck constant labeling the pages of the book like structure formed by singular covering spaces of the imbedding space  $M^4 \times CP_2$  glued together along a four-dimensional back. Particles at different pages are dark relative to each other since purely local interactions defined in terms of the vertices of Feynman diagram involve only particles at the same page.
3. The new view about energy and time finding a justification in the framework of zero energy ontology means that the sign of the inertial energy depends on the time orientation of the space-time sheet and that negative energy space-time sheets serve as correlates for communications to the geometric future. This alone leads to profoundly new views about metabolism, long term memory, and realization of intentional action.
4. The general properties of Kähler action, in particular its vacuum degeneracy and the failure of the classical determinism in the conventional sense, have also strong implications. Space-time surface as a generalization of Bohr orbit provides not only a representation of quantum states but also of sequences of quantum jumps and thus contents of consciousness. Vacuum degeneracy implies spin glass degeneracy in 4-D sense reflecting quantum criticality which is the fundamental characteristic of TGD Universe.
5. The detailed study of the simplest extremals of Kähler action interpreted as correlates for asymptotic self organization patterns provides additional insights.  $CP_2$  type extremals representing elementary particles, cosmic strings, vacuum extremals, topological light rays ("massless extremal", ME), flux quanta of magnetic and electric fields represent the basic extremals. Pairs of wormhole throats identifiable as parton pairs define a completely new kind of particle carrying only color quantum numbers in ideal case and I have proposed their interpretation as quantum correlates for Boolean cognition. MEs and flux quanta of magnetic and electric fields are of special importance in living matter.

Topological light rays have interpretation as space-time correlates of "laser beams" of ordinary or dark photons or their electro-weak and gluonic counterparts. Neutral MEs carrying em and  $Z^0$  fields are ideal for communication purposes and charged  $W$  MEs ideal for quantum control. Magnetic flux quanta containing dark matter are identified as intentional agents quantum controlling the behavior of the corresponding biological body parts utilizing negative energy  $W$  MEs. Bio-system in turn is populated by electrets identifiable as electric flux quanta.

### 2. *Physics as infinite-dimensional geometry in the "world of classical worlds"*

Physics as infinite-dimensional Kähler geometry of the "world of classical worlds" with classical spinor fields representing the quantum states of the universe and gamma matrix algebra geometrizing fermionic statistics is the first vision.

The mere existence of infinite-dimensional non-flat Kähler geometry has impressive implications. Configuration space must decompose to a union of infinite-dimensional symmetric spaces labelled by zero modes having interpretation as classical dynamical degrees of freedom assumed in quantum measurement theory. Infinite-dimensional symmetric space has maximal isometry group identifiable as a generalization of Kac Moody group obtained by replacing finite-dimensional group with the group of canonical transformations of  $\delta M_{\pm}^4 \times CP_2$ , where  $\delta M_{\pm}^4$  is the boundary of 4-dimensional future light-cone. The infinite-dimensional Clifford algebra of configuration space gamma matrices in turn can be expressed as direct sum of von Neumann algebras known as hyper-finite factors of type  $II_1$  having very close connections with conformal field theories, quantum and braid groups, and topological quantum field theories.

### 3. Physics as a generalized number theory

Second vision is physics as a generalized number theory. This vision forces to fuse real physics and various p-adic physics to a single coherent whole having rational physics as their intersection and poses extremely strong conditions on real physics.

A further aspect of this vision is the reduction of the classical dynamics of space-time sheets to number theory with space-time sheets identified as what I have christened hyper-quaternionic sub-manifolds of hyper-octonionic imbedding space. Field equations would state that space-time surfaces are Kähler calibrations with Kähler action density reducing to a closed 4-form at space-time surfaces. Hence TGD would define a generalized topological quantum field theory with conserved Noether charges (in particular rest energy) serving as generalized topological invariants having extremum in the set of topologically equivalent 3-surfaces.

Infinite primes, integers, and rationals define the third aspect of this vision. The construction of infinite primes is structurally similar to a repeated second quantization of an arithmetic quantum field theory and involves also bound states. Infinite rationals can be also represented as space-time surfaces somewhat like finite numbers can be represented as space-time points.

### 4. The organization of the book

The first part of the book describes basic quantum TGD in its recent form.

1. The properties of the preferred extremals of Kähler action are crucial for the construction and the discussion of known extremals is therefore included.
2. General coordinate invariance and generalized super-conformal symmetries - the latter present only for 4-dimensional space-time surfaces and for 4-D Minkowski space - define the basic symmetries of quantum TGD. A generalization of Equivalence Principle can be formulated as a generalized coset construction.
3. In zero energy ontology S-matrix is replaced with M-matrix and identified as time-like entanglement coefficients between positive and negative energy parts of zero energy states assignable to the past and future boundaries of 4-surfaces inside causal diamond defined as intersection of future and past directed light-cones. M-matrix is a product of diagonal density matrix and unitary S-matrix and there are reasons to believe that S-matrix is universal. Generalized Feynman rules based on the generalization of Feynman diagrams obtained by replacing lines with light-like 3-surfaces and vertices with 2-D surfaces at which the lines meet.
4. A category theoretical formulation of quantum TGD is considered. Finite measurement resolution realized in terms of a fractal hierarchy of causal diamonds inside causal diamonds leads to a stringy formulation of quantum TGD involving effective replacement of the 3-D light-like surface with a collection of braid strands representing the ends of strings. A formulation in terms of category theoretic concepts is proposed and leads to a hierarchy of algebras forming what is known as operads.
5. Twistors emerge naturally in TGD framework and could allow the formulation of low energy limit of the theory in the approximation that particles are massless. The replacement of massless plane waves with states for which amplitudes are localized are light-rays is suggestive in twistor

theoretic framework. Twistors could allow also a dual representation of space-time surfaces in terms of surfaces of  $X \times CP_2$ , where  $X$  is 8-D twistor space or its 6-D projective variant. These surfaces would have dimension higher than four in non-perturbative phases meaning an analogy with branes. In full theory a massive particles must be included but represent a problem in approach based on standard twistors. The interpretation of massive particles in 4-D sense as massless particles in 8-D sense would resolve the problem and requires a generalization of twistor concept involving in essential manner the triality of vector and spinor representations of  $SO(7, 1)$ .

6. In TGD Universe bosons are in well-defined sense bound states of fermion and anti-fermion. This leads to the notion of bosonic emergence meaning that the fundamental action is just Dirac action coupled to gauge potentials and bosonic action emerges as part of effective action as one functionally integrates over the spinor fields. This kind of approach predicts the evolution of all coupling constants if one is able to fix the necessary UV cutoffs of mass and hyperbolic angle in loop integrations. The guess for the hyperbolic cutoff motivated by the geometric view about finite measurement resolution predicts coupling constant evolution which is consistent with that predicted by standard model. The condition that all N-vertices defined by fermionic loops vanish for  $N > 3$  when incoming particles are massless gives hopes of fixing completely the hyperbolic cutoff from fundamental principles.

Second part of the book is devoted to hyper-finite factors and hierarchy of Planck constants.

1. Configuration space spinors indeed define a canonical example about hyper-finite factor of type  $II_1$ . The work with TGD inspired model for quantum computation led to the realization that von Neumann algebras, in particular hyper-finite factors of type  $II_1$  could provide the mathematics needed to develop a more explicit view about the construction of M-matrix. This has turned out to be the case to the extent that a general master formula for M-matrix with interactions described as a deformation of ordinary tensor product to Connes tensor products emerges.
2. The idea about hierarchy of Planck constants emerged from anomalies of biology and the strange finding that planetary orbits could be regarded as Bohr orbits but with a gigantic value of Planck constant. This led to the vision that dark matter corresponds to ordinary particles but with non-standard value of Planck constant and to a generalization of the 8-D imbedding space to a book like structure with pages partially characterized by the value of Planck constant. Using the intuition provided by the inclusions of hyper-finite factors of type  $II_1$  one ends up to a prediction for the spectrum of Planck constants associated with  $M^4$  and  $CP_2$  degrees of freedom. This inspires the proposal that dark matter could be in quantum Hall like phase localized at light-like 3-surfaces with macroscopic size and behaving in many respects like black hole horizons.

The seven online books about TGD [79, 60, 61, 69, 54, 48, 67] and eight online books about TGD inspired theory of consciousness and quantum biology [73, 10, 58, 9, 34, 39, 42, 66] are warmly recommended for the reader willing to get overall view about what is involved.

## 1.5 The contents of the book

### 1.5.1 Part I: General Theory

#### Basic extremals of the Kähler action

The physical interpretation of the Kähler function and the TGD based space-time concept are the basic themes of this book. The aim is to develop what might be called classical TGD at fundamental level. The strategy is simple: try to guess the general physical consequences of the configuration space geometry and of the TGD based gauge field concept and study the simplest extremals of Kähler action and try to abstract general truths from their properties.

The fundamental underlying assumptions are the following:

1. The 4-surface associated with given 3-surface defined by Kähler function  $K$  as a preferred extremal of the Kähler action is identifiable as a classical space-time. Number theoretically preferred extremals would decompose to hyper-quaternionic and co-hyper-quaternionic regions.

The reduction of the classical theory to the level of the modified Dirac action implies that the preferred extremals are critical in the sense of allowing infinite number of deformations for which the second variation of Kähler action vanishes [?] It is not clear whether criticality and hyper-quaternionicity are consistent with each other.

Due to the preferred extremal property classical space-time can be also regarded as a generalized Bohr orbit so that the quantization of the various parameters associated with a typical extremal of the Kähler action is expected to take place in general. In TGD quantum states corresponds to quantum superpositions of these classical space-times so that this classical space-time is certainly not some kind of effective quantum average space-time.

2. The bosonic vacuum functional of the theory is the exponent of the Kähler function  $\Omega_B = \exp(K)$ . This assumption is the only assumption about the dynamics of the theory and is necessitated by the requirement of divergence cancellation in perturbative approach.
3. Renormalization group invariance and spin glass analogy. The value of the Kähler coupling strength is such that the vacuum functional  $\exp(K)$  is analogous to the exponent  $\exp(H/T)$  defining the partition function of a statistical system at critical temperature. This allows Kähler coupling strength to depend on zero modes of the configuration space metric and as already found there is very attractive hypothesis determining completely the dependence of the Kähler coupling strength on the zero modes based on p-adic considerations motivated by the spin glass analogy.
4. In spin degrees of freedom the massless Dirac equation for the induced spinor fields with modified Dirac action defines classical theory: this is in complete accordance with the proposed definition of the configuration space spinor structure.

The geometrization of the classical gauge fields in terms of the induced gauge field concept is also important concerning the physical interpretation. Electro-weak gauge potentials correspond to the space-time projections of the spinor connection of  $CP_2$ , gluonic gauge potentials to the projections of the Killing vector fields of  $CP_2$  and gravitational field to the induced metric. The topics to be discussed in this part of the book are summarized briefly in the following.

What the selection of preferred extremals of Kähler action might mean has remained a long standing problem and real progress occurred only quite recently (I am writing this towards the end of year 2003).

1. The vanishing of Lorentz 4-force for the induced Kähler field means that the vacuum 4-currents are in a mechanical equilibrium. Lorentz 4-force vanishes for all known solutions of field equations which inspires the hypothesis that all preferred extremals of Kähler action satisfy the condition. The vanishing of the Lorentz 4-force in turn implies local conservation of the ordinary energy momentum tensor. The corresponding condition is implied by Einstein's equations in General Relativity. The hypothesis would mean that the solutions of field equations are what might be called generalized Beltrami fields. The condition implies that vacuum currents can be non-vanishing only provided the dimension  $D_{CP_2}$  of the  $CP_2$  projection of the space-time surface is less than four so that in the regions with  $D_{CP_2} = 4$ , Maxwell's vacuum equations are satisfied.
2. The hypothesis that Kähler current is proportional to a product of an arbitrary function  $\psi$  of  $CP_2$  coordinates and of the instanton current generalizes Beltrami condition and reduces to it when electric field vanishes. Instanton current has a vanishing divergence for  $D_{CP_2} < 4$ , and Lorentz 4-force indeed vanishes. Four 4-dimensional projection the scalar function multiplying the instanton current can make it divergenceless. The remaining task would be the explicit construction of the imbeddings of these fields and the demonstration that field equations can be satisfied.
3. By quantum classical correspondence the non-deterministic space-time dynamics should mimic the dissipative dynamics of the quantum jump sequence. Beltrami fields appear in physical applications as asymptotic self organization patterns for which Lorentz force and dissipation vanish. This suggests that preferred extremals of Kähler action correspond to space-time sheets which at least asymptotically satisfy the generalized Beltrami conditions so that one can indeed assign to the final 3-surface a unique 4-surface apart from effects related to non-determinism. Preferred

extremal property abstracted to purely algebraic generalized Beltrami conditions makes sense also in the p-adic context.

This chapter is mainly devoted to the study of the basic extremals of the Kähler action besides the detailed arguments supporting the view that the preferred extrema satisfy generalized Beltrami conditions at least asymptotically.

The newest results discussed in the last section about the weak form of electric-magnetic duality suggest strongly that Beltrami property is general and together with the weak form of electric-magnetic duality allows a reduction of quantum TGD to almost topological field theory with Kähler function allowing expression as a Chern-Simons term.

The surprising implication of the duality is that Kähler form of  $CP_2$  must be replaced with that for  $S^2 \times CP_2$  in order to obtain a configuration space metric which is non-trivial in  $M^4$  degrees of freedom. This modification implies much richer vacuum structure than the original Kähler action which is a good news as far as the description of classical gravitational fields in terms of small deformations of vacuum extremals with the four-momentum density of the topologically condensed matter given by Einstein's equations is considered. The breaking of Lorentz invariance from  $SO(3,1)$  to  $SO(3)$  is implied already by the geometry of  $CD$  but is extremely small for a given causal diamond ( $CD$ ). Since a wave function over the Lorentz boosts and translates of  $CD$  is allowed, there is no actual breaking of Poincaré invariance at the level of the basic theory. Beltrami property leads to a rather explicit construction of the general solution of field equations based on the hydrodynamic picture implying that single particle quantum numbers are conserved along flow lines defined by the instanton current. The construction generalizes also to the fermionic sector.

### Construction of Quantum Theory: Symmetries

This chapter provides a summary about the role of symmetries in the construction of quantum TGD. The discussions are based on the general vision that quantum states of the Universe correspond to the modes of classical spinor fields in the "world of the classical worlds" identified as the infinite-dimensional configuration space of light-like 3-surfaces of  $H = M^4 \times CP_2$  (more or less-equivalently, the corresponding 4-surfaces defining generalized Bohr orbits). The following topics are discussed on basis of this vision.

TGD relies heavily on geometric ideas, which have gradually generalized during the years. Symmetries play a key role as one might expect on basis of general definition of geometry as a structure characterized by a given symmetry.

#### 1. *Physics as infinite-dimensional Kähler geometry*

1. The basic idea is that it is possible to reduce quantum theory to configuration space geometry and spinor structure. The geometrization of loop spaces inspires the idea that the mere existence of Riemann connection fixes configuration space Kähler geometry uniquely. Accordingly, configuration space can be regarded as a union of infinite-dimensional symmetric spaces labeled by zero modes labeling classical non-quantum fluctuating degrees of freedom.

The huge symmetries of the configuration space geometry deriving from the light-likeness of 3-surfaces and from the special conformal properties of the boundary of 4-D light-cone would guarantee the maximal isometry group necessary for the symmetric space property. Quantum criticality is the fundamental hypothesis allowing to fix the Kähler function and thus dynamics of TGD uniquely. Quantum criticality leads to surprisingly strong predictions about the evolution of coupling constants.

2. Configuration space spinors correspond to Fock states and anti-commutation relations for fermionic oscillator operators correspond to anti-commutation relations for the gamma matrices of the configuration space. Configuration space gamma matrices contracted with Killing vector fields give rise to a super-symplectic algebra which together with Hamiltonians of the configuration space forms what I have used to call super-symplectic algebra.

Super-symplectic degrees of freedom represent completely new degrees of freedom and have no electroweak couplings. In the case of hadrons super-symplectic quanta correspond to what has been identified as non-perturbative sector of QCD: they define TGD correlate for the degrees of

freedom assignable to hadronic strings. They are responsible for the most of the mass of hadron and resolve spin puzzle of proton.

3. Besides super-symplectic symmetries there are Super-Kac Moody symmetries assignable to light-like 3-surfaces and together these algebras extend the conformal symmetries of string models to dynamical conformal symmetries instead of mere gauge symmetries. The construction of the representations of these symmetries is one of the main challenges of quantum TGD. Modular invariance is one aspect of conformal symmetries and plays a key role in the understanding of elementary particle vacuum functionals and the description of family replication phenomenon in terms of the topology of partonic 2-surfaces.
4. Modified Dirac equation gives also rise to a hierarchy super-conformal algebras assignable to zero modes. These algebras follow from the existence of conserved fermionic currents. The corresponding deformations of the space-time surface correspond to vanishing second variations of Kähler action and provide a realization of quantum criticality. This led to a breakthrough in the understanding of the modified Dirac action via the addition of a measurement interaction term to the action allowing to obtain among other things stringy propagator and the coding of quantum numbers of super-conformal representations to the geometry of space-time surfaces required by quantum classical correspondence.

### 2. *p-adic physics and p-adic variants of basic symmetries*

p-Adic mass calculations relying on p-adic length scale hypothesis led to an understanding of elementary particle masses using only super-conformal symmetries and p-adic thermodynamics. The need to fuse real physics and various p-adic physics to single coherent whole led to a generalization of the notion of number obtained by gluing together reals and p-adics together along common rationals and algebraics. The interpretation of p-adic space-time sheets is as correlates for cognition and intentionality. p-Adic and real space-time sheets intersect along common rationals and algebraics and the subset of these points defines what I call number theoretic braid in terms of which both configuration space geometry and S-matrix elements should be expressible. Thus one would obtain number theoretical discretization which involves no adhoc elements and is inherent to the physics of TGD.

### 3. *Hierarchy of Planck constants and dark matter hierarchy*

The realization for the hierarchy of Planck constants proposed as a solution to the dark matter puzzles leads to a profound generalization of quantum TGD through a generalization of the notion of imbedding space to characterize quantum criticality. The resulting space has a book like structure with various almost-copies of the imbedding space representing the pages of the book meeting at quantum critical sub-manifolds. A particular page of the book can be seen as an n-fold singular covering or factor space of  $CP_2$  or of a causal diamond ( $CD$ ) of  $M^4$  defined as an intersection of the future and past directed light-cones. Therefore the cyclic groups  $Z_n$  appear as discrete symmetry groups.

### 4. *Number theoretical symmetries*

TGD as a generalized number theory vision leads to the idea that also number theoretical symmetries are important for physics.

1. There are good reasons to believe that the strands of number theoretical braids can be assigned with the roots of a polynomial which suggests the interpretation corresponding Galois groups as purely number theoretical symmetries of quantum TGD. Galois groups are subgroups of the permutation group  $S_\infty$  of infinitely many objects acting as the Galois group of algebraic numbers. The group algebra of  $S_\infty$  is HFF which can be mapped to the HFF defined by configuration space spinors. This picture suggests a number theoretical gauge invariance stating that  $S_\infty$  acts as a gauge group of the theory and that global gauge transformations in its completion correspond to the elements of finite Galois groups represented as diagonal groups of  $G \times G \times \dots$  of the completion of  $S_\infty$ .
2. HFFs inspire also an idea about how entire TGD emerges from classical number fields, actually their complexifications. In particular,  $SU(3)$  acts as subgroup of octonion automorphisms leaving

invariant preferred imaginary unit. If space-time surfaces are hyper-quaternionic (meaning that the octonionic counterparts of the modified gamma matrices span complex quaternionic sub-algebra of octonions) and contain at each point a preferred plane  $M^2$  of  $M^4$ , one ends up with  $M^8 - H$  duality stating that space-time surfaces can be equivalently regarded as surfaces in  $M^8$  or  $M^4 \times CP_2$ . One can actually generalize  $M^2$  to a two-dimensional Minkowskian sub-manifold of  $M^4$ . One ends up with quantum TGD by considering associative sub-algebras of the local octonionic Clifford algebra of  $M^8$  or  $H$ . so that TGD could be seen as a generalized number theory.

### Construction of Quantum Theory: M-matrix

The construction of  $M$ -matrix has remained the key challenge of quantum TGD from the very beginning when it had become clear that path integral approach and canonical quantization make no sense in TGD framework. My intuitive feeling that the problems are not merely technical has turned out to be correct.

The rapid evolution of a bundle of new ideas has taken place during last five years (zero energy ontology, the notion of finite measurement resolution, the role of hyper-finite factors of type  $II_1$ , the hierarchy of Planck constants, the construction of configuration space geometry in terms of second quantized induced spinor fields, number theoretic compactification,...). These ideas are now converging to an overall view in which various approaches to quantum TGD (physics as infinite dimensional geometry, physics as generalized number theory, physics from number theoretical universality, physics from finite measurement resolution implying effective discretization, TGD as almost topological QFT) neatly fuse together to single coherent overall view. Many ideas have been of course thrown away because they have not produced anything useful.

In this chapter the overall view about the construction of the TGD counterpart of  $S$ -matrix -  $M$ -matrix - is discussed. It is perhaps wise to summarize briefly the vision about  $M$ -matrix.

#### 1. Zero energy ontology and interpretation of light-like 3-surfaces as generalized Feynman diagrams

1. Zero energy ontology is the cornerstone of the construction. Zero energy states have vanishing net quantum numbers and consist of positive and negative energy parts, which can be thought of as being localized at the boundaries of light-like 3-surface  $X_l^3$  connecting the light-like boundaries of a causal diamond  $CD$  identified as intersection of future and past directed light-cones. There is entire hierarchy of  $CD$ s, whose scales are suggested to come as powers of 2. A more general proposal is that prime powers of fundamental size scale are possible and would conform with the most general form of p-adic length scale hypothesis. The hierarchy of size scales assignable to  $CD$ s corresponds to a hierarchy of length scales and code for a hierarchy of radiative corrections to generalized Feynman diagrams.
2. Light-like 3-surfaces are the basic dynamical objects of quantum TGD and have interpretation as generalized Feynman diagrams having light-like 3-surfaces as lines glued together along their ends defining vertices as 2-surfaces. By effective 2-dimensionality (holography) of light-like 3-surfaces the interiors of light-like 3-surfaces are analogous to gauge degrees of freedom and partially parameterized by Kac-Moody group respecting the light-likeness of 3-surfaces. This picture differs dramatically from that of string models since light-like 3-surfaces replacing stringy diagrams are singular as manifolds whereas 2-surfaces representing vertices are not.

#### 2. Identification of the counterpart of $S$ -matrix as time-like entanglement coefficients

1. The TGD counterpart of  $S$ -matrix - call it  $M$ -matrix- defines time-like entanglement coefficients between positive and negative energy parts of zero energy state located at the light-like boundaries of  $CD$ . One can also assign to quantum jump between zero energy states a matrix- call it  $U$ -matrix - which is unitary and assumed to be expressible in terms of  $M$ -matrices.  $M$ -matrix need not be unitary unlike the  $U$ -matrix characterizing the unitary process forming part of quantum jump. There are several good arguments suggesting that that  $M$ -matrix cannot be unitary but can be regarded as thermal  $S$ -matrix so that thermodynamics would become an essential

part of quantum theory. In fact,  $M$ -matrix can be decomposed to a product of positive diagonal matrix identifiable as square root of density matrix and unitary matrix so that quantum theory would be kind of square root of thermodynamics. Path integral formalism is given up although functional integral over the 3-surfaces is present.

2. In the general case only thermal  $M$ -matrix defines a normalizable zero energy state so that thermodynamics becomes part of quantum theory. One can assign to  $M$ -matrix a complex parameter whose real part has interpretation as interaction time and imaginary part as the inverse temperature.

### 3. Hyper-finite factors and $M$ -matrix

HFFs of type  $\text{III}_1$  provide a general vision about  $M$ -matrix.

1. The factors of type III allow unique modular automorphism  $\Delta^{it}$  (fixed apart from unitary inner automorphism). This raises the question whether the modular automorphism could be used to define the  $M$ -matrix of quantum TGD. This is not the case as is obvious already from the fact that unitary time evolution is not a sensible concept in zero energy ontology.
2. Concerning the identification of  $M$ -matrix the notion of state as it is used in theory of factors is a more appropriate starting point than the notion modular automorphism but as a generalization of thermodynamical state is certainly not enough for the purposes of quantum TGD and quantum field theories (algebraic quantum field theorists might disagree!). Zero energy ontology requires that the notion of thermodynamical state should be replaced with its "complex square root" abstracting the idea about  $M$ -matrix as a product of positive square root of a diagonal density matrix and a unitary  $S$ -matrix. This generalization of thermodynamical state -if it exists- would provide a firm mathematical basis for the notion of  $M$ -matrix and for the fuzzy notion of path integral.
3. The existence of the modular automorphisms relies on Tomita-Takesaki theorem, which assumes that the Hilbert space in which HFF acts allows cyclic and separable vector serving as ground state for both HFF and its commutant. The translation to the language of physicists states that the vacuum is a tensor product of two vacua annihilated by annihilation oscillator type algebra elements of HFF and creation operator type algebra elements of its commutant isomorphic to it. Note however that these algebras commute so that the two algebras are not hermitian conjugates of each other. This kind of situation is exactly what emerges in zero energy ontology: the two vacua can be assigned with the positive and negative energy parts of the zero energy states entangled by  $M$ -matrix.
4. There exists infinite number of thermodynamical states related by modular automorphisms. This must be true also for their possibly existing "complex square roots". Physically they would correspond to different measurement interactions giving rise to Kähler functions of WCW differing only by a real part of holomorphic function of complex coordinates of WCW and arbitrary function of zero mode coordinates and giving rise to the same Kähler metric of WCW.

### 4. Connes tensor product as a realization of finite measurement resolution

The inclusions  $\mathcal{N} \subset \mathcal{M}$  of factors allow an attractive mathematical description of finite measurement resolution in terms of Connes tensor product but do not fix  $M$ -matrix as was the original optimistic belief.

1. In zero energy ontology  $\mathcal{N}$  would create states experimentally indistinguishable from the original one. Therefore  $\mathcal{N}$  takes the role of complex numbers in non-commutative quantum theory. The space  $\mathcal{M}/\mathcal{N}$  would correspond to the operators creating physical states modulo measurement resolution and has typically fractal dimension given as the index of the inclusion. The corresponding spinor spaces have an identification as quantum spaces with non-commutative  $\mathcal{N}$ -valued coordinates.

2. This leads to an elegant description of finite measurement resolution. Suppose that a universal M-matrix describing the situation for an ideal measurement resolution exists as the idea about square root of state encourages to think. Finite measurement resolution forces to replace the probabilities defined by the M-matrix with their  $\mathcal{N}$  "averaged" counterparts. The "averaging" would be in terms of the complex square root of  $\mathcal{N}$ -state and a direct analog of functionally or path integral over the degrees of freedom below measurement resolution defined by (say) length scale cutoff.
3. One can construct also directly M-matrices satisfying the measurement resolution constraint. The condition that  $\mathcal{N}$  acts like complex numbers on M-matrix elements as far as  $\mathcal{N}$ -"averaged" probabilities are considered is satisfied if M-matrix is a tensor product of M-matrix in  $\mathcal{M}(\mathcal{N})$  interpreted as finite-dimensional space with a projection operator to  $\mathcal{N}$ . The condition that  $\mathcal{N}$  averaging in terms of a complex square root of  $\mathcal{N}$  state produces this kind of M-matrix poses a very strong constraint on M-matrix if it is assumed to be universal (apart from variants corresponding to different measurement interactions).

#### 5. *Input from the construction of configuration space spinor structure*

The construction of configuration space spinor structure in terms of second quantized induced spinor fields is certainly the most important step made hitherto towards explicit formulas for M-matrix elements.

1. Number theoretical compactification ( $M^8 - H$  duality) states that space-time surfaces can be equivalently regarded as 4-dimensional surfaces of either  $H = M^4 \times CP_2$  or of 8-D Minkowski space  $M^8$ , and consisting of hyper-quaternionic and co-hyper-quaternionic regions identified as regions with Minkowskian and Euclidian signatures of induced metric. Duality preserves induced metric and Kähler form. This duality poses very strong constraints on the geometry of the preferred extremals of Kähler action implying dual slicings of the space-time surface by string worlds sheets and partonic 2-surfaces as also by light-like 1-surfaces and light-like 3-surfaces. These predictions are consistent what is known about the extremals of Kähler action. The predictions of number theoretical compactification lead to dramatic progress in the construction of configurations space spinor structure and geometry. One consequence is dimensional reduction of space-time surface to string world sheet allowing to understand how the space-time correlate for Equivalence Principle is realized in TGD framework (its quantum counterpart emerges from coset construction for super-symplectic and super Kac-Moody algebras).
2. The construction of configuration space geometry and spinor structure in terms of induced spinor fields leads to the conclusion that finite measurement resolution is an intrinsic property of quantum states basically due to the vacuum degeneracy of Kähler action. This gives a justification for the notion of number theoretic braid effectively replacing light-like 3-surfaces. Hence the infinite-dimensional configuration space is replaced with a finite-dimensional space  $(\delta M_{\pm}^4 \times CP_2)^n / S_n$ . A possible interpretation is that the finite fermionic oscillator algebra for given partonic 2-surface  $X^2$  represents the factor space  $\mathcal{M}/\mathcal{N}$  identifiable as quantum variant of Clifford algebra.  $(\delta M_{\pm}^4 \times CP_2)^n / S_n$  would represent its bosonic analog.
3. The isometries of the configuration space corresponds to  $X^2$  local symplectic transformations  $\delta M_{\pm}^4 \times CP_2$  depending only on the value of the invariant  $\epsilon^{\mu\nu} J_{\mu\nu}$ , where  $J_{\mu\nu}$  can correspond to the Kähler form induced from  $\delta M_{\pm}^4$  or  $CP_2$ . This group parameterizes quantum fluctuating degrees of freedom. Zero modes correspond to coordinates which cannot be made complex, in particular to the values of the induced symplectic form which thus behaves as a classical field so that configuration space allows a slicing by the classical field patterns  $J_{\mu\nu}(x)$  representing zero modes.
4. By the effective 2-dimensionality of light-like 3-surfaces  $X_l^3$  (holography) the interiors of light-like 3-surfaces are analogous to gauge degrees of freedom and partially parameterized by Kac-Moody group respecting the light-likeness of 3-surfaces. Quantum classical correspondence suggests that gauge fixing in Kac-Moody degrees of freedom takes place and implies correlation between the quantum numbers of the physical state and  $X_l^3$ . There would be no path integral over  $X_l^3$  and only functional integral defined by configuration space geometry over partonic 2-surfaces.

5. The condition that the Noether currents assignable to the modified Dirac equation are conserved requires that space-time surfaces correspond to extremals for which second variation of Kähler action vanishes. A milder condition is that the rank of the matrix defined by the second variation of Kähler action is less than maximal. Preferred extremals of Kähler action can be identified as this kind of 4-surface and the interpretation is in terms of quantum criticality.

#### 6. Conformal symmetries and stringy diagrammatics

The modified Dirac equation has rich super-conformal symmetries helping to achieve concrete vision about the structure of  $M$ -matrix in terms of generalized Feynman diagrammatics

1. Both super-conformal symmetries, the slicing of space-time surface by string worlds sheets, and the reduction of space-time sheet to string world sheet as a consequence of finite measurement resolution suggest that the generalized Feynman diagrams have as vertices  $N$ -point functions of a conformal field theory assignable to the partonic 2-surfaces at which the lines of Feynman diagram meet. Finite measurement resolution means that this conformal theory is defined in the discrete set defined by the number theoretic braid. The presence of symplectic invariants in turn suggest a symplectic variant of conformal field theory leading to a concrete construction of symplectic fusion rules relying in crucial manner to discretization.
2. The effective 3-dimensionality implied by the modified Dirac operator associated with Kähler action plays crucial role in the construction of both configuration space geometry (Kähler function is identified as Dirac determinant assignable to the modified Dirac operator) and of  $M$ -matrix. By effective 3-dimensionality the propagators reduce to the propagators assignable the light-like 3-surfaces. This does not give stringy propagators and massive stringy excitations would not appear at all in propagators. This does not conform with what  $p$ -adic mass calculations and conformal symmetries suggest.
3. The solution of the problem is provided by the addition of measurement interaction term to the modified Dirac action and assignable to wormhole throats or equivalently any light-like 3-surface parallel to them in the slicing of space-time sheet: this condition defines additional symmetry. Measurement interaction term implies that the preferred extremals of Kähler action depend on quantum numbers of the states of super-conformal representations as quantum classical correspondence requires. The coupling constants appearing in the measurement interaction term are fixed by the condition that Kähler function transforms only by a real part of a holomorphic function of complex coordinates of WCW depending also on zero modes so that Kähler metric of WCW remains unchanged. This realizes also the effective 2-dimensionality of space-like 3-surfaces but only in finite regions where the slicing by light-like 3-surfaces makes sense.

#### 7. TGD as almost topological QFT

The idea that TGD could be regarded as almost topological QFT has been very fruitful although the hypothesis that Chern-Simons term for induced Kähler gauge potential assignable to light-like 3-surfaces identified as regions of space-time where the Euclidian signature of induced metric assignable to the interior or generalized Feynman diagram changes to Minkowskian one turned out to be too strong. The reduction of configuration space and its Clifford algebra to finite dimensional structures due to finite measurement resolution however realizes this idea but in different manner.

1. There is functional integral over the small deformations of Feynman cobordisms corresponding to the maxima of Kähler function which is finite-dimensional if finite measurement resolution is taken into account. Almost topological QFT property of quantum suggests the identification of  $M$ -matrix as a functor from the category of generalized Feynman cobordisms (generalized Feynman diagrams) to the category of operators mapping the Hilbert space of positive energy states to that for negative energy states: these Hilbert spaces are assignable to partonic 2-surfaces.
2. The limit at which momenta vanish is well-defined for  $M$ -matrix since the modified Dirac action contains measurement interaction term and at this limit one indeed obtains topological QFT.

3. Almost TQFT property suggests that braiding S-matrices should have important role in the construction. It is indeed possible to assign the with the lines of the generalized Feynman diagram. The reduction of quantum TGD to topological QFT should occur at quantum criticality with respect to the change of Planck constant since in this situation the  $M$ -matrix should not depend at all on Planck constant. Factoring QFTs in 1+1 dimensions give examples of this kind of theories.

#### 8. Bosonic emergence

The construction of QFT limit of quantum TGD based on the notion of bosonic emergence led to the most concrete picture about M-matrix achieved hitherto.

1. An "almost stringy" fermion propagator arises as one adds to the modified Dirac action a term coupling the charges in a Cartan algebra of the isometry group of  $H = M^4 \times CP_2$  to conserved fermionic currents (there are several of them). Also more general observables allow this kind of coupling and the interpretation in terms of measurement interaction. This term also realizes quantum classical correspondence by feeding information about quantum numbers of partons to the geometry of space-time sheet so that quantum numbers entangle with the geometry of space-time sheet as holography requires. This measurement interaction was the last piece in the puzzle "What are the basic equations of quantum TGD" and unified several visions about the physics predicted by quantum TGD. "Almost stringy" means that the on mass shell fermions obey stringy mass formulas dictated by super-conformal symmetry but that propagator itself -although it depends on four-momentum- is not the inverse of super-Virasoro generator  $G_0$  as it would be in string models.
2. The identification of bosons as wormhole contacts means that bosonic propagation reduces to a propagation of fermion and antifermion at opposite throats of the wormhole throat. In this framework bosonic n-vertex would correspond to the decay of bosons to fermion-antifermion pairs in the loop. Purely bosonic gauge boson couplings would be generated radiatively from triangle and box diagrams involving only fermion-boson couplings. In particular, bosonic propagator would be generated as a self-energy loop: bosons would propagate by decaying to fermion-antifermion pair and then fusing back to the boson. TGD counterpart for gauge theory dynamics would be emergent and bosonic couplings would have form factors with IR and UV behaviors allowing finiteness of the loops constructed from them since the constraint that virtual fermion pair corresponds to wormhole contact poses strong constraint on virtual momenta of fermion and antifermion.

This picture leads to generalized Feynman rules for M-matrix. The QFT limit based on this picture is able to reproduce the p-adic length scale evolution of various gauge coupling strengths with simple cutoffs on mass squared and hyperbolic angle characterizing the state of fermion in the rest system of virtual boson. The presence of these cutoffs is dictated by geometric picture about loops provided by zero energy ontology. The condition that the bosonic  $N > 3$ -vertices vanish when incoming states are on mass shell gives an infinite number of conditions which could fix the cutoffs uniquely.

### Category Theory and Quantum TGD

Possible applications of category theory to quantum TGD are discussed. The so called 2-plectic structure generalizing the ordinary symplectic structure by replacing symplectic 2-form with 3-form and Hamiltonians with Hamiltonian 1-forms has a natural place in TGD since the dynamics of the light-like 3-surfaces is characterized by Chern-Simons type action. The notion of planar operad was developed for the classification of hyper-finite factors of type  $II_1$  and its mild generalization allows to understand the combinatorics of the generalized Feynman diagrams obtained by gluing 3-D light-like surfaces representing the lines of Feynman diagrams along their 2-D ends representing the vertices.

The fusion rules for the symplectic variant of conformal field theory, whose existence is strongly suggested by quantum TGD, allow rather precise description using the basic notions of category theory and one can identify a series of finite-dimensional nilpotent algebras as discretized versions of field algebras defined by the fusion rules. These primitive fusion algebras can be used to construct more complex algebras by replacing any algebra element by a primitive fusion algebra. Trees with arbitrary

numbers of branches in any node characterize the resulting collection of fusion algebras forming an operad. One can say that an exact solution of symplectic scalar field theory is obtained.

Conformal fields and symplectic scalar field can be combined to form symplecto-formal fields. The combination of symplectic operad and Feynman graph operad leads to a construction of Feynman diagrams in terms of n-point functions of conformal field theory. M-matrix elements with a finite measurement resolution are expressed in terms of a hierarchy of symplecto-conformal n-point functions such that the improvement of measurement resolution corresponds to an algebra homomorphism mapping conformal fields in given resolution to composite conformal fields in improved resolution. This expresses the idea that composites behave as independent conformal fields. Also other applications are briefly discussed.

## 1.5.2 Part II: Twistors, Bosonic Emergence, Space-time Supersymmetry

### Twistors, $N = 4$ Super-Conformal Symmetry, and Quantum TGD

Twistors - a notion discovered by Penrose - have provided a fresh approach to the construction of perturbative scattering amplitudes in Yang-Mills theories and in  $N = 4$  supersymmetric Yang-Mills theory. This approach was pioneered by Witten. The latest step in the progress was the proposal by Nima Arkani-Hamed and collaborators that super Yang Mills and super gravity amplitudes might be formulated in 8-D twistor space possessing real metric signature  $(4, 4)$ . The questions considered in this chapter are following.

1. Could twistor space could provide a natural realization of  $N = 4$  super-conformal theory requiring critical dimension  $D = 8$  and signature metric  $(4, 4)$ ? Could string like objects in TGD sense be understood as strings in twistor space? More concretely, could one in some sense lift quantum TGD from  $M^4 \times CP_2$  to 8-D twistor space  $T$  so that one would have three equivalent descriptions of quantum TGD.
2. Could one construct the preferred extremals of Kähler action in terms of twistors -may be by mimicking the construction of hyper-quaternionic *resp.* co-hyper-quaternionic surfaces in  $M^8$  as surfaces having hyper-quaternionic tangent space *resp.* normal space at each point with the additional property that one can assign to each point  $x$  a plane  $M^2(x) \subset M^4$  as sub-space or as sub-space defined by light-like tangent vector in  $M^4$ . Could one mimic this construction by assigning to each point of  $X^4$  regarded as a 4-surface in  $T$  a 4-D plane of twistor space satisfying some conditions making possible the interpretation as a tangent plane and guaranteeing the existence of a map of  $X^4$  to a surface in  $M^4 \times CP_2$ . Could twistor formalism help to resolve the integrability conditions involved?
3. Could one define 8-D counterpart of twistors in order to avoid the problems posed by the description of massive states by regarding them as massless states in 8-D context. Could the octonionic realization of 8-D gamma matrices allow to define twistors in 8-D framework? Could associativity constraint reducing twistors to quaternionic twistors locally imply effective reduction to four-dimensional twistors.

The arguments of this chapter suggest that some these questions might have affirmative answers.

### Yangian Symmetry, Twistors, and TGD

There has been impressive steps in the understanding of  $\mathcal{N} = 4$  maximally supersymmetric YM theory possessing 4-D super-conformal symmetry. This theory is related by AdS/CFT duality to certain string theory in  $AdS_5 \times S^5$  background. Second stringy representation was discovered by Witten and is based on 6-D Calabi-Yau manifold defined by twistors. The unifying proposal is that so called Yangian symmetry is behind the mathematical miracles involved.

In the following I will discuss briefly the notion of Yangian symmetry and suggest its generalization in TGD framework by replacing conformal algebra with appropriate super-conformal algebras. Also a possible realization of twistor approach and the construction of scattering amplitudes in terms of Yangian invariants defined by Grassmannian integrals is considered in TGD framework and based on the idea that in zero energy ontology one can represent massive states as bound states of massless particles. There is also a proposal for a physical interpretation of the Cartan algebra of Yangian

algebra allowing to understand at the fundamental level how the mass spectrum of n-particle bound states could be understood in terms of the n-local charges of the Yangian algebra.

Twistors were originally introduced by Penrose to characterize the solutions of Maxwell's equations. Kähler action is Maxwell action for the induced Kähler form of  $CP_2$ . The preferred extremals allow a very concrete interpretation in terms of modes of massless non-linear field. Both conformally compactified Minkowski space identifiable as so called causal diamond and  $CP_2$  allow a description in terms of twistors. These observations inspire the proposal that a generalization of Witten's twistor string theory relying on the identification of twistor string world sheets with certain holomorphic surfaces assigned with Feynman diagrams could allow a formulation of quantum TGD in terms of 3-dimensional holomorphic surfaces of  $CP_3 \times CP_3$  mapped to 6-surfaces dual  $CP_3 \times CP_3$ , which are sphere bundles so that they are projected in a natural manner to 4-D space-time surfaces. Very general physical and mathematical arguments lead to a highly unique proposal for the holomorphic differential equations defining the complex 3-surfaces conjectured to correspond to the preferred extremals of Kähler action.

### Quantum Field Theory Limit of TGD from Bosonic Emergence

This chapter summarizes the basic mathematical realization of the modified Feynman rules hoped to give rise to a unitary M-matrix (recall that M-matrix is product of a positive square root of density matrix and unitary S-matrix in TGD framework and need not be unitary in the general case). The basic idea is that bosonic propagators emerge as fermionic loops. The approach is bottom up and leads to a precise general formulation for how the counterpart of YM action emerges from Dirac action coupled to gauge bosons and to modified Feynman rules. An essential element of the approach is a physical formulation for UV cutoff. Actually cutoff in both mass squared and hyperbolic angle is needed since Wick rotation does not make sense in TGD framework. This approach predicts all gauge couplings and assuming a geometrically very natural hyperbolic UV cutoff motivated by zero energy ontology one can understand the evolution of standard model gauge couplings and reproduce correctly the values of fine structure constant at electron and intermediate boson length scales. Also asymptotic freedom follows as a basic prediction. The UV cutoff for the hyperbolic angle as a function of p-adic length scale is somewhat ad hoc element of the model and a quantitative model for how this function could follow from the requirement of quantum criticality is formulated and discussed.

These considerations and numerical calculations lead to a general vision about how real and p-adic variants of TGD relate to each other and how p-adic fractalization takes place. As in case of twistorialization Cutkosky rules allowing unitarization of the tree amplitudes in terms of  $TT^\dagger$  contribution involving only light-like momenta seems to be the only working option and requires that  $TT^\dagger$  makes sense p-adically. The vanishing of the fermionic loops defining bosonic vertices for the incoming massless momenta emerges as a consistency condition suggested also by quantum criticality and by the fact that only BFF vertex is fundamental vertex if bosonic emergence is accepted. The vanishing of on mass shell N-vertices gives an infinite number of conditions on the hyperbolic cutoff as function of the integer  $k$  labeling p-adic length scale at the limit when bosons are massless and IR cutoff for the loop mass scale is taken to zero. It is not yet clear whether dynamical symmetries, in particular super-conformal symmetries, are involved with the realization of the vanishing conditions or whether hyperbolic cutoff is all that is needed.

### Does the QFT Limit of TGD Have Space-Time Super-Symmetry?

Contrary to the original expectations, TGD seems to allow a generalization of the space-time super-symmetry. This became clear with the increased understanding of the modified Dirac action. The introduction of a measurement interaction term to the action allows to understand how stringy propagator results and provides profound insights about physics predicted by TGD.

The appearance of the momentum and color quantum numbers in the measurement interaction couples space-time degrees of freedom to quantum numbers and allows also to define SUSY algebra at fundamental level as anti-commutation relations of fermionic oscillator operators. Depending on the situation a finite-dimensional SUSY algebra or the fermionic part of super-conformal algebra with an infinite number of oscillator operators results. The addition of a fermion in particular mode would define particular super-symmetry. Zero energy ontology implies that fermions as wormhole throats correspond to chiral super-fields assignable to positive or negative energy SUSY algebra whereas

bosons as wormhole contacts with two throats correspond to the direct sum of positive and negative energy algebra and fields which are chiral or antichiral with respect to both positive and negative energy theta parameters. This super-symmetry is badly broken due to the dynamics of the modified Dirac operator which also mixes  $M^4$  chiralities inducing massivation. Since righthanded neutrino has no electro-weak couplings the breaking of the corresponding super-symmetry should be weakest.

The question is whether this SUSY has a realization as a SUSY algebra at space-time level and whether the QFT limit of TGD could be formulated as a generalization of SUSY QFT. There are several problems involved.

1. In TGD framework super-symmetry means addition of fermion to the state and since the number of spinor modes is larger states with large spin and fermion numbers are obtained. This picture does not fit to the standard view about super-symmetry. In particular, the identification of theta parameters as Majorana spinors and super-charges as Hermitian operators is not possible.
2. The belief that Majorana spinors are somehow an intrinsic aspect of super-symmetry is however only a belief. Weyl spinors meaning complex theta parameters are also possible. Theta parameters can also carry fermion number meaning only the supercharges carry fermion number and are non-hermitian. The the general classification of super-symmetric theories indeed demonstrates that for  $D = 8$  Weyl spinors and complex and non-hermitian super-charges are possible. The original motivation for Majorana spinors might come from MSSM assuming that right handed neutrino does not exist. This belief might have also led to string theories in  $D=10$  and  $D=11$  as the only possible candidates for TOE after it turned out that chiral anomalies cancel.
3. The massivation of particles is basic problem of both SUSYs and twistor approach. The fact that particles which are massive in  $M^4$  sense can be interpreted as massless particles in  $M^4 \times CP_2$  suggests a manner to understand super-symmetry breaking and massivation in TGD framework. The octonionic realization of twistors is a very attractive possibility in this framework and quaternionicity condition guaranteeing associativity leads to twistors which are almost equivalent with ordinary 4-D twistors.
4. The first approach is based on an approximation assuming only the super-multiplets generated by right-handed neutrino or both right-handed neutrino and its antineutrino. The assumption that right-handed neutrino has fermion number opposite to that of the fermion associated with the wormhole throat implies that bosons correspond to  $\mathcal{N} = (1, 1)$  SUSY and fermions to  $\mathcal{N} = 1$  SUSY identifiable also as a short representation of  $\mathcal{N} = (1, 1)$  SUSY algebra trivial with respect to positive or negative energy algebra. This means a deviation from the standard view but the standard SUSY gauge theory formalism seems to apply in this case.
5. A more ambitious approach would put the modes of induced spinor fields up to some cutoff into super-multiplets. At the level next to the one described above the lowest modes of the induced spinor fields would be included. The very large value of  $\mathcal{N}$  means that  $\mathcal{N} \leq \exists \in$  SUSY cannot define the QFT limit of TGD for higher cutoffs. One must generalize SUSYs gauge theories to arbitrary value of  $\mathcal{N}$  but there are reasons to expect that the formalism becomes rather complex. More ambitious approach working at TGD however suggest a more general manner to avoid this problem.
  - (a) One of the key predictions of TGD is that gauge bosons and Higgs can be regarded as bound states of fermion and antifermion located at opposite throats of a wormhole contact. This implies bosonic emergence meaning that it QFT limit can be defined in terms of Dirac action. The resulting theory was discussed in detail in [?] and it was shown that bosonic propagators and vertices can be constructed as fermionic loops so that all coupling constant follow as predictions. One must however pose cutoffs in mass squared and hyperbolic angle assignable to the momenta of fermions appearing in the loops in order to obtain finite theory and to avoid massivation of bosons. The resulting coupling constant evolution is consistent with low energy phenomenology if the cutoffs in hyperbolic angle as a function of p-adic length scale is chosen suitably.
  - (b) The generalization of bosonic emergence that the TGD counterpart of SUSY is obtained by the replacement of Dirac action with action for chiral super-field coupled to vector field

as the action defining the theory so that the propagators of bosons and all their super-counterparts would emerge as fermionic loops.

- (c) The huge super-symmetries give excellent hopes about the cancelation of infinities so that this approach would work even without the cutoffs in mass squared and hyperbolic angle assignable to the momenta of fermions appearing in the loops. Cutoffs have a physical motivation in zero energy ontology but it could be an excellent approximation to take them to infinity. Alternatively, super-symmetric dynamics provides cutoffs dynamically.
6. The condition that  $\mathcal{N} = \infty$  variants for chiral and vector superfields exist fixes completely the identification of these fields in zero energy ontology.
- (a) In this framework chiral fields are generalizations of induced spinor fields and vector fields those of gauge potentials obtained by replacing them with their super-space counterparts. Chiral condition reduces to analyticity in theta parameters thanks to the different definition of hermitian conjugation in zero energy ontology ( $\theta$  is mapped to a derivative with respect to theta rather than to  $\bar{\theta}$ ) and conjugated super-field acts on the product of all theta parameters.
  - (b) Chiral action is a straightforward generalization of the Dirac action coupled to gauge potentials. The counterpart of YM action can emerge only radiatively as an effective action so that the notion emergence is now unavoidable and indeed basic prediction of TGD.
  - (c) The propagators associated with the monomials of  $n$  theta parameters behave as  $1/p^n$  so that only  $J = 0, 1/2, 1$  states propagate in normal manner and correspond to normal particles. The presence of monomials with number of thetas higher than 2 is necessary for the propagation of bosons since by the standard argument fermion and scalar loops cancel each other by super-symmetry. This picture conforms with the identification of graviton as a bound state of wormhole throats at opposite ends of string like object.
  - (d) This formulation allows also to use modified gamma matrices in the measurement interaction defining the counterpart of super variant of Dirac operator. Poincare invariance is not lost since momenta and color charges act on the tip of  $CD$  rather than the coordinates of the space-time sheet. Hence what is usually regarded as a quantum theory in the background defined by classical fields follows as exact theory. This feeds all data about space-time sheet associated with the maximum of Kähler function. In this approach WCW as a Kähler manifold is replaced by a cartesian power of  $CP_2$ , which is indeed quaternionic Kähler manifold. The replacement of light-like 3-surfaces with number theoretic braids when finite measurement resolution is introduced, leads to a similar replacement.
  - (e) Quantum TGD as a "complex square root" of thermodynamics approach suggests that one should take a superposition of the amplitudes defined by the points of a coherence region (identified in terms of the slicing associated with a given wormhole throat) by weighting the points with the Kähler action density. The situation would be highly analogous to a spin glass system since the modified gamma matrices defining the propagators would be analogous to the parameters of spin glass Hamiltonian allowed to have a spatial dependence. This would predict the proportionality of the coupling strengths to Kähler coupling strength and bring in the dependence on the size of  $CD$  coming as a power of 2 and give rise to p-adic coupling constant evolution. Since TGD Universe is analogous to 4-D spin glass, also a sum over different preferred extremals assignable to a given coherence regions and weighted by  $\exp(K)$  is probably needed.
  - (f) In TGD Universe graviton is necessarily a bi-local object and the emission and absorption of graviton are bi-local processes involving two wormhole contacts: a pair of particles rather than single particle emits graviton. This is definitely something new and defies a description in terms of QFT limit using point like particles. Graviton like states would be entangled states of vector bosons at both ends of stringy curve so that gravitation could be regarded as a square of YM interactions in rather concrete sense. The notion of emergence would suggest that graviton propagator is defined by a bosonic loop. Since bosonic loop is dimensionless, IR cutoff defined by the largest  $CD$  present must be actively involved. At QFT limit one can hope a description as a bi-local process using a bi-local generalization

of the QFT limit. It turns out that surprisingly simple candidate for the bi-local action exists.

### 1.5.3 Part III: Hyper-Finite Factors of Type II and Hierarchy of Planck Constants

The work with TGD inspired model for quantum computation led to the realization that von Neumann algebras, in particular hyper-finite factors, could provide the mathematics needed to develop a more explicit view about the construction of M-matrix generalizing the notion of S-matrix in zero energy ontology. In this chapter I will discuss various aspects of hyper-finite factors and their possible physical interpretation in TGD framework. The original discussion has transformed during years from free speculation reflecting in many aspects my ignorance about the mathematics involved to a more realistic view about the role of these algebras in quantum TGD.

#### 1. Hyper-finite factors in quantum TGD

The following argument suggests that von Neumann algebras known as hyper-finite factors (HFFs) of type  $III_1$  appearing in relativistic quantum field theories provide also the proper mathematical framework for quantum TGD.

1. The Clifford algebra of the infinite-dimensional Hilbert space is a von Neumann algebra known as HFF of type  $II_1$ . There also the Clifford algebra at a given point (light-like 3-surface) of world of classical worlds (WCW) is therefore HFF of type  $II_1$ . If the fermionic Fock algebra defined by the fermionic oscillator operators assignable to the induced spinor fields (this is actually not obvious!) is infinite-dimensional it defines a representation for HFF of type  $II_1$ . Super-conformal symmetry suggests that the extension of the Clifford algebra defining the fermionic part of a super-conformal algebra by adding bosonic super-generators representing symmetries of WCW respects the HFF property. It could however occur that HFF of type  $II_\infty$  results.
2. WCW is a union of sub-WCWs associated with causal diamonds ( $CD$ ) defined as intersections of future and past directed light-cones. One can allow also unions of  $CD$ s and the proposal is that  $CD$ s within  $CD$ s are possible. Whether  $CD$ s can intersect is not clear.
3. The assumption that the  $M^4$  proper distance  $a$  between the tips of  $CD$  is quantized in powers of 2 reproduces p-adic length scale hypothesis but one must also consider the possibility that  $a$  can have all possible values. Since  $SO(3)$  is the isotropy group of  $CD$ , the  $CD$ s associated with a given value of  $a$  and with fixed lower tip are parameterized by the Lobatchevski space  $L(a) = SO(3, 1)/SO(3)$ . Therefore the  $CD$ s with a free position of lower tip are parameterized by  $M^4 \times L(a)$ . A possible interpretation is in terms of quantum cosmology with  $a$  identified as cosmic time [?] Since Lorentz boosts define a non-compact group, the generalization of so called crossed product construction strongly suggests that the local Clifford algebra of WCW is HFF of type  $III_1$ . If one allows all values of  $a$ , one ends up with  $M^4 \times M^4_+$  as the space of moduli for WCW.
4. An interesting special aspect of 8-dimensional Clifford algebra with Minkowski signature is that it allows an octonionic representation of gamma matrices obtained as tensor products of unit matrix 1 and 7-D gamma matrices  $\gamma_k$  and Pauli sigma matrices by replacing 1 and  $\gamma_k$  by octonions. This inspires the idea that it might be possible to end up with quantum TGD from purely number theoretical arguments. This seems to be the case. One can start from a local octonionic Clifford algebra in  $M^8$ . Associativity condition is satisfied if one restricts the octonionic algebra to a subalgebra associated with any hyper-quaternionic and thus 4-D sub-manifold of  $M^8$ . This means that the modified gamma matrices associated with the Kähler action span a complex quaternionic sub-space at each point of the sub-manifold. This associative sub-algebra can be mapped a matrix algebra. Together with  $M^8 - H$  duality [?]his leads automatically to quantum TGD and therefore also to the notion of WCW and its Clifford algebra which is however only mappable to an associative algebra and thus to HFF of type  $II_1$ .

#### 4. Hyper-finite factors and M-matrix

HFFs of type  $III_1$  provide a general vision about M-matrix.

1. The factors of type III allow unique modular automorphism  $\Delta^{it}$  (fixed apart from unitary inner automorphism). This raises the question whether the modular automorphism could be used to define the M-matrix of quantum TGD. This is not the case as is obvious already from the fact that unitary time evolution is not a sensible concept in zero energy ontology.
2. Concerning the identification of M-matrix the notion of state as it is used in theory of factors is a more appropriate starting point than the notion modular automorphism but as a generalization of thermodynamical state is certainly not enough for the purposes of quantum TGD and quantum field theories (algebraic quantum field theorists might disagree!). Zero energy ontology requires that the notion of thermodynamical state should be replaced with its "complex square root" abstracting the idea about M-matrix as a product of positive square root of a diagonal density matrix and a unitary S-matrix. This generalization of thermodynamical state -if it exists- would provide a firm mathematical basis for the notion of M-matrix and for the fuzzy notion of path integral.
3. The existence of the modular automorphisms relies on Tomita-Takesaki theorem, which assumes that the Hilbert space in which HFF acts allows cyclic and separable vector serving as ground state for both HFF and its commutant. The translation to the language of physicists states that the vacuum is a tensor product of two vacua annihilated by annihilation oscillator type algebra elements of HFF and creation operator type algebra elements of its commutant isomorphic to it. Note however that these algebras commute so that the two algebras are not hermitian conjugates of each other. This kind of situation is exactly what emerges in zero energy ontology: the two vacua can be assigned with the positive and negative energy parts of the zero energy states entangled by M-matrix.
4. There exists infinite number of thermodynamical states related by modular automorphisms. This must be true also for their possibly existing "complex square roots". Physically they would correspond to different measurement interactions giving rise to Kähler functions of WCW differing only by a real part of holomorphic function of complex coordinates of WCW and arbitrary function of zero mode coordinates and giving rise to the same Kähler metric of WCW.

The concrete construction of M-matrix utilizing the idea of bosonic emergence (bosons as fermion anti-fermion pairs at opposite throats of wormhole contact) meaning that bosonic propagators reduce to fermionic loops identifiable as wormhole contacts leads to generalized Feynman rules for M-matrix in which modified Dirac action containing measurement interaction term defines stringy propagators. This M-matrix should be consistent with the above proposal.

*5. Connes tensor product as a realization of finite measurement resolution*

The inclusions  $\mathcal{N} \subset \mathcal{M}$  of factors allow an attractive mathematical description of finite measurement resolution in terms of Connes tensor product but do not fix M-matrix as was the original optimistic belief.

1. In zero energy ontology  $\mathcal{N}$  would create states experimentally indistinguishable from the original one. Therefore  $\mathcal{N}$  takes the role of complex numbers in non-commutative quantum theory. The space  $\mathcal{M}/\mathcal{N}$  would correspond to the operators creating physical states modulo measurement resolution and has typically fractal dimension given as the index of the inclusion. The corresponding spinor spaces have an identification as quantum spaces with non-commutative  $\mathcal{N}$ -valued coordinates.
2. This leads to an elegant description of finite measurement resolution. Suppose that a universal M-matrix describing the situation for an ideal measurement resolution exists as the idea about square root of state encourages to think. Finite measurement resolution forces to replace the probabilities defined by the M-matrix with their  $\mathcal{N}$  "averaged" counterparts. The "averaging" would be in terms of the complex square root of  $\mathcal{N}$ -state and a direct analog of functionally or path integral over the degrees of freedom below measurement resolution defined by (say) length scale cutoff.
3. One can construct also directly M-matrices satisfying the measurement resolution constraint. The condition that  $\mathcal{N}$  acts like complex numbers on M-matrix elements as far as  $\mathcal{N}$ -"averaged"

probabilities are considered is satisfied if M-matrix is a tensor product of M-matrix in  $\mathcal{M}(\mathcal{N})$  interpreted as finite-dimensional space with a projection operator to  $\mathcal{N}$ . The condition that  $\mathcal{N}$  averaging in terms of a complex square root of  $\mathcal{N}$  state produces this kind of M-matrix poses a very strong constraint on M-matrix if it is assumed to be universal (apart from variants corresponding to different measurement interactions).

### 6. Quantum spinors and fuzzy quantum mechanics

The notion of quantum spinor leads to a quantum mechanical description of fuzzy probabilities. For quantum spinors state function reduction cannot be performed unless quantum deformation parameter equals to  $q = 1$ . The reason is that the components of quantum spinor do not commute: it is however possible to measure the commuting operators representing moduli squared of the components giving the probabilities associated with 'true' and 'false'. The universal eigenvalue spectrum for probabilities does not in general contain (1,0) so that quantum qbits are inherently fuzzy. State function reduction would occur only after a transition to  $q=1$  phase and decoherence is not a problem as long as it does not induce this transition.

### Does TGD predict the spectrum of Planck constants?

The quantization of Planck constant has been the basic theme of TGD since 2005. The basic idea was stimulated by the finding of Nottale that planetary orbits could be seen as Bohr orbits with enormous value of Planck constant given by  $\hbar_{gr} = GM_1M_2/v_0$ ,  $v_0 \simeq 2^{-11}$  for the inner planets. This inspired the ideas that quantization is due to a condensation of ordinary matter around dark matter concentrated near Bohr orbits and that dark matter is in macroscopic quantum phase in astrophysical scales. The second crucial empirical input were the anomalies associated with living matter. The revised version of the chapter represents the vision about quantization of Planck constants from a perspective given by almost five years work with the idea. A very concise summary about the situation is as follows.

1. The hierarchy of Planck constants cannot be realized without generalizing the notions of imbedding space  $M^4 \times CP_2$  and space-time since particles with different values of Planck constant cannot appear in the same interaction vertex. This suggests some kind of book like structure for both  $M^4$  and  $CP_2$  factors of the generalized imbedding space is suggestive.
2. Schrödinger equation suggests that Planck constant corresponds to a scaling factor of  $M^4$  metric whose value labels different pages of the book. The scaling of  $M^4$  coordinate so that original metric results in  $M^4$  factor is possible so that the scaling of  $\hbar$  corresponds to the scaling of the size of causal diamond  $CD$  defined as the intersection of future and past directed light-cones. The light-like 3-surfaces having their 2-D and light-boundaries of  $CD$  are in a key role in the realization of zero energy states. The infinite-D spaces formed by these 3-surfaces define the fundamental sectors of the configuration space (world of classical worlds). Since the scaling of  $CD$  does not simply scale space-time surfaces, the coding of radiative corrections to the geometry of space-time sheets becomes possible and Kähler action can be seen as expansion in powers of  $\hbar/\hbar_0$ .
3. Quantum criticality of TGD Universe is one of the key postulates of quantum TGD. The most important implication is that Kähler coupling strength is analogous to critical temperature. The exact realization of quantum criticality would be in terms of critical sub-manifolds of  $M^4$  and  $CP_2$  common to all sectors of the generalized imbedding space. Quantum criticality would mean that the two kinds of number theoretic braids assignable to  $M^4$  and  $CP_2$  projections of the partonic 2-surface belong by the definition of number theoretic braids to these critical sub-manifolds. At the boundaries of  $CD$  associated with positive and negative energy parts of zero energy state in given time scale partonic two-surfaces belong to a fixed page of the Big Book whereas light-like 3-surface decomposes into regions corresponding to different values of Planck constant much like matter decomposes to several phases at thermodynamical criticality.
4. The connection with Jones inclusions was originally a purely heuristic guess based on the observation that the finite groups characterizing Jones inclusion characterize also pages of the Big Book. The key observation is that Jones inclusions are characterized by a finite subgroup

$G \subset SU(2)$  and that this group also characterizes the singular covering or factor spaces associated with  $CD$  or  $CP_2$  so that the pages of generalized imbedding space could indeed serve as correlates for Jones inclusions. The elements of the included algebra  $\mathcal{M}$  are invariant under the action of  $G$  and  $\mathcal{M}$  takes the role of complex numbers in the resulting non-commutative quantum theory.

5. The understanding of quantum TGD at parton level led to the realization that the dynamics of Kähler action realizes finite measurement resolution in terms of finite number of modes of the induced spinor field. This automatically implies cutoffs to the representations of various super-conformal algebras typical for the representations of quantum groups closely associated with Jones inclusions. The Clifford algebra spanned by the fermionic oscillator operators would provide a realization for the factor space  $\mathcal{N}/\mathcal{M}$  of hyper-finite factors of type  $II_1$  identified as the infinite-dimensional Clifford algebra  $\mathcal{N}$  of the configuration space and included algebra  $\mathcal{M}$  determining the finite measurement resolution. The resulting quantum Clifford algebra has anti-commutation relations dictated by the fractionization of fermion number so that its unit becomes  $r = \hbar/\hbar_0$ .  $SU(2)$  Lie algebra transforms to its quantum variant corresponding to the quantum phase  $q = \exp(i2\pi/r)$ .
6. Jones inclusions appear as two variants corresponding to  $\mathcal{N} : \mathcal{M} < 4$  and  $\mathcal{N} : \mathcal{M} = 4$ . The tentative interpretation is in terms of singular  $G$ -factor spaces and  $G$ -coverings of  $M^4$  or  $CP_2$  in some sense. The alternative interpretation in terms of two geodesic spheres of  $CP_2$  would mean asymmetry between  $M^4$  and  $CP_2$  degrees of freedom.
7. Number theoretic Universality suggests an answer why the hierarchy of Planck constants is necessary. One must be able to define the notion of angle -or at least the notion of phase and of trigonometric functions- also in p-adic context. All that one can achieve naturally is the notion of phase defined as root of unity and introduced by allowing algebraic extension of p-adic number field by introducing the phase if needed. In the framework of TGD inspired theory of consciousness this inspires a vision about cognitive evolution as the gradual emergence of increasingly complex algebraic extensions of p-adic numbers and involving also the emergence of improved angle resolution expressible in terms of phases  $\exp(i2\pi/n)$  up to some maximum value of  $n$ . The coverings and factor spaces would realize these phases geometrically and quantum phases  $q$  naturally assignable to Jones inclusions would realize them algebraically. Besides p-adic coupling constant evolution based on hierarchy of p-adic length scales there would be coupling constant evolution with respect to  $\hbar$  and associated with angular resolution.

### Quantum Hall effect and Hierarchy of Planck Constants

I have already earlier proposed the explanation of FQHE, anyons, and fractionization of quantum numbers in terms of hierarchy of Planck constants realized as a generalization of the imbedding space  $H = M^4 \times CP_2$  to a book like structure. The book like structure applies separately to  $CP_2$  and to causal diamonds ( $CD \subset M^4$ ) defined as intersections of future and past directed light-cones. The pages of the Big Book correspond to singular coverings and factor spaces of  $CD$  ( $CP_2$ ) glued along 2-D subspace of  $CD$  ( $CP_2$ ) and are labeled by the values of Planck constants assignable to  $CD$  and  $CP_2$  and appearing in Lie algebra commutation relations. The observed Planck constant  $\hbar$ , whose square defines the scale of  $M^4$  metric corresponds to the ratio of these Planck constants. The key observation is that fractional filling factor results if  $\hbar$  is scaled up by a rational number.

In this chapter I try to formulate more precisely this idea. The outcome is a rather detailed view about anyons on one hand, and about the Kähler structure of the generalized imbedding space on the other hand.

1. The key idea in the formulation of quantum TGD in terms of modified Dirac equation associated with Kähler action is that the Dirac determinant defined by the generalized eigenvalues assignable to the Dirac operator  $D_K$  equals to the vacuum functional defined as the exponent of Kähler function in turn identifiable as Kähler action for a preferred extremal for which second variation of Kähler action vanishes at least for the variations responsible for dynamical symmetries. The interpretation is in terms of quantum criticality. This representation generalizes. One can add imaginary instanton term to the Kähler function and corresponding modified Dirac

operator: the hypothesis is that the resulting Dirac determinant equals the exponent of Kähler action and imaginary instanton term.

2. Fundamental role is played by the assumption that the Kähler gauge potential of  $CP_2$  contains a gauge part with no physical implications in the context of gauge theories but contributing to physics in TGD framework since  $U(1)$  gauge transformations are representations of symplectic transformations of  $CP_2$ . Also in the case of  $CD$  it makes also sense to speak about Kähler gauge potential. The gauge part codes for Planck constants of  $CD$  and  $CP_2$  and leads to the identification of anyons as states associated with partonic 2-surfaces surrounding the tip of  $CD$  and fractionization of quantum numbers. Explicit formulas relating fractionized charges to the coefficients characterizing the gauge parts of Kähler gauge potentials of  $CD$  and  $CP_2$  are proposed based on some empirical input.
3. One important implication is that Poincare and Lorentz invariance are broken inside given  $CD$  although they remain exact symmetries at the level of the geometry of world of classical worlds (WCW). The interpretation is as a breaking of symmetries forced by the selection of quantization axis.
4. Anyons would basically correspond to matter at 2-dimensional "partonic" surfaces of macroscopic size surrounding the tip of the light-cone boundary of  $CD$  and could be regarded as gigantic elementary particle states with very large quantum numbers and by charge fractionization confined around the tip of  $CD$ . Charge fractionization and anyons would be basic characteristic of dark matter (dark only in relative sense). Hence it is not surprising that anyons would have applications going far beyond condensed matter physics. Anyonic dark matter concentrated at 2-dimensional surfaces would play key key role in the the physics of stars and black holes, and also in the formation of planetary system via the condensation of the ordinary matter around dark matter. This assumption was the basic starting point leading to the discovery of the hierarchy of Planck constants. In living matter membrane like structures would represent a key example of anyonic systems as the model of DNA as topological quantum computer indeed assumes.
5. One of the basic questions has been whether TGD forces the hierarchy of Planck constants realized in terms of generalized imbedding space or not. The condition that the choice of quantization axes has a geometric correlate at the imbedding space level motivated by quantum classical correspondence of course forces the hierarchy: this has been clear from the beginning. It is now clear that first principle description of anyons requires the hierarchy in TGD Universe. The hierarchy reveals also new light to the huge vacuum degeneracy of TGD and reduces it dramatically at pages for which  $CD$  corresponds to a non-trivial covering or factor space, which suggests that mathematical existence of the theory necessitates the hierarchy of Planck constants.

Part I

**GENERAL THEORY**

## Chapter 2

# Basic Extremals of the Kähler Action

### 2.1 Introduction

In this chapter the classical field equations associated with the Kähler action are studied. The study of the extremals of the Kähler action has turned out to be extremely useful for the development of TGD. Towards the end of year 2003 quite dramatic progress occurred in the understanding of field equations and it seems that field equations might be in well-defined sense exactly solvable. The progress made during next five years led to a detailed understanding of quantum TGD at the fundamental parton level and this provides considerable additional insights concerning the interpretation of field equations.

#### 2.1.1 General considerations

The vanishing of Lorentz 4-force for the induced Kähler field means that the vacuum 4-currents are in a mechanical equilibrium. Lorentz 4-force vanishes for all known solutions of field equations which inspires the hypothesis that preferred extremals satisfy the condition. The vanishing of the Lorentz 4-force in turn implies a local conservation of the ordinary energy momentum tensor. The corresponding condition is implied by Einstein's equations in General Relativity. The hypothesis would mean that the solutions of field equations are what might be called generalized Beltrami fields. If Kähler action is defined by  $CP_2$  Kähler form alone, the condition implies that vacuum currents can be non-vanishing only provided the dimension  $D_{CP_2}$  of the  $CP_2$  projection of the space-time surface is less than four so that in the regions with  $D_{CP_2} = 4$ , Maxwell's vacuum equations are satisfied.

The hypothesis that Kähler current is proportional to a product of an arbitrary function  $\psi$  of  $CP_2$  coordinates and of the instanton current generalizes Beltrami condition and reduces to it when electric field vanishes. Instanton current has vanishing divergence for  $D_{CP_2} < 4$ , and Lorentz 4-force indeed vanishes. The remaining task would be the explicit construction of the imbeddings of these fields and the demonstration that field equations can be satisfied.

Under additional conditions magnetic field reduces to what is known as Beltrami field. Beltrami fields are known to be extremely complex but highly organized structures. The natural conjecture is that topologically quantized many-sheeted magnetic and  $Z^0$  magnetic Beltrami fields and their generalizations serve as templates for the helical molecules populating living matter, and explain both chirality selection, the complex linking and knotting of DNA and protein molecules, and even the extremely complex and self-organized dynamics of biological systems at the molecular level.

Field equations can be reduced to algebraic conditions stating that energy momentum tensor and second fundamental form have no common components (this occurs also for minimal surfaces in string models) and only the conditions stating that Kähler current vanishes, is light-like, or proportional to instanton current, remain and define the remaining field equations. The conditions guaranteeing topologization to instanton current can be solved explicitly. Solutions can be found also in the more general case when Kähler current is not proportional to instanton current. On basis of these findings there are strong reasons to believe that classical TGD is exactly solvable.

An important outcome is the notion of Hamilton-Jacobi structure meaning dual slicings of  $M^4$

projection of preferred extremals to string world sheets and partonic 2-surfaces. The necessity of this slicing was discovered years later from number theoretic compactification and is now a key element of quantum TGD allowing to deduce Equivalence Principle in its stringy form from quantum TGD and formulate and understand quantum TGD in terms of modified Dirac action assignable to Kähler action. The conservation of Noether charges associated with modified Dirac action requires the vanishing of the second second variation of Kähler action for preferred extremals - at least for the deformations generating dynamical symmetries. Preferred extremals would thus define space-time representation for quantum criticality. Infinite-dimensional variant for the hierarchy of criticalities analogous to the hierarchy assigned to the extrema of potential function with levels labeled by the rank of the matrix defined by the second derivatives of the potential function in catastrophe theory would suggest itself.

### 2.1.2 In what sense field equations mimic dissipative dynamics?

By quantum classical correspondence the non-deterministic space-time dynamics should mimic the dissipative dynamics of the quantum jump sequence. The nontrivial question is what this means in TGD framework.

1. Beltrami fields appear in physical applications as asymptotic self organization patterns for which Lorentz force and dissipation vanish. This suggests that preferred extremals of Kähler action correspond to space-time sheets which at least asymptotically satisfy generalized Beltrami conditions so that one can indeed assign to the final (rather than initial!) 3-surface a unique 4-surface apart from effects related to non-determinism. Preferred extremal property of Kähler action abstracted to purely algebraic generalized Beltrami conditions would make sense also in the p-adic context. The general solution ansatz discussed in the last section of the chapter assumes that all conserved isometry currents are proportional to instanton current so that various charges are conserved separately for all flow lines: this means essentially the integrability of the theory. This ansatz is forced by the hypothesis that TGD reduces to almost topological QFT and this idea. The basic consequence is that dissipation is impossible classically.
2. A more radical view inspired by zero energy ontology is that the light-like 3-surfaces and corresponding space-time regions with Euclidian signature defining generalized Feynman diagrams provide a space-time representation of dissipative dynamics just as they provide this representation in quantum field theory. Minkowskian regions would represent empty space so that the vanishing of Lorentz 4-force and absence of dissipation would be natural. This would mean very precise particle field duality and the topological pattern associated with the generalized Feynman diagram would represent dissipation. One could also interpret dissipation as transfer of energy between sheets of the many-sheeted space time and thus as an essentially topological phenomenon. This option seems to be the only viable one.

### 2.1.3 The dimension of $CP_2$ projection as classifier for the fundamental phases of matter

The dimension  $D_{CP_2}$  of  $CP_2$  projection of the space-time sheet encountered already in p-adic mass calculations classifies the fundamental phases of matter. For  $D_{CP_2} = 4$  empty space Maxwell equations hold true. The natural guess would be that this phase is chaotic and analogous to de-magnetized phase.  $D_{CP_2} = 2$  phase is analogous to ferromagnetic phase: highly ordered and relatively simple. It seems however that preferred extremals can correspond only to small perturbations of these extremals resulting by topological condensation of  $CP_2$  type vacuum extremals and through topological condensation to larger space-time sheets.  $D_{CP_2} = 3$  is the analog of spin glass and liquid crystal phases, extremely complex but highly organized by the properties of the generalized Beltrami fields. This phase could be seen as the boundary between chaos and order and corresponds to life emerging in the interaction of magnetic bodies with bio-matter. It is possible only in a finite temperature interval (note however the p-adic hierarchy of critical temperatures) and characterized by chirality just like life.

The original proposal was that  $D(CP_2) = 4$  phase is completely chaotic. This is not true if the reduction to almost topological QFT takes place. This phase must correspond to Maxwellian phase with a vanishing Kähler current as concluded already earlier. Various isometry currents are however

proportional to the instanton current and conserved along the flow lines of the instanton current whose flow parameter extends to a global coordinate. Hence a completely chaotic phase is not in question even in this case.

### 2.1.4 Specific extremals of Kähler action

The study of extremals of Kähler action represents more than decade old layer in the development of TGD.

1. The huge vacuum degeneracy is the most characteristic feature of Kähler action (any 4-surface having  $CP_2$  projection which is Legendre sub-manifold is vacuum extremal, Legendre sub-manifolds of  $CP_2$  are in general 2-dimensional). This vacuum degeneracy is behind the spin glass analogy and leads to the p-adic TGD. As found in the second part of the book, various particle like vacuum extremals also play an important role in the understanding of the quantum TGD.
2. The so called  $CP_2$  type vacuum extremals have finite, negative action and are therefore an excellent candidate for real particles whereas vacuum extremals with vanishing Kähler action are candidates for the virtual particles. These extremals have one dimensional  $M^4$  projection, which is light like curve but not necessarily geodesic and locally the metric of the extremal is that of  $CP_2$ : the quantization of this motion leads to Virasoro algebra. Space-times with topology  $CP_2 \# CP_2 \# \dots CP_2$  are identified as the generalized Feynmann diagrams with lines thickened to 4-manifolds of "thickness" of the order of  $CP_2$  radius. The quantization of the random motion with light velocity associated with the  $CP_2$  type extremals in fact led to the discovery of Super Virasoro invariance, which through the construction of the configuration space geometry, becomes a basic symmetry of quantum TGD.
3. There are also various non-vacuum extremals.
  - (a) String like objects, with string tension of same order of magnitude as possessed by the cosmic strings of GUTs, have a crucial role in TGD inspired model for the galaxy formation and in the TGD based cosmology.
  - (b) The so called massless extremals describe non-linear plane waves propagating with the velocity of light such that the polarization is fixed in given point of the space-time surface. The purely TGD:ish feature is the light like Kähler current: in the ordinary Maxwell theory vacuum gauge currents are not possible. This current serves as a source of coherent photons, which might play an important role in the quantum model of bio-system as a macroscopic quantum system.
  - (c) In the so called Maxwell's phase, ordinary Maxwell equations for the induced Kähler field are satisfied in an excellent approximation. A special case is provided by a radially symmetric extremal having an interpretation as the space-time exterior to a topologically condensed particle. The sign of the gravitational mass correlates with that of the Kähler charge and one can understand the generation of the matter antimatter asymmetry from the basic properties of this extremal. The possibility to understand the generation of the matter antimatter asymmetry directly from the basic equations of the theory gives strong support in favor of TGD in comparison to the ordinary EYM theories, where the generation of the matter antimatter asymmetry is still poorly understood.

### 2.1.5 The weak form of electric-magnetic duality and modification of Kähler action

The newest results discussed in the last section about the weak form of electric-magnetic duality suggest strongly that Beltrami property is general and together with the weak form of electric-magnetic duality allows a reduction of quantum TGD to almost topological field theory with Kähler function allowing expression as a Chern-Simons term.

Generalized Beltrami property leads to a rather explicit construction of the general solution of field equations based on the hydrodynamic picture implying that single particle quantum numbers are

conserved along flow lines defined by the instanton current. The construction generalizes also to the fermionic sector and there are reasons to hope that TGD is completely integrable theory.

## 2.2 General considerations

The solution families of field equations studied in this chapter were found already during eighties. The physical interpretation turned out to be the really tough problem. What is the principle selecting preferred extremals of Kähler action as analogs of Bohr orbits assigning to 3-surface  $X^3$  a unique space-time surface  $X^4(X^3)$ ? Does Equivalence Principle hold true and if so, in what sense? These have been the key questions. The realization that light-like 3-surfaces  $X_l^3$  associated with the light-like wormhole throats at which the signature of the induced metric changes from Minkowskian to Euclidian led to the formulation of quantum TGD in terms of second quantized induced spinor fields at these surfaces. Together with the notion of number theoretical compactification this approach allowed to identify the conditions characterizing the preferred extremals. What is remarkable that these conditions are consistent with what is known about extremals. Also a connection with string models and understanding of the space-time realization of Equivalence Principle emerged. In this section the theoretical background behind field equations is briefly summarized. I will not repeat the discussion of previous two chapters [32, 33] summarizing the general vision about many-sheeted space-time, and consideration will be restricted to those aspects of vision leading to direct predictions about the properties of preferred extremals of Kähler action.

### 2.2.1 Number theoretical compactification and $M^8 - H$ duality

The notion of hyper-quaternionic and octonionic manifold makes sense but it not plausible that  $H = M^4 \times CP_2$  could be endowed with a hyper-octonionic manifold structure. Situation changes if  $H$  is replaced with hyper-octonionic  $M^8$ . Suppose that  $X^4 \subset M^8$  consists of hyper-quaternionic and co-hyper-quaternionic regions. The basic observation is that the hyper-quaternionic sub-spaces of  $M^8$  with a fixed hyper-complex structure (containing in their tangent space a fixed hyper-complex subspace  $M^2$  or at least one of the light-like lines of  $M^2$ ) are labeled by points of  $CP_2$ . Hence each hyper-quaternionic and co-hyper-quaternionic four-surface of  $M^8$  defines a 4-surface of  $M^4 \times CP_2$ . One can loosely say that the number-theoretic analog of spontaneous compactification occurs: this of course has nothing to do with dynamics.

This picture was still too naive and it became clear that not all known extremals of Kähler action contain fixed  $M^2 \subset M^4$  or light-like line of  $M^2$  in their tangent space.

1. The first option represents the minimal form of number theoretical compactification.  $M^8$  is interpreted as the tangent space of  $H$ . Only the 4-D tangent spaces of light-like 3-surfaces  $X_l^3$  (wormhole throats or boundaries) are assumed to be hyper-quaternionic or co-hyper-quaternionic and contain fixed  $M^2$  or its light-like line in their tangent space. Hyper-quaternionic regions would naturally correspond to space-time regions with Minkowskian signature of the induced metric and their co-counterparts to the regions for which the signature is Euclidian. What is of special importance is that this assumption solves the problem of identifying the boundary conditions fixing the preferred extremals of Kähler action since in the generic case the intersection of  $M^2$  with the 3-D tangent space of  $X_l^3$  is 1-dimensional. The surfaces  $X^4(X_l^3) \subset M^8$  would be hyper-quaternionic or co-hyper-quaternionic but would not allow a local mapping between the 4-surfaces of  $M^8$  and  $H$ .
2. One can also consider a more local map of  $X^4(X_l^3) \subset H$  to  $X^4(X_l^3) \subset M^8$ . The idea is to allow  $M^2 \subset M^4 \subset M^8$  to vary from point to point so that  $S^2 = SO(3)/SO(2)$  characterizes the local choice of  $M^2$  in the interior of  $X^4$ . This leads to a quite nice view about strong geometric form of  $M^8 - H$  duality in which  $M^8$  is interpreted as tangent space of  $H$  and  $X^4(X_l^3) \subset M^8$  has interpretation as tangent for a curve defined by light-like 3-surfaces at  $X_l^3$  and represented by  $X^4(X_l^3) \subset H$ . Space-time surfaces  $X^4(X_l^3) \subset M^8$  consisting of hyper-quaternionic and co-hyper-quaternionic regions would naturally represent a preferred extremal of  $E^4$  Kähler action. The value of the action would be same as  $CP_2$  Kähler action.  $M^8 - H$  duality would apply also at the induced spinor field and at the level of configuration space. The possibility to assign  $M^2(x) \subset M^4$  to each point of  $M^4$  projection  $P_{M^4}(X^4(X_l^3))$  is consistent with what is known

about extremals of Kähler action with only one exception:  $CP_2$  type vacuum extremals. In this case  $M^2$  can be assigned to the normal space.

3. Strong form of  $M^8 - H$  duality satisfies all the needed constraints if it represents Kähler isometry between  $X^4(X_l^3) \subset M^8$  and  $X^4(X_l^3) \subset H$ . This implies that light-like 3-surface is mapped to light-like 3-surface and induced metrics and Kähler forms are identical so that also Kähler action and field equations are identical. The only differences appear at the level of induced spinor fields at the light-like boundaries since due to the fact that gauge potentials are not identical.
4. The map of  $X_l^3 \subset H \rightarrow X_l^3 \subset M^8$  would be crucial for the realization of the number theoretical universality.  $M^8 = M^4 \times E^4$  allows linear coordinates as those preferred coordinates in which the points of imbedding space are rational/algebraic. Thus the point of  $X^4 \subset H$  is algebraic if it is mapped to algebraic point of  $M^8$  in number theoretic compactification. This of course restricts the symmetry groups to their rational/algebraic variants but this does not have practical meaning. Number theoretical compactification could thus be motivated by the number theoretical universality.
5. The possibility to use either  $M^8$  or  $H$  picture might be extremely useful for calculational purposes. In particular,  $M^8$  picture based on  $SO(4)$  gluons rather than  $SU(3)$  gluons could perturbative description of low energy hadron physics. The strong  $SO(4)$  symmetry of low energy hadron physics can be indeed seen direct experimental support for the  $M^8 - H$  duality.

Number theoretical compactification has quite deep implications for quantum TGD and is actually responsible for most of the progress in the understanding of the mathematical structure of quantum TGD. A very powerful prediction is that preferred extremals should allow slicings to either stringy world sheets or dual partonic 2-surfaces as well as slicing by light-like 3-surfaces. Both predictions are consistent with what is known about extremals.

1. If the distribution of planes  $M^2(x)$  is integrable, it is possible to slice  $X^4(X^3)$  to a union of 2-dimensional surfaces having interpretation as string world sheets and dual 2-dimensional copies of partonic surfaces  $X^2$ . This decomposition defining 2+2 Kaluza-Klein type structure realizes quantum gravitational holography and allows to understand Equivalence Principle at space-time level in the sense that dimensional reduction defined by the integral of Kähler action over the 2-dimensional space labeling stringy world sheets gives rise to the analog of stringy action and one obtains string model like description of quantum TGD as dual for a description based on light-like partonic 3-surfaces. String tension is not however equal to the inverse of gravitational constant as one might naively expect but the connection is more delicate.
2. Second implication is the slicing of  $X^4(X_l^3)$  to light-like 3-surfaces  $Y_l^3$  "parallel" to  $X_l^3$ . Also this slicing realizes quantum gravitational holography if one requires General Coordinate Invariance in the sense that the Dirac determinant defined by the generalized eigenvalues of the transverse part  $D_K(X^2)$  of  $D_K$  differs for two 3-surfaces  $Y_l^3$  in the slicing only by an exponent of a real part of a holomorphic function of configuration space complex coordinates giving no contribution to the Kähler metric. The requirement that the zero modes of the 4-D modified Dirac operators  $D_K$  reduce to the analogs of 3-D shock waves for all 3-surfaces  $Y_l^3$  in the slicing requires that Noether currents are parallel to  $Y_l^3$ . Clearly, 3+1 type Kaluza-Klein structure is in question. This slicing allows to realize RG flow at space-time level using the light-like coordinate associated with the slicing as RG parameter [33]. The prediction is RG invariance of couplings for a causal diamond ( $CD$ ) in given p-adic length scale meaning a justification of the hypothesis that coupling constant evolution reduces to a discrete p-adic coupling constant evolution with p-adic length scales coming as half octaves. This prediction follows if the known properties of extremals of Kähler action hold true quite generally.
3. The assumption that Kähler current and other gauge currents flow along the slices  $Y_l^3$  of the slicing of  $X^4(X_l^3)$  is enough for the renormalization group invariance of gauge couplings inside  $CD$  guaranteeing p-adic coupling constant evolution [33]. The current could thus have also a component parallel to the transverse cross section in which case the current would be space-like. Space-likeness brings in mind the Euclidian signature of the effective metric defined by the modified gamma matrices  $\hat{\Gamma}^\alpha = (\partial L_K / \partial h_\alpha^k) \gamma^k$  necessary for the Higgs mechanism. Dissipation

would be absent but Lorentz force would be non-vanishing. The general solution ansatz for the field equations allows besides light-like Kähler currents also space-like gauge currents, which can be regarded as topological currents. The gluing of  $CP_2$  type vacuum extremals to the known extremals with light-like gauge currents could generate the transversal part of the currents and increase the dimension  $D_{CP_2}$  of the  $CP_2$  projection to at least  $D_{CP_2} = 3$ .

### 2.2.2 The exponent of Kähler function as Dirac determinant for the modified Dirac action

Although quantum criticality in principle predicts the possible values of Kähler coupling strength, one might hope that there exists even more fundamental approach involving no coupling constants and predicting even quantum criticality and realizing quantum gravitational holography.

The identification of the light-like partonic 3-surfaces as carriers of elementary particle quantum numbers inspired by the TGD based quantum measurement theory suggests the identification of the modified Dirac action as that associated with the Chern-Simons action for the induced Kähler gauge potential. It however turned out that it is 4-D modified Dirac action associated with Kähler action, which is the correct choice. The point is that only the solutions of  $D_K$  which are effectively 3-dimensional by generalized super-conformal gauge invariance are physical. The effective metric defined by the modified gamma matrices is non-singular even for light-like 3-surfaces  $Y_l^3$ , and this allows to develop a well-defined theory involving also metric degrees of freedom. In this framework  $C - S$  action emerges as a phase factor of quantum states for phases with non-standard value of Planck constant and is related to anyons and charge fractionization.

Absolutely essential role is played by number theoretical compactification predicted that space-time sheets have dual slicings to string world sheets and partonic 2-surfaces. This prediction is supported by the properties of known extremals of Kähler action. This allows the decompositions  $D_K = D_K(Y^2) + D_K(X^2)$  generalized eigenvalues can be associated associated with  $D_K(X^2)$  for zero modes of  $D_K$ .

1. The Dirac determinant defined by the product of Dirac determinants associated with the light-like partonic 3-surfaces  $X_l^3$  associated with a given space-time sheet  $X^4$  is the simplest candidate for vacuum functional identifiable as the exponent of the Kähler function. One can of course worry about the finiteness of the Dirac determinant. p-Adicization requires that the eigenvalues belong to a given algebraic extension of rationals. This restriction would imply a hierarchy of physics corresponding to different extensions and could automatically imply the finiteness and algebraic number property of the Dirac determinants if only finite number of eigenvalues would contribute. The regularization would be performed by physics itself if this were the case.
- 2.
3. The basic problem has been how to feed in the information about the preferred extremal of Kähler action to the eigenvalue spectrum  $D_K(X^2)$  at light-like 3-surface  $X_l^3$ . The identification of the preferred extremal came possible via boundary conditions at  $X_l^3$  dictated by number theoretical compactification. The basic observation is that the Dirac equation associated with the 4-D Dirac operator  $D_K$  defined by Kähler action can be seen as a conservation law for a super current. By restricting the super current to flow along  $X_l^3$  by requiring that its normal component vanishes, one obtains a singular solution of 4-D modified Dirac equation restricted to  $X_l^3$ . The "energy" spectrum to the spectrum of eigenvalues for  $D_K(X^2)$  and the product of the eigenvalues defines the Dirac determinant in standard manner. Since the eigenmodes are restricted to those localized to regions of non-vanishing induced Kähler form, the number of eigen modes is finite and therefore also Dirac determinant is finite. The eigenvalues can be also algebraic numbers.
4. It remains to be proven that the product of eigenvalues gives rise to the exponent of Kähler action for the preferred extremal of Kähler action. At this moment the only justification for the conjecture is that this the only thing that one can imagine.
5. An additional bonus is precise definition of quantum criticality. The Noether currents associated with the modified Dirac action are conserved if its variation with respect to  $H$ -coordinates

vanishes. This means that the second variation of Kähler action varies. One can consider also a weaker form of quantum criticality in which case only the variations with respect to deformations defining the conserved currents are vanishing. This would give to a hierarchy of criticalities defined by the second variations of Kähler action. The vacuum degeneracy of Kähler action would be essential for the realization of quantum criticality and could correspond to a hierarchy of dynamical gauge symmetries characterizing finite measurement resolution suggested by the hierarchy of Jones inclusions [27].

6. A long-standing conjecture has been that the zeros of Riemann Zeta are somehow relevant for quantum TGD. Riemann zeta is however naturally replaced Dirac zeta defined by the eigenvalues of  $D_K(X^2)$  and closely related to Riemann Zeta since the spectrum consists essentially for the cyclotron energy spectra for localized solutions region of non-vanishing induced Kähler magnetic field and hence is in good approximation integer valued up to some cutoff integer. In zero energy ontology the Dirac zeta function associated with these eigenvalues defines "square root" of thermodynamics assuming that the energy levels of the system in question are expressible as logarithms of the eigenvalues of the modified Dirac operator defining kind of fundamental constants. Critical points correspond to approximate zeros of Dirac zeta and if Kähler function vanishes at criticality as it indeed should, the thermal energies at critical points are in first order approximation proportional to zeros themselves so that a connection between quantum criticality and approximate zeros of Dirac zeta emerges.
7. The discretization induced by the number theoretic braids reduces the world of classical worlds to effectively finite-dimensional space and configuration space Clifford algebra reduces to a finite-dimensional algebra. The interpretation is in terms of finite measurement resolution represented in terms of Jones inclusion  $\mathcal{M} \subset \mathcal{N}$  of HFFs with  $\mathcal{M}$  taking the role of complex numbers. The finite-D quantum Clifford algebra spanned by fermionic oscillator operators is identified as a representation for the coset space  $\mathcal{N}/\mathcal{M}$  describing physical states modulo measurement resolution. In the sectors of generalized imbedding space corresponding to non-standard values of Planck constant quantum version of Clifford algebra is in question.

Concerning the understanding of preferred extremals, the basic prediction (assuming that Kähler gauge potential has no gauge part in  $M^4$ ) is that the  $CP_2$  projection of the light-like 3-surfaces is 3-dimensional for non-vacuum partons. One implication is that a very general family of cosmic string type solutions with 2-D  $CP_2$  projection cannot correspond to preferred extremals. If ideal cosmic strings were preferred extremals, the most general realization for the hierarchy of Planck constants in terms of a book like structure of the imbedding space would not be possible [27]. Also massless extremals have 2-D  $CP_2$  projection and are excluded as preferred extremals. The interpretation is that the preferred extremals must be deformations of these extremals containing topologically condensed  $CP_2$  type vacuum extremals representing elementary particles and that these extremals provide only smoothed out representation of the actual physics. The general principle would be that matter is present only if light-like 3-surfaces at which the signature of the induced metric changes (light-like boundary components cannot be excluded but in this case gauge charges would vanish). That the interaction with a larger Minkowskian space-time sheet creates matter could be seen as a variant of Mach Principle.

### 2.2.3 Preferred extremal property as classical correlate for quantum criticality, holography, and quantum classical correspondence

The Noether currents assignable to the modified Dirac equation are conserved only if the first variation of the modified Dirac operator  $D_K$  defined by Kähler action vanishes. This is equivalent with the vanishing of the second variation of Kähler action -at least for the variations corresponding to dynamical symmetries having interpretation as dynamical degrees of freedom which are below measurement resolution and therefore effectively gauge symmetries. The weaker condition would mean that the inner product defined by the integral of  $D_\alpha \partial L_K / \partial h_\alpha^k \delta h^k$  over the space-time surface vanishes for the deformations defining dynamical symmetries but the field equations are not satisfied completely generally. The weaker condition would mean that the inner product defined by the integral of  $D_\alpha \partial L_K / \partial h_\alpha^k \delta h^k$  over the space-time surface vanishes for the deformations defining dynamical symmetries but the field equations are not satisfied completely generally.

The vanishing of the second variation in interior of  $X^4(X_l^3)$  is what corresponds exactly to quantum criticality so that the basic vision about quantum dynamics of quantum TGD would lead directly to a precise identification of the preferred extremals. Something which I should have noticed for more than decade ago! The question whether these extremals correspond to absolute minima remains however open.

The vanishing of second variations of preferred extremals -at least for deformations representing dynamical symmetries, suggests a generalization of catastrophe theory of Thom, where the rank of the matrix defined by the second derivatives of potential function defines a hierarchy of criticalities with the tip of bifurcation set of the catastrophe representing the complete vanishing of this matrix. In the recent case this theory would be generalized to infinite-dimensional context. There are three kind of variables now but quantum classical correspondence (holography) allows to reduce the types of variables to two.

1. The variations of  $X^4(X_l^3)$  vanishing at the intersections of  $X^4(X_l^3)$  with the light-like boundaries of causal diamonds  $CD$  would represent behavior variables. At least the vacuum extremals of Kähler action would represent extremals for which the second variation vanishes identically (the "tip" of the multi-furcation set).
2. The zero modes of Kähler function would define the control variables interpreted as classical degrees of freedom necessary in quantum measurement theory. By effective 2-dimensionality (or holography or quantum classical correspondence) meaning that the configuration space metric is determined by the data coming from partonic 2-surfaces  $X^2$  at intersections of  $X_l^3$  with boundaries of  $CD$ , the interiors of 3-surfaces  $X^3$  at the boundaries of  $CD$ s in rough sense correspond to zero modes so that there is indeed huge number of them. Also the variables characterizing 2-surface, which cannot be complexified and thus cannot contribute to the Kähler metric of configuration space represent zero modes. Fixing the interior of the 3-surface would mean fixing of control variables. Extremum property would fix the 4-surface and behavior variables if boundary conditions are fixed to sufficient degree.
3. The complex variables characterizing  $X^2$  would represent third kind of variables identified as quantum fluctuating degrees of freedom contributing to the configuration space metric. Quantum classical correspondence requires 1-1 correspondence between zero modes and these variables. This would be essentially holography stating that the 2-D "causal boundary"  $X^2$  of  $X^3(X^2)$  codes for the interior. Preferred extremal property identified as criticality condition would realize the holography by fixing the values of zero modes once  $X^2$  is known and give rise to the holographic correspondence  $X^2 \rightarrow X^3(X^2)$ . The values of behavior variables determined by extremization would fix then the space-time surface  $X^4(X_l^3)$  as a preferred extremal.
4. Clearly, the presence of zero modes would be absolutely essential element of the picture. Quantum criticality, quantum classical correspondence, holography, and preferred extremal property would all represent more or less the same thing. One must of course be very cautious since the boundary conditions at  $X_l^3$  involve normal derivative and might bring in delicacies forcing to modify the simplest heuristic picture.

The basic question is whether number theoretic view about preferred extremals imply absolute minimization or something analogous to it.

1. The number theoretic conditions defining preferred extremals are purely algebraic and make sense also p-adically and this is enough since p-adic variants of field equations make sense although the notion of Kähler action does not make sense as integral. Despite this the identification of the vacuum functional as exponent of Kähler function as Dirac determinant allows to define the exponent of Kähler function as a p-adic number [15].
2. The general objection against all extremization principles is that they do not make sense p-adically since p-adic numbers are not well-ordered.
3. These observations do not encourage the idea about equivalence of the two approaches. On the other hand, real and p-adic sectors are related by algebraic continuation and it could be quite enough if the equivalence were true in real context alone.

The finite-dimensional analogy allows to compare absolute minimization and criticality with each other.

1. Absolute minimization would select the branch of Thom's catastrophe surface with the smallest value of potential function for given values of control variables. In general this value would not correspond to criticality since absolute minimization says nothing about the values of control variables (zero modes).
2. Criticality forces the space-time surface to belong to the bifurcation set and thus fixes the values of control variables, that is the interior of 3-surface assignable to the partonic 2-surface, and realized holography. If the catastrophe has more than  $N = 3$  sheets, several preferred extremals are possible for given values of control variables fixing  $X^3(X^2)$  unless one assumes that absolute minimization or some other criterion is applied in the bifurcation set. In this sense absolute minimization might make sense in the real context and if the selection is between finite number of alternatives is in question, it should be possible carry out the selection in number theoretically universal manner.

### 2.2.4 Can one determine experimentally the shape of the space-time surface?

The question 'Can one determine experimentally the shape of the space-time surface?' does not relate directly to the topic of this chapter in technical sense, and the only excuse for its inclusion is the title of this section plus the fact that the general conceptual framework behind quantum TGD assumes an affirmative answer to this question. If physics were purely classical physics, operationalism in the strong sense of the word would require that one can experimentally determine the shape of the space-time as a surface of the imbedding space with arbitrary accuracy by measuring suitable classical observables. In quantum physics situation is considerably more complex and quantum effects are both a blessing and a curse.

#### Measuring classically the shape of the space-time surface

Consider first the purely classical situation to see what is involved.

1. All classical gauge fields are expressible in terms of  $CP_2$  coordinates and their space-time gradients so that the measurement of four field quantities with some finite resolution in some space-time volume could in principle give enough information to deduce the remaining field quantities. The requirement that space-time surface corresponds to an extremal of Kähler action gives a further strong consistency constraint and one can in principle test whether this constraint is satisfied. A highly over-determined system is in question.
2. The freedom to choose the space-time coordinates freely causes complications and it seems that one must be able to determine also the distances between the points at which the field quantities are determined. At purely classical Riemannian level this boils down to the measurement of the induced metric defining classical gravitational field. In macroscopic length scales one could base the approach to iterative procedure in which one starts from the assumption that the coordinates used are Minkowski coordinates and gravitational corrections are very weak.
3. The measurement of induced Kähler form in some space-time volume determines space-time surface only modulo canonical transformations of  $CP_2$  and isometries of the imbedding space. If one measures classical electromagnetic field, which is not canonical invariant in general case, with some precision, one can determine to what kind of surface space-time region corresponds apart from the action of the isometries of  $H$ .

#### Quantum measurement of the shape of the space-time surface

In practice the measurement of the shape of the space-time surface is necessarily a bootstrap procedure based on the model for space-time region and on the requirement of internal consistency. Many-sheeted space-time and quantum phenomena produce considerable complications but also provide universal measurement standards.

Consider first how quantum effects could help to measure classical fields and distances.

1. The measurement of distances by measuring first induced metric at each point of space-time sheet is rather unpractical procedure. Many-sheeted space-time however comes in rescue here. p-Adic length scale hypothesis provides a hierarchy of natural length scales and one can use p-adic length and time scales as natural units of length and time: space-time sheets serve as meter sticks. For instance, length measurement reduces in principle to a finite number of operations using various space-time sheets with standardized lengths given by p-adic length scales. Also various transition frequencies and corresponding wavelengths provide universal time and length units. Atomic clock provides a standard example of this kind of time unit. A highly nontrivial implication is the possibility to deduce the composition of distant star from its spectral lines. Without p-adic length scale hypothesis the scales for the mass spectra of the elementary particles would be variable and atomic spectra would vary from point to point in TGD universe.

Do the p-adic length scales correspond to the length units of the induced metric or of  $M_+^4$  metric? If the topological condensation a meter stick space-time sheet at a larger space-time sheet does not stretch the meter stick but only bends it, the length topologically condensed meter stick in the induced metric equals to its original length measured using  $M_+^4$  metric.

2. If superconducting order parameters are expressible in terms of the  $CP_2$  coordinates (there is evidence for this, see the chapter "Macroscopic quantum phenomena and  $CP_2$  geometry"), one might determine directly the  $CP_2$  coordinates as functions of Minkowski coordinates and this would allow to estimate all classical fields directly and thus to deduce strong consistency constraints.
3. At quantum level only the fluxes of the classical fields through surface areas with some minimum size determined by the length scale resolution can be measured. In case of magnetic fields the quantization of the magnetic flux simplifies the situation dramatically. Topological field quantization quite generally modifies the measurement of continuous field variables to the measurement of fluxes. Interestingly, the construction of the configuration space geometry uses as configuration space coordinates various electric and magnetic fluxes over 2-dimensional cross sections of 3-surface.

Quantum effects introduce also difficulties and restrictions.

1. Canonical transformations localized with respect to the boundary of the light cone or more general light like surfaces act as isometries of the configuration space and one can determine the space-time surface only modulo these isometries. Even more, only the values of the non-quantum fluctuating zero modes characterizing the shape and size of the space-time surface are measurable with arbitrary precision in quantum theory. At the level of conscious experience quantum fluctuating degrees of freedom correspond to sensory qualia like color having no classical geometric content.
2. Space-time surface is replaced by a new one in each quantum jump (or rather the superposition of perceptively equivalent space-time surfaces). Only in the approximation that the change of the space-time region in single quantum jump is negligible, the measurement of the shape of space-time surface makes sense. The physical criterion for this is that dissipation is negligible. The change of the space-time region in single quantum jump can indeed be negligible if the measurement is performed with a finite resolution.
3. Conscious experience of self is an average over quantum jumps defining moments of consciousness. In particular, only the average increment of the zero modes is experienced and this means that one cannot fix the space-time surface apart from canonical transformation affecting the zero modes. Again the notion of measurement resolution comes in rescue.
4. The possibility of coherent states of photons and gravitons brings in a further quantum complication since the effective classical em and gravitational fields are superpositions of classical field and the order parameter describing the coherent state. In principle the extremely strong constraints between the classical field quantities allow to measure both the order parameters of the coherent phases and classical fields.

### Quantum holography and the shape of the space-time surface

If the Dirac determinant associated with the generalized eigenvalue spectrum of the modified Dirac operator  $D_K(X^2)$  indeed codes for Kähler action of a preferred extremal, it is fair to say that a lot of information about the shape of the space-time surface is coded to physical observables, which eigenvalues indeed represent. Quantum gravitational holography due to the Bohr orbit like character of space-time surface reduces the amount of information needed. Only a finite number of eigenvalues is involved and the eigen modes are associated with the 3-D light-like wormhole throats rather than with the space-time surface itself. If the eigenvalues were known or could be measured with infinite accuracy, one could in principle fix the boundary conditions at  $X_l^3$  and solve field equations determining the preferred extremal of Kähler action.

What is of course needed is the complete knowledge of the light-like 3-surfaces  $X_l^3$ . Needless to say, in practice a complete knowledge of  $X_l^3$  is impossible since measurement resolution is finite. The notion number theoretic braid provides a precise realization for the finite measurement accuracy at space-time level. At the level of configuration space spinors fields (world of classical worlds) just the fact that the number of eigenvalues is finite is correlate for the finite measurement accuracy. Furthermore, quantum states are actually quantum superpositions of 3-surfaces, which means that one can only speak about quantum average space-time surface for which the phase factors coding for the quantum numbers of elementary particles assigned to the strands of number theoretic braids are stationary so that correlation of classical gauge charges with quantum gauge charges is obtained.

## 2.3 General view about field equations

In this section field equations are deduced and discussed in general level. The fact that the divergence of the energy momentum tensor, Lorentz 4-force, does not vanish in general, in principle makes possible the mimicry of even dissipation and of the second law. For asymptotic self organization patterns for which dissipation is absent the Lorentz 4-force must vanish. This condition is guaranteed if Kähler current is proportional to the instanton current in the case that  $CP_2$  projection of the space-time sheet is smaller than four and vanishes otherwise. An attractive identification for the vanishing of Lorentz 4-force is as a condition equivalent with the selection of preferred extremal of Kähler action. If preferred extremals correspond to absolute minima this principle would be essentially equivalent with the second law of thermodynamics.

### 2.3.1 Field equations

The requirement that Kähler action is stationary leads to the following field equations in the interior of the four-surface

$$\begin{aligned} D_\beta(T^{\alpha\beta}h_\alpha^k) - j^\alpha J_l^k \partial_\alpha h^l &= 0 \ , \\ T^{\alpha\beta} &= J^{\nu\alpha} J_\nu^\beta - \frac{1}{4} g^{\alpha\beta} J^{\mu\nu} J_{\mu\nu} \ . \end{aligned} \quad (2.3.1)$$

Here  $T^{\alpha\beta}$  denotes the traceless canonical energy momentum tensor associated with the Kähler action. An equivalent form for the first equation is

$$\begin{aligned} T^{\alpha\beta} H_{\alpha\beta}^k - j^\alpha (J_\alpha^\beta h_\beta^k + J_l^k \partial_\alpha h^l) &= 0 \ . \\ H_{\alpha\beta}^k &= D_\beta \partial_\alpha h^k \ . \end{aligned} \quad (2.3.2)$$

$H_{\alpha\beta}^k$  denotes the components of the second fundamental form and  $j^\alpha = D_\beta J^{\alpha\beta}$  is the gauge current associated with the Kähler field.

On the boundaries of  $X^4$  and at wormhole throats the field equations are given by the expression

$$\frac{\partial L_K}{\partial_n h^k} = T^{n\beta} \partial_\beta h^k - J^{n\alpha} (J_\alpha^\beta \partial_\beta h^k + J_l^k) \partial_\alpha h^k = 0 \ . \quad (2.3.3)$$

At wormhole throats problems are caused by the vanishing of metric determinant implying that contravariant metric is singular.

For  $M^4$  coordinates boundary conditions are satisfied if one assumes

$$T^{n\beta} = 0 \quad (2.3.4)$$

stating that there is no flow of four-momentum through the boundary component or wormhole throat. This means that there is no energy exchange between Euclidian and Minkowskian regions so that Euclidian regions provide representations for particles as autonomous units. This is in accordance with the general picture [33]. Note that momentum transfer with external world necessarily involves generalized Feynman diagrams also at classical level.

For  $CP_2$  coordinates the boundary conditions are more delicate. The construction of configuration space spinor structure [15] led to the conditions

$$g_{ni} = 0, \quad J_{ni} = 0. \quad (2.3.5)$$

$J^{ni} = 0$  does not and should not follow from this condition since contravariant metric is singular. It seems that limiting procedure is necessary in order to see what comes out.

The condition that Kähler electric charge defined as a gauge flux is non-vanishing would require that the quantity  $J^{nr}\sqrt{g}$  is finite (here  $r$  refers to the light-like coordinate of  $X_l^3$ ). Also  $g^{nr}\sqrt{g_4}$  which is analogous to gravitational flux if  $n$  is interpreted as time coordinate could be non-vanishing. These conditions are consistent with the above condition if one has

$$\begin{aligned} J_{ni} = 0, \quad g_{ni} = 0, \quad J_{ir} = 0, \quad g_{ir} = 0, \\ J^{nk} = 0 \quad k \neq r, \quad g^{nk} = 0 \quad k \neq r, \quad J^{nr}\sqrt{g_4} \neq 0, \quad g^{nr}\sqrt{g_4} \neq 0. \end{aligned} \quad (2.3.6)$$

The interpretation of this conditions is rather transparent.

1. The first two conditions state that covariant form of the induced Kähler electric field is in direction normal to  $X_l^3$  and metric separate into direct sum of normal and tangential contributions. Fifth and sixth condition state the same in contravariant form for  $k \neq n$ .
2. Third and fourth condition state that the induced Kähler field at  $X_l^3$  is purely magnetic and that the metric of  $x_l^3$  reduces to a block diagonal form. The reduction to purely magnetic field is of obvious importance as far as the understanding of the generalized eigen modes of the modified Dirac operator is considered [15].
3. The last two conditions must be understood as a limit and  $\neq$  means only the possibility of non-vanishing Kähler gauge flux or analog of gravitational flux through  $X_l^3$ .
4. The vision inspired by number theoretical compactification allows to identify  $r$  and  $n$  in terms of the light-like coordinates assignable to an integrable distribution of planes  $M^2(x)$  assumed to be assignable to  $M^4$  projection of  $X^4(X_l^3)$ . Later it will be found that Hamilton-Jacobi structure assignable to the extremals indeed means the existence of this kind of distribution meaning slicing of  $X^4(X_l^3)$  both by string world sheets and dual partonic 2-surfaces as well as by light-like 3-surfaces  $Y_l^3$ .
5. The physical analogy for the situation is the surface of an ideal conductor. It would not be surprising that these conditions are satisfied by all induced gauge fields.

### 2.3.2 Topologization and light-likeness of the Kähler current as alternative manners to guarantee vanishing of Lorentz 4-force

The general solution of 4-dimensional Einstein-Yang Mills equations in Euclidian 4-metric relies on self-duality of the gauge field, which topologizes gauge charge. This topologization can be achieved by a weaker condition, which can be regarded as a dynamical generalization of the Beltrami condition. An alternative manner to achieve vanishing of the Lorentz 4-force is light-likeness of the Kähler 4-current. This does not require topologization.

### Topologization of the Kähler current for $D_{CP_2} = 3$ : covariant formulation

The condition states that Kähler 4-current is proportional to the instanton current whose divergence is instanton density and vanishes when the dimension of  $CP_2$  projection is smaller than four:  $D_{CP_2} < 4$ . For  $D_{CP_2} = 2$  the instanton 4-current vanishes identically and topologization is equivalent with the vanishing of the Kähler current.

If the simplest vision about light-like 3-surfaces as basic dynamical objects is accepted  $D_{CP_2} = 2$ , corresponds to a non-physical situation and only the deformations of these surfaces - most naturally resulting by gluing of  $CP_2$  type vacuum extremals on them - can represent preferred extremals of Kähler action. One can however speak about  $D_{CP_2} = 2$  phase if 4-surfaces are obtained are obtained in this manner.

$$j^\alpha \equiv D_\beta J^{\alpha\beta} = \psi \times j_I^\alpha = \psi \times \epsilon^{\alpha\beta\gamma\delta} J_{\beta\gamma} A_\delta . \quad (2.3.7)$$

Here the function  $\psi$  is an arbitrary function  $\psi(s^k)$  of  $CP_2$  coordinates  $s^k$  regarded as functions of space-time coordinates. It is essential that  $\psi$  depends on the space-time coordinates through the  $CP_2$  coordinates only. Hence the representation as an imbedded gauge field is crucial element of the solution ansatz.

The field equations state the vanishing of the divergence of the 4-current. This is trivially true for instanton current for  $D_{CP_2} < 4$ . Also the contraction of  $\nabla\psi$  (depending on space-time coordinates through  $CP_2$  coordinates only) with the instanton current is proportional to the winding number density and therefore vanishes for  $D_{CP_2} < 4$ .

The topologization of the Kähler current guarantees the vanishing of the Lorentz 4-force. Indeed, using the self-duality condition for the current, the expression for the Lorentz 4-force reduces to a term proportional to the instanton density:

$$\begin{aligned} j^\alpha J_{\alpha\beta} &= \psi \times j_I^\alpha J_{\alpha\beta} \\ &= \psi \times \epsilon^{\alpha\mu\nu\delta} J_{\mu\nu} A_\delta J_{\alpha\beta} . \end{aligned} \quad (2.3.8)$$

Since all vector quantities appearing in the contraction with the four-dimensional permutation tensor are proportional to the gradients of  $CP_2$  coordinates, the expression is proportional to the instanton density, and thus winding number density, and vanishes for  $D_{CP_2} < 4$ .

Remarkably, the topologization of the Kähler current guarantees also the vanishing of the term  $j^\alpha J^{ki} \partial_\alpha s^k$  in the field equations for  $CP_2$  coordinates. This means that field equations reduce in both  $M_+^4$  and  $CP_2$  degrees of freedom to

$$T^{\alpha\beta} H_{\alpha\beta}^k = 0 . \quad (2.3.9)$$

These equations differ from the equations of minimal surface only by the replacement of the metric tensor with energy momentum tensor. The earlier proposal that quaternion conformal invariance in a suitable sense might provide a general solution of the field equations could be seen as a generalization of the ordinary conformal invariance of string models. If the topologization of the Kähler current implying effective dimensional reduction in  $CP_2$  degrees of freedom is consistent with quaternion conformal invariance, the quaternion conformal structures must differ for the different dimensions of  $CP_2$  projection.

### Topologization of the Kähler current for $D_{CP_2} = 3$ : non-covariant formulation

In order to gain a concrete understanding about what is involved it is useful to repeat these arguments using the 3-dimensional notation. The components of the instanton 4-current read in three-dimensional notation as

$$\bar{j}_I = \bar{E} \times \bar{A} + \phi \bar{B} , \quad \rho_I = \bar{B} \cdot \bar{A} . \quad (2.3.10)$$

The self duality conditions for the current can be written explicitly using 3-dimensional notation and read

$$\begin{aligned}\nabla \times \bar{B} - \partial_t \bar{E} &= \bar{j} = \psi \bar{j}_I = \psi (\phi \bar{B} + \bar{E} \times \bar{A}) , \\ \nabla \cdot \bar{E} &= \rho = \psi \rho_I .\end{aligned}\tag{2.3.11}$$

For a vanishing electric field the self-duality condition for Kähler current reduces to the Beltrami condition

$$\nabla \times \bar{B} = \alpha \bar{B} , \quad \alpha = \psi \phi .\tag{2.3.12}$$

The vanishing of the divergence of the magnetic field implies that  $\alpha$  is constant along the field lines of the flow. When  $\phi$  is constant and  $\bar{A}$  is time independent, the condition reduces to the Beltrami condition with  $\alpha = \phi = \text{constant}$ , which allows an explicit solution [48] .

One can check also the vanishing of the Lorentz 4-force by using 3-dimensional notation. Lorentz 3-force can be written as

$$\rho_I \bar{E} + \bar{j} \times \bar{B} = \psi \bar{B} \cdot \bar{A} \bar{E} + \psi (\bar{E} \times \bar{A} + \phi \bar{B}) \times \bar{B} = 0 .\tag{2.3.13}$$

The fourth component of the Lorentz force reads as

$$\bar{j} \cdot \bar{E} = \psi \bar{B} \cdot \bar{E} + \psi (\bar{E} \times \bar{A} + \phi \bar{B}) \cdot \bar{E} = 0 .\tag{2.3.14}$$

The remaining conditions come from the induction law of Faraday and could be guaranteed by expressing  $\bar{E}$  and  $\bar{B}$  in terms of scalar and vector potentials.

The density of the Kähler electric charge of the vacuum is proportional to the the helicity density of the so called helicity charge  $\rho = \psi \rho_I = \psi \bar{B} \cdot \bar{A}$ . This charge is topological charge in the sense that it does not depend on the induced metric at all. Note the presence of arbitrary function  $\psi$  of  $CP_2$  coordinates.

Further conditions on the functions appearing in the solution ansatz come from the 3 independent field equations for  $CP_2$  coordinates. What is remarkable that the generalized self-duality condition for the Kähler current allows to understand the general features of the solution ansatz to very high degree without any detailed knowledge about the detailed solution. The question whether field equations allow solutions consistent with the self duality conditions of the current will be dealt later. The optimistic guess is that the field equations and topologization of the Kähler current relate to each other very intimately.

### Vanishing or light likeness of the Kähler current guarantees vanishing of the Lorentz 4-force for $D_{CP_2} = 2$

For  $D_{CP_2} = 2$  one can always take two  $CP_2$  coordinates as space-time coordinates and from this it is clear that instanton current vanishes so that topologization gives a vanishing Kähler current. In particular, the Beltrami condition  $\nabla \times \bar{B} = \alpha \bar{B}$  is not consistent with the topologization of the instanton current for  $D_{CP_2} = 2$ .

$D_{CP_2} = 2$  case can be treated in a coordinate invariant manner by using the two coordinates of  $CP_2$  projection as space-time coordinates so that only a magnetic or electric field is present depending on whether the gauge current is time-like or space-like. Light-likeness of the gauge current provides a second manner to achieve the vanishing of the Lorentz force and is realized in case of massless extremals having  $D_{CP_2} = 2$ : this current is in the direction of propagation whereas magnetic and electric fields are orthogonal to it so that Beltrami conditions is certainly not satisfied.

### Under what conditions topologization of Kähler current yields Beltrami conditions?

Topologization of the Kähler 4-current gives rise to magnetic Beltrami fields if either of the following conditions is satisfied.

1. The  $\overline{E} \times \overline{A}$  term contributing besides  $\phi \overline{B}$  term to the topological current vanishes. This requires that  $\overline{E}$  and  $\overline{A}$  are parallel to each other

$$\overline{E} = \nabla \Phi - \partial_t \overline{A} = \beta \overline{A} \quad (2.3.15)$$

This condition is analogous to the Beltrami condition. Now only the 3-space has as its coordinates time coordinate and two spatial coordinates and  $\overline{B}$  is replaced with  $\overline{A}$ . Since  $E$  and  $B$  are orthogonal, this condition implies  $\overline{B} \cdot \overline{A} = 0$  so that Kähler charge density is vanishing.

2. The vector  $\overline{E} \times \overline{A}$  is parallel to  $\overline{B}$ .

$$\overline{E} \times \overline{A} = \beta \overline{B} \quad (2.3.16)$$

The condition is consistent with the orthogonality of  $\overline{E}$  and  $\overline{B}$  but implies the orthogonality of  $\overline{A}$  and  $\overline{B}$  so that electric charge density vanishes

In both cases vector potential fails to define a contact structure since  $B \cdot A$  vanishes (contact structures are discussed briefly below), and there exists a global coordinate along the field lines of  $A$  and the full contact structure is lost again. Note however that the Beltrami condition for magnetic field means that magnetic field defines a contact structure irrespective of whether  $\overline{B} \cdot \overline{A}$  vanishes or not. The transition from the general case to Beltrami field would thus involve the replacement

$$(\overline{A}, \overline{B}) \rightarrow_{\nabla \times} (\overline{B}, \overline{j})$$

induced by the rotor.

One must of course take these considerations somewhat cautiously since the inner product depends on the induced 4-metric and it might be that induced metric could allow small vacuum charge density and make possible genuine contact structure.

### Hydrodynamic analogy

The field equations of TGD are basically hydrodynamic equations stating the local conservation of the currents associated with the isometries of the imbedding space. Therefore it is intriguing that Beltrami fields appear also as solutions of ideal magnetohydrodynamics equations and as steady solutions of non-viscous incompressible flow described by Euler equations [26].

In hydrodynamics the role of the magnetic field is taken by the velocity field. This raises the idea that the incompressible flow could occur along the field lines of some natural vector field. The considerations of the last section show that the instanton current defines a universal candidate as far as the general solution of the field equations is considered. All conserved currents defined by the isometry charges would be parallel to the instanton current: one can say each flow line of instanton current is a carrier of conserved quantum numbers. Perhaps even the flow lines of an incompressible hydrodynamic flow could in reasonable approximation correspond to those of instanton current.

The conservation laws are satisfied for each flow line separately and therefore it seems that one cannot have the analog of viscous hydrodynamic flow in this framework. On the other hand, quantum classical correspondence requires that also dissipative effects have space-time correlates. Does something go badly wrong?

One must however take this argument with a grain of salt. Dissipation, that is the transfer of conserved quantities to degrees of freedom corresponding to shorter scales, could correspond to a transfer of these quantities between different space-time sheets of the many-sheeted space-time. Here the opponent could however argue that larger space-time sheets mimic the dissipative dynamics in shorter scales and that classical currents represent "symbolically" averaged currents in shorter length scales, and that the local non-conservation of energy momentum tensor consistent with local conservation of isometry currents provides a unique manner to mimic the dissipative dynamics.

An argument allowing to circumvent the objection in a more convincing manner emerged more than decade after the emergence of the interpretation in terms of asymptotic self-organization patterns [15, 28].

1. The construction of quantum TGD through second quantization of the modified Dirac equation led through several twists to the realization that the addition of a 3-dimensional measurement interaction term to the modified Dirac action is necessary in order to have quantum classical correspondence in the sense that the preferred extremals depend on the quantum numbers labeling states of super-conformal representations. Among many other things this also guarantees that the fermionic propagator has stringy character.
2. This term characterizes measurement interaction inducing state function reductions and hence also dissipation. It induces to a Kähler function a term which is real part of a holomorphic function of complex coordinates of the configuration space ("world of classical worlds") and a priori arbitrary function of zero modes and does not therefore contribute to the Kähler metric of configuration space. Kähler action is however affected by a term describing at space-time level the measurement interaction so that extremals do not remain the same.
3. Dissipation is absent in space-time regions where the measurement interaction term vanishes and there are good reasons to expect that also Kähler action reduces to Kähler action. Therefore preferred extremals can be interpreted as space-time correlates for asymptotic self-organization patterns.

### The stability of generalized Beltrami fields

The stability of generalized Beltrami fields is of high interest since unstable points of space-time sheets are those around which macroscopic changes induced by quantum jumps are expected to be localized.

#### 1. Contact forms and contact structures

The stability of Beltrami flows has been studied using the theory of contact forms in three-dimensional Riemann manifolds [34]. Contact form is a one-form  $A$  (that is covariant vector field  $A_\alpha$ ) with the property  $A \wedge dA \neq 0$ . In the recent case the induced Kähler gauge potential  $A_\alpha$  and corresponding induced Kähler form  $J_{\alpha\beta}$  for any 3-sub-manifold of space-time surface define a contact form so that the vector field  $A^\alpha = g^{\alpha\beta} A_\beta$  is not orthogonal with the magnetic field  $B^\alpha = \epsilon^{\alpha\beta\gamma} J_{\beta\gamma}$ . This requires that magnetic field has a helical structure. Induced metric in turn defines the Riemann structure.

If the vector potential defines a contact form, the charge density associated with the topologized Kähler current must be non-vanishing. This can be seen as follows.

1. The requirement that the flow lines of a one-form  $X_\mu$  defined by the vector field  $X^\mu$  as its dual allows to define a global coordinate  $x$  varying along the flow lines implies that there is an integrating factor  $\phi$  such that  $\phi X = dx$  and therefore  $d(\phi X) = 0$ . This implies  $d \log(\phi) \wedge X = -dX$ . From this the necessary condition for the existence of the coordinate  $x$  is  $X \wedge dX = 0$ . In the three-dimensional case this gives  $\bar{X} \cdot (\nabla \times \bar{X}) = 0$ .
2. This condition is by definition not satisfied by the vector potential defining a contact form so that one cannot identify a global coordinate varying along the flow lines of the vector potential. The condition  $\bar{B} \cdot \bar{A} \neq 0$  states that the charge density for the topologized Kähler current is non-vanishing. The condition that the field lines of the magnetic field allow a global coordinate requires  $\bar{B} \cdot \nabla \times \bar{B} = 0$ . The condition is not satisfied by Beltrami fields with  $\alpha \neq 0$ . Note that in this case magnetic field defines a contact structure.

Contact structure requires the existence of a vector  $\xi$  satisfying the condition  $A(\xi) = 0$ . The vector field  $\xi$  defines a plane field, which is orthogonal to the vector field  $A^\alpha$ . Reeb field in turn is a vector field for which  $A(X) = 1$  and  $dA(X; ) = 0$  hold true. The latter condition states the vanishing of the cross product  $X \times B$  so that  $X$  is parallel to the Kähler magnetic field  $B^\alpha$  and has unit projection in the direction of the vector field  $A^\alpha$ . Any Beltrami field defines a Reeb field irrespective of the Riemannian structure.

#### 2. Stability of the Beltrami flow and contact structures

Contact structures are used in the study of the topology and stability of the hydrodynamical flows [34], and one might expect that the notion of contact structure and its proper generalization to the four-dimensional context could be useful in TGD framework also. An example giving some idea

about the complexity of the flows defined by Beltrami fields is the Beltrami field in  $R^3$  possessing closed orbits with all possible knot and link types simultaneously [34] !

Beltrami flows associated with Euler equations are known to be unstable [34] . Since the flow is volume preserving, the stationary points of the Beltrami flow are saddle points at which also vorticity vanishes and linear instabilities of Navier-Stokes equations can develop. From the point of view of biology it is interesting that the flow is stabilized by vorticity which implies also helical structures. The stationary points of the Beltrami flow correspond in TGD framework to points at which the induced Kähler magnetic field vanishes. They can be unstable by the vacuum degeneracy of Kähler action implying classical non-determinism. For generalized Beltrami fields velocity and vorticity (both divergence free) are replaced by Kähler current and instanton current.

More generally, the points at which the Kähler 4-current vanishes are expected to represent potential instabilities. The instanton current is linear in Kähler field and can vanish in a gauge invariant manner only if the induced Kähler field vanishes so that the instability would be due to the vacuum degeneracy also now. Note that the vanishing of the Kähler current allows also the generation of region with  $D_{CP_2} = 4$ . The instability of the points at which induce Kähler field vanish is manifested in quantum jumps replacing the generalized Beltrami field with a new one such that something new is generated around unstable points. Thus the regions in which induced Kähler field becomes weak are the most interesting ones. For example, unwinding of DNA could be initiated by an instability of this kind.

### 2.3.3 How to satisfy field equations?

The topologization of the Kähler current guarantees also the vanishing of the term  $j^\alpha J^{k\iota} \partial_\alpha s^k$  in the field equations for  $CP_2$  coordinates. This means that field equations reduce in both  $M_+^4$  and  $CP_2$  degrees of freedom to

$$T^{\alpha\beta} H_{\alpha\beta}^k = 0 . \quad (2.3.17)$$

These equations differ from the equations of minimal surface only by the replacement of the metric tensor with energy momentum tensor. The following approach utilizes the properties of Hamilton Jacobi structures of  $M_+^4$  introduced in the study of massless extremals and contact structures of  $CP_2$  emerging naturally in the case of generalized Beltrami fields.

#### String model as a starting point

String model serves as a starting point.

1. In the case of Minkowskian minimal surfaces representing string orbit the field equations reduce to purely algebraic conditions in light cone coordinates  $(u, v)$  since the induced metric has only the component  $g_{uv}$ , whereas the second fundamental form has only diagonal components  $H_{uu}^k$  and  $H_{vv}^k$ .
2. For Euclidian minimal surfaces  $(u, v)$  is replaced by complex coordinates  $(w, \bar{w})$  and field equations are satisfied because the metric has only the component  $g^{w\bar{w}}$  and second fundamental form has only components of type  $H_{ww}^k$  and  $H_{\bar{w}\bar{w}}^k$ . The mechanism should generalize to the recent case.

#### The general form of energy momentum tensor as a guideline for the choice of coordinates

Any 3-dimensional Riemann manifold allows always a orthogonal coordinate system for which the metric is diagonal. Any 4-dimensional Riemann manifold in turn allows a coordinate system for which 3-metric is diagonal and the only non-diagonal components of the metric are of form  $g^{ti}$ . This kind of coordinates might be natural also now. When  $\bar{E}$  and  $\bar{B}$  are orthogonal, energy momentum tensor has the form

$$T = \begin{pmatrix} \frac{E^2+B^2}{2} & 0 & 0 & EB \\ 0 & \frac{E^2+B^2}{2} & 0 & 0 \\ 0 & 0 & \frac{-E^2+B^2}{2} & 0 \\ EB & 0 & 0 & \frac{E^2-B^2}{2} \end{pmatrix} \quad (2.3.18)$$

in the tangent space basis defined by time direction and longitudinal direction  $\bar{E} \times \bar{B}$ , and transversal directions  $\bar{E}$  and  $\bar{B}$ . Note that  $T$  is traceless.

The optimistic guess would be that the directions defined by these vectors integrate to three orthogonal coordinates of  $X^4$  and together with time coordinate define a coordinate system containing only  $g^{ti}$  as non-diagonal components of the metric. This however requires that the fields in question allow an integrating factor and, as already found, this requires  $\nabla \times X \cdot X = 0$  and this is not the case in general.

Physical intuition suggests however that  $X^4$  coordinates allow a decomposition into longitudinal and transversal degrees freedom. This would mean the existence of a time coordinate  $t$  and longitudinal coordinate  $z$  the plane defined by time coordinate and vector  $\bar{E} \times \bar{B}$  such that the coordinates  $u = t - z$  and  $v = t + z$  are light like coordinates so that the induced metric would have only the component  $g^{uv}$  whereas  $g^{vv}$  and  $g^{uu}$  would vanish in these coordinates. In the transversal space-time directions complex space-time coordinate coordinate  $w$  could be introduced. Metric could have also non-diagonal components besides the components  $g^{w\bar{w}}$  and  $g^{uv}$ .

### Hamilton Jacobi structures in $M_+^4$

Hamilton Jacobi structure in  $M_+^4$  can understood as a generalized complex structure combing transversal complex structure and longitudinal hyper-complex structure so that notion of holomorphy and Kähler structure generalize.

1. Denote by  $m^i$  the linear Minkowski coordinates of  $M^4$ . Let  $(S^+, S^-, E^1, E^2)$  denote local coordinates of  $M_+^4$  defining a *local* decomposition of the tangent space  $M^4$  of  $M_+^4$  into a direct, not necessarily orthogonal, sum  $M^4 = M^2 \oplus E^2$  of spaces  $M^2$  and  $E^2$ . This decomposition has an interpretation in terms of the longitudinal and transversal degrees of freedom defined by local light-like four-velocities  $v_{\pm} = \nabla S_{\pm}$  and polarization vectors  $\epsilon_i = \nabla E^i$  assignable to light ray. Assume that  $E^2$  allows complex coordinates  $w = E^1 + iE^2$  and  $\bar{w} = E^1 - iE^2$ . The simplest decomposition of this kind corresponds to the decomposition  $(S^+ \equiv u = t + z, S^- \equiv v = t - z, w = x + iy, \bar{w} = x - iy)$ .
2. In accordance with this physical picture,  $S^+$  and  $S^-$  define light-like curves which are normals to light-like surfaces and thus satisfy the equation:

$$(\nabla S_{\pm})^2 = 0 \quad .$$

The gradients of  $S_{\pm}$  are obviously analogous to local light like velocity vectors  $v = (1, \bar{v})$  and  $\bar{v} = (1, -\bar{v})$ . These equations are also obtained in geometric optics from Hamilton Jacobi equation by replacing photon's four-velocity with the gradient  $\nabla S$ : this is consistent with the interpretation of massless extremals as Bohr orbits of em field.  $S_{\pm} = \text{constant}$  surfaces can be interpreted as expanding light fronts. The interpretation of  $S_{\pm}$  as Hamilton Jacobi functions justifies the term Hamilton Jacobi structure.

The simplest surfaces of this kind correspond to  $t = z$  and  $t = -z$  light fronts which are planes. They are dual to each other by hyper complex conjugation  $u = t - z \rightarrow v = t + z$ . One should somehow generalize this conjugation operation. The simplest candidate for the conjugation  $S^+ \rightarrow S^-$  is as a conjugation induced by the conjugation for the arguments:  $S^+(t - z, t + z, x, y) \rightarrow S^-(t - z, t + z, x, y) = S^+(t + z, t - z, x, -y)$  so that a dual pair is mapped to a dual pair. In transversal degrees of freedom complex conjugation would be involved.

3. The coordinates  $(S_{\pm}, w, \bar{w})$  define local light cone coordinates with the line element having the form

$$\begin{aligned}
ds^2 &= g_{+-} dS^+ dS^- + g_{w\bar{w}} dw d\bar{w} \\
&+ g_{+w} dS^+ dw + g_{+\bar{w}} dS^+ d\bar{w} \\
&+ g_{-w} dS^- dw + g_{-\bar{w}} dS^- d\bar{w} .
\end{aligned} \tag{2.3.19}$$

Conformal transformations of  $M_+^4$  leave the general form of this decomposition invariant. Also the transformations which reduces to analytic transformations  $w \rightarrow f(w)$  in transversal degrees of freedom and hyper-analytic transformations  $S^+ \rightarrow f(S^+), S^- \rightarrow f(S^-)$  in longitudinal degrees of freedom preserve this structure.

4. The basic idea is that of generalized Kähler structure meaning that the notion of Kähler function generalizes so that the non-vanishing components of metric are expressible as

$$\begin{aligned}
g_{w\bar{w}} &= \partial_w \partial_{\bar{w}} K , & g_{+-} &= \partial_{S^+} \partial_{S^-} K , \\
g_{w\pm} &= \partial_w \partial_{S^\pm} K , & g_{\bar{w}\pm} &= \partial_{\bar{w}} \partial_{S^\pm} K .
\end{aligned} \tag{2.3.20}$$

for the components of the metric. The expression in terms of Kähler function is coordinate invariant for the same reason as in case of ordinary Kähler metric. In the standard lightcone coordinates the Kähler function is given by

$$K = w_0 \bar{w}_0 + uv , \quad w_0 = x + iy , \quad u = t - z , \quad v = t + z . \tag{2.3.21}$$

The Christoffel symbols satisfy the conditions

$$\left\{ \begin{smallmatrix} k \\ w \bar{w} \end{smallmatrix} \right\} = 0 , \quad \left\{ \begin{smallmatrix} k \\ +- \end{smallmatrix} \right\} = 0 . \tag{2.3.22}$$

If energy momentum tensor has only the components  $T^{w\bar{w}}$  and  $T^{+-}$ , field equations are satisfied in  $M_+^4$  degrees of freedom.

5. The Hamilton Jacobi structures related by these transformations can be regarded as being equivalent. Since light-like 3- surface is, as the dynamical evolution defined by the light front, fixed by the 2-surface serving as the light source, these structures should be in one-one correspondence with 2-dimensional surfaces with two surfaces regarded as equivalent if they correspond to different time=constant snapshots of the same light front, or are related by a conformal transformation of  $M_+^4$ . Obviously there should be quite large number of them. Note that the generating two-dimensional surfaces relate also naturally to quaternion conformal invariance and corresponding Kac Moody invariance for which deformations defined by the  $M^4$  coordinates as functions of the light-cone coordinates of the light front evolution define Kac Moody algebra, which thus seems to appear naturally also at the level of solutions of field equations.

The task is to find all possible local light cone coordinates defining one-parameter families 2-surfaces defined by the condition  $S_i = \text{constant}$ ,  $i = + \text{ or } -$ , dual to each other and expanding with light velocity. The basic open questions are whether the generalized Kähler function indeed makes sense and whether the physical intuition about 2-surfaces as light sources parameterizing the set of all possible Hamilton Jacobi structures makes sense.

Hamilton Jacobi structure means the existence of foliations of the  $M^4$  projection of  $X^4$  by 2-D surfaces analogous to string world sheets labeled by  $w$  and the dual of this foliation defined by partonic 2-surfaces labeled by the values of  $S_i$ . Also the foliation by light-like 3-surfaces  $Y_l^3$  labeled by  $S_\pm$  with  $S_\mp$  serving as light-like coordinate for  $Y_l^3$  is implied. This is what number theoretic compactification and  $M^8 - H$  duality predict when space-time surface corresponds to hyper-quaternionic surface of  $M^8$  [33, 72] .

### Contact structure and generalized Kähler structure of $CP_2$ projection

In the case of 3-dimensional  $CP_2$  projection it is assumed that one can introduce complex coordinates  $(\xi, \bar{\xi})$  and the third coordinate  $s$ . These coordinates would correspond to a contact structure in 3-dimensional  $CP_2$  projection defining transversal symplectic and Kähler structures. In these coordinates the transversal parts of the induced  $CP_2$  Kähler form and metric would contain only components of type  $g_{w\bar{w}}$  and  $J_{w\bar{w}}$ . The transversal Kähler field  $J_{w\bar{w}}$  would induce the Kähler magnetic field and the components  $J_{sw}$  and  $J_{s\bar{w}}$  the Kähler electric field.

It must be emphasized that the non-integrability of the contact structure implies that  $J$  cannot be parallel to the tangent planes of  $s = \text{constant}$  surfaces,  $s$  cannot be parallel to neither  $A$  nor the dual of  $J$ , and  $\xi$  cannot vary in the tangent plane defined by  $J$ . A further important conclusion is that for the solutions with 3-dimensional  $CP_2$  projection topologized Kähler charge density is necessarily non-vanishing by  $A \wedge J \neq 0$  whereas for the solutions with  $D_{CP_2} = 2$  topologized Kähler current vanishes.

Also the  $CP_2$  projection is assumed to possess a generalized Kähler structure in the sense that all components of the metric except  $s_{ss}$  are derivable from a Kähler function by formulas similar to  $M_+^4$  case.

$$s_{w\bar{w}} = \partial_w \partial_{\bar{w}} K \quad , \quad s_{ws} = \partial_w \partial_s K \quad , \quad s_{\bar{w}s} = \partial_{\bar{w}} \partial_s K \quad . \quad (2.3.23)$$

Generalized Kähler property guarantees that the vanishing of the Christoffel symbols of  $CP_2$  (rather than those of 3-dimensional projection), which are of type  $\{\xi^k_{\bar{\xi}}\}$ .

$$\{\xi^k_{\bar{\xi}}\} = 0 \quad . \quad (2.3.24)$$

Here the coordinates of  $CP_2$  have been chosen in such a manner that three of them correspond to the coordinates of the projection and fourth coordinate is constant at the projection. The upper index  $k$  refers also to the  $CP_2$  coordinate, which is constant for the  $CP_2$  projection. If energy momentum tensor has only components of type  $T^{+-}$  and  $T^{w\bar{w}}$ , field equations are satisfied even when if non-diagonal Christoffel symbols of  $CP_2$  are present. The challenge is to discover solution ansatz, which guarantees this property of the energy momentum tensor.

A stronger variant of Kähler property would be that also  $s_{ss}$  vanishes so that the coordinate lines defined by  $s$  would define light like curves in  $CP_2$ . The topologization of the Kähler current however implies that  $CP_2$  projection is a projection of a 3-surface with strong Kähler property. Using  $(s, \xi, \bar{\xi}, S^-)$  as coordinates for the space-time surface defined by the ansatz  $(w = w(\xi, s), S^+ = S^+(s))$  one finds that  $g_{ss}$  must be vanishing so that stronger variant of the Kähler property holds true for  $S^- = \text{constant}$  3-surfaces.

The topologization condition for the Kähler current can be solved completely generally in terms of the induced metric using  $(\xi, \bar{\xi}, s)$  and some coordinate of  $M_+^4$ , call it  $x^4$ , as space-time coordinates. Topologization boils down to the conditions

$$\begin{aligned} \partial_\beta (J^{\alpha\beta} \sqrt{g}) &= 0 \quad \text{for } \alpha \in \{\xi, \bar{\xi}, s\} \quad , \\ g^{4i} &\neq 0 \quad . \end{aligned} \quad (2.3.25)$$

Thus 3-dimensional empty space Maxwell equations and the non-orthogonality of  $X^4$  coordinate lines and the 3-surfaces defined by the lift of the  $CP_2$  projection.

### A solution ansatz yielding light-like current in $D_{CP_2} = 3$ case

The basic idea is that of generalized Kähler structure and solutions of field equations as maps or deformations of canonically imbedded  $M_+^4$  respecting this structure and guaranteeing that the only non-vanishing components of the energy momentum tensor are  $T^{\xi\bar{\xi}}$  and  $T^{s-}$  in the coordinates  $(\xi, \bar{\xi}, s, S^-)$ .

1. The coordinates  $(w, S^+)$  are assumed to holomorphic functions of the  $CP_2$  coordinates  $(s, \xi)$

$$S^+ = S^+(s) \ , \quad w = w(\xi, s) \ . \quad (2.3.26)$$

Obviously  $S^+$  could be replaced with  $S^-$ . The ansatz is completely symmetric with respect to the exchange of the roles of  $(s, w)$  and  $(S^+, \xi)$  since it maps longitudinal degrees of freedom to longitudinal ones and transverse degrees of freedom to transverse ones.

2. Field equations are satisfied if the only non-vanishing components of the energy momentum tensor are of type  $T^{\xi\bar{\xi}}$  and  $T^{s-}$ . The reason is that the  $CP_2$  Christoffel symbols for projection and projections of  $M_+^4$  Christoffel symbols are vanishing for these lower index pairs.
3. By a straightforward calculation one can verify that the only manner to achieve the required structure of energy momentum tensor is to assume that the induced metric in the coordinates  $(\xi, \bar{\xi}, s, S^-)$  has as non-vanishing components only  $g_{\xi\bar{\xi}}$  and  $g_{s-}$

$$g_{ss} = 0 \ , \quad g_{\xi s} = 0 \ , \quad g_{\bar{\xi} s} = 0 \ . \quad (2.3.27)$$

Obviously the space-time surface must factorize into an orthogonal product of longitudinal and transversal spaces.

4. The condition guaranteing the product structure of the metric is

$$\begin{aligned} s_{ss} &= m_{+w} \partial_s w(\xi, s) \partial_s S^+(s) + m_{+\bar{w}} \partial_s \bar{w}(\xi, s) \partial_s S^+(s) \ , \\ s_{s\xi} &= m_{+w} \partial_\xi w(\xi) \partial_s S^+(s) \ , \\ s_{s\bar{\xi}} &= m_{+w} \partial_{\bar{\xi}} w(\bar{\xi}) \partial_s S^+(s) \ . \end{aligned} \quad (2.3.28)$$

Thus the function of dynamics is to diagonalize the metric and provide it with strong Kähler property. Obviously the  $CP_2$  projection corresponds to a light-like surface for all values of  $S^-$  so that space-time surface is foliated by light-like surfaces and the notion of generalized conformal invariance makes sense for the entire space-time surface rather than only for its boundary or elementary particle horizons.

5. The requirement that the Kähler current is proportional to the instanton current means that only the  $j^-$  component of the current is non-vanishing. This gives the following conditions

$$\begin{aligned} j^\xi \sqrt{g} &= \partial_\beta (J^{\xi\beta} \sqrt{g}) = 0 \ , \quad j^{\bar{\xi}} \sqrt{g} = \partial_\beta (J^{\bar{\xi}\beta} \sqrt{g}) = 0 \ , \\ j^+ \sqrt{g} &= \partial_\beta (J^{+\beta} \sqrt{g}) = 0 \ . \end{aligned} \quad (2.3.29)$$

Since  $J^{+\beta}$  vanishes, the condition

$$\sqrt{g} j^+ = \partial_\beta (J^{+\beta} \sqrt{g}) = 0 \quad (2.3.30)$$

is identically satisfied. Therefore the number of field equations reduces to three.

The physical interpretation of the solution ansatz deserves some comments.

1. The light-like character of the Kähler current brings in mind  $CP_2$  extremals for which  $CP_2$  projection is light like. This suggests that the topological condensation of  $CP_2$  type extremal occurs on  $D_{CP_2} = 3$  helical space-time sheet representing zitterbewegung. In the case of many-body system light-likeness of the current does not require that particles are massless if particles of opposite charges can be present. Field tensor has the form  $(J^{\xi\bar{\xi}}, J^{\xi-}, J^{\bar{\xi}-})$ . Both helical magnetic field and electric field present as is clear when one replaces the coordinates  $(S^+, S^-)$  with time-like and space-like coordinate. Magnetic field dominates but the presence of electric field means that genuine Beltrami field is not in question.
2. Since the induced metric is product metric, 3-surface is metrically product of 2-dimensional surface  $X^2$  and line or circle and obeys product topology. If absolute minima correspond to asymptotic self-organization patterns, the appearance of the product topology and even metric is not so surprising. Thus the solutions can be classified by the genus of  $X^2$ . An interesting question is how closely the explanation of family replication phenomenon in terms of the topology of the boundary component of elementary particle like 3-surface relates to this. The heaviness and instability of particles which correspond to genera  $g > 2$  (sphere with more than two handles) might have simple explanation as absence of (stable)  $D_{CP_2} = 3$  solutions of field equations with genus  $g > 2$ .
3. The solution ansatz need not be the most general. Kähler current is light-like and already this is enough to reduce the field equations to the form involving only energy momentum tensor. One might hope of finding also solution ansätze for which Kähler current is time-like or space-like. Space-likeness of the Kähler current might be achieved if the complex coordinates  $(\xi, \bar{\xi})$  and hyper-complex coordinates  $(S^+, S^-)$  change the role. For this solution ansatz electric field would dominate. Note that the possibility that Kähler current is always light-like cannot be excluded.
4. Suppose that  $CP_2$  projection quite generally defines a foliation of the space-time surface by light-like 3-surfaces, as is suggested by the conformal invariance. If the induced metric has Minkowskian signature, the fourth coordinate  $x^4$  and thus also Kähler current must be time-like or light-like so that magnetic field dominates. Already the requirement that the metric is non-degenerate implies  $g_{s4} \neq 0$  so that the metric for the  $\xi = \text{constant}$  2-surfaces has a Minkowskian signature. Thus space-like Kähler current does not allow the lift of the  $CP_2$  projection to be light-like.

### Are solutions with time-like or space-like Kähler current possible in $D_{CP_2} = 3$ case?

As noticed in the section about number theoretical compactification, the flow of gauge currents along slices  $Y_l^3$  of  $X^4(X_l^3)$  "parallel" to  $X_l^3$  requires only that gauge currents are parallel to  $Y_l^3$  and can thus space-like. The following ansatz gives good hopes for obtaining solutions with space-like and perhaps also time-like Kähler currents.

1. Assign to light-like coordinates coordinates  $(T, Z)$  by the formula  $T = S^+ + S^-$  and  $Z = S^+ - S^-$ . Space-time coordinates are taken to be  $(\xi, \bar{\xi}, s)$  and coordinate  $Z$ . The solution ansatz with time-like Kähler current results when the roles of  $T$  and  $Z$  are changed. It will however found that same solution ansatz can give rise to both space-like and time-like Kähler current.
2. The solution ansatz giving rise to a space-like Kähler current is defined by the equations

$$T = T(Z, s) \quad , \quad w = w(\xi, s) \quad . \quad (2.3.31)$$

If  $T$  depends strongly on  $Z$ , the  $g_{ZZ}$  component of the induced metric becomes positive and Kähler current time-like.

3. The components of the induced metric are

$$\begin{aligned}
g_{ZZ} &= m_{ZZ} + m_{TT} \partial_Z T \partial_s T , & g_{Zs} &= m_{TT} \partial_Z T \partial_s T , \\
g_{ss} &= s_{ss} + m_{TT} \partial_s T \partial_s T , & g_{w\bar{w}} &= s_{w\bar{w}} + m_{w\bar{w}} \partial_\xi w \partial_{\bar{\xi}} \bar{w} , \\
g_{s\xi} &= s_{s\xi} , & g_{s\bar{\xi}} &= s_{s\bar{\xi}} .
\end{aligned} \tag{2.3.32}$$

Topologized Kähler current has only  $Z$ -component and 3-dimensional empty space Maxwell's equations guarantee the topologization.

In  $CP_2$  degrees of freedom the contractions of the energy momentum tensor with Christoffel symbols vanish if  $T^{ss}$ ,  $T^{\xi s}$  and  $T^{\xi\xi}$  vanish as required by internal consistency. This is guaranteed if the condition

$$J^{\xi s} = 0 \tag{2.3.33}$$

holds true. Note however that  $J^{\xi Z}$  is non-vanishing. Therefore only the components  $T^{\xi\bar{\xi}}$  and  $T^{Z\xi}$ ,  $T^{Z\bar{\xi}}$  of energy momentum tensor are non-vanishing, and field equations reduce to the conditions

$$\begin{aligned}
\partial_{\bar{\xi}}(J^{\xi\bar{\xi}} \sqrt{g}) + \partial_Z(J^{\xi Z} \sqrt{g}) &= 0 , \\
\partial_\xi(J^{\bar{\xi}\xi} \sqrt{g}) + \partial_Z(J^{\bar{\xi} Z} \sqrt{g}) &= 0 .
\end{aligned} \tag{2.3.34}$$

In the special case that the induced metric does not depend on  $z$ -coordinate equations reduce to holomorphicity conditions. This is achieved if  $T$  depends linearly on  $Z$ :  $T = aZ$ .

The contractions with  $M_+^4$  Christoffel symbols come from the non-vanishing of  $T^{Z\xi}$  and vanish if the Hamilton Jacobi structure satisfies the conditions

$$\begin{aligned}
\{T^k_w\} &= 0 , & \{T^k_{\bar{w}}\} &= 0 , \\
\{Z^k_w\} &= 0 , & \{Z^k_{\bar{w}}\} &= 0
\end{aligned} \tag{2.3.35}$$

hold true. The conditions are equivalent with the conditions

$$\{\pm^k_w\} = 0 , \quad \{\pm^k_{\bar{w}}\} = 0 . \tag{2.3.36}$$

These conditions possess solutions (standard light cone coordinates are the simplest example). Also the second derivatives of  $T(s, Z)$  contribute to the second fundamental form but they do not give rise to non-vanishing contractions with the energy momentum tensor. The cautious conclusion is that also solutions with time-like or space-like Kähler current are possible.

#### $DCP_2 = 4$ case

The preceding discussion was for  $DCP_2 = 3$  and one should generalize the discussion to  $DCP_2 = 4$  case.

1. Hamilton Jacobi structure for  $M_+^4$  is expected to be crucial also now.
2. One might hope that for  $DCP_2 = 4$  the Kähler structure of  $CP_2$  defines a foliation of  $CP_2$  by 3-dimensional contact structures. This requires that there is a coordinate varying along the field lines of the normal vector field  $X$  defined as the dual of the three-form  $A \wedge dA = A \wedge J$ . By the previous considerations the condition for this reads as  $dX = d(\log \phi) \wedge X$  and implies  $X \wedge dX = 0$ . Using the self duality of the Kähler form one can express  $X$  as  $X^k = J^{kl} A_l$ . By a brief calculation one finds that  $X \wedge dX \propto X$  holds true so that (somewhat disappointingly) a foliation of  $CP_2$  by contact structures does not exist.

For  $D_{CP_2} = 4$  case Kähler current vanishes and this case corresponds to what I have called earlier Maxwellian phase since empty space Maxwell's equations are indeed satisfied.

1. *Solution ansatz with a 3-dimensional  $M_+^4$  projection*

The basic idea is that the complex structure of  $CP_2$  is preserved so that one can use complex coordinates  $(\xi^1, \xi^2)$  for  $CP_2$  in which  $CP_2$  Christoffel symbols and energy momentum tensor have automatically the desired properties. This is achieved the second light like coordinate, say  $v$ , is non-dynamical so that the induced metric does not receive any contribution from the longitudinal degrees of freedom. In this case one has

$$S^+ = S^+(\xi^1, \xi^2) , \quad w = w(\xi^1, \xi^2) , \quad S^- = \text{constant} . \quad (2.3.37)$$

The induced metric does possess only components of type  $g_{i\bar{j}}$  if the conditions

$$g_{+w} = 0 , \quad g_{+\bar{w}} = 0 . \quad (2.3.38)$$

This guarantees that energy momentum tensor has only components of type  $T^{i\bar{j}}$  in coordinates  $(\xi^1, \xi^2)$  and their contractions with the Christoffel symbols of  $CP_2$  vanish identically. In  $M_+^4$  degrees of freedom one must pose the conditions

$$\{^k_{w+}\} = 0 , \quad \{^k_{\bar{w}+}\} = 0 , \quad \{^k_{++}\} = 0 . \quad (2.3.39)$$

on Christoffel symbols. These conditions are satisfied if the the  $M_+^4$  metric does not depend on  $S^+$ :

$$\partial_+ m_{kl} = 0 . \quad (2.3.40)$$

This means that  $m_{-w}$  and  $m_{-\bar{w}}$  can be non-vanishing but like  $m_{+-}$  they cannot depend on  $S^+$ .

The second derivatives of  $S^+$  appearing in the second fundamental form are also a source of trouble unless they vanish. Hence  $S^+$  must be a linear function of the coordinates  $\xi^k$ :

$$S^+ = a_k \xi^k + \bar{a}_k \bar{\xi}^k . \quad (2.3.41)$$

Field equations are the counterparts of empty space Maxwell equations  $j^\alpha = 0$  but with  $M_+^4$  coordinates  $(u, w)$  appearing as dynamical variables and entering only through the induced metric. By holomorphy the field equations can be written as

$$\partial_j (J^{\bar{j}} \sqrt{g}) = 0 , \quad \partial_{\bar{j}} (J^{\bar{j}i} \sqrt{g}) = 0 , \quad (2.3.42)$$

and can be interpreted as conditions stating the holomorphy of the contravariant Kähler form.

What is remarkable is that the  $M_+^4$  projection of the solution is 3-dimensional light like surface and that the induced metric has Euclidian signature. Light front would become a concrete geometric object with one compactified dimension rather than being a mere conceptualization. One could see this as topological quantization for the notion of light front or of electromagnetic shock wave, or perhaps even as the realization of the particle aspect of gauge fields at classical level.

If the latter interpretation is correct, quantum classical correspondence would be realized very concretely. Wave and particle aspects would both be present. One could understand the interactions of charged particles with electromagnetic fields both in terms of absorption and emission of topological field quanta and in terms of the interaction with a classical field as particle topologically condenses at the photonic light front.

For  $CP_2$  type extremals for which  $M_+^4$  projection is a light like curve correspond to a special case of this solution ansatz: transversal  $M_+^4$  coordinates are constant and  $S^+$  is now arbitrary function of  $CP_2$  coordinates. This is possible since  $M_+^4$  projection is 1-dimensional.

2. *Are solutions with a 4-dimensional  $M_+^4$  projection possible?*

The most natural solution ansatz is the one for which  $CP_2$  complex structure is preserved so that energy momentum tensor has desired properties. For four-dimensional  $M_+^4$  projection this ansatz does not seem to make promising since the contribution of the longitudinal degrees of freedom implies that the induced metric is not anymore of desired form since the components  $g_{ij} = m_{+-}(\partial_{\xi^i} S^+ \partial_{\xi^j} S^- + m_{+-} \partial_{\xi^i} S^- \partial_{\xi^j} S^+)$  are non-vanishing.

1. The natural dynamical variables are still Minkowski coordinates  $(w, \bar{w}, S^+, S^-)$  for some Hamilton Jacobi structure. Since the complex structure of  $CP_2$  must be given up,  $CP_2$  coordinates can be written as  $(\xi, s, r)$  to stress the fact that only "one half" of the Kähler structure of  $CP_2$  is respected by the solution ansatz.
2. The solution ansatz has the same general form as in  $D_{CP_2} = 3$  case and must be symmetric with respect to the exchange of  $M_+^4$  and  $CP_2$  coordinates. Transverse coordinates are mapped to transverse ones and longitudinal coordinates to longitudinal ones:

$$(S^+, S^-) = (S^+(s, r), S^-(s, r)) \quad , \quad w = w(\xi) \quad . \quad (2.3.43)$$

This ansatz would describe ordinary Maxwell field in  $M_+^4$  since the roles of  $M_+^4$  coordinates and  $CP_2$  coordinates are interchangeable.

It is however far from obvious whether there are any solutions with a 4-dimensional  $M_+^4$  projection. That empty space Maxwell's equations would allow only the topologically quantized light fronts as its solutions would realize quantum classical correspondence very concretely.

#### $D_{CP_2} = 2$ case

Hamilton Jacobi structure for  $M_+^4$  is assumed also for  $D_{CP_2} = 2$ , whereas the contact structure for  $CP_2$  is in  $D_{CP_2} = 2$  case replaced by the induced Kähler structure. Topologization yields vanishing Kähler current. Light-likeness provides a second manner to achieve vanishing Lorentz force but one cannot exclude the possibility of time- and space-like Kähler current.

##### 1. Solutions with vanishing Kähler current

1. String like objects, which are products  $X^2 \times Y^2 \subset M_+^4 \times CP_2$  of minimal surfaces  $Y^2$  of  $M_+^4$  with geodesic spheres  $S^2$  of  $CP_2$  and carry vanishing gauge current. String like objects allow considerable generalization from simple Cartesian products of  $X^2 \times Y^2 \subset M^4 \times S^2$ . Let  $(w, \bar{w}, S^+, S^-)$  define the Hamilton Jacobi structure for  $M_+^4$ .  $w = \text{constant}$  surfaces define minimal surfaces  $X^2$  of  $M_+^4$ . Let  $\xi$  denote complex coordinate for a sub-manifold of  $CP_2$  such that the imbedding to  $CP_2$  is holomorphic:  $(\xi^1, \xi^2) = (f^1(\xi), f^2(\xi))$ . The resulting surface  $Y^2 \subset CP_2$  is a minimal surface and field equations reduce to the requirement that the Kähler current vanishes:  $\partial_{\bar{\xi}}(J^{\xi\bar{\xi}} \sqrt{g_2}) = 0$ . One-dimensional strings are deformed to 3-dimensional cylinders representing magnetic flux tubes. The oscillations of string correspond to waves moving along string with light velocity, and for more general solutions they become TGD counterparts of Alfven waves associated with magnetic flux tubes regarded as oscillations of magnetic flux lines behaving effectively like strings. It must be emphasized that Alfven waves are a phenomenological notion not really justified by the properties of Maxwell's equations.
2. Also electret type solutions with the role of the magnetic field taken by the electric field are possible.  $(\xi, \bar{\xi}, u, v)$  would provide the natural coordinates and the solution ansatz would be of the form

$$(s, r) = (s(u, v), r(u, v)) \quad , \quad \xi = \text{constant} \quad , \quad (2.3.44)$$

and corresponds to a vanishing Kähler current.

3. Both magnetic and electric fields are necessarily present only for the solutions carrying non-vanishing electric charge density (proportional to  $\bar{B} \cdot \bar{A}$ ). Thus one can ask whether more general solutions carrying both magnetic and electric field are possible. As a matter fact, one must first answer the question what one really means with the magnetic field. By choosing the coordinates of 2-dimensional  $CP_2$  projection as space-time coordinates one can define what one means with magnetic and electric field in a coordinate invariant manner. Since the  $CP_2$  Kähler form for the  $CP_2$  projection with  $D_{CP_2} = 2$  can be regarded as a pure Kähler magnetic field, the induced Kähler field is either magnetic field or electric field.

The form of the ansatz would be

$$(s, r) = (s, r)(u, v, w, \bar{w}) , \quad \xi = \text{constant} . \quad (2.3.45)$$

As a matter fact,  $CP_2$  coordinates depend on two properly chosen  $M^4$  coordinates only.

#### 1. Solutions with light-like Kähler current

There are large classes of solutions of field equations with a light-like Kähler current and 2-dimensional  $CP_2$  projection.

1. Massless extremals for which  $CP_2$  coordinates are arbitrary functions of one transversal coordinate  $e = f(w, \bar{w})$  defining local polarization direction and light like coordinate  $u$  of  $M^4_{\mp}$  and carrying in the general case a light like current. In this case the holomorphy does not play any role.
2. The string like solutions thickened to magnetic flux tubes carrying TGD counterparts of Alfven waves generalize to solutions allowing also light-like Kähler current. Also now Kähler metric is allowed to develop a component between longitudinal and transversal degrees of freedom so that Kähler current develops a light-like component. The ansatz is of the form

$$\xi^i = f^i(\xi) , \quad w = w(\xi) , \quad S^- = s^- , \quad S^+ = s^+ + f(\xi, \bar{\xi}) .$$

Only the components  $g_{+\xi}$  and  $g_{+\bar{\xi}}$  of the induced metric receive contributions from the modification of the solution ansatz. The contravariant metric receives contributions to  $g^{-\xi}$  and  $g^{-\bar{\xi}}$  whereas  $g^{+\xi}$  and  $g^{+\bar{\xi}}$  remain zero. Since the partial derivatives  $\partial_{\xi}\partial_+h^k$  and  $\partial_{\bar{\xi}}\partial_+h^k$  and corresponding projections of Christoffel symbols vanish, field equations are satisfied. Kähler current develops a non-vanishing component  $j^-$ . Apart from the presence of the electric field, these solutions are highly analogous to Beltrami fields.

#### Could $D_{CP_2} = 2 \rightarrow 3$ transition occur in rotating magnetic systems?

I have studied the imbeddings of simple cylindrical and helical magnetic fields in various applications of TGD to condensed matter systems, in particular in attempts to understand the strange findings about rotating magnetic systems [74] .

Let  $S^2$  be the homologically non-trivial geodesic sphere of  $CP_2$  with standard spherical coordinates ( $U \equiv \cos(\theta), \Phi$ ) and let  $(t, \rho, \phi, z)$  denote cylindrical coordinates for a cylindrical space-time sheet. The simplest possible space-time surfaces  $X^4 \subset M^4_{\mp} \times S^2$  carrying helical Kähler magnetic field depending on the radial cylindrical coordinate  $\rho$ , are given by:

$$\begin{aligned} U &= U(\rho) , & \Phi &= n\phi + kz , \\ J_{\rho\phi} &= n\partial_{\rho}U , & J_{\rho z} &= k\partial_{\rho}U . \end{aligned} \quad (2.3.46)$$

This helical field is not Beltrami field as one can easily find. A more general ansatz corresponding defined by

$$\Phi = \omega t + kz + n\phi$$

would in cylindrical coordinates give rise to both helical magnetic field and radial electric field depending on  $\rho$  only. This field can be obtained by simply replacing the vector potential with its rotated

version and provides the natural first approximation for the fields associated with rotating magnetic systems.

A non-vanishing vacuum charge density is however generated when a constant magnetic field is put into rotation and is implied by the condition  $\bar{E} = \bar{v} \times \bar{B}$  stating vanishing of the Lorentz force. This condition does not follow from the induction law of Faraday although Faraday observed this effect first. This is also clear from the fact that the sign of the charge density depends on the direction of rotation.

The non-vanishing charge density is not consistent with the vanishing of the Kähler 4-current and requires a 3-dimensional  $CP_2$  projection and topologization of the Kähler current. Beltrami condition cannot hold true exactly for the rotating system. The conclusion is that rotation induces a phase transition  $D_{CP_2} = 2 \rightarrow 3$ . This could help to understand various strange effects related to the rotating magnetic systems [74]. For instance, the increase of the dimension of  $CP_2$  projection could generate join along boundaries contacts and wormhole contacts leading to the transfer of charge between different space-time sheets. The possibly resulting flow of gravitational flux to larger space-time sheets might help to explain the claimed antigravity effects.

### 2.3.4 $D_{CP_2} = 3$ phase allows infinite number of topological charges characterizing the linking of magnetic field lines

When space-time sheet possesses a  $D = 3$ -dimensional  $CP_2$  projection, one can assign to it a non-vanishing and conserved topological charge characterizing the linking of the magnetic field lines defined by Chern-Simons action density  $A \wedge dA/4\pi$  for induced Kähler form. This charge can be seen as classical topological invariant of the linked structure formed by magnetic field lines.

The topological charge can also vanish for  $D_{CP_2} = 3$  space-time sheets. In Darboux coordinates for which Kähler gauge potential reads as  $A = P_k dQ^k$ , the surfaces of this kind result if one has  $Q^2 = f(Q^1)$  implying  $A = fdQ^1$ ,  $f = P_1 + P_2 \partial_{Q^1} Q^2$ , which implies the condition  $A \wedge dA = 0$ . For these space-time sheets one can introduce  $Q^1$  as a global coordinate along field lines of  $A$  and define the phase factor  $\exp(i \int A_\mu dx^\mu)$  as a wave function defined for the entire space-time sheet. This function could be interpreted as a phase of an order parameter of super-conductor like state and there is a high temptation to assume that quantum coherence in this sense is lost for more general  $D_{CP_2} = 3$  solutions.

Chern-Simons action is known as helicity in electrodynamics [54]. Helicity indeed describes the linking of magnetic flux lines as is easy to see by interpreting magnetic field as incompressible fluid flow having  $A$  as vector potential:  $B = \nabla \times A$ . One can write  $A$  using the inverse of  $\nabla \times$  as  $A = (1/\nabla \times)B$ . The inverse is non-local operator expressible as

$$\frac{1}{\nabla \times} B(r) = \int dV' \frac{(r - r')}{|r - r'|^3} \times B(r') ,$$

as a little calculation shows. This allows to write  $\int A \cdot B$  as

$$\int dV A \cdot B = \int dV dV' B(r) \cdot \left( \frac{(r - r')}{|r - r'|^3} \times B(r') \right) ,$$

which is completely analogous to the Gauss formula for linking number when linked curves are replaced by a distribution of linked curves and an average is taken.

For  $D_{CP_2} = 3$  field equations imply that Kähler current is proportional to the helicity current by a factor which depends on  $CP_2$  coordinates, which implies that the current is automatically divergence free and defines a conserved charge for  $D = 3$ -dimensional  $CP_2$  projection for which the instanton density vanishes identically. Kähler charge is not equal to the helicity defined by the inner product of magnetic field and vector potential but to a more general topological charge.

The number of conserved topological charges is infinite since the product of any function of  $CP_2$  coordinates with the helicity current has vanishing divergence and defines a topological charge. A very natural function basis is provided by the scalar spherical harmonics of  $SU(3)$  defining Hamiltonians of  $CP_2$  canonical transformations and possessing well defined color quantum numbers. These functions define an infinite number of conserved charges which are also classical knot invariants in the sense that they are not affected at all when the 3-surface interpreted as a map from  $CP_2$  projection to  $M_+^4$  is deformed in  $M_+^4$  degrees of freedom. Also canonical transformations induced by Hamiltonians in

irreducible representations of color group affect these invariants via Poisson bracket action when the  $U(1)$  gauge transformation induced by the canonical transformation corresponds to a single valued scalar function. These link invariants are additive in union whereas the quantum invariants defined by topological quantum field theories are multiplicative.

Also non-Abelian topological charges are well-defined. One can generalize the topological current associated with the Kähler form to a corresponding current associated with the induced electro-weak gauge fields whereas for classical color gauge fields the Chern-Simons form vanishes identically. Also in this case one can multiply the current by  $CP_2$  color harmonics to obtain an infinite number of invariants in  $D_{CP_2} = 3$  case. The only difference is that  $A \wedge dA$  is replaced by  $Tr(A \wedge (dA + 2A \wedge A/3))$ .

There is a strong temptation to assume that these conserved charges characterize colored quantum states of the conformally invariant quantum theory as a functional of the light-like 3-surface defining boundary of space-time sheet or elementary particle horizon surrounding wormhole contacts. They would be TGD analogs of the states of the topological quantum field theory defined by Chern-Simons action as highest weight states associated with corresponding Wess-Zumino-Witten theory. These charges could be interpreted as topological counterparts of the isometry charges of configuration space of 3-surfaces defined by the algebra of canonical transformations of  $CP_2$ .

The interpretation of these charges as contributions of light-like boundaries to configuration space Hamiltonians would be natural. The dynamics of the induced second quantized spinor fields relates to that of Kähler action by a super-symmetry, so that it should define super-symmetric counterparts of these knot invariants. The anti-commutators of these super charges cannot however contribute to configuration space Kähler metric so that topological zero modes are in question. These Hamiltonians and their super-charge counterparts would be responsible for the topological sector of quantum TGD.

### 2.3.5 Preferred extremal property and the topologization/light-likeness of Kähler current?

The basic question is under what conditions the Kähler current is either topologized or light-like so that the Lorentz force vanishes. Does this hold for all preferred extremals of Kähler action? Or only asymptotically as suggested by the fact that generalized Beltrami fields can be interpreted as asymptotic self-organization patterns, when dissipation has become insignificant. Or does topologization take place in regions of space-time surface having Minkowskian signature of the induced metric? And what asymptotia actually means? Do absolute minima of Kähler action correspond to preferred extremals?

One can challenge the interpretation in terms of asymptotic self organization patterns assigned to the Minkowskian regions of space-time surface.

1. Zero energy ontology challenges the notion of approach to asymptotia in Minkowskian sense since the dynamics of light-like 3-surfaces is restricted inside finite volume  $CD \subset M^4$  since the partonic 2-surfaces representing their ends are at the light-like boundaries of causal diamond in a given p-adic time scale.
2. One can argue that generic non-asymptotic field configurations have  $D_{CP_2} = 4$ , and would thus carry a vanishing Kähler four-current if Beltrami conditions were satisfied universally rather than only asymptotically.  $j^\alpha = 0$  would obviously hold true also for the asymptotic configurations, in particular those with  $D_{CP_2} < 4$  so that empty space Maxwell's field equations would be universally satisfied for asymptotic field configurations with  $D_{CP_2} < 4$ . The weak point of this argument is that it is 3-D light-like 3-surfaces rather than space-time surfaces which are the basic dynamical objects so that the generic and only possible case corresponds to  $D_{CP_2} = 3$  for  $X_1^3$ . It is quite possible that preferred extremal property implies that  $D_{CP_2} = 3$  holds true in the Minkowskian regions since these regions indeed represent empty space. Geometrically this would mean that the  $CP_2$  projection does not change as the light-like coordinate labeling  $Y_i^3$  varies. This conforms nicely with the notion of quantum gravitational holography.
3. The failure of the generalized Beltrami conditions would mean that Kähler field is completely analogous to a dissipative Maxwell field for which also Lorentz force vanishes since  $\vec{j} \cdot \vec{E}$  is non-vanishing (note that isometry currents are conserved although energy momentum tensor is not). Quantum classical correspondence states that classical space-time dynamics is by its classical non-determinism able to mimic the non-deterministic sequence of quantum jumps at

space-time level, in particular dissipation in various length scales defined by the hierarchy of space-time sheets. Classical fields would represent "symbolically" the average dynamics, in particular dissipation, in shorter length scales. For instance, vacuum 4-current would be a symbolic representation for the average of the currents consisting of elementary particles. This would seem to support the view that  $D_{CP_2} = 4$  Minkowskian regions are present. The weak point of this argument is that there is fractal hierarchy of length scales represented by the hierarchy of causal diamonds ( $CDs$ ) and that the resulting hierarchy of generalized Feynman graphs might be enough to represent dissipation classically.

4. One objection to the idea is that second law realized as an asymptotic vanishing of Lorentz-Kähler force implies that all space-like 3-surfaces approaching same asymptotic state have the same value of Kähler function assuming that the Kähler function assignable to space-like 3-surface is same for all space-like sections of  $X^4(X_l^3)$  (assuming that one can realize general coordinate invariance also in this sense). This need not be the case. In any case, this need not be a problem since it would mean an additional symmetry extending general coordinate invariance. The exponent of Kähler function would be highly analogous to a partition function defined as an exponent of Hamiltonian with Kähler coupling strength playing the role of temperature.

It seems that asymptotic self-organization pattern need not be correct interpretation for non-dissipating regions, and the identification of light-like 3-surfaces as generalized Feynman diagrams encourages an alternative interpretation.

1.  $M^8 - H$  duality states that also the  $H$  counterparts of co-hyper-hyperquaternionic surfaces of  $M^8$  are preferred extremals of Kähler action.  $CP_2$  type vacuum extremals represent the basic example of these and a plausible conjecture is that the regions of space-time with Euclidian signature of the induced metric represent this kind of regions. If this conjecture is correct, dissipation could be assigned with regions having Euclidian signature of the induced metric. This makes sense since dissipation has quantum description in terms of Feynman graphs and regions of Euclidian signature indeed correspond to generalized Feynman graphs. This argument would suggest that generalized Beltrami conditions or light-likeness hold true inside Minkowskian regions rather than only asymptotically.
2. One could of course play language games and argue that asymptotia is with respect to the Euclidian time coordinate inside generalized Feynman graphs and is achieved exactly when the signature of the induced metric becomes Minkowskian. This is somewhat artificial attempt to save the notion of asymptotic self-organization pattern since the regions outside Feynman diagrams represent empty space providing a holographic representations for the matter at  $X_l^3$  so that the vanishing of  $j^\alpha F_{\alpha\beta}$  is very natural.
3. What is then the correct identification of asymptotic self-organization pattern. Could correspond to the negative energy part of the zero energy state at the upper light-like boundary  $\delta M_-^4$  of  $CD$ ? Or in the case of phase conjugate state to the positive energy part of the state at  $\delta M_+^4$ ? An identification consistent with the fractal structure of zero energy ontology and TGD inspired theory of consciousness is that the entire zero energy state reached by a sequence of quantum jumps represents asymptotic self-organization pattern represented by the asymptotic generalized Feynman diagram or their superposition. Biological systems represent basic examples about self-organization, and one cannot avoid the questions relating to the relationship between experience and geometric time. A detailed discussion of these points can be found in [4].

Absolute minimization of Kähler action was the first guess for the criterion selecting preferred extremals. Absolute minimization in a strict sense of the word does not make sense in the p-adic context since p-adic numbers are not well-ordered, and one cannot even define the action integral as a p-adic number. The generalized Beltrami conditions and the boundary conditions defining the preferred extremals are however local and purely algebraic and make sense also p-adically. If absolute minimization reduces to these algebraic conditions, it would make sense.

### 2.3.6 Generalized Beltrami fields and biological systems

The following arguments support the view that generalized Beltrami fields play a key role in living systems, and that  $D_{CP_2} = 2$  corresponds to ordered phase,  $D_{CP_2} = 3$  to spin glass phase and  $D_{CP_2} = 4$

to chaos, with  $D_{CP_2} = 3$  defining life as a phenomenon at the boundary between order and chaos. If the criteria suggested by the number theoretic compactification are accepted, it is not clear whether  $D_{CP_2}$  extremals can define preferred extremals of Kähler action. For instance, cosmic strings are not preferred extremals and the  $Y_I^3$  associated with MEs allow only covariantly constant right handed neutrino eigenmode of  $D_K(X^2)$ . The topological condensation of  $CP_2$  type vacuum extremals around  $D_{CP_2} = 2$  type extremals is however expected to give preferred extremals and if the density of the condensate is low enough one can still speak about  $D_{CP_2} = 2$  phase. A natural guess is also that the deformation of  $D_{CP_2} = 2$  extremals transforms light-like gauge currents to space-like topological currents allowed by  $D_{CP_2} = 3$  phase.

### Why generalized Beltrami fields are important for living systems?

Chirality, complexity, and high level of organization make  $D_{CP_2} = 3$  generalized Beltrami fields excellent candidates for the magnetic bodies of living systems.

1. Chirality selection is one of the basic signatures of living systems. Beltrami field is characterized by a chirality defined by the relative sign of the current and magnetic field, which means parity breaking. Chirality reduces to the sign of the function  $\psi$  appearing in the topologization condition and makes sense also for the generalized Beltrami fields.
2. Although Beltrami fields can be extremely complex, they are also extremely organized. The reason is that the function  $\alpha$  is constant along flux lines so that flux lines must in the case of compact Riemann 3-manifold belong to 2-dimensional  $\alpha = \text{constant}$  closed surfaces, in fact two-dimensional invariant tori [26].

For generalized Beltrami fields the function  $\psi$  is constant along the flow lines of the Kähler current. Space-time sheets with 3-dimensional  $CP_2$  projection serve as an illustrative example. One can use the coordinates for the  $CP_2$  projection as space-time coordinates so that one space-time coordinate disappears totally from consideration. Hence the situation reduces to a flow in a 3-dimensional sub-manifold of  $CP_2$ . One can distinguish between three types of flow lines corresponding to space-like, light-like and time-like topological current. The 2-dimensional  $\psi = \text{constant}$  invariant manifolds are sub-manifolds of  $CP_2$ . Ordinary Beltrami fields are a special case of space-like flow with flow lines belonging to the 2-dimensional invariant tori of  $CP_2$ . Time-like and light-like situations are more complex since the flow lines need not be closed so that the 2-dimensional  $\psi = \text{constant}$  surfaces can have boundaries.

For periodic self-organization patterns flow lines are closed and  $\psi = \text{constant}$  surfaces of  $CP_2$  must be invariant tori. The dynamics of the periodic flow is obtained from that of a steady flow by replacing one spatial coordinate with effectively periodic time coordinate. Therefore topological notions like helix structure, linking, and knotting have a dynamical meaning at the level of  $CP_2$  projection. The periodic generalized Beltrami fields are highly organized also in the temporal domain despite the potentiality for extreme topological complexity.

For these reasons topologically quantized generalized Beltrami fields provide an excellent candidate for a generic model for the dynamics of biological self-organization patterns. A natural guess is that many-sheeted magnetic and  $Z^0$  magnetic fields and their generalizations serve as templates for the helical molecules populating living matter, and explain both chiral selection, the complex linking and knotting of DNA and protein molecules, and even the extremely complex and self-organized dynamics of biological systems at the molecular level.

The intricate topological structures of DNA, RNA, and protein molecules are known to have a deep significance besides their chemical structure, and they could even define something analogous to the genetic code. Usually the topology and geometry of bio-molecules is believed to reduce to chemistry. TGD suggests that space-like generalized Beltrami fields serve as templates for the formation of bio-molecules and bio-structures in general. The dynamics of bio-systems would in turn utilize the time-like Beltrami fields as templates. There could even exist a mapping from the topology of magnetic flux tube structures serving as templates for bio-molecules to the templates of self-organized dynamics. The helical structures, knotting, and linking of bio-molecules would thus define a symbolic representation, and even coding for the dynamics of the bio-system analogous to written language.

**$D_{CP_2} = 3$  systems as boundary between  $D_{CP_2} = 2$  order and  $D_{CP_2} = 4$  chaos**

The dimension of  $CP_2$  projection is basic classifier for the asymptotic self-organization patterns.

1.  $D_{CP_2} = 4$  phase, dead matter, and chaos

$D_{CP_2} = 4$  corresponds to the ordinary Maxwellian phase in which Kähler current and charge density vanish and there is no topologization of Kähler current. By its maximal dimension this phase would naturally correspond to disordered phase, ordinary "dead matter". If one assumes that Kähler charge corresponds to either em charge or  $Z^0$  charge then the signature of this state of matter would be em neutrality or  $Z^0$  neutrality.

2.  $D_{CP_2} = 2$  phase as ordered phase

By the low dimension of  $CP_2$  projection  $D_{CP_2} = 2$  phase is the least stable phase possible only at cold space-time sheets. Kähler current is either vanishing or light-like, and Beltrami fields are not possible. This phase is highly ordered and much like a topological quantized version of ferro-magnet. In particular, it is possible to have a global coordinate varying along the field lines of the vector potential also now. The magnetic and  $Z^0$  magnetic body of any system is a candidate for this kind of system.  $Z^0$  field is indeed always present for vacuum extremals having  $D_{CP_2} = 2$  and the vanishing of em field requires that that  $\sin^2(\theta_W)$  ( $\theta_W$  is Weinberg angle) vanishes.

3.  $D_{CP_2} = 3$  corresponds to living matter

$D_{CP_2} = 3$  corresponds to highly organized phase characterized in the case of space-like Kähler current by complex helical structures necessarily accompanied by topologized Kähler charge density  $\propto \bar{A} \cdot \bar{B} \neq 0$  and Kähler current  $\bar{E} \times \bar{A} + \phi \bar{B}$ . For time like Kähler currents the helical structures are replaced by periodic oscillation patterns for the state of the system. By the non-maximal dimension of  $CP_2$  projection this phase must be unstable against too strong external perturbations and cannot survive at too high temperatures. Living matter is thus excellent candidate for this phase and it might be that the interaction of the magnetic body with living matter makes possible the transition from  $D_{CP_2} = 2$  phase to the self-organizing  $D_{CP_2} = 3$  phase.

Living matter which is indeed populated by helical structures providing examples of space-like Kähler current. Strongly charged lipid layers of cell membrane might provide example of time-like Kähler current. Cell membrane, micro-tubuli, DNA, and proteins are known to be electrically charged and  $Z^0$  charge plays key role in TGD based model of catalysis discussed in [30]. For instance, denaturing of DNA destroying its helical structure could be interpreted as a transition leading from  $D_{CP_2} = 3$  phase to  $D_{CP_2} = 4$  phase. The prediction is that the denatured phase should be electromagnetically (or  $Z^0$ ) neutral.

Beltrami fields result when Kähler charge density vanishes. For these configurations magnetic field and current density take the role of the vector potential and magnetic field as far as the contact structure is considered. For Beltrami fields there exist a global coordinate along the field lines of the vector potential but not along those of the magnetic field. As a consequence, the covariant consistency condition  $(\partial_s - qeA_s)\Psi = 0$  frequently appearing in the physics of super conducting systems would make sense along the flow lines of the vector potential for the order parameter of Bose-Einstein condensate. If Beltrami phase is super-conducting, then the state of the system must change in the transition to a more general phase. It is impossible to assign slicing of 4-surface by 3-D surfaces labeled by a coordinate  $t$  varying along the flow lines. This means that one cannot speak about a continuous evolution of Schrödinger amplitude with  $t$  playing the role of time coordinate. One could perhaps say that the entire space-time sheet represents single quantum event which cannot be decomposed to evolution. This would conform with the assignment of macroscopic and macro-temporal quantum coherence with living matter.

The existence of these three phases brings in mind systems allowing chaotic de-magnetized phase above critical temperature  $T_c$ , spin glass phase at the critical point, and ferromagnetic phase below  $T_c$ . Similar analogy is provided by liquid phase, liquid crystal phase possible in the vicinity of the critical point for liquid to solid transition, and solid phase. Perhaps one could regard  $D_{CP_2} = 3$  phase and life as a boundary region between  $D_{CP_2} = 2$  order and  $D_{CP_2} = 4$  chaos. This would naturally explain why life as it is known is possible in relatively narrow temperature interval.

### Can one assign a continuous Schrödinger time evolution to light-like 3-surfaces?

Alain Connes wrote [64] about factors of various types using as an example Schrödinger equation for various kinds of foliations of space-time to time=constant slices. If this kind of foliation does not exist, one cannot speak about time evolution of Schrödinger equation at all. Depending on the character of the foliation one can have factor of type I, II, or III. For instance, torus with slicing  $dx = a dy$  in flat coordinates, gives a factor of type I for rational values of  $a$  and factor of type II for irrational values of  $a$ .

#### 1. 3-D foliations and type III factors

Connes mentioned 3-D foliations  $V$  which give rise to type III factors. Foliation property requires a slicing of  $V$  by a one-form  $v$  to which slices are orthogonal (this requires metric).

1. The foliation property requires that  $v$  multiplied by suitable scalar is gradient. This gives the integrability conditions  $dv = w \wedge v$ ,  $w = -d\psi/\psi = -d\log(\psi)$ . Something proportional to  $\log(\psi)$  can be taken as a third coordinate varying along flow lines of  $v$ : the flow defines a continuous sequence of maps of 2-dimensional slice to itself.
2. If the so called Godbillon-Vey invariant defined as the integral of  $dw \wedge w$  over  $V$  is non-vanishing, factor of type III is obtained using Schrödinger amplitudes for which the flow lines of foliation define the time evolution. The operators of the algebra in question are transversal operators acting on Schrödinger amplitudes at each slice. Essentially Schrödinger equation in 3-D space-time would be in question with factor of type III resulting from the exotic choice of the time coordinate defining the slicing.

#### 2. What happens in case of light-like 3-surfaces?

In TGD light-like 3-surfaces are natural candidates for  $V$  and it is interesting to look what happens in this case. Light-likeness is of course a disturbing complication since orthogonality condition and thus contravariant metric is involved with the definition of the slicing. Light-likeness is not however involved with the basic conditions.

1. The one-form  $v$  defined by the induced Kähler gauge potential  $A$  defining also a braiding is a unique identification for  $v$ . If foliation exists, the braiding flow defines a continuous sequence of maps of partonic 2-surface to itself.
2. Physically this means the possibility of a super-conducting phase with order parameter satisfying covariant constancy equation  $D\psi = (d/dt - ieA)\psi = 0$ . This would describe a supra current flowing along flow lines of  $A$ .
3. If the integrability fails to be true, one *cannot* assign Schrödinger time evolution with the flow lines of  $v$ . One might perhaps say that 3-surface behaves like single quantum event not allowing slicing into a continuous Schrödinger time evolution.
4. In TGD Schrödinger amplitudes are replaced by second quantized induced spinor fields. Hence one does not face the problem whether it makes sense to speak about Schrödinger time evolution of complex order parameter along the flow lines of a foliation or not. Also the fact that the "time evolution" for the modified Dirac operator corresponds to single position dependent generalized eigenvalue identified as Higgs expectation same for all transversal modes (essentially  $z^n$  labeled by conformal weight) is crucial since it saves from the problems caused by the possible non-existence of Schrödinger evolution.

#### 4. Extremals of Kähler action

Some comments relating to the interpretation of the classification of the extremals of Kähler action by the dimension of their  $CP_2$  projection are in order. It has been already found that the extremals can be classified according to the dimension  $D$  of the  $CP_2$  projection of space-time sheet in the case that  $A_a = 0$  holds true.

1. For  $D_{CP_2} = 2$  integrability conditions for the vector potential can be satisfied for  $A_a = 0$  so that one has generalized Beltrami flow and one can speak about Schrödinger time evolution associated with the flow lines of vector potential defined by covariant constancy condition  $D\psi = 0$  makes sense. Kähler current is vanishing or light-like. This phase is analogous to a super-conductor or a ferromagnetic phase. For non-vanishing  $A_a$  the Beltrami flow property is lost but the analogy with ferromagnetism makes sense still.
2. For  $D_{CP_2} = 3$  foliations are lost. The phase is dominated by helical structures. This phase is analogous to spin glass phase around phase transition point from ferromagnetic to non-magnetized phase and expected to be important in living matter systems.
3.  $D_{CP_2} = 4$  is analogous to a chaotic phase with vanishing Kähler current and to a phase without magnetization. The interpretation in terms of non-quantum coherent "dead" matter is suggestive.

An interesting question is whether the ordinary 8-D imbedding space which defines one sector of the generalized imbedding space could correspond to  $A_a = 0$  phase. If so, then all states for this sector would be vacua with respect to  $M^4$  quantum numbers.  $M^4$ -trivial zero energy states in this sector could be transformed to non-trivial zero energy states by a leakage to other sectors.

### 2.3.7 About small perturbations of field equations

The study of small perturbations of the known solutions of field equations is a standard manner to get information about the properties of the solutions, their stability in particular. Fourier expansion is the standard manner to do the perturbation theory. In the recent case an appropriate modification of this ansatz might make sense if the solution in question is representable as a map  $M^4_+ \rightarrow CP_2$ , and the perturbations are rapidly varying when compared to the components of the induced metric and Kähler form so that one can make adiabatic approximation and approximate them as being effectively constant. Presumably also restrictions on directions of wave 4-vectors  $k_\mu = (\omega, \vec{k})$  are necessary so that the direction of wave vector adapts to the slowly varying background as in ray optics. Also Hamilton Jacobi structure is expected to modify the most straightforward approach. The four  $CP_2$  coordinates are the dynamical variables so that the situation is relatively simple.

A completely different approach is inspired by the physical picture. In this approach one glues  $CP_2$  type vacuum extremal to a known extremal and tries to deduce the behavior of the deformed extremal in the vicinity of wormhole throat by posing the general conditions on the slicing by light-like 3-surfaces  $Y^3_l$ . This approach is not followed now.

#### Generalized plane waves

Individual plane waves are geometrically very special since they represent a deformation of the space-time surface depending on single coordinate only. Despite this one might hope that plane waves or their appropriate modifications allowing to algebraize the treatment of small perturbations could give useful information also now.

1. Lorentz invariance plus the translational invariance due to the assumption that the induced metric and Kähler form are approximately constant encourage to think that the coordinates reduce Minkowski coordinates locally with the orientation of the local Minkowski frame depending slowly on space-time position. Hamilton Jacobi  $(S^+, S^-, w, \bar{w})$  are a good candidate for this kind of coordinates. The properties of the Hamilton Jacobi structure and of the solution ansatz suggest that excitations are generalized plane waves in longitudinal degrees of freedom only so that four-momentum would be replaced by the longitudinal momentum. In transverse degrees of freedom one might expect that holomorphic plane-waves  $exp(ik_T w)$ , where  $k_T$  is transverse momentum, make algebraization possible.

For time-like longitudinal momenta one can choose the local  $M^4$  coordinates in such a manner that longitudinal momentum reduces to  $(\omega_0, 0)$ , where  $\omega_0$  plays the role of rest mass and is analogous to the plasma frequency serving as an infrared cutoff for plasma waves. In these coordinates the simplest candidates for excitations with time-like momentum would be of form  $\Delta s^k = \epsilon a^k exp(i\omega_0 u)$ , where  $s^k$  are some real coordinates for  $CP_2$ ,  $a^k$  are Fourier coefficients,

and time-like coordinate is defined as  $u = S^+ + S^-$ . The excitations moving with light velocity correspond to  $\omega_0 = 0$ , and one must treat this case separately using plane wave  $\exp(i\omega S^\pm)$ , where  $\omega$  has continuum of values.

2. It is possible that only some preferred  $CP_2$  coordinates are excited in longitudinal degrees of freedom. For  $D_{CP_2} = 3$  ansatz the simplest option is that the complex  $CP_2$  coordinate  $\xi$  depends analytically on  $w$  and the longitudinal  $CP_2$  coordinate  $s$  obeys the plane wave ansatz.  $\xi(w) = a \times \exp(ik_T w)$ , where  $k_T$  is transverse momentum allows the algebraization of the solution ansatz also in the transversal degrees of freedom so that a dispersion relation results. For imaginary values of  $k_T$  and  $\omega$  the equations are real.

### 2. General form for the second variation of the field equations

For time-like four-momentum the second variation of field equations contains three kinds of terms. There are terms quadratic in  $\omega_0$  and coming from the second derivatives of the deformation, terms proportional to  $i\omega_0$  coming from the variation with respect to the derivatives of  $CP_2$  coordinates, and terms which do not depend on  $\omega_0$  and come from the variations of metric and Kähler form with respect to the  $CP_2$  coordinates.

In standard perturbation theory the terms proportional to  $i\omega_0$  would have interpretation as analogs of dissipative terms. This forces to assume that  $\omega_0$  is complex: note that in purely imaginary  $\omega_0$  the equations are real. The basic assumption is that Kähler action is able to mimic dissipation despite the fact that energy and momentum are conserved quantities. The vanishing of the Lorentz force has an interpretation as the vanishing of the dissipative effects. This would suggest that the terms proportional to  $i\omega_0$  vanish for the perturbations of the solution preserving the non-dissipative character of the asymptotic solutions. This might quite well result from the vanishing of the contractions with the deformation of the energy momentum tensor with the second fundamental form and of energy momentum tensor with the deformation of the second fundamental form coming from first derivatives.

Physical intuition would suggest that dissipation-less propagation is possible only along special directions. Thus the vanishing of the linear terms should occur only for special directions of the longitudinal momentum vector, say for light-like four-momenta in the direction of coordinate lines of  $S^+$  or  $S^-$ . Quite generally, the sub-space of allowed four-momenta is expected to depend on position since the components of metric and Kähler form are slowly varying. This dependence is completely analogous with that appearing in the Hamilton Jacobi (ray-optics) approach to the approximate treatment of wave equations and makes sense if the phase of the plane wave varies rapidly as compared to the variation of  $CP_2$  coordinates for the unperturbed solution.

Complex values of  $\omega_0$  are also possible, and would allow to deduce important information about the rate at which small deviations from asymptotia vanish as well as about instabilities of the asymptotic solutions. In particular, for imaginary values of  $\omega_0$  one obtains completely well-defined solution ansatz representing exponentially decaying or increasing perturbation.

### High energy limit

One can gain valuable information by studying the perturbations at the limit of very large four-momentum. At this limit the terms which are quadratic in the components of momentum dominate and come from the second derivatives of the  $CP_2$  coordinates appearing in the second fundamental form. The resulting equations reduce for all  $CP_2$  coordinates to the same condition

$$T^{\alpha\beta} k_\alpha k_\beta = 0 \quad .$$

This condition is generalization of masslessness condition with metric replaced by the energy momentum tensor, which means that light velocity is replaced by an effective light velocity. In fact, energy momentum tensor effectively replaces metric also in the modified Dirac equation whose form is dictated by super symmetry. Light-like four momentum is a rather general solution to the condition and corresponds to  $\omega_0 = 0$  case.

### Reduction of the dispersion relation to the graph of swallowtail catastrophe

Also the general structure of the equations for small perturbations allows to deduce highly non-trivial conclusions about the character of perturbations.

1. The equations for four  $CP_2$  coordinates are simultaneously satisfied if the determinant associated with the equations vanishes. This condition defines a 3-dimensional surface in the 4-dimensional space defined by  $\omega_0$  and coordinates of 3-space playing the role of slowly varying control parameters.  $4 \times 4$  determinant results and corresponds to a polynomial which is of order  $d = 8$  in  $\omega_0$ . If the determinant is real, the polynomial can depend on  $\omega_0^2$  only so that a fourth order polynomial in  $w = \omega_0^2$  results.
2. Only complex roots are possible in the case that the terms linear in  $i\omega_0$  are non-vanishing. One might hope that the linear term vanishes for certain choices of the direction of slowly varying four-momentum vector  $k^\mu(x)$  at least. For purely imaginary values of  $\omega_0$  the equations determinant are real always. Hence catastrophe theoretic description applies in this case at least, and the so called swallow tail [131] with three control parameters applies to the situation.
3. The general form of the vanishing determinant is

$$D(w, a, b, c) = w^4 - ew^3 - cw^2 - bw - a \quad .$$

The transition from the oscillatory to purely dissipative case changes only the sign of  $w$ . By the shift  $w = \hat{w} + e/4$  the determinant reduces to the canonical form

$$D(\hat{w}, a, b, c) = \hat{w}^4 - c\hat{w}^2 - b\hat{w} - a$$

of the swallowtail catastrophe. This catastrophe has three control variables, which basically correspond to the spatial 3-coordinates on which the induced metric and Kähler form depend. The variation of these coefficients at the space-time sheet of course covers only a finite region of the parameter space of the swallowtail catastrophe. The number of real roots for  $w = \omega_0^2$  is four, two, or none since complex roots appear in complex conjugate pairs for a real polynomial. The general shape of the region of 3-space is that for a portion of swallow tail catastrophe.

Figure 2.1: The projection of the bifurcation set of the swallowtail catastrophe to the 3-dimensional space of control variables. The potential function has four extrema in the interior of the swallowtail bounded by the triangles, no extrema in the valley above the swallowtail, and 2 extrema elsewhere.

4. The dispersion relation for the "rest mass"  $\omega_0$  (decay rate for the imaginary value of  $\omega_0$ ) has at most four real branches, which conforms with the fact that there are four dynamical variables. In real case  $\omega_0$  is analogous to plasma frequency acting as an infrared cutoff for the frequencies of plasma excitations. To get some grasp on the situation notice that for  $a = 0$  the swallowtail reduces to  $\hat{w} = 0$  and

$$\hat{w}^3 - c\hat{w} - b = 0 \quad ,$$

which represents the cusp catastrophe easy to illustrate in 3-dimensional space. Cusp in turn reduces for  $b = 0$  to  $\hat{w} = 0$  and fold catastrophe  $\hat{w} = \pm\sqrt{c}$ . Thus the catastrophe surface becomes 4-sheeted for  $c \geq 0$  for sufficiently small values of the parameters  $a$  and  $b$ . The possibility of negative values of  $\hat{w}$  in principle allows  $\omega^2 = \hat{w} + e/4 < 0$  solutions identifiable as exponentially decaying or amplified perturbations. At the high frequency limit the 4 branches degenerate to a single branch  $T^{\alpha\beta}k_\alpha k_\beta = 0$ , which as a special case gives light-like four-momenta corresponding to  $\omega_0 = 0$  and the origin of the swallowtail catastrophe.

Figure 2.2: Cusp catastrophe. Vertical direction corresponds to the behavior variable and orthogonal directions to control variables.

5. It is quite possible that the imaginary terms proportional to  $i\omega_0$  cannot be neglected in the time-like case. The interpretation would be as dissipative effects. If these effects are not too large, an approximate description in terms of butterfly catastrophe makes still sense. Note however that the second variation contains besides gravitational terms potentially large dissipative terms coming from the variation of the induced Kähler form and from the variation of  $CP_2$  Christoffel symbols.
6. Additional complications are encountered at the points, where the induced Kähler field vanishes since the second variation vanishes identically at these points. By the arguments represented earlier, these points quite generally represent instabilities.

## 2.4 Vacuum extremals

Vacuum extremals come as two basic types:  $CP_2$  type vacuum extremals for which the induced Kähler field and Kähler action are non-vanishing and the extremals for which the induced Kähler field vanishes. The deformations of both extremals are expected to be of fundamental importance in TGD universe. Vacuum extremals are not gravitational vacua and they are indeed fundamental in TGD inspired cosmology.

### 2.4.1 $CP_2$ type extremals

#### $CP_2$ type vacuum extremals

These extremals correspond to various isometric imbeddings of  $CP_2$  to  $M_+^4 \times CP_2$ . One can also drill holes to  $CP_2$ . Using the coordinates of  $CP_2$  as coordinates for  $X^4$  the imbedding is given by the formula

$$\begin{aligned} m^k &= m^k(u) , \\ m_{kl}\dot{m}^k\dot{m}^l &= 0 , \end{aligned} \tag{2.4.1}$$

where  $u(s^k)$  is an arbitrary function of  $CP_2$  coordinates. The latter condition tells that the curve representing the projection of  $X^4$  to  $M^4$  is light like curve. One can choose the functions  $m^i, i = 1, 2, 3$  freely and solve  $m^0$  from the condition expressing light likeness so that the number of this kind of extremals is very large.

The induced metric and Kähler field are just those of  $CP_2$  and energy momentum tensor  $T^{\alpha\beta}$  vanishes identically by the self duality of the Kähler form of  $CP_2$ . Also the canonical current  $j^\alpha =$

$D_\beta J^{\alpha\beta}$  associated with the Kähler form vanishes identically. Therefore the field equations in the interior of  $X^4$  are satisfied. The field equations are also satisfied on the boundary components of  $CP_2$  type extremal because the non-vanishing boundary term is, besides the normal component of Kähler electric field, also proportional to the projection operator to the normal space and vanishes identically since the induced metric and Kähler form are identical with the metric and Kähler form of  $CP_2$ .

As a special case one obtains solutions for which  $M^4$  projection is light like geodesic. The projection of  $m^0 = \text{constant}$  surfaces to  $CP_2$  is  $u = \text{constant}$  3-submanifold of  $CP_2$ . Geometrically these solutions correspond to a propagation of a massless particle. In a more general case the interpretation as an orbit of a massless particle is not the only possibility. For example, one can imagine a situation, where the center of mass of the particle is at rest and motion occurs along a circle at say  $(m^1, m^2)$  plane. The interpretation as a massive particle is natural. Amusingly, there is nice analogy with the classical theory of Dirac electron: massive Dirac fermion moves also with the velocity of light (zitterbewegung). The quantization of this random motion with light velocity leads to Virasoro conditions and this led to a breakthrough in the understanding of the p-adic QFT limit of TGD. Furthermore, it has turned out that Super Virasoro invariance is a general symmetry of the configuration space geometry and quantum TGD and appears both at the level of imbedding space and space-time surfaces.

The action for all extremals is same and given by the Kähler action for the imbedding of  $CP_2$ . The value of the action is given by

$$S = -\frac{\pi}{8\alpha_K} . \quad (2.4.2)$$

To derive this expression we have used the result that the value of Lagrangian is constant:  $L = 4/R^4$ , the volume of  $CP_2$  is  $V(CP_2) = \pi^2 R^4/2$  and the definition of the Kähler coupling strength  $k_1 = 1/16\pi\alpha_K$  (by definition,  $\pi R$  is the length of  $CP_2$  geodesics). Four-momentum vanishes for these extremals so that they can be regarded as vacuum extremals. The value of the action is negative so that these vacuum extremals are indeed favored by the minimization of the Kähler action. The absolute minimization of Kähler action suggests that ordinary vacuums with vanishing Kähler action density are unstable against the generation of  $CP_2$  type extremals. There are even reasons to expect that  $CP_2$  type extremals are for TGD what black holes are for GRT. Indeed, the nice generalization of the area law for the entropy of black hole [31] supports this view.

In accordance with the basic ideas of TGD topologically condensed vacuum extremals should somehow correspond to massive particles. The properties of the  $CP_2$  type vacuum extremals are in accordance with this interpretation. Although these objects move with a velocity of light, the motion can be transformed to a mere zitterbewegung so that the center of mass motion is trivial. Even the generation of the rest mass could be understood classically as a consequence of the minimization of action. Long range Kähler fields generate negative action for the topologically condensed vacuum extremal (momentum zero massless particle) and Kähler field energy in turn is identifiable as the rest mass of the topologically condensed particle.

An interesting feature of these objects is that they can be regarded as gravitational instantons [79]. A further interesting feature of  $CP_2$  type extremals is that they carry nontrivial classical color charges. The possible relationship of this feature to color confinement raises interesting questions. Could one model classically the formation of the color singlets to take place through the emission of "colorons": states with zero momentum but non-vanishing color? Could these peculiar states reflect the infrared properties of the color interactions?

#### Are $CP_2$ type non-vacuum extremals possible?

The isometric imbeddings of  $CP_2$  are all vacuum extremals so that these extremals as such cannot correspond to physical particles. One obtains however nonvacuum extremals as deformations of these solutions. There are several types of deformations leading to nonvacuum solutions. In order to describe some of them, recall the expressions of metric and Kähler form of  $CP_2$  in the coordinates  $(r, \Theta, \Psi, \Phi)$  [119] are given by

$$\begin{aligned}
\frac{ds^2}{R^2} &= \frac{dr^2}{(1+r^2)^2} + \frac{r}{2(1+r^2)^2} (d\Psi + \cos(\Theta)d\Phi)^2 \\
&+ \frac{r^2}{4(1+r^2)} (d\Theta^2 + \sin^2\Theta d\Phi^2) , \\
J &= \frac{r}{(1+r^2)} dr \wedge (d\Psi + \cos(\Theta)d\Phi) \\
&- \frac{r^2}{2(1+r^2)} \sin(\Theta) d\Theta \wedge d\Phi .
\end{aligned} \tag{2.4.3}$$

The scaling of the line element is defined so that  $\pi R$  is the length of the  $CP_2$  geodesic line. Note that  $\Phi$  and  $\Psi$  appear as "cyclic" coordinates in metric and Kähler form: this feature plays important role in the solution ansatz to be described.

Let  $M^4 = M^2 \times E^2$  denote the decomposition of  $M^4$  to a product of 2-dimensional Minkowski space and 2-dimensional Euclidian plane. This decomposition corresponds physically to the decomposition of momentum degrees of freedom for massless particle:  $E^2$  corresponds to polarization degrees of freedom.

There are several types of nonvacuum extremals.

1. "Virtual particle" extremals: the mass spectrum is continuous (also Euclidian momenta are allowed) but these extremals reduce to vacuum extremals in the massless limit.
2. Massless extremals.

Consider first an example of virtual particle extremal. The simplest extremal of this type is obtained in the following form

$$m^k = a^k \Psi + b^k \Phi . \tag{2.4.4}$$

Here  $a^k$  and  $b^k$  are some constant quantities. Field equations are equivalent to the conditions expressing four-momentum conservation and are identically satisfied the reason being that induced metric and Kähler form do not depend on the coordinates  $\Psi$  and  $\Phi$ .

Extremal describes 3-surface, which moves with constant velocity in  $M^4$ . Four-momentum of the solution can be both space and time like. In the massless limit solution however reduces to a vacuum extremal. Therefore the interpretation as an off mass shell massless particle seems appropriate.

Massless extremals are obtained from the following solution ansatz.

$$\begin{aligned}
m^0 &= m^3 = a\Psi + b\Phi , \\
(m^1, m^2) &= (m^1(r, \Theta), m^2(r, \Theta)) .
\end{aligned} \tag{2.4.5}$$

Only  $E^2$  degrees of freedom contribute to the induced metric and the line element is obtained from

$$ds^2 = ds_{CP_2}^2 - (dm^1)^2 - (dm^2)^2 . \tag{2.4.6}$$

Field equations reduce to conservation condition for the components of four-momentum in  $E^2$  plane. By their cyclicity the coordinates  $\Psi$  and  $\Phi$  disappear from field equations and one obtains essentially current conservation condition for two-dimensional field theory defined in space spanned by the coordinates  $r$  and  $\Theta$ .

$$\begin{aligned}
(J_a^i)_{,i} &= 0 , \\
J_a^i &= T^{ij} f_{,j}^a \sqrt{g} .
\end{aligned} \tag{2.4.7}$$

Figure 2.3: Topological sum of  $CP_2$ :s as Feynman graph with lines thickened to four-manifolds

Here the index  $i$  and  $a$  refer to  $r$  and  $\Theta$  and to  $E^2$  coordinates  $m^1$  and  $m^2$  respectively.  $T^{ij}$  denotes the canonical energy momentum tensor associated with Kähler action. One can express the components of  $T^{ij}$  in terms of induced metric and  $CP_2$  metric in the following form

$$T^{ij} = (-g^{ik}g^{jl} + g^{ij}g^{kl}/2)s_{kl} . \quad (2.4.8)$$

This expression holds true for all components of the energy momentum tensor.

Since field equations are essentially two-dimensional conservation conditions they imply that components of momentum currents can be regarded as vector fields of some canonical transformations

$$J_a^i = \varepsilon^{ij} H_{,j}^a , \quad (2.4.9)$$

where  $\varepsilon^{ij}$  denotes two-dimensional constant symplectic form. An open problem is whether one could solve field equations exactly and whether there exists some nonlinear superposition principle for the solutions of these equations. Solutions are massless since transversal momentum densities vanish identically.

Consider as a special case the solution obtained by assuming that one  $E^2$  coordinate is constant and second coordinate is function  $f(r)$  of the variable  $r$  only. Field equations reduce to the following form

$$f_{,r} = \pm \frac{k}{(1+r^2)^{1/3}} \sqrt{r^2 - k^2(1+r^2)^{4/3}} . \quad (2.4.10)$$

The solution is well defined only for sufficiently small values of the parameter  $k$  appearing as integration constant and becomes ill defined at two singular values of the variable  $r$ . Boundary conditions are identically satisfied at the singular values of  $r$  since the radial component of induced metric diverges at these values of  $r$ . The result leads to suspect that the generation of boundary components dynamically is a general phenomenon so that all nonvacuum solutions have boundary components in accordance with basic ideas of TGD.

#### $CP_2 \# CP_2 \# \dots \# CP_2$ :s as generalized Feynman graphs

There are reasons to believe that point like particles might be identified as  $CP_2$  type extremals in TGD approach. Also the geometric counterparts of the massless on mass shell particles and virtual particles have been identified. It is natural to extend this idea to the level of particle interactions: the lines of Feynman diagrams of quantum field theory are thickened to four-manifolds, which are in a good approximation  $CP_2$  type vacuum extremals. This would mean that generalized Feynman graphs are essentially connected sums of  $CP_2$ :s (see Fig. 2.4.1):  $X^4 = CP_2 \# CP_2 \dots \# CP_2$ .

Unfortunately, this picture seems to be oversimplified. First, it is questionable whether the cross sections for the scattering of  $CP_2$  type extremals have anything to do with the cross sections associated with the standard gauge interactions. A naive geometric argument suggests that the cross section should reflect the geometric size of the scattered objects and therefore be of the order of  $CP_2$  radius for topologically non-condensed  $CP_2$  type extremals. The observed cross sections would result at the first level of condensation, where particles are effectively replaced by surfaces with size of order Compton length. Secondly, the  $h_{vac} = -D$  rule, considered in the previous chapter, suggests that only real particles correspond to the  $CP_2$  type extremals whereas virtual particles in general correspond to the vacuum extremals with a vanishing Kähler action. The reason is that the negative exponent of the Kähler action reduces the contribution of the  $CP_2$  type extremals to the functional integral very effectively. Therefore the exchanges of  $CP_2$  type extremals are suppressed by the negative exponent of the Kähler action very effectively so that geometric scattering cross section is obtained.

### 2.4.2 Vacuum extremals with vanishing Kähler field

Vacuum extremals correspond to 4-surfaces with vanishing Kähler field and therefore to gauge field zero configurations of gauge field theory. These surfaces have  $CP_2$  projection, which is Legendre manifold. The condition expressing Legendre manifold property is obtained in the following manner. Kähler potential of  $CP_2$  can be expressed in terms of the canonical coordinates  $(P_i, Q_i)$  for  $CP_2$  as

$$A = \sum_k P_k dQ^k . \quad (2.4.11)$$

The conditions

$$P_k = \partial_{Q^k} f(Q^i) , \quad (2.4.12)$$

where  $f(Q^i)$  is arbitrary function of its arguments, guarantee that Kähler potential is pure gauge. It is clear that canonical transformations, which act as local  $U(1)$  gauge transformations, transform different vacuum configurations to each other so that vacuum degeneracy is enormous. Also  $M_+^4$  diffeomorphisms act as the dynamical symmetries of the vacuum extremals. Some sub-group of these symmetries extends to the isometry group of the configuration space in the proposed construction of the configuration space metric. The vacuum degeneracy is still enhanced by the fact that the topology of the four-surface is practically free.

Vacuum extremals are certainly not absolute minima of the action. For the induced metric having Minkowski signature the generation of Kähler electric fields lowers the action. For Euclidian signature both electric and magnetic fields tend to reduce the action. Therefore the generation of Euclidian regions of space-time is expected to occur.  $CP_2$  type extremals, identifiable as real (as contrast to virtual) elementary particles, can be indeed regarded as these Euclidian regions.

Particle like vacuum extremals can be classified roughly by the number of the compactified dimensions  $D$  having size given by  $CP_2$  length. Thus one has  $D_{CP_2} = 3$  for  $CP_2$  type extremals,  $D_{CP_2} = 2$  for string like objects,  $D_{CP_2} = 1$  for membranes and  $D_{CP_2} = 0$  for pieces of  $M^4$ . As already mentioned, the rule  $h_{vac} = -D$  relating the vacuum weight of the Super Virasoro representation to the number of compactified dimensions of the vacuum extremal is very suggestive.  $D < 3$  vacuum extremals would correspond in this picture to virtual particles, whose contribution to the generalized Feynman diagram is not suppressed by the exponential of Kähler action unlike that associated with the virtual  $CP_2$  type lines.

$M^4$  type vacuum extremals (representable as maps  $M_+^4 \rightarrow CP_2$  by definition) are also expected to be natural idealizations of the space-time at long length scales obtained by smoothing out small scale topological inhomogenities (particles) and therefore they should correspond to space-time of GRT in a reasonable approximation.

The reason would be "Yin-Yang principle".

1. Consider first the option for which Kähler function corresponds to an absolute minimum of Kähler action. Vacuum functional as an exponent of Kähler function is expected to concentrate on those 3-surfaces for which the Kähler action is non-negative. On the other hand, the

requirement that Kähler action is absolute minimum for the space-time associated with a given 3-surface, tends to make the action negative. Therefore the vacuum functional is expected to differ considerably from zero only for 3-surfaces with a vanishing Kähler action per volume. It could also occur that the degeneracy of 3-surfaces with same large negative action compensates the exponent of Kähler function.

2. If preferred extrema correspond to Kähler calibrations or their duals [72] , Yin-Yang principle is modified to a more local principle. For Kähler calibrations (their duals) the absolute value of action in given region is minimized (maximized). A given region with positive (negative sign) of action density favors Kähler electric (magnetic) fields. In long length scales the average density of Kähler action per four-volume tends to vanish so that Kähler function of the entire universe is expected to be very nearly zero. This regularizes the theory automatically and implies that average Kähler action per volume vanishes. Positive and finite values of Kähler function are of course favored.

In both cases the vanishing of Kähler action per volume in long length scales makes vacuum extremals excellent idealizations for the smoothed out space-time surface. Robertson-Walker cosmologies provide a good example in this respect. As a matter fact the smoothed out space-time is not a mere fictive concept since larger space-time sheets realize it as a essential part of the Universe.

Several absolute minima could be possible and the non-determinism of the vacuum extremals is not expected to be reduced completely. The remaining degeneracy could be even infinite. A good example is provided by the vacuum extremals representable as maps  $M_+^4 \rightarrow D^1$ , where  $D^1$  is one-dimensional curve of  $CP_2$ . This degeneracy could be interpreted as a space-time correlate for the non-determinism of quantum jumps with maximal deterministic regions representing quantum states in a sequence of quantum jumps.

## 2.5 Non-vacuum extremals

### 2.5.1 Cosmic strings

Cosmic strings are extremals of type  $X^2 \times S^2$ , where  $X^2$  is minimal surface in  $M_+^4$  (analogous to the orbit of a bosonic string) and  $S^2$  is the homologically non-trivial geodesic sphere of  $CP_2$ . The action of these extremals is positive and thus absolute minima are certainly not in question. One can however consider the possibility that these extremals are building blocks of the absolute minimum space-time surfaces since the absolute minimization of the Kähler action is global rather than a local principle. Cosmic strings can contain also Kähler charged matter in the form of small holes containing elementary particle quantum numbers on their boundaries and the negative Kähler electric action for a topologically condensed cosmic string could cancel the Kähler magnetic action.

The string tension of the cosmic strings is given by

$$T = \frac{1}{8\alpha_K R^2} \simeq .2210^{-6} \frac{1}{G} , \quad (2.5.1)$$

where  $\alpha_K \simeq \alpha_{em}$  has been used to get the numerical estimate. The string tension is of the same order of magnitude as the string tension of the cosmic strings of GUTs and this leads to the model of the galaxy formation providing a solution to the dark matter puzzle as well as to a model for large voids as caused by the presence of a strongly Kähler charged cosmic string. Cosmic strings play also fundamental role in the TGD inspired very early cosmology.

### 2.5.2 Massless extremals

Massless extremals (or topological light rays) are characterized by massless wave vector  $p$  and polarization vector  $\varepsilon$  orthogonal to this wave vector. Using the coordinates of  $M^4$  as coordinates for  $X^4$  the solution is given as

$$\begin{aligned} s^k &= f^k(u, v) , \\ u &= p \cdot m , & v &= \varepsilon \cdot m , \\ p \cdot \varepsilon &= 0 , & p^2 &= 0 . \end{aligned}$$

$CP_2$  coordinates are arbitrary functions of  $p \cdot m$  and  $\varepsilon \cdot m$ . Clearly these solutions correspond to plane wave solutions of gauge field theories. It is important to notice however that linear super position doesn't hold as it holds in Maxwell phase. Gauge current is proportional to wave vector and its divergence vanishes as a consequence. Also cylindrically symmetric solutions for which the transverse coordinate is replaced with the radial coordinate  $\rho = \sqrt{m_1^2 + m_2^2}$  are possible. In fact,  $v$  can be *any* function of the coordinates  $m^1, m^2$  transversal to the light like vector  $p$ .

Boundary conditions on the boundaries of the massless extremal are satisfied provided the normal component of the energy momentum tensor vanishes. Since energy momentum tensor is of the form  $T^{\alpha\beta} \propto p^\alpha p^\beta$  the conditions  $T^{n\beta} = 0$  are satisfied if the  $M^4$  projection of the boundary is given by the equations of form

$$\begin{aligned} H(p \cdot m, \varepsilon \cdot m, \varepsilon_1 \cdot m) &= 0 \quad , \\ \varepsilon \cdot p &= 0 \quad , \quad \varepsilon_1 \cdot p = 0 \quad , \quad \varepsilon \cdot \varepsilon_1 = 0 \quad . \end{aligned} \tag{2.5.2}$$

where  $H$  is arbitrary function of its arguments. Recall that for  $M^4$  type extremals the boundary conditions are also satisfied if Kähler field vanishes identically on the boundary.

The following argument suggests that there are not very many manners to satisfy boundary conditions in case of  $M^4$  type extremals. The boundary conditions, when applied to  $M^4$  coordinates imply the vanishing of the normal component of energy momentum tensor. Using coordinates, where energy momentum tensor is diagonal, the requirement boils down to the condition that at least one of the eigen values of  $T^{\alpha\beta}$  vanishes so that the determinant  $\det(T^{\alpha\beta})$  must vanish on the boundary: this condition defines 3-dimensional surface in  $X^4$ . In addition, the normal of this surface must have same direction as the eigen vector associated with the vanishing eigen value: this means that three additional conditions must be satisfied and this is in general true in single point only. The boundary conditions in  $CP_2$  coordinates are satisfied provided that the conditions

$$J^{n\beta} J_l^k \partial_\beta s^l = 0$$

are satisfied. The identical vanishing of the normal components of Kähler electric and magnetic fields on the boundary of massless extremal property provides a manner to satisfy all boundary conditions but it is not clear whether there are any other manners to satisfy them.

The characteristic feature of the massless extremals is that in general the Kähler gauge current is non-vanishing. In ordinary Maxwell electrodynamicis this is not possible. This means that these extremals are accompanied by vacuum current, which contains in general case both weak and electromagnetic terms as well as color part.

A possible interpretation of the solution is as the exterior space-time to a topologically condensed particle with vanishing mass described by massless  $CP_2$  type extremal, say photon or neutrino. In general the surfaces in question have boundaries since the coordinates  $s^k$  are bounded this is in accordance with the general ideas about topological condensation. The fact that massless plane wave is associated with  $CP_2$  type extremal combines neatly the wave and particle aspects at geometrical level.

The fractal hierarchy of space-time sheets implies that massless extremals should interesting also in long length scales. The presence of a light like electromagnetic vacuum current implies the generation of coherent photons and also coherent gravitons are generated since the Einstein tensor is also non-vanishing and light like (proportional to  $k^\alpha k^\beta$ ). Massless extremals play an important role in the TGD based model of bio-system as a macroscopic quantum system. The possibility of vacuum currents is what makes possible the generation of the highly desired coherent photon states.

### 2.5.3 Generalization of the solution ansatz defining massless extremals (MEs)

The solution ansatz for MEs has developed gradually to an increasingly general form and the following formulation is the most general one achieved hitherto. Rather remarkably, it rather closely resembles the solution ansatz for the  $CP_2$  type extremals and has direct interpretation in terms of geometric optics. Equally remarkable is that the latest generalization based on the introduction of the local light cone coordinates was inspired by quantum holography principle.

The solution ansatz for MEs has developed gradually to an increasingly general form and the following formulation is the most general one achieved hitherto. Rather remarkably, it rather closely resembles the solution ansatz for the  $CP_2$  type extremals and has direct interpretation in terms of geometric optics. Equally remarkable is that the latest generalization based on the introduction of the local light cone coordinates was inspired by quantum holography principle.

### Local light cone coordinates

The solution involves a decomposition of  $M^4_+$  tangent space localizing the decomposition of Minkowski space to an orthogonal direct sum  $M^2 \oplus E^2$  defined by light-like wave vector and polarization vector orthogonal to it. This decomposition defines what might be called local light cone coordinates.

1. Denote by  $m^i$  the linear Minkowski coordinates of  $M^4$ . Let  $(S^+, S^-, E^1, E^2)$  denote local coordinates of  $M^4_+$  defining a *local* decomposition of the tangent space  $M^4$  of  $M^4_+$  into a direct *orthogonal* sum  $M^4 = M^2 \oplus E^2$  of spaces  $M^2$  and  $E^2$ . This decomposition has interpretation in terms of the longitudinal and transversal degrees of freedom defined by local light-like four-velocities  $v_{\pm} = \nabla S_{\pm}$  and polarization vectors  $\epsilon_i = \nabla E^i$  assignable to light ray.
2. With these assumptions the coordinates  $(S_{\pm}, E^i)$  define local light cone coordinates with the metric element having the form

$$ds^2 = 2g_{+-}dS^+dS^- + g_{11}(dE^1)^2 + g_{22}(dE^2)^2. \quad (2.5.3)$$

If complex coordinates are used in transversal degrees of freedom one has  $g_{11} = g_{22}$ .

3. This family of light cone coordinates is not the most general family since longitudinal and transversal spaces are orthogonal. One can also consider light-cone coordinates for which one non-diagonal component, say  $m_{1+}$ , is non-vanishing if the solution ansatz is such that longitudinal and transversal spaces are orthogonal for the induced metric.

### A conformally invariant family of local light cone coordinates

The simplest solutions to the equations defining local light cone coordinates are of form  $S_{\pm} = k \cdot m$  giving as a special case  $S_{\pm} = m^0 \pm m^3$ . For more general solutions of from

$$S_{\pm} = m^0 \pm f(m^1, m^2, m^3) \quad , \quad (\nabla_3 f)^2 = 1 \quad ,$$

where  $f$  is an otherwise arbitrary function, this relationship reads as

$$S^+ + S^- = 2m^0 \quad .$$

This condition defines a natural rest frame. One can integrate  $f$  from its initial data at some two-dimensional  $f = \text{constant}$  surface and solution describes curvilinear light rays emanating from this surface and orthogonal to it. The flow velocity field  $\bar{v} = \nabla f$  is irrotational so that closed flow lines are not possible in a connected region of space and the condition  $\bar{v}^2 = 1$  excludes also closed flow line configuration with singularity at origin such as  $v = 1/\rho$  rotational flow around axis.

One can identify  $E^2$  as a local tangent space spanned by polarization vectors and orthogonal to the flow lines of the velocity field  $\bar{v} = \nabla f(m^1, m^2, m^3)$ . Since the metric tensor of any 3-dimensional space allows always diagonalization in suitable coordinates, one can always find coordinates  $(E^1, E^2)$  such that  $(f, E^1, E^2)$  form orthogonal coordinates for  $m^0 = \text{constant}$  hyperplane. Obviously one can select the coordinates  $E^1$  and  $E^2$  in infinitely many manners.

### Closer inspection of the conditions defining local light cone coordinates

Whether the conformal transforms of the local light cone coordinates  $\{S_{\pm} = m^0 \pm f(m^1, m^2, m^3), E^i\}$  define the only possible compositions  $M^2 \oplus E^2$  with the required properties, remains an open question. The best that one might hope is that any function  $S^+$  defining a family of light-like curves defines a local decomposition  $M^4 = M^2 \oplus E^2$  with required properties.

1. Suppose that  $S^+$  and  $S^-$  define light-like vector fields which are not orthogonal (proportional to each other). Suppose that the polarization vector fields  $\epsilon_i = \nabla E^i$  tangential to local  $E^2$  satisfy the conditions  $\epsilon_i \cdot \nabla S^+ = 0$ . One can formally integrate the functions  $E^i$  from these condition since the initial values of  $E^i$  are given at  $m^0 = \text{constant}$  slice.
2. The solution to the condition  $\nabla S_+ \cdot \epsilon_i = 0$  is determined only modulo the replacement

$$\epsilon_i \rightarrow \hat{\epsilon}_i = \epsilon_i + k \nabla S_+ \quad ,$$

where  $k$  is any function. With the choice

$$k = -\frac{\nabla E^i \cdot \nabla S^-}{\nabla S^+ \cdot \nabla S^-}$$

one can satisfy also the condition  $\hat{\epsilon}_i \cdot \nabla S^- = 0$ .

3. The requirement that also  $\hat{\epsilon}_i$  is gradient is satisfied if the integrability condition

$$k = k(S^+)$$

is satisfied in this case  $\hat{\epsilon}_i$  is obtained by a gauge transformation from  $\epsilon_i$ . The integrability condition can be regarded as an additional, and obviously very strong, condition for  $S^-$  once  $S^+$  and  $E^i$  are known.

4. The problem boils down to that of finding local momentum and polarization directions defined by the functions  $S^+$ ,  $S^-$  and  $E^1$  and  $E^2$  satisfying the orthogonality and integrability conditions

$$\begin{aligned} (\nabla S^+)^2 = (\nabla S^-)^2 = 0 \quad , \quad \nabla S^+ \cdot \nabla S^- \neq 0 \quad , \\ \nabla S^+ \cdot \nabla E^i = 0 \quad , \quad \frac{\nabla E^i \cdot \nabla S^-}{\nabla S^+ \cdot \nabla S^-} = k_i(S^+) \quad . \end{aligned}$$

The number of integrability conditions is 3+3 (all derivatives of  $k_i$  except the one with respect to  $S^+$  vanish): thus it seems that there are not much hopes of finding a solution unless some discrete symmetry relating  $S^+$  and  $S^-$  eliminates the integrability conditions altogether.

A generalization of the spatial reflection  $f \rightarrow -f$  working for the separable Hamilton Jacobi function  $S_{\pm} = m^0 \pm f$  ansatz could relate  $S^+$  and  $S^-$  to each other and trivialize the integrability conditions. The symmetry transformation of  $M_+^4$  must perform the permutation  $S^+ \leftrightarrow S^-$ , preserve the light-likeness property, map  $E^2$  to  $E^2$ , and multiply the inner products between  $M^2$  and  $E^2$  vectors by a mere conformal factor. This encourages the conjecture that all solutions are obtained by conformal transformations from the solutions  $S_{\pm} = m^0 \pm f$ .

### General solution ansatz for MEs for given choice of local light cone coordinates

Consider now the general solution ansatz assuming that a local wave-vector-polarization decomposition of  $M_+^4$  tangent space has been found.

1. Let  $E(S^+, E^1, E^2)$  be an arbitrary function of its arguments: the gradient  $\nabla E$  defines at each point of  $E^2$  an  $S^+$ -dependent (and thus time dependent) polarization direction orthogonal to the direction of local wave vector defined by  $\nabla S^+$ . Polarization vector depends on  $E^2$  position only.
2. Quite a general family of MEs corresponds to the solution family of the field equations having the general form

$$s^k = f^k(S^+, E) \quad ,$$

where  $s^k$  denotes  $CP_2$  coordinates and  $f^k$  is an arbitrary function of  $S^+$  and  $E$ . The solution represents a wave propagating with light velocity and having definite  $S^+$  dependent polarization

in the direction of  $\nabla E$ . By replacing  $S^+$  with  $S^-$  one obtains a dual solution. Field equations are satisfied because energy momentum tensor and Kähler current are light-like so that all tensor contractions involved with the field equations vanish: the orthogonality of  $M^2$  and  $E^2$  is essential for the light-likeness of energy momentum tensor and Kähler current.

3. The simplest solutions of the form  $S_{\pm} = m^0 \pm m^3$ ,  $(E^1, E^2) = (m^1, m^2)$  and correspond to a cylindrical MEs representing waves propagating in the direction of the cylinder axis with light velocity and having polarization which depends on point  $(E^1, E^2)$  and  $S^+$  (and thus time). For these solutions four-momentum is light-like: for more general solutions this cannot be the case. Polarization is in general case time dependent so that both linearly and circularly polarized waves are possible. If  $m^3$  varies in a finite range of length  $L$ , then 'free' solution represents geometrically a cylinder of length  $L$  moving with a light velocity. Of course, ends could be also anchored to the emitting or absorbing space-time surfaces.
4. For the general solution the cylinder is replaced by a three-dimensional family of light like curves and in this case the rectilinear motion of the ends of the cylinder is replaced with a curvilinear motion with light velocity unless the ends are anchored to emitting/absorbing space-time surfaces. The non-rotational character of the velocity flow suggests that the freely moving particle like 3-surface defined by ME cannot remain in a infinite spatial volume. The most general ansatz for MEs should be useful in the intermediate and nearby regions of a radiating object whereas in the far away region radiation solution is expected to decompose to cylindrical ray like MEs for which the function  $f(m^1, m^2, m^3)$  is a linear function of  $m^i$ .
5. One can try to generalize the solution ansatz further by allowing the metric of  $M_{\pm}^4$  to have components of type  $g_{i+}$  or  $g_{i-}$  in the light cone coordinates used. The vanishing of  $T^{11}$ ,  $T^{+1}$ , and  $T^{-}$  is achieved if  $g_{i\pm} = 0$  holds true for the induced metric. For  $s^k = s^k(S^+, E^1)$  ansatz neither  $g_{2\pm}$  nor  $g_{1-}$  is affected by the imbedding so that these components of the metric must vanish for the Hamilton Jacobi structure:

$$ds^2 = 2g_{+-}dS^+dS^- + 2g_{1+}dE^1dS^+ + g_{11}(dE^1)^2 + g_{22}(dE^2)^2 . \quad (2.5.4)$$

$g_{1+} = 0$  can be achieved by an additional condition

$$m_{1+} = s_{kl}\partial_1 s^k \partial_+ s^k . \quad (2.5.5)$$

The diagonalization of the metric seems to be a general aspect of absolute minima. The absence of metric correlations between space-time degrees of freedom for asymptotic self-organization patterns is somewhat analogous to the minimization of non-bound entanglement in the final state of the quantum jump.

### Are the boundaries of space-time sheets quite generally light like surfaces with Hamilton Jacobi structure?

Quantum holography principle naturally generalizes to an approximate principle expected to hold true also in non-cosmological length and time scales.

1. The most general ansatz for topological light rays or massless extremals (MEs) inspired by the quantum holographic thinking relies on the introduction of the notion of local light cone coordinates  $S_+, S_-, E_1, E_2$ . The gradients  $\nabla S_+$  and  $\nabla S_-$  define two light like directions just like Hamilton Jacobi functions define the direction of propagation of wave in geometric optics. The two polarization vector fields  $\nabla E_1$  and  $\nabla E_2$  are orthogonal to the direction of propagation defined by either  $S_+$  or  $S_-$ . Since also  $E_1$  and  $E_2$  can be chosen to be orthogonal, the metric of  $M_{\pm}^4$  can be written locally as  $ds^2 = g_{+-}dS_+dS_- + g_{11}dE_1^2 + g_{22}dE_2^2$ . In the earlier ansatz  $S_+$  and  $S_-$  were restricted to the variables  $k \cdot m$  and  $\tilde{k} \cdot m$ , where  $k$  and  $\tilde{k}$  correspond to light like momentum and its mirror image and  $m$  denotes linear  $M^4$  coordinates: these MEs describe cylindrical structures with constant direction of wave propagation expected to be most important in regions faraway from the source of radiation.

2. Boundary conditions are satisfied if the 3-dimensional boundaries of MEs have one light like direction ( $S_+$  or  $S_-$  is constant). This means that the boundary of ME has metric dimension  $d = 2$  and is characterized by an infinite-dimensional super-symplectic and super-conformal symmetries just like the boundary of the imbedding space  $M_+^4 \times CP_2$ : The boundaries are like moments for mini big bangs (in TGD based fractal cosmology big bang is replaced with a silent whisper amplified to not necessarily so big bang).
3. These observations inspire the conjecture that boundary conditions for  $M^4$  like space-time sheets fixed by the absolute minimization of Kähler action quite generally require that space-time boundaries correspond to light like 3-surfaces with metric dimension equal to  $d = 2$ . This does not yet imply that light like surfaces of imbedding space would take the role of the light cone boundary: these light like surface could be seen only as a special case of causal determinants analogous to event horizons.

### 2.5.4 Maxwell phase

"Maxwell phase" corresponds to small deformations of the  $M^4$  type vacuum extremals. Since energy momentum tensor is quadratic in Kähler field the term proportional to the contraction of the energy momentum tensor with second fundamental form drops from field equations and one obtains in lowest order the following field equations

$$j^\alpha J_l^k s_{,\alpha}^l = 0 . \quad (2.5.6)$$

These equations are satisfied if Maxwell's equations

$$j^\alpha = 0 \quad (2.5.7)$$

hold true. Massless extremals and Maxwell phase clearly exclude each other and it seems that they must corresponds to different space-time sheets.

The explicit construction of these extremals reduces to the task of finding an imbedding for an arbitrary free Maxwell field to  $H$ . One can also allow source terms corresponding to the presence of the point like charges: these should correspond to the regions of the space-time, where the flat space-time approximation of the space-time fails. The regions where the approximation defining the Maxwell phase fails might correspond to a topologically condensed  $CP_2$  type extremals, for example. As a consequence, Kähler field is superposition of radiation type Kähler field and of Coulombic term. A second possibility is the generation of "hole" with similar Coulombic Kähler field.

An important property of the Maxwell phase (also of massless extremals) is its approximate canonical invariance. Canonical transformations do not spoil the extremal property of the four-surface in the approximation used, since it corresponds to a mere  $U(1)$  gauge transformation. This implies the counter part of the vacuum degeneracy, that is, the existence of an enormous number of four-surfaces with very nearly the same action. Also there is an approximate  $Diff(M_+^4)$  invariance.

The canonical degeneracy has some very interesting consequences concerning the understanding of the electro-weak symmetry breaking and color confinement. Kähler field is canonical invariant and satisfies Maxwells equations. This is in accordance with the identification of Kähler field as  $U(1)$  part of the electro-weak gauge field. Electromagnetic gauge field is a superposition of Kähler field and  $Z^0$  field  $\gamma = 3J - \sin^2(\theta_W)Z^0/2$  so that also electromagnetic gauge field is long ranged assuming that  $Z^0$  and  $W^+$  fields are short ranged. These fields are not canonical invariants and their behavior seems to be essentially random, which implies short range correlations and the consequent massivation.

There is an objection against this argument. For the known  $D < 4$  solutions of field equations weak fields are not random at all. These situations could represent asymptotic configurations assignable to space-time sheets. This conforms with the interpretation that weak gauge fields are essentially massless within the asymptotic space-time sheets representing weak bosons. Gauge fields are however transferred between space-time sheets through # contacts modelable as pieces of  $CP_2$  type extremals having  $D_{CP_2} = 4$ . In contrast to Kähler and color gauge fluxes, weak gauge fluxes are not conserved in the Euclidian time evolution between the 3-D causal horizons separating the Euclidian # contact from space-time sheets with Minkowskian signature. This non-conservation implying the loss of coherence

in the transfer of fields between space-time sheets is a plausible mechanism for the loss of correlations and massivation of the weak gauge fields.

Classical gluon fields are proportional to Kähler field and to the Hamiltonians associated with the color isometry generators.

$$g_{\alpha\beta}^A = kH^A J_{\alpha\beta} . \quad (2.5.8)$$

This implies that the direction of gluon fields in color algebra is random. One can always perform a canonical transformation, which reduces to a global color rotation in some arbitrary small region of space-time and reduces to identity outside this region. The proportionality of a gluon field to Kähler form implies that there is a classical long range correlation in  $X^4$  degrees of freedom: in this sense classical gluon fields differ from massive electro-weak fields in Maxwell phase.

### 2.5.5 Stationary, spherically symmetric extremals

The stationary, spherically symmetric extremals of the Kähler action imbeddable in  $M^4 \times S^2$ , where  $S^2$  is geodesic sphere, are the simplest extremals, which one can study as models for the space-time surrounding a topologically condensed particle, say  $CP_2$  type vacuum extremal. In the region near the particle the spherical symmetry is an unrealistic assumption since it excludes the presence of magnetic fields needed to cancel the total Kähler action. The stationarity is also unrealistic assumption since zitterbewegung seems to provide a necessary mechanism for generating Kähler magnetic field and for satisfying boundary conditions. Also the imbeddability to  $M^4 \times S^2$  implies unrealistic relationship between  $Z^0$  and photon charges.

According to the general wisdom, the generation of a Kähler electric field must take place in order to minimize the action and it indeed turns out that the extremal is characterized by essentially  $1/r^2$  Kähler electric field. The necessary presence of a hole or of a topologically condensed object is also demonstrated: it is impossible to find extremals well defined in the region surrounding the origin. It is impossible to satisfy boundary conditions at a hole: this is in accordance with the idea that Euclidian region corresponding to a  $CP_2$  type extremal performing zitterbewegung is generated. In case of  $CP_2$  extremal radius is of the order of the Compton length of the particle and in case of a "hole" of the order of Planck length. The value of the vacuum frequency  $\omega$  is of order of particle mass whereas for macroscopic vacuum extremals it must be of the order of  $1/R$ . This does not lead to a contradiction if the concept of a many-sheeted space-time is accepted.

The Poincare energy of the exterior region is considerably smaller than the gravitational mass; this conforms with the interpretation that gravitational mass is sum of absolute values of positive and negative inertial masses associated with matter and negative energy antimatter. It is quite possible that classical considerations cannot provide much understanding concerning the inertial masses of topologically condensed particles. Electro-weak gauge forces are considerably weaker than the gravitational force at large distances, when the value of the frequency parameter  $\omega$  is of order  $1/R$ . Both these desirable properties fail to be true if  $CP_2$  radius is of order Planck length as believed earlier.

In light of the general ideas about topological condensation it is clear that in planetary length scales these kind of extremals cannot provide a realistic description of space-time. Indeed, spherically symmetric extremals predict a wrong rate for the precession of the perihelion of Mercury. Schwarzschild and Reissner-Nordström metric do this and indeed allow imbedding as vacuum extremals for which the inertial masses of positive energy matter and negative energy antimatter sum up to zero.

This does not yet resolve the interpretational challenge due to the unavoidable long range color and weak gauge fields. A dark matter hierarchy giving rise to a hierarchy of color and electro-weak physics characterized by increasing values of weak and confinement scales explains these fields. # contacts involve a pair of causal horizons at which the Euclidian metric signature of # contact transforms to Minkowskian one. These causal horizons have interpretation as partons so that # contact can be regarded as a bound state of partons bound together by a gravitational instanton ( $CP_2$  type extremal). # contacts provide basic example of dark matter creating long ranged weak fields.

An important result is the correlation between the sign of the vacuum frequency  $\omega$  and that of the Kähler charge, which is of opposite sign for fermions and anti-fermions. This suggests an explanation for matter-antimatter asymmetry. Matter and antimatter condense stably on disjoint regions of the space-time surface at different space-time sheets. Stable antimatter could correspond

to negative time orientation and negative energy. This leads to a model for the primordial generation of matter as spontaneous generation of zero energy # contacts between space-time sheets of opposite time orientations. If  $CP$  conjugation is not exact symmetry, # contacts and their  $CP$  conjugates are created with slightly different rates and this gives rise to  $CP$  asymmetry at each of the two space-time sheets involved. After the splitting of # contacts and subsequent annihilation of particles and antiparticles at each space-time sheet, the two space-time sheets contain only positive energy matter and negative energy antimatter.

### General solution ansatz

The general form of the solution ansatz is obtained by assuming that the space-time surface in question is a sub-manifold of  $M^4 \times S^2$ , where  $S^2$  is the homologically non-trivial geodesic sphere of  $CP_2$ .  $S^2$  is most conveniently realized as  $r = \infty$  surface of  $CP_2$ , for which all values of the coordinate  $\Psi$  correspond to same point of  $CP_2$  so that one can use  $\Theta$  and  $\Phi$  as the coordinates of  $S^2$ .

The solution ansatz is given by the expression

$$\begin{aligned} \cos(\Theta) &= u(r) , \\ \Phi &= \omega t , \\ m^0 &= \lambda t , \\ r_M &= r , \quad \theta_M = \theta , \quad \phi_M = \phi . \end{aligned} \quad (2.5.9)$$

The induced metric is given by the expression

$$ds^2 = \left[ \lambda^2 - \frac{R^2}{4} \omega^2 (1 - u^2) \right] dt^2 - \left( 1 + \frac{R^2}{4} \theta_{,r}^2 \right) dr^2 - r^2 d\Omega^2 . \quad (2.5.10)$$

The value of the parameter  $\lambda$  is fixed by the condition  $g_{tt}(\infty) = 1$ :

$$\lambda^2 - \frac{R^2}{4} \omega^2 (1 - u(\infty)^2) = 1 . \quad (2.5.11)$$

From the condition  $e^0 \wedge e^3 = 0$  the non-vanishing components of the induced Kähler field are given by the expression

$$J_{tr} = \frac{\omega}{4} u_{,r} . \quad (2.5.12)$$

Geodesic sphere property implies that  $Z^0$  and photon fields are proportional to Kähler field:

$$\begin{aligned} \gamma &= (3 - p/2) J , \\ Z^0 &= J . \end{aligned} \quad (2.5.13)$$

From this formula one obtains the expressions

$$\begin{aligned} Q_{em} &= \frac{(3 - p/2)}{4\pi\alpha_{em}} Q_K , \quad Q_Z = \frac{1}{4\pi\alpha_Z} Q , \\ Q &\equiv \frac{J_{tr} 4\pi r^2}{\sqrt{-g_{rr} g_{tt}}} . \end{aligned} \quad (2.5.14)$$

for the electromagnetic and  $Z^0$  charges of the solution using  $e$  and  $g_Z$  as unit.

Field equations can be written as conditions for energy momentum conservation (two equations is in principle all what is needed in the case of geodesic sphere). Energy conservation holds identically true and conservation of momentum, say, in  $z$ -direction gives the equation

$$(T^{rr}z_{,r})_{,r} + (T^{\theta\theta}z_{,\theta})_{,\theta} = 0 . \quad (2.5.15)$$

Using the explicit expressions for the components of the energy momentum tensor

$$\begin{aligned} T^{rr} &= g^{rr}L/2 , \\ T^{\theta\theta} &= -g^{\theta\theta}L/2 , \\ L &= g^{tt}g^{rr}(J_{tr})^2\sqrt{g}/2 , \end{aligned} \quad (2.5.16)$$

and the following notations

$$\begin{aligned} A &= g^{tt}g^{rr}r^2\sqrt{-g_{tt}g_{rr}} , \\ X &\equiv (J_{tr})^2 , \end{aligned} \quad (2.5.17)$$

the field equations reduce to the following form

$$(g^{rr}AX)_{,r} - \frac{2AX}{r} = 0 . \quad (2.5.18)$$

In the approximation  $g^{rr} = 1$  this equation can be readily integrated to give  $AX = C/r^2$ . Integrating Eq. (13.4.7), one obtains integral equation for  $X$

$$J_{tr} = \frac{q}{r_c} (|g_{rr}|^3 g_{tt})^{1/4} \exp\left(\int_{r_c}^r dr \frac{g_{rr}}{r}\right) \frac{1}{r} , \quad (2.5.19)$$

where  $q$  is integration constant, which is related to the charge parameter of the long range Kähler electric field associated with the solution.  $r_c$  denotes the critical radius at which the solution ceases to be well defined.

The inspection of this formula shows that  $J_{tr}$  behaves essentially as  $1/r^2$  Coulomb field. This behavior doesn't depend on the detailed properties of the solution ansatz (for example the imbeddability to  $M^4 \times S^2$ ): stationarity and spherical symmetry is what matters only. The compactness of  $CP_2$  means that stationary, spherically symmetric solution is not possible in the region containing origin. This is in concordance with the idea that either a hole surrounds the origin or there is a topologically condensed  $CP_2$  extremal performing zitterbewegung near the origin and making the solution non-stationary and breaking spherical symmetry.

Second integration gives the following integral equation for  $CP_2$  coordinate  $u = \cos(\Theta)$

$$u(r) = u_0 + \frac{4q}{\omega} \int_{r_c}^r (-g_{rr}^3 g_{tt})^{1/4} \frac{1}{r} \exp\left(\int_{r_c}^r dr \frac{g_{rr}}{r}\right) . \quad (2.5.20)$$

Here  $u_0$  denotes the value of the coordinate  $u$  at  $r = r_0$ .

The form of the field equation suggests a natural iterative procedure for the numerical construction of the solution for large values of  $r$ .

$$u_n(r) = T_{n-1} , \quad (2.5.21)$$

where  $T_{n-1}$  is evaluated using the induced metric associated with  $u_{n-1}$ . The physical content of the approximation procedure is clear: estimate the gravitational effects using lower order solution since these are expected to be small.

A more convenient manner to solve  $u$  is based on Taylor expansion around the point  $V \equiv 1/r = 0$ . The coefficients appearing in the power series expansion  $u = \sum_n u_n A^n V^n$  :  $A = q/\omega$  can be solved by calculating successive derivatives of the integral equation for  $u$ .

The lowest order solution is simply

$$u_0 = u_\infty , \quad (2.5.22)$$

and the corresponding metric is flat metric. In the first order one obtains for  $u(r)$  the expression

$$u = u_\infty - \frac{4q}{\omega r} , \quad (2.5.23)$$

which expresses the fact that Kähler field behaves essentially as  $1/r^2$  Coulomb field. The behavior of  $u$  as a function of  $r$  is identical with that obtained for the imbedding of the Reissner-Nordström solution.

To study the properties of the solution we fix the signs of the parameters in the following manner:

$$u_\infty < 0 , \quad q < 0 , \quad \omega > 0 \quad (2.5.24)$$

(reasons become clear later).

Concerning the behavior of the solution one can consider two different cases.

1) The condition  $g_{tt} > 0$  hold true for all values of  $\Theta$ . In this case  $u$  decreases and the rate of decrease gets faster for small values of  $r$ . This means that in the lowest order the solution becomes certainly ill defined at a critical radius  $r = r_c$  given by the the condition  $u = 1$ : the reason is that  $u$  cannot get values large than one. The expression of the critical radius is given by

$$\begin{aligned} r_c &\geq \frac{4q}{(|u_\infty| + 1)\omega} \\ &= \frac{4\alpha Q_{em}}{(3 - p/2)(|u_\infty| + 1)\omega} . \end{aligned} \quad (2.5.25)$$

The presence of the critical radius for the actual solution is also a necessity as the inspection of the expression for  $J_{tr}$  shows:  $\partial_r \theta$  grows near the origin without bound and  $u = 1$  is reached at some finite value of  $r$ . Boundary conditions require that the quantity  $X = T^{rr} \sqrt{g}$  vanishes at critical radius (no momentum flows through the boundary). Substituting the expression of  $J_{tr}$  from the field equation to  $T^{rr}$  the expression for  $X$  reduces to a form, from which it is clear that  $X$  cannot vanish. The cautious conclusion is that boundary conditions cannot be satisfied and the underlying reason is probably the stationarity and spherical symmetry of the solution. Physical intuition suggests that that  $CP_2$  type extremal performing zitterbewegung is needed to satisfy the boundary conditions.

2)  $g_{tt}$  vanishes for some value of  $\Theta$ . In this case the radial derivative of  $u$  together with  $g_{tt}$  can become zero for some value of  $r = r_c$ . Boundary conditions can be satisfied only provided  $r_c = 0$ . Thus it seems that for the values of  $\omega$  satisfying the condition  $\omega^2 = \frac{4\lambda^2}{R^2 \sin^2(\Theta_0)}$  it might be possible to find a globally defined solution. The study of differential equation for  $u$  however shows that the ansatz doesn't work. The conclusion is that although the boundary is generated it is not possible to satisfy boundary conditions.

A direct calculation of the coefficients  $u_n$  from power series expansion gives the following third order polynomial approximation for  $u$  ( $V = 1/r$ )

$$\begin{aligned} u &= \sum_n u_n A^n V^n , \\ u_0 &= u_\infty (< 0) , \quad u_1 = 1 , \\ u_2 &= K|u_\infty| , \quad u_3 = K(1 + 4K|u_\infty|) , \\ A &\equiv \frac{4q}{\omega} , \quad K \equiv \omega^2 \frac{R^2}{4} . \end{aligned} \quad (2.5.26)$$

The coefficients  $u_2$  and  $u_3$  are indeed positive which means that the value of the critical radius gets larger at least in these orders.

Solution contains three parameters: Kähler electric flux  $Q = 4\pi q$ , parameter  $\omega R$  and parameter  $u_\infty$ . The latter parameters can be regarded as parameters describing the properties of a flat vacuum extremal (lowest order solution) to which particle like solution is glued and are analogous to the parameters describing symmetry broken vacuum in gauge theories.

### Solution is not a realistic model for topological condensation

The solution does not provide realistic model for topological condensation although it gives indirect support for some essential assumptions of TGD based description of Higgs mechanism.

1. When the value of  $\omega$  is of the order of  $CP_2$  mass the solution could be interpreted as the "exterior metric" of a "hole".
  - i) The radius of the hole is of the order of  $CP_2$  length and its mass is of the order of  $CP_2$  mass.
  - ii) Kähler electric field is generated and charge renormalization takes place classically at  $CP_2$  length scales as is clear from the expression of  $Q(r)$ :  $Q(r) \propto (\frac{-g_{rr}}{g_{tt}})^{1/4}$  and charge increases at short distances.
  - iii) The existence of the critical radius is unavoidable but boundary conditions cannot be satisfied. The failure to satisfy boundary conditions might be related to stationarity or to the absence of magnetic field. The motion of the boundary component with velocity of light might be the only manner to satisfy boundary conditions. Second possibility is the breaking of spherical symmetry by the generation of a static magnetic field.
  - iv) The absence of the Kähler magnetic field implies that the Kähler action has an infinite magnitude and the probability of the configuration is zero. A more realistic solution ansatz would break spherical symmetry containing dipole type magnetic field in the nearby region of the hole. The motion of the boundary with a velocity of light could serve as an alternative mechanism for the generation of magnetic field. The third possibility, supported by physical intuition, is that one must give up "hole" type extremal totally.
2. For sufficiently large values of  $r$  and for small values of  $\omega$  (of the order of elementary particle mass scale), the solution might provide an approximate description for the region surrounding elementary particle. Although it is not possible to satisfy boundary conditions the order of magnitude estimate for the size of critical radius ( $r_c \simeq \alpha/\omega$ ) should hold true for more realistic solutions, too. The order of magnitude for the critical radius is smaller than Compton length or larger if the vacuum parameter  $\omega$  is larger than the mass of the particle. In macroscopic length scales the value of  $\omega$  is of order  $1/R$ . This does not lead to a contradiction if the many-sheeted space-time concept is accepted so that  $\omega < m$  corresponds to elementary particle space-time sheet. An unrealistic feature of the solution is that the relationship between  $Z^0$  and em charges is not correct:  $Z^0$  charge should be very small in these length scales.

### Exterior solution cannot be identified as a counter part of Schwarzschild solution

The first thing, which comes into mind is to ask whether one might identify exterior solution as the TGD counterpart of the Schwarzschild solution. The identification of gravitational mass as absolute value of inertial mass which is negative for antimatter implies that vacuum extremals are vacua only with respect to the inertial four-momentum and have a non-vanishing gravitational four-momentum. Hence, in the approximation that the net density of inertial mass vanishes, vacuum extremals provide the proper manner to model matter, and the identification of spherically symmetric extremal as the counterpart of Schwarzschild metric is certainly not possible. It is however useful to show explicitly that the identification is indeed unrealistic. The solution is consistent with Equivalence Principle but the electro-weak gauge forces are considerably weaker than gravitational forces. A wrong perihelion shift is also predicted so that the identification as an exterior metric of macroscopic objects is out of question.

#### 1. Is Equivalence Principle respected?

TGD predicts the possibility of negative classical energy for space-time sheets with negative time orientation, and the only manner to second quantize induced spinor fields without diverging vacuum energy is by assuming that fermions have positive energies and anti-fermions negative energies (vice

versa for phase conjugate fermions). This modifies the original form of Equivalence Principle: gravitational mass can be interpreted as absolute value of inertial mass so that the density of gravitational mass becomes the difference of densities of inertial mass for matter and antimatter (or vice versa). This interpretation leads to an elegant solution of the basic interpretational difficulties created by the conservation of inertial four-momentum and non-conservation of gravitational four-momentum.

The gravitational mass of the solution is determined from the asymptotic behavior of  $g_{tt}$  and is given by

$$M_{gr} = \frac{R^2}{G} \omega q u_\infty , \quad (2.5.27)$$

and is proportional to the Kähler charge  $q$  of the solution.

One can estimate the gravitational mass density also by applying Newtonian approximation to the time component of the metric  $g_{tt} = 1 - 2\Phi_{gr}$ . One obtains  $\Phi_{gr}$  corresponds in the lowest order approximation to a solution of Einstein's equations with the source consisting of a mass point at origin and the energy density of the Kähler electric field. The effective value of gravitational constant is however  $G_{eg} = 8R^2\alpha_K$ . Thus the only sensible interpretation is that the density of Kähler (inertial) energy is only a fraction  $G/G_{eg} \equiv \epsilon \simeq .22 \times 10^{-6}$  of the density of gravitational mass. Hence the densities of positive energy matter and negative energy antimatter cancel each other in a good approximation.

The work with cosmic strings lead to a possible interpretation of the solution as a space-time sheet containing topologically condensed magnetic flux tube idealizable as a point. The negative Kähler electric action must cancel the positive Kähler magnetic action. The resulting structure in turn can condense to a vacuum extremal and Schwarzschild metric is a good approximation for the metric.

One can estimate the contribution of the exterior region ( $r > r_c$ ) to the inertial mass of the system and Equivalence principle requires this to be a fraction of order  $\epsilon$  about the gravitational mass unless the region  $r < r_c$  contains negative inertial mass density, which is of course quite possible. Approximating the metric with a flat metric and using first order approximation for  $u(r)$  the energy reduces just to the standard Coulomb energy of charged sphere with radius  $r_c$

$$\begin{aligned} M_I(ext) &= \frac{1}{32\pi\alpha_K} \int_{r>r_c} E^2 \sqrt{g} d^3x \\ &\simeq \frac{\lambda q^2}{2\alpha_K r_c} , \\ \lambda &= \sqrt{1 + \frac{R^2}{4} \omega^2 (1 - u_\infty^2)} (> 1) . \end{aligned} \quad (2.5.28)$$

Approximating the metric with flat metric the contribution of the region  $r > r_c$  to the energy of the solution is given by

$$M_I(ext) = \frac{1}{8\alpha_K} \lambda q \omega (1 + |u_\infty|) . \quad (2.5.29)$$

The contribution is proportional to Kähler charge as expected. The ratio of external inertial and gravitational masses is given by the expression

$$\begin{aligned} \frac{M_I(ext)}{M_{gr}} &= \frac{G}{4R^2\alpha_K} x , \\ x &= \frac{(1 + |u_\infty|)}{|u_\infty|} > 1 . \end{aligned} \quad (2.5.30)$$

In the approximation used the the ratio of external inertial and gravitational masses is of order  $10^{-6}$  for  $R \sim 10^4 \sqrt{G}$  implied by the p-adic length scale hypothesis and for  $x \sim 1$ . The result conforms with the above discussed interpretation.

2.  $Z^0$  and electromagnetic forces are much weaker than gravitational force

The extremal in question carries Kähler charge and therefore also  $Z^0$  and electromagnetic charge. This implies long range gauge interactions, which ought to be weaker than gravitational interaction in the astrophysical scales. This is indeed the case as the following argument shows.

Expressing the Kähler charge using Planck mass as unit and using the relationships between gauge fields one obtains a direct measure for the strength of the  $Z^0$  force as compared with the strength of gravitational force.

$$Q_Z \equiv \varepsilon_Z M_{gr} \sqrt{G} . \quad (2.5.31)$$

The value of the parameter  $\varepsilon_Z$  should be smaller than one. A transparent form for this condition is obtained, when one writes  $\Phi = \omega t = \Omega m^0 : \Omega = \lambda \omega$ :

$$\varepsilon_Z = \frac{\alpha_K}{\alpha_Z} \frac{1}{\pi(1 + |u_\infty|)\Omega R} \sqrt{\frac{G}{R}} . \quad (2.5.32)$$

The order of magnitude is determined by the values of the parameters  $\sqrt{\frac{G}{R^2}} \sim 10^{-4}$  and  $\Omega R$ . Global Minkowskian signature of the induced metric implies the condition  $\Omega R < 2$  for the allowed values of the parameter  $\Omega R$ . In macroscopic length scales one has  $\Omega R \sim 1$  so that  $Z^0$  force is by a factor of order  $10^{-4}$  weaker than gravitational force. In elementary particle length scales with  $\omega \sim m$  situation is completely different as expected.

### 3. The shift of the perihelion is predicted incorrectly

The  $g_{rr}$  component of Reissner-Nordström and TGD metrics are given by the expressions

$$g_{rr} = -\frac{1}{\left(1 - \frac{2GM}{r}\right)} , \quad (2.5.33)$$

and

$$g_{rr} \simeq 1 - \frac{\frac{Rq}{\omega^2}}{\left[1 - \left(u_\infty - \frac{4q}{\omega r}\right)^2\right] r^4} , \quad (2.5.34)$$

respectively. For reasonable values of  $q$ ,  $\omega$  and  $u_\infty$  the this terms is extremely small as compared with  $1/r$  term so that these expressions differ by  $1/r$  term.

The absence of the  $1/r$  term from  $g_{rr}$ -component of the metric predicts that the shift of the perihelion for elliptic plane orbits is about  $2/3$  times that predicted by GRT so that the identification as a metric associated with objects of a planetary scale leads to an experimental contradiction. Reissner-Nordström solutions are obtained as vacuum extremals so that standard predictions of GRT are obtained for the planetary motion.

One might hope that the generalization of the form of the spherically symmetric ansatz by introducing the same modification as needed for the imbedding of Reissner-Nordström metric might help. The modification would read as

$$\begin{aligned} \cos(\Theta) &= u(r) , \\ \Phi &= \omega t + f(r) , \\ m^0 &= \lambda t + h(r) , \\ r_M &= r , \quad \theta_M = \theta , \quad \phi_M = \phi . \end{aligned} \quad (2.5.35)$$

The vanishing of the  $g_{tr}$  component of the metric gives the condition

$$\lambda \partial_r h - \frac{R^2}{4} \sin^2(\Theta) \omega \partial_r f = 0 . \quad (2.5.36)$$

The expression for the radial component of the metric transforms to

$$g_{rr} \simeq \partial_r h^2 - 1 - \frac{R^2}{4} (\partial_r \Theta)^2 - \frac{R^2}{4} \sin^2(\Theta) \partial_r f^2 , \quad (2.5.37)$$

Essentially the same perihelion shift as for Schwarzschild metric is obtained if  $g_{rr}$  approaches asymptotically to its expression for Schwarzschild metric. This is guaranteed if the following conditions hold true:

$$f(r)_{r \rightarrow \infty} \rightarrow \omega r , \quad \Lambda^2 - 1 = \frac{R^2 \omega^2}{4} \sin^2(\Theta_\infty) \ll \frac{2GM}{\langle r \rangle} . \quad (2.5.38)$$

In the second equation  $\langle r \rangle$  corresponds to the average radius of the planetary orbit.

The field equations for this ansatz can be written as conditions for energy momentum and color charge conservation. Two equations are enough to determine the functions  $\Theta(r)$  and  $f(r)$ . The equation for momentum conservation is same as before. Second field equation corresponds to the conserved isometry current associated with the color isometry  $\Phi \rightarrow \Phi + \epsilon$  and gives equation for  $f$ .

$$[T^{rr} f_{,r} s_{\Phi\Phi} \sqrt{g}]_{,r} = 0 . \quad (2.5.39)$$

The conservation laws associated with other infinitesimal  $SU(2)$  rotations of  $S_I^2$  should be satisfied identically. This equation can be readily integrated to give

$$T^{rr} f_{,r} s_{\Phi\Phi} \sqrt{g_{tt} g_{rr}} = \frac{C}{r^2} . \quad (2.5.40)$$

Unfortunately, the result is inconsistent with the  $1/r^4$  behavior of  $T^{rr}$  and  $f \rightarrow \omega r$  implies by correct red shift.

It seems that the only possible way out of the difficulty is to replace spherical symmetry with a symmetry with respect to the rotations around z-axis. The simplest modification of the solution ansatz is as follows:

$$m^0 = \lambda t + h(\rho) , \quad \Phi = \omega t + k\rho .$$

Thanks to the linear dependence of  $\Phi$  on  $\rho$ , the conservation laws for momentum and color isospin reduce to the same condition. The ansatz induces a small breaking of spherical symmetry by adding to  $g_{\rho\rho}$  the term

$$(\partial_\rho h)^2 - \frac{R^2}{4} \sin^2(\Theta) k^2 .$$

One might hope that in the plane  $\theta = \pi/2$ , where  $r = \rho$  holds true, the ansatz could behave like Schwarzschild metric if the conditions discussed above are posed (including the condition  $k = \omega$ ). The breaking of the spherical symmetry in the planetary system would be coded already to the gravitational field of Sun.

Also the study of the imbeddings of Reissner-Nordström metric as vacuum extremals and the investigation of spherically symmetric (inertial) vacuum extremals for which gravitational four-momentum is conserved [77] leads to the conclusion that the loss of spherical symmetry due to rotation is inevitable characteristic of realistic solutions.

## 2.5.6 Maxwell hydrodynamics as a toy model for TGD

The field equations of TGD are extremely non-linear and all known solutions have been discovered by symmetry arguments. Chern-Simons term plays essential role also in the construction of solutions of field equations and at partonic level defines braiding for light-like partonic 3-surfaces expected to play key role in the construction of S-matrix. The inspiration for this section came from Terence Tao's blog posting *2006 ICM: Etienne Ghys, Knots and dynamics* [121] giving an elegant summary about amazing mathematical results related to knots, links, braids and hydrodynamical flows in dimension  $D = 3$ . Posting tells about really amazing mathematical results related to knots.

### Chern-Simons term as helicity invariant

Tao mentions helicity as an invariant of fluid flow. Chern-Simons action defined by the induced Kähler gauge potential for light-like 3-surfaces has interpretation as helicity when Kähler gauge potential is identified as fluid velocity. This flow can be continued to the interior of space-time sheet. Also the dual of the induced Kähler form defines a flow at the light-like partonic surfaces but not in the interior of space-time sheet. The lines of this flow can be interpreted as magnetic field lines. This flow is incompressible and represents a conserved charge (Kähler magnetic flux).

The question is which of these flows should define number theoretical braids. Perhaps both of them can appear in the definition of S-matrix and correspond to different kinds of partonic matter (electric/magnetic charges, quarks/leptons?,...). Second kind of matter could not flow in the interior of space-time sheet. Or could interpretation in terms of electric magnetic duality make sense?

Helicity is not gauge invariant and this is as it must be in TGD framework since  $CP_2$  symplectic transformations induce  $U(1)$  gauge transformation, which deforms space-time surface and modifies induced metric as well as classical electroweak fields defined by induced spinor connection. Gauge degeneracy is transformed to spin glass degeneracy.

### Maxwell hydrodynamics

In TGD Maxwell's equations are replaced with field equations which express conservation laws and are thus hydrodynamical in character. With this background the idea that the analogy between gauge theory and hydrodynamics might be applied also in the reverse direction is natural. Hence one might ask what kind of relativistic hydrodynamics results if assumes that the action principle is Maxwell action for the four-velocity  $u^\alpha$  with the constraint term saying that light velocity is maximal signal velocity.

1. For massive particles the length of four-velocity equals to 1:  $u^\alpha u_\alpha = 1$ . In massless case one has  $u^\alpha u_\alpha = 0$ . Geometrically this means that one has sigma model with target space which is 3-D Lobatschevski space or at light-cone boundary. This condition means the addition of constraint term

$$\lambda(u^\alpha u_\alpha - \epsilon) \quad (2.5.41)$$

to the Maxwell action.  $\epsilon = 1/0$  holds for massive/massless flow. In the following the notation of electrodynamics is used to make easier the comparison with electrodynamics.

2. The constraint term destroys gauge invariance by allowing to express  $A^0$  in terms of  $A^i$  but in general the constraint is not equivalent to a choice of gauge in electrodynamics since the solutions to the field equations with constraint term are not solutions of field equations without it. One obtains field equations for an effectively massive em field with Lagrange multiplier  $\lambda$  having interpretation as photon mass depending on space-time point:

$$\begin{aligned} j^\alpha &= \partial_\beta F^{\alpha\beta} = \lambda A^\alpha , \\ A^\alpha &\equiv u^\alpha , \quad F^{\alpha\beta} = \partial^\beta A^\alpha - \partial^\alpha A^\beta . \end{aligned} \quad (2.5.42)$$

3. In electrodynamic context the natural interpretation would be in terms of spontaneous massivation of photon and seems to occur for both values of  $\epsilon$ . The analog of em current given by  $\lambda A^\alpha$  is in general non-vanishing and conserved. This conservation law is quite strong additional constraint on the hydrodynamics. What is interesting is that breaking of gauge invariance does not lead to a loss of charge conservation.

4. One can solve  $\lambda$  by contracting the equations with  $A_\alpha$  to obtain

$$\lambda = j^\alpha A_\alpha$$

for  $\epsilon = 1$ . For  $\epsilon = 0$  one obtains

$$j^\alpha A_\alpha = 0$$

stating that the field does not dissipate energy:  $\lambda$  can be however non-vanishing unless field equations imply  $j^\alpha = 0$ . One can say that for  $\epsilon = 0$  spontaneous massivation can occur. For  $\epsilon = 1$  massivation is present from the beginning and dissipation rate determines photon mass: a natural interpretation for  $\epsilon = 1$  would be in terms of thermal massivation of photon. Non-tachyonicity fixes the sign of the dissipation term so that the thermodynamical arrow of time is fixed by causality.

5. For  $\epsilon = 0$  massless plane wave solutions are possible and one has

$$\partial_\alpha \partial_\beta A^\beta = \lambda A_\alpha \ .$$

$\lambda = 0$  is obtained in Lorentz gauge which is consistent with the condition  $\epsilon = 0$ . Also superpositions of plane waves with same polarization and direction of propagation are solutions of field equations: these solutions represent dispersionless precisely targeted pulses. For superpositions of plane waves  $\lambda$  with 4-momenta, which are not all parallel  $\lambda$  is non-vanishing so that non-linear self interactions due to the constraint can be said to induce massivation. In asymptotic states for which gauge symmetry is not broken one expects a decomposition of solutions to regions of space-time carrying this kind of pulses, which brings in mind final states of particle reactions containing free photons with fixed polarizations.

6. Gradient flows satisfying the conditions

$$A_\alpha = \partial_\alpha \Phi \ , \ A^\alpha A_\alpha = \epsilon \tag{2.5.43}$$

give rise to identically vanishing hydrodynamical gauge fields and  $\lambda = 0$  holds true. These solutions are vacua since energy momentum tensor vanishes identically. There is huge number of this kind of solutions and spin glass degeneracy suggests itself. Small deformations of these vacuum flows are expected to give rise to non-vacuum flows.

7. The counterparts of charged solutions are of special interest. For  $\epsilon = 0$  the solution  $(u^0, u^r) = (Q/r)(1, 1)$  is a solution of field equations outside origin and corresponds to electric field of a point charge  $Q$ . In fact, for  $\epsilon = 0$  any ansatz  $(u^0, u^r) = f(r)(1, 1)$  satisfies field equations for a suitable choice of  $\lambda(r)$  since the ratio of equations associate with  $j^0$  and  $j^r$  gives an equation which is trivially satisfied. For  $\epsilon = 1$  the ansatz  $(u^0, u^r) = (\cosh(u), \sinh(u))$  expressing solution in terms of hyperbolic angle linearizes the field equation obtained by dividing the equations for  $j^0$  and  $j^r$  to eliminate  $\lambda$ . The resulting equation is

$$\partial_r^2 u + \frac{2\partial_r u}{r} = 0$$

for ordinary Coulomb potential and one obtains  $(u^0, u^r) = (\cosh(u_0 + k/r), \sinh(u_0 + k/r))$ . The charge of the solution at the limit  $r \rightarrow \infty$  approaches to the value  $Q = \sinh(u_0)k$  and diverges at the limit  $r \rightarrow 0$ . The charge increases exponentially as a function of  $1/r$  near origin rather than logarithmically as in QED and the interpretation in terms of thermal screening suggests itself. Hyperbolic ansatz might simplify considerably the field equations also in the general case.

### Similarities with TGD

There are strong similarities with TGD which suggests that the proposed model might provide a toy model for the dynamics defined by Kähler action.

1. Also in TGD field equations are essentially hydrodynamical equations stating the conservation of various isometry charges. Gauge invariance is broken for the induced Kähler field although Kähler charge is conserved. There is huge vacuum degeneracy corresponding to vanishing of induced Kähler field and the interpretation is in terms of spin glass degeneracy.
2. Also in TGD dissipation rate vanishes for the known solutions of field equations and a possible interpretation is as space-time correlates for asymptotic non-dissipating self organization patterns.
3. In TGD framework massless extremals represent the analogs for superpositions of plane waves with fixed polarization and propagation direction and representing targeted and dispersionless propagation of signal. Gauge currents are light-like and non-vanishing for these solutions. The decomposition of space-time surface to space-time sheets representing particles is much more general counterpart for the asymptotic solutions of Maxwell hydrodynamics with vanishing  $\lambda$ .
4. In TGD framework one can consider the possibility that the four-velocity assignable to a macroscopic quantum phase is proportional to the induced Kähler gauge potential. In this kind of situation one could speak of a quantal variant of Maxwell hydrodynamics, at least for light-like partonic 3-surfaces. For instance, the condition

$$D^\alpha D_\alpha \Psi = 0 \quad , \quad D_\alpha \Psi = (\partial_\alpha - iq_K A_\alpha) \Psi$$

for the order parameter of the quantum phase corresponds at classical level to the condition  $p^\alpha = q_K Q^\alpha + l^\alpha$ , where  $q_K$  is Kähler charge of fermion and  $l^\alpha$  is a light-like vector field naturally assignable to the partonic boundary component. This gives  $u^\alpha = (q_K Q^\alpha + l^\alpha)/m$ ,  $m^2 = p^\alpha p_\alpha$ , which is somewhat more general condition. The expressibility of  $u^\alpha$  in terms of the vector fields provided by the induced geometry is very natural.

The value  $\epsilon$  depends on space-time region and it would seem that also  $\epsilon = -1$  is possible meaning tachyonicity and breaking of causality. Kähler gauge potential could however have a time-like pure gauge component in  $M^4$  possibly saving the situation. The construction of quantum TGD at parton level indeed forces to assume that Kähler gauge potential has Lorentz invariant  $M^4$  component  $A_a = \text{constant}$  in the direction of the light-cone proper time coordinate axis  $a$ . Note that the decomposition of configuration space to sectors consisting of space-time sheets inside future or past light-cone of  $M^4$  is an essential element of the construction of configuration space geometry and does not imply breaking of Poincare invariance. Without this component  $u_\alpha u^\alpha$  could certainly be negative. The contribution of  $M^4$  component could prevent this for preferred extremals.

If TGD is taken seriously, these similarities force to ask whether Maxwell hydrodynamics might be interpreted as a nonlinear variant of electrodynamics. Probably not: in TGD em field is proportional to the induced Kähler form only in special cases and is in general non-vanishing also for vacuum extremals.

## 2.6 Weak form electric-magnetic duality and its implications

The notion of electric-magnetic duality [10] was proposed first by Olive and Montonen and is central in  $\mathcal{N} = 4$  supersymmetric gauge theories. It states that magnetic monopoles and ordinary particles are two different phases of theory and that the description in terms of monopoles can be applied at the limit when the running gauge coupling constant becomes very large and perturbation theory fails to converge. The notion of electric-magnetic self-duality is more natural since for  $CP_2$  geometry Kähler form is self-dual and Kähler magnetic monopoles are also Kähler electric monopoles and Kähler coupling strength is by quantum criticality renormalization group invariant rather than running coupling constant. The notion of electric-magnetic (self-)duality emerged already two decades ago in the attempts to formulate the Kähler geometric of world of classical worlds. Quite recently a considerable step of progress took place in the understanding of this notion [17]. What seems to be essential is that one adopts a weaker form of the self-duality applying at partonic 2-surfaces. What this means will be discussed in the sequel.

Every new idea must be of course taken with a grain of salt but the good sign is that this concept leads to precise predictions. The point is that elementary particles do not generate monopole fields in macroscopic length scales: at least when one considers visible matter. The first question is whether elementary particles could have vanishing magnetic charges: this turns out to be impossible. The next question is how the screening of the magnetic charges could take place and leads to an identification of the physical particles as string like objects identified as pairs magnetic charged wormhole throats connected by magnetic flux tubes.

1. The first implication is a new view about electro-weak massivation reducing it to weak confinement in TGD framework. The second end of the string contains particle having electroweak isospin neutralizing that of elementary fermion and the size scale of the string is electro-weak scale would be in question. Hence the screening of electro-weak force takes place via weak confinement realized in terms of magnetic confinement.
2. This picture generalizes to the case of color confinement. Also quarks correspond to pairs of magnetic monopoles but the charges need not vanish now. Rather, valence quarks would be connected by flux tubes of length of order hadron size such that magnetic charges sum up to zero. For instance, for baryonic valence quarks these charges could be  $(2, -1, -1)$  and could be proportional to color hyper charge.
3. The highly non-trivial prediction making more precise the earlier stringy vision is that elementary particles are string like objects in electro-weak scale: this should become manifest at LHC energies.
4. The weak form electric-magnetic duality together with Beltrami flow property of Kähler leads to the reduction of Kähler action to Chern-Simons action so that TGD reduces to almost topological QFT and that Kähler function is explicitly calculable. This has enormous impact concerning practical calculability of the theory.
5. One ends up also to a general solution ansatz for field equations from the condition that the theory reduces to almost topological QFT. The solution ansatz is inspired by the idea that all isometry currents are proportional to Kähler current which is integrable in the sense that the flow parameter associated with its flow lines defines a global coordinate. The proposed solution ansatz would describe a hydrodynamical flow with the property that isometry charges are conserved along the flow lines (Beltrami flow). A general ansatz satisfying the integrability conditions is found. The solution ansatz applies also to the extremals of Chern-Simons action and and to the conserved currents associated with the modified Dirac equation defined as contractions of the modified gamma matrices between the solutions of the modified Dirac equation. The strongest form of the solution ansatz states that various classical and quantum currents flow along flow lines of the Beltrami flow defined by Kähler current (Kähler magnetic field associated with Chern-Simons action). Intuitively this picture is attractive. A more general ansatz would allow several Beltrami flows meaning multi-hydrodynamics. The integrability conditions boil down to two scalar functions: the first one satisfies massless d'Alembert equation in the induced metric and the the gradients of the scalar functions are orthogonal. The interpretation in terms of momentum and polarization directions is natural.
6. The general solution ansatz works for induced Kähler Dirac equation and Chern-Simons Dirac equation and reduces them to ordinary differential equations along flow lines. The induced spinor fields are simply constant along flow lines of induced spinor field for Dirac equation in suitable gauge. Also the generalized eigen modes of the modified Chern-Simons Dirac operator can be deduced explicitly if the throats and the ends of space-time surface at the boundaries of  $CD$  are extremals of Chern-Simons action. Chern-Simons Dirac equation reduces to ordinary differential equations along flow lines and one can deduce the general form of the spectrum and the explicit representation of the Dirac determinant in terms of geometric quantities characterizing the 3-surface (eigenvalues are inversely proportional to the lengths of strands of the flow lines in the effective metric defined by the modified gamma matrices).

### 2.6.1 Could a weak form of electric-magnetic duality hold true?

Holography means that the initial data at the partonic 2-surfaces should fix the configuration space metric. A weak form of this condition allows only the partonic 2-surfaces defined by the wormhole throats at which the signature of the induced metric changes. A stronger condition allows all partonic 2-surfaces in the slicing of space-time sheet to partonic 2-surfaces and string world sheets. Number theoretical vision suggests that hyper-quaternionicity *resp.* co-hyperquaternionicity constraint could be enough to fix the initial values of time derivatives of the imbedding space coordinates in the space-time regions with Minkowskian *resp.* Euclidian signature of the induced metric. This is a condition on modified gamma matrices and hyper-quaternionicity states that they span a hyper-quaternionic sub-space.

#### Definition of the weak form of electric-magnetic duality

One can also consider alternative conditions possibly equivalent with this condition. The argument goes as follows.

1. The expression of the matrix elements of the metric and Kähler form of  $WCW$  in terms of the Kähler fluxes weighted by Hamiltonians of  $\delta M_{\pm}^4$  at the partonic 2-surface  $X^2$  looks very attractive. These expressions however carry no information about the 4-D tangent space of the partonic 2-surfaces so that the theory would reduce to a genuinely 2-dimensional theory, which cannot hold true. One would like to code to the  $WCW$  metric also information about the electric part of the induced Kähler form assignable to the complement of the tangent space of  $X^2 \subset X^4$ .
2. Electric-magnetic duality of the theory looks a highly attractive symmetry. The trivial manner to get electric magnetic duality at the level of the full theory would be via the identification of the flux Hamiltonians as sums of of the magnetic and electric fluxes. The presence of the induced metric is however troublesome since the presence of the induced metric means that the simple transformation properties of flux Hamiltonians under symplectic transformations -in particular color rotations- are lost.
3. A less trivial formulation of electric-magnetic duality would be as an initial condition which eliminates the induced metric from the electric flux. In the Euclidian version of 4-D YM theory this duality allows to solve field equations exactly in terms of instantons. This approach involves also quaternions. These arguments suggest that the duality in some form might work. The full electric magnetic duality is certainly too strong and implies that space-time surface at the partonic 2-surface corresponds to piece of  $CP_2$  type vacuum extremal and can hold only in the deep interior of the region with Euclidian signature. In the region surrounding wormhole throat at both sides the condition must be replaced with a weaker condition.
4. To formulate a weaker form of the condition let us introduce coordinates  $(x^0, x^3, x^1, x^2)$  such  $(x^1, x^2)$  define coordinates for the partonic 2-surface and  $(x^0, x^3)$  define coordinates labeling partonic 2-surfaces in the slicing of the space-time surface by partonic 2-surfaces and string world sheets making sense in the regions of space-time sheet with Minkowskian signature. The assumption about the slicing allows to preserve general coordinate invariance. The weakest condition is that the generalized Kähler electric fluxes are apart from constant proportional to Kähler magnetic fluxes. This requires the condition

$$J^{03}\sqrt{g_4} = K J_{12} . \quad (2.6.1)$$

A more general form of this duality is suggested by the considerations of [35] reducing the hierarchy of Planck constants to basic quantum TGD and also reducing Kähler function for preferred extremals to Chern-Simons terms [1] at the boundaries of  $CD$  and at light-like wormhole throats. This form is following

$$J^{n\beta}\sqrt{g_4} = K \epsilon \times \epsilon^{n\beta\gamma\delta} J_{\gamma\delta}\sqrt{g_4} . \quad (2.6.2)$$

Here the index  $n$  refers to a normal coordinate for the space-like 3-surface at either boundary of  $CD$  or for light-like wormhole throat.  $\epsilon$  is a sign factor which is opposite for the two ends of  $CD$ . It could be also opposite of opposite at the opposite sides of the wormhole throat. Note that the dependence on induced metric disappears at the right hand side and this condition eliminates the potentials singularity due to the reduction of the rank of the induced metric at wormhole throat.

- Information about the tangent space of the space-time surface can be coded to the configuration space metric with loosing the nice transformation properties of the magnetic flux Hamiltonians if Kähler electric fluxes or sum of magnetic flux and electric flux satisfying this condition are used and  $K$  is symplectic invariant. Using the sum

$$J_e + J_m = (1 + K)J_{12} , \quad (2.6.3)$$

where  $J$  denotes the Kähler magnetic flux, , makes it possible to have a non-trivial configuration space metric even for  $K = 0$ , which could correspond to the ends of a cosmic string like solution carrying only Kähler magnetic fields. This condition suggests that it can depend only on Kähler magnetic flux and other symplectic invariants. Whether local symplectic coordinate invariants are possible at all is far from obvious, If the slicing itself is symplectic invariant then  $K$  could be a non-constant function of  $X^2$  depending on string world sheet coordinates. The light-like radial coordinate of the light-cone boundary indeed defines a symplectically invariant slicing and this slicing could be shifted along the time axis defined by the tips of  $CD$ .

### Electric-magnetic duality physically

What could the weak duality condition mean physically? For instance, what constraints are obtained if one assumes that the quantization of electro-weak charges reduces to this condition at classical level?

- The first thing to notice is that the flux of  $J$  over the partonic 2-surface is analogous to magnetic flux

$$Q_m = \frac{e}{\hbar} \oint B dS = n .$$

$n$  is non-vanishing only if the surface is homologically non-trivial and gives the homology charge of the partonic 2-surface.

- The expressions of classical electromagnetic and  $Z^0$  fields in terms of Kähler form [2] , [2] read as

$$\begin{aligned} \gamma &= \frac{eF_{em}}{\hbar} = 3J - \sin^2(\theta_W)R_{03} , \\ Z^0 &= \frac{g_Z F_Z}{\hbar} = 2R_{03} . \end{aligned} \quad (2.6.4)$$

Here  $R_{03}$  is one of the components of the curvature tensor in vielbein representation and  $F_{em}$  and  $F_Z$  correspond to the standard field tensors. From this expression one can deduce

$$J = \frac{e}{3\hbar} F_{em} + \sin^2(\theta_W) \frac{g_Z}{6\hbar} F_Z . \quad (2.6.5)$$

3. The weak duality condition when integrated over  $X^2$  implies

$$\begin{aligned} \frac{e^2}{3\hbar}Q_{em} + \frac{g_Z^2 p}{6}Q_{Z,V} &= K \oint J = Kn \ , \\ Q_{Z,V} &= \frac{I_V^3}{2} - Q_{em} \ , \ p = \sin^2(\theta_W) \ . \end{aligned} \quad (2.6.6)$$

Here the vectorial part of the  $Z^0$  charge rather than as full  $Z^0$  charge  $Q_Z = I_L^3 + \sin^2(\theta_W)Q_{em}$  appears. The reason is that only the vectorial isospin is same for left and right handed components of fermion which are in general mixed for the massive states.

The coefficients are dimensionless and expressible in terms of the gauge coupling strengths and using  $\hbar = r\hbar_0$  one can write

$$\begin{aligned} \alpha_{em}Q_{em} + p\frac{\alpha_Z}{2}Q_{Z,V} &= \frac{3}{4\pi} \times rnK \ , \\ \alpha_{em} &= \frac{e^2}{4\pi\hbar_0} \ , \ \alpha_Z = \frac{g_Z^2}{4\pi\hbar_0} = \frac{\alpha_{em}}{p(1-p)} \ . \end{aligned} \quad (2.6.7)$$

4. There is a great temptation to assume that the values of  $Q_{em}$  and  $Q_Z$  correspond to their quantized values and therefore depend on the quantum state assigned to the partonic 2-surface. The linear coupling of the modified Dirac operator to conserved charges implies correlation between the geometry of space-time sheet and quantum numbers assigned to the partonic 2-surface. The assumption of standard quantized values for  $Q_{em}$  and  $Q_Z$  would be also seen as the identification of the fine structure constants  $\alpha_{em}$  and  $\alpha_Z$ . This however requires weak isospin invariance.

### The value of $K$ from classical quantization of Kähler electric charge

The value of  $K$  can be deduced by requiring classical quantization of Kähler electric charge.

1. The condition that the flux of  $F^{03} = (\hbar/g_K)J^{03}$  defining the counterpart of Kähler electric field equals to the Kähler charge  $g_K$  would give the condition  $K = g_K^2/\hbar$ , where  $g_K$  is Kähler coupling constant which should invariant under coupling constant evolution by quantum criticality. Within experimental uncertainties one has  $\alpha_K = g_K^2/4\pi\hbar_0 = \alpha_{em} \simeq 1/137$ , where  $\alpha_{em}$  is finite structure constant in electron length scale and  $\hbar_0$  is the standard value of Planck constant.
2. The quantization of Planck constants makes the condition highly non-trivial. The most general quantization of  $r$  is as rationals but there are good arguments favoring the quantization as integers corresponding to the allowance of only singular coverings of  $CD$  and  $CP_2$ . The point is that in this case a given value of Planck constant corresponds to a finite number pages of the "Big Book". The quantization of the Planck constant implies a further quantization of  $K$  and would suggest that  $K$  scales as  $1/r$  unless the spectrum of values of  $Q_{em}$  and  $Q_Z$  allowed by the quantization condition scales as  $r$ . This is quite possible and the interpretation would be that each of the  $r$  sheets of the covering carries (possibly same) elementary charge. Kind of discrete variant of a full Fermi sphere would be in question. The interpretation in terms of anyonic phases [57] supports this interpretation.
3. The identification of  $J$  as a counterpart of  $eB/\hbar$  means that Kähler action and thus also Kähler function is proportional to  $1/\alpha_K$  and therefore to  $\hbar$ . This implies that for large values of  $\hbar$  Kähler coupling strength  $g_K^2/4\pi$  becomes very small and large fluctuations are suppressed in the functional integral. The basic motivation for introducing the hierarchy of Planck constants was indeed that the scaling  $\alpha \rightarrow \alpha/r$  allows to achieve the convergence of perturbation theory: Nature itself would solve the problems of the theoretician. This of course does not mean that the physical states would remain as such and the replacement of single particles with anyonic states in order to satisfy the condition for  $K$  would realize this concretely.

4. The condition  $K = g_K^2/\hbar$  implies that the Kähler magnetic charge is always accompanied by Kähler electric charge. A more general condition would read as

$$K = n \times \frac{g_K^2}{\hbar}, n \in Z . \quad (2.6.8)$$

This would apply in the case of cosmic strings and would allow vanishing Kähler charge possible when the partonic 2-surface has opposite fermion and antifermion numbers (for both leptons and quarks) so that Kähler electric charge should vanish. For instance, for neutrinos the vanishing of electric charge strongly suggests  $n = 0$  besides the condition that abelian  $Z^0$  flux contributing to em charge vanishes.

It took a year to realize that this value of  $K$  is natural at the Minkowskian side of the wormhole throat. At the Euclidian side much more natural condition is

$$K = \frac{1}{\hbar} . \quad (2.6.9)$$

In fact, the self-duality of  $CP_2$  Kähler form favours this boundary condition at the Euclidian side of the wormhole throat. Also the fact that one cannot distinguish between electric and magnetic charges in Euclidian region since all charges are magnetic can be used to argue in favor of this form. The same constraint arises from the condition that the action for  $CP_2$  type vacuum extremal has the value required by the argument leading to a prediction for gravitational constant in terms of the square of  $CP_2$  radius and  $\alpha_K$  the effective replacement  $g_K^2 \rightarrow 1$  would spoil the argument.

The boundary condition  $J_E = J_B$  for the electric and magnetic parts of Kähler form at the Euclidian side of the wormhole throat inspires the question whether all Euclidian regions could be self-dual so that the density of Kähler action would be just the instanton density. Self-duality follows if the deformation of the metric induced by the deformation of the canonically imbedded  $CP_2$  is such that in  $CP_2$  coordinates for the Euclidian region the tensor  $(g^{\alpha\beta}g^{\mu\nu} - g^{\alpha\nu}g^{\mu\beta})/\sqrt{g}$  remains invariant. This is certainly the case for  $CP_2$  type vacuum extremals since by the light-likeness of  $M^4$  projection the metric remains invariant. Also conformal scalings of the induced metric would satisfy this condition. Conformal scaling is not consistent with the degeneracy of the 4-metric at the wormhole

### Reduction of the quantization of Kähler electric charge to that of electromagnetic charge

The best manner to learn more is to challenge the form of the weak electric-magnetic duality based on the induced Kähler form.

1. Physically it would seem more sensible to pose the duality on electromagnetic charge rather than Kähler charge. This would replace induced Kähler form with electromagnetic field, which is a linear combination of induced Kähler field and classical  $Z^0$  field

$$\begin{aligned} \gamma &= 3J - \sin^2\theta_W R_{03} , \\ Z^0 &= 2R_{03} . \end{aligned} \quad (2.6.10)$$

Here  $Z_0 = 2R_{03}$  is the appropriate component of  $CP_2$  curvature form [2]. For a vanishing Weinberg angle the condition reduces to that for Kähler form.

2. For the Euclidian space-time regions having interpretation as lines of generalized Feynman diagrams Weinberg angle should be non-vanishing. In Minkowskian regions Weinberg angle could however vanish. If so, the condition guaranteeing that electromagnetic charge of the partonic 2-surfaces equals to the above condition stating that the em charge assignable to the fermion content of the partonic 2-surfaces reduces to the classical Kähler electric flux at the Minkowskian side of the wormhole throat. One can argue that Weinberg angle must increase smoothly from a vanishing value at both sides of wormhole throat to its value in the deep interior of the Euclidian region.

3. The vanishing of the Weinberg angle in Minkowskian regions conforms with the physical intuition. Above elementary particle length scales one sees only the classical electric field reducing to the induced Kähler form and classical  $Z^0$  fields and color gauge fields are effectively absent. Only in phases with a large value of Planck constant classical  $Z^0$  field and other classical weak fields and color gauge field could make themselves visible. Cell membrane could be one such system [59]. This conforms with the general picture about color confinement and weak massivation.

The GRT limit of TGD suggests a further reason for why Weinberg angle should vanish in Minkowskian regions.

1. The value of the Kähler coupling strength must be very near to the value of the fine structure constant in electron length scale and these constants can be assumed to be equal.
2. GRT limit of TGD with space-time surfaces replaced with abstract 4-geometries would naturally correspond to Einstein-Maxwell theory with cosmological constant which is non-vanishing only in Euclidian regions of space-time so that both Reissner-Nordström metric and  $CP_2$  are allowed as simplest possible solutions of field equations [77]. The extremely small value of the observed cosmological constant needed in GRT type cosmology could be equal to the large cosmological constant associated with  $CP_2$  metric multiplied with the 3-volume fraction of Euclidian regions.
3. Also at GRT limit quantum theory would reduce to almost topological QFT since Einstein-Maxwell action reduces to 3-D term by field equations implying the vanishing of the Maxwell current and of the curvature scalar in Minkowskian regions and curvature scalar + cosmological constant term in Euclidian regions. The weak form of electric-magnetic duality would guarantee also now the preferred extremal property and prevent the reduction to a mere topological QFT.
4. GRT limit would make sense only for a vanishing Weinberg angle in Minkowskian regions. A non-vanishing Weinberg angle would make sense in the deep interior of the Euclidian regions where the approximation as a small deformation of  $CP_2$  makes sense.

The weak form of electric-magnetic duality has surprisingly strong implications for the basic view about quantum TGD as following considerations show.

### 2.6.2 Magnetic confinement, the short range of weak forces, and color confinement

The weak form of electric-magnetic duality has surprisingly strong implications if one combines it with some very general empirical facts such as the non-existence of magnetic monopole fields in macroscopic length scales.

#### How can one avoid macroscopic magnetic monopole fields?

Monopole fields are experimentally absent in length scales above order weak boson length scale and one should have a mechanism neutralizing the monopole charge. How electroweak interactions become short ranged in TGD framework is still a poorly understood problem. What suggests itself is the neutralization of the weak isospin above the intermediate gauge boson Compton length by neutral Higgs bosons. Could the two neutralization mechanisms be combined to single one?

1. In the case of fermions and their super partners the opposite magnetic monopole would be a wormhole throat. If the magnetically charged wormhole contact is electromagnetically neutral but has vectorial weak isospin neutralizing the weak vectorial isospin of the fermion only the electromagnetic charge of the fermion is visible on longer length scales. The distance of this wormhole throat from the fermionic one should be of the order weak boson Compton length. An interpretation as a bound state of fermion and a wormhole throat state with the quantum numbers of a neutral Higgs boson would therefore make sense. The neutralizing throat would have quantum numbers of  $X_{-1/2} = \nu_L \bar{\nu}_R$  or  $X_{1/2} = \bar{\nu}_L \nu_R$ .  $\nu_L \bar{\nu}_R$  would not be neutral Higgs boson (which should correspond to a wormhole contact) but a super-partner of left-handed neutrino obtained by adding a right handed neutrino. This mechanism would apply separately

to the fermionic and anti-fermionic throats of the gauge bosons and corresponding space-time sheets and leave only electromagnetic interaction as a long ranged interaction.

2. One can of course wonder what is the situation for the bosonic wormhole throats feeding gauge fluxes between space-time sheets. It would seem that these wormhole throats must always appear as pairs such that for the second member of the pair monopole charges and  $I_V^3$  cancel each other at both space-time sheets involved so that one obtains at both space-time sheets magnetic dipoles of size of weak boson Compton length. The proposed magnetic character of fundamental particles should become visible at TeV energies so that LHC might have surprises in store!

### Magnetic confinement and color confinement

Magnetic confinement generalizes also to the case of color interactions. One can consider also the situation in which the magnetic charges of quarks (more generally, of color excited leptons and quarks) do not vanish and they form color and magnetic singlets in the hadronic length scale. This would mean that magnetic charges of the state  $q_{\pm 1/2} - X_{\mp 1/2}$  representing the physical quark would not vanish and magnetic confinement would accompany also color confinement. This would explain why free quarks are not observed. To how degree then quark confinement corresponds to magnetic confinement is an interesting question.

For quark and antiquark of meson the magnetic charges of quark and antiquark would be opposite and meson would correspond to a Kähler magnetic flux so that a stringy view about meson emerges. For valence quarks of baryon the vanishing of the net magnetic charge takes place provided that the magnetic net charges are  $(\pm 2, \mp 1, \mp 1)$ . This brings in mind the spectrum of color hyper charges coming as  $(\pm 2, \mp 1, \mp 1)/3$  and one can indeed ask whether color hyper-charge correlates with the Kähler magnetic charge. The geometric picture would be three strings connected to single vertex. Amusingly, the idea that color hypercharge could be proportional to color hyper charge popped up during the first year of TGD when I had not yet discovered  $CP_2$  and believed on  $M^4 \times S^2$ .

p-Adic length scale hypothesis and hierarchy of Planck constants defining a hierarchy of dark variants of particles suggest the existence of scaled up copies of QCD type physics and weak physics. For p-adically scaled up variants the mass scales would be scaled by a power of  $\sqrt{2}$  in the most general case. The dark variants of the particle would have the same mass as the original one. In particular, Mersenne primes  $M_k = 2^k - 1$  and Gaussian Mersennes  $M_{G,k} = (1 + i)^k - 1$  has been proposed to define zoomed copies of these physics. At the level of magnetic confinement this would mean hierarchy of length scales for the magnetic confinement.

One particular proposal is that the Mersenne prime  $M_{89}$  should define a scaled up variant of the ordinary hadron physics with mass scaled up roughly by a factor  $2^{(107-89)/2} = 512$ . The size scale of color confinement for this physics would be same as the weak length scale. It would look more natural that the weak confinement for the quarks of  $M_{89}$  physics takes place in some shorter scale and  $M_{61}$  is the first Mersenne prime to be considered. The mass scale of  $M_{61}$  weak bosons would be by a factor  $2^{(89-61)/2} = 2^{14}$  higher and about  $1.6 \times 10^4$  TeV.  $M_{89}$  quarks would have virtually no weak interactions but would possess color interactions with weak confinement length scale reflecting themselves as new kind of jets at collisions above TeV energies.

In the biologically especially important length scale range 10 nm -2500 nm there are as many as four Gaussian Mersennes corresponding to  $M_{G,k}$ ,  $k = 151, 157, 163, 167$ . This would suggest that the existence of scaled up scales of magnetic-, weak- and color confinement. An especially interesting possibly testable prediction is the existence of magnetic monopole pairs with the size scale in this range. There are recent claims about experimental evidence for magnetic monopole pairs [7].

### Magnetic confinement and stringy picture in TGD sense

The connection between magnetic confinement and weak confinement is rather natural if one recalls that electric-magnetic duality in super-symmetric quantum field theories means that the descriptions in terms of particles and monopoles are in some sense dual descriptions. Fermions would be replaced by string like objects defined by the magnetic flux tubes and bosons as pairs of wormhole contacts would correspond to pairs of the flux tubes. Therefore the sharp distinction between gravitons and physical particles would disappear.

The reason why gravitons are necessarily stringy objects formed by a pair of wormhole contacts is that one cannot construct spin two objects using only single fermion states at wormhole throats. Of course, also super partners of these states with higher spin obtained by adding fermions and anti-fermions at the wormhole throat but these do not give rise to graviton like states [29]. The upper and lower wormhole throat pairs would be quantum superpositions of fermion anti-fermion pairs with sum over all fermions. The reason is that otherwise one cannot realize graviton emission in terms of joining of the ends of light-like 3-surfaces together. Also now magnetic monopole charges are necessary but now there is no need to assign the entities  $X_{\pm}$  with gravitons.

Graviton string is characterized by some p-adic length scale and one can argue that below this length scale the charges of the fermions become visible. Mersenne hypothesis suggests that some Mersenne prime is in question. One proposal is that gravitonic size scale is given by electronic Mersenne prime  $M_{127}$ . It is however difficult to test whether graviton has a structure visible below this length scale.

What happens to the generalized Feynman diagrams is an interesting question. It is not at all clear how closely they relate to ordinary Feynman diagrams. All depends on what one is ready to assume about what happens in the vertices. One could of course hope that zero energy ontology could allow some very simple description allowing perhaps to get rid of the problematic aspects of Feynman diagrams.

1. Consider first the recent view about generalized Feynman diagrams which relies zero energy ontology. A highly attractive assumption is that the particles appearing at wormhole throats are on mass shell particles. For incoming and outgoing elementary bosons and their super partners they would be positive it resp. negative energy states with parallel on mass shell momenta. For virtual bosons they the wormhole throats would have opposite sign of energy and the sum of on mass shell states would give virtual net momenta. This would make possible twistor description of virtual particles allowing only massless particles (in 4-D sense usually and in 8-D sense in TGD framework). The notion of virtual fermion makes sense only if one assumes in the interaction region a topological condensation creating another wormhole throat having no fermionic quantum numbers.
2. The addition of the particles  $X^{\pm}$  replaces generalized Feynman diagrams with the analogs of stringy diagrams with lines replaced by pairs of lines corresponding to fermion and  $X_{\pm 1/2}$ . The members of these pairs would correspond to 3-D light-like surfaces glued together at the vertices of generalized Feynman diagrams. The analog of 3-vertex would not be splitting of the string to form shorter strings but the replication of the entire string to form two strings with same length or fusion of two strings to single string along all their points rather than along ends to form a longer string. It is not clear whether the duality symmetry of stringy diagrams can hold true for the TGD variants of stringy diagrams.
3. How should one describe the bound state formed by the fermion and  $X^{\pm}$ ? Should one describe the state as superposition of non-parallel on mass shell states so that the composite state would be automatically massive? The description as superposition of on mass shell states does not conform with the idea that bound state formation requires binding energy. In TGD framework the notion of negentropic entanglement has been suggested to make possible the analogs of bound states consisting of on mass shell states so that the binding energy is zero [44]. If this kind of states are in question the description of virtual states in terms of on mass shell states is not lost. Of course, one cannot exclude the possibility that there is infinite number of this kind of states serving as analogs for the excitations of string like object.
4. What happens to the states formed by fermions and  $X_{\pm 1/2}$  in the internal lines of the Feynman diagram? Twistor philosophy suggests that only the higher on mass shell excitations are possible. If this picture is correct, the situation would not change in an essential manner from the earlier one.

The highly non-trivial prediction of the magnetic confinement is that elementary particles should have stringy character in electro-weak length scales and could behaving to become manifest at LHC energies. This adds one further item to the list of non-trivial predictions of TGD about physics at LHC energies [45].

### Should $J + J_1$ appear in Kähler action?

The presence of the  $S^2$  Kähler form  $J_1$  in weak form of electric-magnetic duality was originally suggested by an erratic argument about the reduction to almost topological QFT to be described in the next subsection. In any case this argument raises the question whether one could replace  $J$  with  $J + J_1$  in the Kähler action. This would not affect the basic non-vacuum extremals but would modify the vacuum degeneracy of the Kähler action. Canonically imbedded  $M^4$  would become a monopole configuration with an infinite magnetic energy and Kähler action due to the monopole singularity at the line connecting tips of the  $CD$ . Action and energy can be made small by drilling a small hole around origin. This is however not consistent with the weak form of electro-weak duality. Amusingly, the modified Dirac equation reduces to ordinary massless Dirac equation in  $M^4$ .

This extremal can be transformed to a vacuum extremal by assuming that the solution is also a  $CP_2$  magnetic monopole with opposite contribution to the magnetic charge so that  $J + J_1 = 0$  holds true. This is achieved if one can regard space-time surface as a map  $M^4 \rightarrow CP_2$  reducing to a map  $(\Theta, \Phi) = (\theta, \pm\phi)$  with the sign chosen by properly projecting the homologically non-trivial  $r_M = \text{constant}$  spheres of  $CD$  to the homologically non-trivial geodesic sphere of  $CP_2$ . Symplectic transformations of  $S^2 \times CP_2$  produce new vacuum extremals of this kind. Using Darboux coordinates in which one has  $J = \sum_{k=1,2} P_k dQ^k$  and assuming that  $(P_1, Q_1)$  corresponds to the  $CP_2$  image of  $S^2$ , one can take  $Q_2$  to be arbitrary function of  $P^2$  which in turn is an arbitrary function of  $M^4$  coordinates to obtain even more general vacuum extremals with 3-D  $CP_2$  projection. Therefore the spectrum of vacuum extremals, which is very relevant for the TGD based description of gravitation in long length scales because it allows to satisfy Einstein's equations as an additional condition, looks much richer than for the original option, and it is natural to ask whether this option might make sense.

An objection is that  $J_1$  is a radial monopole field and this breaks Lorentz invariance to  $SO(3)$ . Lorentz invariance is broken to  $SO(3)$  for a given  $CD$  also by the presence of the preferred time direction defined by the time-like line connecting the tips of the  $CD$  becoming carrying the monopole charge but is compensated since Lorentz boosts of  $CD$ s are possible. Could one consider similar compensation also now? Certainly the extremely small breaking of Lorentz invariance and the vanishing of the monopole charge for the vacuum extremals is all that is needed at the space-time level. No new gauge fields would be introduced since only the Kähler field part of photon and  $Z^0$  boson would receive an additional contribution.

The ultimate fate of the modification depends on whether it is consistent with the general relativistic description of gravitation. Since a breaking of spherical symmetry is involved, it is not at all clear whether one can find vacuum extremals which represent small deformations of the Reissner-Nordström metric and Robertson-Walker metric. The argument below shows that this option does not allow the imbedding of small deformations of physically plausible space-time metrics as vacuum extremals.

The basic vacuum extremal whose deformations should give vacuum extremals allowing interpretation as solutions of Einstein's equations is given by a map  $M^4 \rightarrow CP_2$  projecting the  $r_M$  constant spheres  $S^2$  of  $M^2$  to the homologically non-trivial geodesic sphere of  $CP_2$ . The winding number of this map is  $-1$  in order to achieve vanishing of the induced Kähler form  $J + J_1$ . For instance, the following two canonical forms of the map are possible

$$\begin{aligned} (\Theta, \Psi) &= (\theta_M, -\phi_M) , \\ (\Theta, \Psi) &= (\pi - \theta_M, \phi_M) . \end{aligned} \tag{2.6.11}$$

Here  $(\Theta, \Psi)$  refers to the geodesic sphere of  $CP_2$  and  $(\theta_M, \phi_M)$  to the sphere of  $M^4$ . The resulting space-time surface is not flat and Einstein tensor is non-vanishing. More complex metrics can be constructed from this metric by a deformation making the  $CP_2$  projection 3-dimensional.

Using the expression of the  $CP_2$  line element in Eguchi-Hanson coordinates [10]

$$\frac{ds^2}{R^2} = \frac{dr^2}{F^2} + \frac{r^2}{F} (d\Psi + \cos\Theta d\Phi)^2 + \frac{r^2}{4F} (d\Theta^2 + \text{frac}{r^2} 4F \sin^2\Theta d\Phi^2) \tag{2.6.12}$$

and s the relationship  $r = \tan(\Theta)$ , one obtains following expression for the  $CP_2$  metric

$$\frac{ds^2}{R^2} = d\theta_M^2 + \sin^2(\theta_M) \left[ (d\phi_M + \cos(\theta)d\Phi)^2 + \frac{1}{4}(d\theta^2 + \sin^2(\theta)d\Phi^2) \right]. \quad (2.6.13)$$

The resulting metric is obtained from the metric of  $S^2$  by replacing  $d\phi^2$  which 3-D line element. The factor  $\sin^2(\theta_M)$  implies that the induced metric becomes singular at North and South poles of  $S^2$ . In particular, the gravitational potential is proportional to  $\sin^2(\theta_M)$  so that gravitational force in the radial direction vanishes at equators. It is very difficult to imagine any manner to produce a small deformation of Reissner-Nordström metric or Robertson-Walker metric. Hence it seems that the vacuum extremals produce by  $J + J_1$  option are not physical.

### 2.6.3 Could Quantum TGD reduce to almost topological QFT?

There seems to be a profound connection with the earlier unrealistic proposal that TGD reduces to almost topological quantum theory in the sense that the counterpart of Chern-Simons action assigned with the wormhole throats somehow dictates the dynamics. This proposal can be formulated also for the modified Dirac action action. I gave up this proposal but the following argument shows that Kähler action with weak form of electric-magnetic duality effectively reduces to Chern-Simons action plus Coulomb term.

1. Kähler action density can be written as a 4-dimensional integral of the Coulomb term  $j_K^\alpha A_\alpha$  plus and integral of the boundary term  $J^{n\beta} A_\beta \sqrt{g_4}$  over the wormhole throats and of the quantity  $J^{0\beta} A_\beta \sqrt{g_4}$  over the ends of the 3-surface.
2. If the self-duality conditions generalize to  $J^{n\beta} = 4\pi\alpha_K \epsilon^{n\beta\gamma\delta} J_{\gamma\delta}$  at throats and to  $J^{0\beta} = 4\pi\alpha_K \epsilon^{0\beta\gamma\delta} J_{\gamma\delta}$  at the ends, the Kähler function reduces to the counterpart of Chern-Simons action evaluated at the ends and throats. It would have same value for each branch and the replacement  $\hbar_0 \rightarrow r\hbar_0$  would effectively describe this. Boundary conditions would however give  $1/r$  factor so that  $\hbar$  would disappear from the Kähler function! The original attempt to realize quantum TGD as an almost topological QFT was in terms of Chern-Simons action but was given up. It is somewhat surprising that Kähler action gives Chern-Simons action in the vacuum sector defined as sector for which Kähler current is light-like or vanishes.

Holography encourages to ask whether also the Coulomb interaction terms could vanish. This kind of dimensional reduction would mean an enormous simplification since TGD would reduce to an almost topological QFT. The attribute "almost" would come from the fact that one has non-vanishing classical Noether charges defined by Kähler action and non-trivial quantum dynamics in  $M^4$  degrees of freedom. One could also assign to space-time surfaces conserved four-momenta which is not possible in topological QFTs. For this reason the conditions guaranteeing the vanishing of Coulomb interaction term deserve a detailed analysis.

1. For the known extremals  $j_K^\alpha$  either vanishes or is light-like ("massless extremals" for which weak self-duality condition does not make sense [8]) so that the Coulombic term vanishes identically in the gauge used. The addition of a gradient to  $A$  induces terms located at the ends and wormhole throats of the space-time surface but this term must be cancelled by the other boundary terms by gauge invariance of Kähler action. This implies that the  $M^4$  part of WCW metric vanishes in this case. Therefore massless extremals as such are not physically realistic: wormhole throats representing particles are needed.
2. The original naive conclusion was that since Chern-Simons action depends on  $CP_2$  coordinates only, its variation with respect to Minkowski coordinates must vanish so that the WCW metric would be trivial in  $M^4$  degrees of freedom. This conclusion is in conflict with quantum classical correspondence and was indeed too hasty. The point is that the allowed variations of Kähler function must respect the weak electro-magnetic duality which relates Kähler electric field depending on the induced 4-metric at 3-surface to the Kähler magnetic field. Therefore the dependence on  $M^4$  coordinates creeps via a Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x \quad (2.6.14)$$

The (1,1) part of second variation contributing to  $M^4$  metric comes from this term.

3. This erratic conclusion about the vanishing of  $M^4$  part WCW metric raised the question about how to achieve a non-trivial metric in  $M^4$  degrees of freedom. The proposal was a modification of the weak form of electric-magnetic duality. Besides  $CP_2$  Kähler form there would be the Kähler form assignable to the light-cone boundary reducing to that for  $r_M = \text{constant}$  sphere - call it  $J^1$ . The generalization of the weak form of self-duality would be  $J^{n\beta} = \epsilon^{n\beta\gamma\delta} K (J_{\gamma\delta} + \epsilon J_{\gamma\delta}^1)$ . This form implies that the boundary term gives a non-trivial contribution to the  $M^4$  part of the WCW metric even without the constraint from electric-magnetic duality. Kähler charge is not affected unless the partonic 2-surface contains the tip of  $CD$  in its interior. In this case the value of Kähler charge is shifted by a topological contribution. Whether this term can survive depends on whether the resulting vacuum extremals are consistent with the basic facts about classical gravitation.
4. The Coulombic interaction term is not invariant under gauge transformations. The good news is that this might allow to find a gauge in which the Coulomb term vanishes. The vanishing condition fixing the gauge transformation  $\phi$  is

$$j_K^\alpha \partial_\alpha \phi = -j^\alpha A_\alpha \quad (2.6.15)$$

This differential equation can be reduced to an ordinary differential equation along the flow lines  $j_K$  by using  $dx^\alpha/dt = j_K^\alpha$ . Global solution is obtained only if one can combine the flow parameter  $t$  with three other coordinates- say those at the either end of  $CD$  to form space-time coordinates. The condition is that the parameter defining the coordinate differential is proportional to the covariant form of Kähler current:  $dt = \phi j_K$ . This condition in turn implies  $d^2t = d(\phi j_K) = d\phi \wedge j_K + \phi dj_K = 0$  implying  $j_K \wedge dj_K = 0$  or more concretely,

$$\epsilon^{\alpha\beta\gamma\delta} j_\beta^K \partial_\gamma j_\delta^K = 0 \quad (2.6.16)$$

$j_K$  is a four-dimensional counterpart of Beltrami field [48] and could be called generalized Beltrami field.

The integrability conditions follow also from the construction of the extremals of Kähler action [8]. The conjecture was that for the extremals the 4-dimensional Lorentz force vanishes (no dissipation): this requires  $j_K \wedge J = 0$ . One manner to guarantee this is the topologization of the Kähler current meaning that it is proportional to the instanton current:  $j_K = \phi j_I$ , where  $j_I = *(J \wedge A)$  is the instanton current, which is not conserved for 4-D  $CP_2$  projection. The conservation of  $j_K$  implies the condition  $j_I^\alpha \partial_\alpha \phi = \partial_\alpha j^\alpha \phi$  and from this  $\phi$  can be integrated if the integrability condition  $j_I \wedge dj_I = 0$  holds true implying the same condition for  $j_K$ . By introducing at least 3 or  $CP_2$  coordinates as space-time coordinates, one finds that the contravariant form of  $j_I$  is purely topological so that the integrability condition fixes the dependence on  $M^4$  coordinates and this selection is coded into the scalar function  $\phi$ . These functions define families of conserved currents  $j_K^\alpha \phi$  and  $j_I^\alpha \phi$  and could be also interpreted as conserved currents associated with the critical deformations of the space-time surface.

5. There are gauge transformations respecting the vanishing of the Coulomb term. The vanishing condition for the Coulomb term is gauge invariant only under the gauge transformations  $A \rightarrow A + \nabla\phi$  for which the scalar function the integral  $\int j_K^\alpha \partial_\alpha \phi$  reduces to a total divergence a giving an integral over various 3-surfaces at the ends of  $CD$  and at throats vanishes. This is satisfied if the allowed gauge transformations define conserved currents

$$D_\alpha(j^\alpha\phi) = 0 . \quad (2.6.17)$$

As a consequence Coulomb term reduces to a difference of the conserved charges  $Q_\phi^e = \int j^0\phi\sqrt{g_4}d^3x$  at the ends of the CD vanishing identically. The change of the imons type term is trivial if the total weighted Kähler magnetic flux  $Q_\phi^m = \sum \int J\phi dA$  over wormhole throats is conserved. The existence of an infinite number of conserved weighted magnetic fluxes is in accordance with the electric-magnetic duality. How these fluxes relate to the flux Hamiltonians central for WCW geometry is not quite clear.

6. The gauge transformations respecting the reduction to almost topological QFT should have some special physical meaning. The measurement interaction term in the modified Dirac interaction corresponds to a critical deformation of the space-time sheet and is realized as an addition of a gauge part to the Kähler gauge potential of  $CP_2$ . It would be natural to identify this gauge transformation giving rise to a conserved charge so that the conserved charges would provide a representation for the charges associated with the infinitesimal critical deformations not affecting Kähler action. The gauge transformed Kähler potential couples to the modified Dirac equation and its effect could be visible in the value of Kähler function and therefore also in the properties of the preferred extremal. The effect on WCW metric would however vanish since  $K$  would transform only by an addition of a real part of a holomorphic function. Kähler function is identified as a Dirac determinant for Chern-Simons Dirac action and the spectrum of this operator should not be invariant under these gauge transformations if this picture is correct. This is achieved if the gauge transformation is carried only in the Dirac action corresponding to the Chern-Simons term: this assumption is motivated by the breaking of time reversal invariance induced by quantum measurements. The modification of Kähler action can be guessed to correspond just to the Chern-Simons contribution from the instanton term.
7. A reasonable looking guess for the explicit realization of the quantum classical correspondence between quantum numbers and space-time geometry is that the deformation of the preferred extremal due to the addition of the measurement interaction term is induced by a  $U(1)$  gauge transformation induced by a transformation of  $\delta CD \times CP_2$  generating the gauge transformation represented by  $\phi$ . This interpretation makes sense if the fluxes defined by  $Q_\phi^m$  and corresponding Hamiltonians affect only zero modes rather than quantum fluctuating degrees of freedom.

To sum up, one could understand the basic properties of WCW metric in this framework. Effective 2-dimensionality would result from the existence of an infinite number of conserved charges in two different time directions (genuine conservation laws plus gauge fixing). The infinite-dimensional symmetric space for given values of zero modes corresponds to the Cartesian product of the WCWs associated with the partonic 2-surfaces at both ends of  $CD$  and the generalized Chern-Simons term decomposes into a sum of terms from the ends giving single particle Kähler functions and to the terms from light-like wormhole throats giving interaction term between positive and negative energy parts of the state. Hence Kähler function could be calculated without any knowledge about the interior of the space-time sheets and TGD would reduce to almost topological QFT as speculated earlier. Needless to say this would have immense boost to the program of constructing WCW Kähler geometry.

#### 2.6.4 Kähler action for Euclidian regions as Kähler function and Kähler action for Minkowskian regions as Morse function?

One of the nasty questions about the interpretation of Kähler action relates to the square root of the metric determinant. If one proceeds completely straightforwardly, the only reason conclusion is that the square root is imaginary in Minkowskian space-time regions so that Kähler action would be complex. The Euclidian contribution would have a natural interpretation as positive definite Kähler function but how should one interpret the imaginary Minkowskian contribution? Certainly the path integral approach to quantum field theories supports its presence. For some mysterious reason I was able to forget this nasty question and serious consideration of the obvious answer to it. Only when I worked between possible connections between TGD and Floer homology [85] I realized that

the Minkowskian contribution is an excellent candidate for Morse function whose critical points give information about WCW homology. This would fit nicely with the vision about TGD as almost topological QFT.

Euclidian regions would guarantee the convergence of the functional integral and one would have a mathematically well-defined theory. Minkowskian contribution would give the quantal interference effects and stationary phase approximation. The analog of Floer homology would represent quantum superpositions of critical points identifiable as ground states defined by the extrema of Kähler action for Minkowskian regions. Perturbative approach to quantum TGD would rely on functional integrals around the extrema of Kähler function. One would have maxima also for the Kähler function but only in the zero modes not contributing to the WCW metric.

There is a further question related to almost topological QFT character of TGD. Should one assume that the reduction to Chern-Simons terms occurs for the preferred extremals in *both* Minkowskian and Euclidian regions or only in Minkowskian regions?

1. All arguments for this have been represented for Minkowskian regions [28] involve local light-like momentum direction which does not make sense in the Euclidian regions. This does not however kill the argument: one can have non-trivial solutions of Laplacian equation in the region of  $CP_2$  bounded by wormhole throats: for  $CP_2$  itself only covariantly constant right-handed neutrino represents this kind of solution and at the same time supersymmetry. In the general case solutions of Laplacian represent broken super-symmetries and should be in one-one correspondences with the solutions of the modified Dirac equation. The interpretation for the counterparts of momentum and polarization would be in terms of classical representation of color quantum numbers.

If the reduction occurs in Euclidian regions, it gives in the case of  $CP_2$  two 3-D terms corresponding to two 3-D gluing regions for three coordinate patches needed to define coordinates and spinor connection for  $CP_2$  so that one would have two Chern-Simons terms. Without any other contributions the first term would be identical with that from Minkowskian region apart from imaginary unit. Second Chern-Simons term would be however independent of this. For wormhole contacts the two terms could be assigned with opposite wormhole throats and would be identical with their Minkowskian cousins from imaginary unit. This looks a little bit strange.

2. There is however a very delicate issue involved. Quantum classical correspondence requires that the quantum numbers of partonic states must be coded to the space-time geometry, and this is achieved by adding to the action a measurement interaction term which reduces to what is almost a gauge term present only in Chern-Simons-Dirac equation but not at space-time interior [28]. This term would represent a coupling to Poincare quantum numbers at the Minkowskian side and to color and electro-weak quantum numbers at  $CP_2$  side. Therefore the net Chern-Simons contributions and would be different.
3. There is also a very beautiful argument stating that Dirac determinant for Chern-Simons-Dirac action equals to Kähler function, which would be lost if Euclidian regions would not obey holography. The argument obviously generalizes and applies to both Morse and Kähler function.

The Minkowskian contribution of Kähler action is imaginary due to the negative of the metric determinant and gives a phase factor to vacuum functional reducing to Chern-Simons terms at wormhole throats. Ground state degeneracy due to the possibility of having both signs for Minkowskian contribution to the exponent of vacuum functional provides a general view about the description of CP breaking in TGD framework.

1. In TGD framework path integral is replaced by inner product involving integral over WCV. The vacuum functional and its conjugate are associated with the states in the inner product so that the phases of vacuum functionals cancel if only one sign for the phase is allowed. Minkowskian contribution would have no physical significance. This of course cannot be the case. The ground state is actually degenerate corresponding to the phase factor and its complex conjugate since  $\sqrt{g}$  can have two signs in Minkowskian regions. Therefore the inner products between states associated with the two ground states define  $2 \times 2$  matrix and non-diagonal elements contain interference terms due to the presence of the phase factor. At the limit of full  $CP_2$  type vacuum extremal the two ground states would reduce to each other and the determinant of the matrix would vanish.

2. A small mixing of the two ground states would give rise to CP breaking and the first principle description of CP breaking in systems like  $K - \bar{K}$  and of CKM matrix should reduce to this mixing.  $K^0$  mesons would be CP even and odd states in the first approximation and correspond to the sum and difference of the ground states. Small mixing would be present having exponential sensitivity to the actions of  $CP_2$  type extremals representing wormhole throats. This might allow to understand qualitatively why the mixing is about 50 times larger than expected for  $B^0$  mesons.
3. There is a strong temptation to assign the two ground states with two possible arrows of geometric time. At the level of M-matrix the two arrows would correspond to state preparation at either upper or lower boundary of CD. Do long- and shortlived neutral K mesons correspond to almost fifty-fifty orthogonal superpositions for the two arrow of geometric time or almost completely to a fixed arrow of time induced by environment? Is the dominant part of the arrow same for both or is it opposite for long and short-lived neutral measons? Different lifetimes would suggest that the arrow must be the same and apart from small leakage that induced by environment. CP breaking would be induced by the fact that CP is performed only  $K^0$  but not for the environment in the construction of states. One can probably imagine also alternative interpretations.

*Remark:* The proportionality of Minkowskian and Euclidian contributions to the same Chern-Simons term implies that the critical points with respect to zero modes appear for both the phase and modulus of vacuum functional. The Kähler function property does not allow extrema for vacuum functional as a function of complex coordinates of WCW since this would mean Kähler metric with non-Euclidian signature. If this were not the case, the stationary values of phase factor and extrema of modulus of the vacuum functional would correspond to different configurations.

### 2.6.5 A general solution ansatz based on almost topological QFT property

The basic vision behind the ansatz is the reduction of quantum TGD to almost topological field theory. This requires that the flow parameters associated with the flow lines of isometry currents and Kähler current extend to global coordinates. This leads to integrability conditions implying generalized Beltrami flow and Kähler action for the preferred extremals reduces to Chern-Simons action when weak electro-weak duality is applied as boundary conditions. The strongest form of the hydrodynamical interpretation requires that all conserved currents are parallel to Kähler current. In the more general case one would have several hydrodynamic flows. Also the braidings (several of them for the most general ansatz) assigned with the light-like 3-surfaces are naturally defined by the flow lines of conserved currents. The independent behavior of particles at different flow lines can be seen as a realization of the complete integrability of the theory. In free quantum field theories on mass shell Fourier components are in a similar role but the geometric interpretation in terms of flow is of course lacking. This picture should generalize also to the solution of the modified Dirac equation.

#### Basic field equations

Consider first the equations at general level.

1. The breaking of the Poincare symmetry due to the presence of monopole field occurs and leads to the isometry group  $T \times SO(3) \times SU(3)$  corresponding to time translations, rotations, and color group. The Cartan algebra is four-dimensional and field equations reduce to the conservation laws of energy  $E$ , angular momentum  $J$ , color isospin  $I_3$ , and color hypercharge  $Y$ .
2. Quite generally, one can write the field equations as conservation laws for  $I, J, I_3$ , and  $Y$ .

$$D_\alpha [D_\beta (J^{\alpha\beta} H_A) - j_K^\alpha H^A + T^{\alpha\beta} j_A^l h_{kl} \partial_\beta h^l] = 0 . \quad (2.6.18)$$

The first term gives a contraction of the symmetric Ricci tensor with antisymmetric Kähler form and vanishes so that one has

$$D_\alpha [j_K^\alpha H^A - T^{\alpha\beta} j_A^k h_{kl} \partial_\beta h^l] = 0 . \quad (2.6.19)$$

For energy one has  $H_A = 1$  and energy current associated with the flow lines is proportional to the Kähler current. Its divergence vanishes identically.

3. One can express the divergence of the term involving energy momentum tensor as a sum of terms involving  $j_K^\alpha J_{\alpha\beta}$  and contraction of second fundamental form with energy momentum tensor so that one obtains

$$j_K^\alpha D_\alpha H^A = j_K^\alpha J_{\alpha\beta} j_\beta^A + T^{\alpha\beta} H_{\alpha\beta}^k j_k^A . \quad (2.6.20)$$

### Hydrodynamical solution ansatz

The characteristic feature of the solution ansatz would be the reduction of the dynamics to hydrodynamics analogous to that for a continuous distribution of particles initially at the end of  $X^3$  of the light-like 3-surface moving along flow lines defined by currents  $j_A$  satisfying the integrability condition  $j_A \wedge dj_A = 0$ . Field theory would reduce effectively to particle mechanics along flow lines with conserved charges defined by various isometry currents. The strongest condition is that all isometry currents  $j_A$  and also Kähler current  $j_K$  are proportional to the same current  $j$ . The more general option corresponds to multi-hydrodynamics.

Conserved currents are analogous to hydrodynamical currents in the sense that the flow parameter along flow lines extends to a global space-time coordinate. The conserved current is proportional to the gradient  $\nabla\Phi$  of the coordinate varying along the flow lines:  $J = \Psi\nabla\Phi$  and by a proper choice of  $\Psi$  one can allow to have conservation. The initial values of  $\Psi$  and  $\Phi$  can be selected freely along the flow lines beginning from either the end of the space-time surface or from wormhole throats.

If one requires hydrodynamics also for Chern-Simons action (effective 2-dimensionality is required for preferred extremals), the initial values of scalar functions can be chosen freely only at the partonic 2-surfaces. The freedom to choose the initial values of the charges conserved along flow lines at the partonic 2-surfaces means the existence of an infinite number of conserved charges so that the theory would be integrable and even in two different coordinate directions. The basic difference as compared to ordinary conservation laws is that the conserved currents are parallel and their flow parameter extends to a global coordinate.

1. The most general assumption is that the conserved isometry currents

$$J_A^\alpha = j_K^\alpha H^A - T^{\alpha\beta} j_A^k h_{kl} \partial_\beta h^l \quad (2.6.21)$$

and Kähler current are integrable in the sense that  $J_A \wedge J_A = 0$  and  $j_K \wedge j_K = 0$  hold true. One could imagine the possibility that the currents are not parallel.

2. The integrability condition  $dJ_A \wedge J_A = 0$  is satisfied if one has

$$J_A = \Psi_A d\Phi_A . \quad (2.6.22)$$

The conservation of  $J_A$  gives

$$d * (\Psi_A d\Phi_A) = 0 . \quad (2.6.23)$$

This would mean separate hydrodynamics for each of the currents involved. In principle there is not need to assume any further conditions and one can imagine infinite basis of scalar function pairs  $(\Psi_A, \Phi_A)$  since criticality implies infinite number deformations implying conserved Noether currents.

3. The conservation condition reduces to d'Alembert equation in the induced metric if one assumes that  $\nabla\Psi_A$  is orthogonal with every  $d\Phi_A$ .

$$d * d\Phi_A = 0 \ , \ d\Psi_A \cdot d\Phi_A = 0 \ . \quad (2.6.24)$$

Taking  $x = \Phi_A$  as a coordinate the orthogonality condition states  $g^{xj}\partial_j\Psi_A = 0$  and in the general case one cannot solve the condition by simply assuming that  $\Psi_A$  depends on the coordinates transversal to  $\Phi_A$  only. These conditions bring in mind  $p \cdot p = 0$  and  $p \cdot e$  condition for massless modes of Maxwell field having fixed momentum and polarization.  $d\Phi_A$  would correspond to  $p$  and  $d\Psi_A$  to polarization. The condition that each isometry current corresponds its own pair  $(\Psi_A, \Phi_A)$  would mean that each isometry current corresponds to independent light-like momentum and polarization. Ordinary free quantum field theory would support this view whereas hydrodynamics and QFT limit of TGD would support single flow.

These are the most general hydrodynamical conditions that one can assume. One can consider also more restricted scenarios.

1. The strongest ansatz is inspired by the hydrodynamical picture in which all conserved isometry charges flow along same flow lines so that one would have

$$J_A = \Psi_A d\Phi \ . \quad (2.6.25)$$

In this case same  $\Phi$  would satisfy simultaneously the d'Alembert type equations.

$$d * d\Phi = 0 \ , \ d\Psi_A \cdot d\Phi = 0. \quad (2.6.26)$$

This would mean that the massless modes associated with isometry currents move in parallel manner but can have different polarizations. The spinor modes associated with light-light like 3-surfaces carry parallel four-momenta, which suggest that this option is correct. This allows a very general family of solutions and one can have a complete 3-dimensional basis of functions  $\Psi_A$  with gradient orthogonal to  $d\Phi$ .

2. Isometry invariance under  $T \times SO(3) \times SU(3)$  allows to consider the possibility that one has

$$J_A = k_A \Psi_A d\Phi_{G(A)} \ , \ d * (d\Phi_{G(A)}) = 0 \ , \ d\Psi_A \cdot d\Phi_{G(A)} = 0 \ . \quad (2.6.27)$$

where  $G(A)$  is  $T$  for energy current,  $SO(3)$  for angular momentum currents and  $SU(3)$  for color currents. Energy would thus flow along its own flux lines, angular momentum along its own flow lines, and color quantum numbers along their own flow lines. For instance, color currents would differ from each other only by a numerical constant. The replacement of  $\Psi_A$  with  $\Psi_{G(A)}$  would be too strong a condition since Killing vector fields are not related by a constant factor.

To sum up, the most general option is that each conserved current  $J_A$  defines its own integrable flow lines defined by the scalar function pair  $(\Psi_A, \Phi_A)$ . A complete basis of scalar functions satisfying the d'Alembert type equation guaranteeing current conservation could be imagined with restrictions coming from the effective 2-dimensionality reducing the scalar function basis effectively to the partonic 2-surface. The diametrically opposite option corresponds to the basis obtained by assuming that only single  $\Phi$  is involved.

The proposed solution ansatz can be compared to the earlier ansatz [35] stating that Kähler current is topologized in the sense that for  $D(CP_2) = 3$  it is proportional to the identically conserved

instanton current (so that 4-D Lorentz force vanishes) and vanishes for  $D(CP_2) = 4$  (Maxwell phase). This hypothesis requires that instanton current is Beltrami field for  $D(CP_2) = 3$ . In the recent case the assumption that also instanton current satisfies the Beltrami hypothesis in strong sense (single function  $\Phi$ ) generalizes the topologization hypothesis for  $D(CP_2) = 3$ . As a matter fact, the topologization hypothesis applies to isometry currents also for  $D(CP_2) = 4$  although instanton current is not conserved anymore.

### Can one require the extremal property in the case of Chern-Simons action?

Effective 2-dimensionality is achieved if the ends and wormhole throats are extremals of Chern-Simons action. The strongest condition would be that space-time surfaces allow orthogonal slicings by 3-surfaces which are extremals of Chern-Simons action.

Also in this case one can require that the flow parameter associated with the flow lines of the isometry currents extends to a global coordinate. Kähler magnetic field  $B = *J$  defines a conserved current so that all conserved currents would flow along the field lines of  $B$  and one would have 3-D Beltrami flow. Note that in magnetohydrodynamics the standard assumption is that currents flow along the field lines of the magnetic field.

For wormhole throats light-likeness causes some complications since the induced metric is degenerate and the contravariant metric must be restricted to the complement of the light-like direction. This means that d'Alembert equation reduces to 2-dimensional Laplace equation. For space-like 3-surfaces one obtains the counterpart of Laplace equation with partonic 2-surfaces serving as sources. The interpretation in terms of analogs of Coulomb potentials created by 2-D charge distributions would be natural.

## 2.6.6 Hydrodynamic picture in fermionic sector

Super-symmetry inspires the conjecture that the hydrodynamical picture applies also to the solutions of the modified Dirac equation.

### 4-dimensional modified Dirac equation and hydrodynamical picture

Consider first the solutions of of the induced spinor field in the interior of space-time surface.

1. The local inner products of the modes of the induced spinor fields define conserved currents

$$\begin{aligned} D_\alpha J_{mn}^\alpha &= 0 , \\ J_{mn}^\alpha &= \bar{u}_m \hat{\Gamma}^\alpha u_n , \\ \hat{\Gamma}^\alpha &= \frac{\partial L_K}{\partial(\partial_\alpha h^k)} \Gamma_k . \end{aligned} \tag{2.6.28}$$

The conjecture is that the flow parameters of also these currents extend to a global coordinate so that one would have in the completely general case the condition

$$\begin{aligned} J_{mn}^\alpha &= \Phi_{mn} d\Psi_{mn} , \\ d * (d\Phi_{mn}) &= 0 , \quad \nabla \Psi_{mn} \cdot \Phi_{mn} = 0 . \end{aligned} \tag{2.6.29}$$

The condition  $\Phi_{mn} = \Phi$  would mean that the massless modes propagate in parallel manner and along the flow lines of Kähler current. The conservation condition along the flow line implies that the current component  $J_{mn}$  is constant along it. Everything would reduce to initial values at the ends of the space-time sheet boundaries of  $CD$  and 3-D modified Dirac equation would reduce everything to initial values at partonic 2-surfaces.

2. One might hope that the conservation of these super currents for all modes is equivalent with the modified Dirac equation. The modes  $u_n$  appearing in  $\Psi$  in quantized theory would be kind of "square roots" of the basis  $\Phi_{mn}$  and the challenge would be to deduce the modes from the conservation laws.
3. The quantization of the induced spinor field in 4-D sense would be fixed by those at 3-D space-like ends by the fact that the oscillator operators are carried along the flow lines as such so that the anti-commutator of the induced spinor field at the opposite ends of the flow lines at the light-like boundaries of  $CD$  is in principle fixed by the anti-commutations at the either end. The anti-commutations at 3-D surfaces cannot be fixed freely since one has 3-D Chern-Simons flow reducing the anti-commutations to those at partonic 2-surfaces.

The following argument suggests that induced spinor fields are in a suitable gauge simply constant along the flow lines of the Kähler current just as massless spinor modes are constant along the geodesic in the direction of momentum.

1. The modified gamma matrices are of form  $T_k^\alpha \Gamma^k$ ,  $T_k^\alpha = \partial L_K / \partial (\partial_\alpha h^k)$ . The H-vectors  $T_k^\alpha$  can be expressed as linear combinations of a subset of Killing vector fields  $j_A^k$  spanning the tangent space of  $H$ . For  $CP_2$  the natural choice are the 4 Lie-algebra generators in the complement of  $U(2)$  sub-algebra. For  $CD$  one can use generator time translation and three generators of rotation group  $SO(3)$ . The completeness of the basis defined by the subset of Killing vector fields gives completeness relation  $h_l^k = j^{Ak} j_{Al}$ . This implies  $T^{\alpha k} = T^{\alpha k} j_k^A j_A^k = T^{\alpha A} j_A^k$ . One can define gamma matrices  $\Gamma_A$  as  $\Gamma_k j_A^k$  to get  $T_k^\alpha \Gamma^k = T^{\alpha A} \Gamma_A$ .
2. This together with the condition that all isometry currents are proportional to the Kähler current (or if this vanishes to same conserved current- say energy current) satisfying Beltrami flow property implies that one can reduce the modified Dirac equation to an ordinary differential equation along flow lines. The quantities  $T^{tA}$  are constant along the flow lines and one obtains

$$T^{tA} j_A D_t \Psi = 0 . \quad (2.6.30)$$

By choosing the gauge suitably the spinors are just constant along flow lines so that the spinor basis reduces by effective 2-dimensionality to a complete spinor basis at partonic 2-surfaces.

### Generalized eigen modes for the modified Chern-Simons Dirac equation and hydrodynamical picture

Hydrodynamical picture helps to understand also the construction of generalized eigen modes of 3-D Chern-Simons Dirac equation.

*The general form of generalized eigenvalue equation for Chern-Simons Dirac action*

Consider first the the general form and interpretation of the generalized eigenvalue equation assigned with the modified Dirac equation for Chern-Simons action [15] . This is of course only an approximation since an additional contribution to the modified gamma matrices from the Lagrangian multiplier term guaranteeing the weak form of electric-magnetic duality must be included.

1. The modified Dirac equation for  $\Psi$  is consistent with that for its conjugate if the coefficient of the instanton term is real and one uses the Dirac action  $\bar{\Psi}(D^\rightarrow - D^\leftarrow)\Psi$  giving modified Dirac equation as

$$D_{C-S} \Psi + \frac{1}{2} (D_\alpha \hat{\Gamma}_{C-S}^\alpha) \Psi = 0 . \quad (2.6.31)$$

As noticed, the divergence  $D_\alpha \hat{\Gamma}_{C-S}^\alpha$  does not contain second derivatives in the case of Chern-Simons action. In the case of Kähler action they occur unless field equations equivalent with the

vanishing of the divergence term are satisfied. The extremals of Chern-Simons action provide a natural manner to define effective 2-dimensionality.

Also the fermionic current is conserved in this case, which conforms with the idea that fermions flow along the light-like 3-surfaces. If one uses the action  $\bar{\Psi}D^{\rightarrow}\Psi$ ,  $\bar{\Psi}$  does not satisfy the Dirac equation following from the variational principle and fermion current is not conserved.

2. The generalized eigen modes of  $D_{C-S}$  should be such that one obtains the counterpart of Dirac propagator which is purely algebraic and does not therefore depend on the coordinates of the throat. This is satisfied if the generalized eigenvalues are expressible in terms of covariantly constant combinations of gamma matrices and here only  $M^4$  gamma matrices are possible. Therefore the eigenvalue equation would read as

$$D\Psi = \lambda^k \gamma_k \Psi, \quad D = D_{C-S} + \frac{1}{2} D_{\alpha} \hat{\Gamma}_{C-S}^{\alpha}, \quad D_{C-S} = \hat{\Gamma}_{C-S}^{\alpha} D_{\alpha}. \quad (2.6.32)$$

Here the covariant derivatives  $D_{\alpha}$  contain the measurement interaction term as an apparent gauge term. For extremals one has

$$D = D_{C-S}. \quad (2.6.33)$$

Covariant constancy allows to take the square of this equation and one has

$$(D^2 + [D, \lambda^k \gamma_k])\Psi = \lambda^k \lambda_k \Psi. \quad (2.6.34)$$

The commutator term is analogous to magnetic moment interaction.

3. The generalized eigenvalues correspond to  $\lambda = \sqrt{\lambda^k \lambda_k}$  and Dirac determinant is defined as a product of the eigenvalues and conjecture to give the exponent of Kähler action reducing to Chern-Simons term.  $\lambda$  is completely analogous to mass.  $\lambda_k$  cannot be however interpreted as ordinary four-momentum: for instance, number theoretic arguments suggest that  $\lambda_k$  must be restricted to the preferred plane  $M^2 \subset M^4$  interpreted as a commuting hyper-complex plane of complexified quaternions. For incoming lines this mass would vanish so that all incoming particles irrespective their actual quantum numbers would be massless in this sense and the propagator is indeed that for a massless particle. Note that the eigen-modes define the boundary values for the solutions of  $D_K \Psi = 0$  so that the values of  $\lambda$  indeed define the counterpart of the momentum space.

This transmutation of massive particles to effectively massless ones might make possible the application of the twistor formalism as such in TGD framework [82].  $N = 4$  SUSY is one of the very few gauge theory which might be UV finite but it is definitely unphysical due to the masslessness of the basic quanta. Could the resolution of the interpretational problems be that the four-momenta appearing in this theory do not directly correspond to the observed four-momenta?

## 2. Inclusion of the constraint term

As already noticed one must include also the constraint term due to the weak form of electric-magnetic duality and this changes somewhat the above simple picture.

1. At the 3-dimensional ends of the space-time sheet and at wormhole throats the 3-dimensionality allows to introduce a coordinate varying along the flow lines of Kähler magnetic field  $B = *J$ . In this case the integrability conditions state that the flow is Beltrami flow. Note that the value of  $B^\alpha$  along the flow line defining magnetic flux appearing in anti-commutation relations is constant. This suggests that the generalized eigenvalue equation for the Chern-Simons action reduces to a collection of ordinary apparently independent differential equations associated with the flow lines beginning from the partonic 2-surface. This indeed happens when the  $CP_2$  projection is 2-dimensional. In this case it however seems that the basis  $u_n$  is not of much help.
2. The conclusion is wrong: the variations of Chern-Simons action are subject to the constraint that electric-magnetic duality holds true expressible in terms of Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x . \quad (2.6.35)$$

This gives a constraint force to the field equations and also a dependence on the induced 4-metric so that one has only almost topological QFT. This term also guarantees the  $M^4$  part of WCW Kähler metric is non-trivial. The condition that the ends of space-time sheet and wormhole throats are extrema of Chern-Simons action subject to the electric-magnetic duality constraint is strongly suggested by the effective 2-dimensionality. Without the constraint term Chern-Simons action would vanish for its extremals so that Kähler function would be identically zero.

This term implies also an additional contribution to the modified gamma matrices besides the contribution coming from Chern-Simons action so that the first guess for the modified Dirac operator would not be quite correct. This contribution is of exactly of the same general form as the contribution for any general coordinate invariant action. The dependence of the induced metric on  $M^4$  degrees of freedom guarantees that also  $M^4$  gamma matrices are present. In the following this term will not be considered.

3. When the contribution of the constraint term to the modified gamma matrices is neglected, the explicit expression of the modified Dirac operator  $D_{C-S}$  associated with the Chern-Simons term is given by

$$\begin{aligned} D &= \hat{\Gamma}^\mu D_\mu + \frac{1}{2} D_\mu \hat{\Gamma}^\mu , \\ \hat{\Gamma}^\mu &= \frac{\partial L_{C-S}}{\partial_\mu \hbar^k} \Gamma_k = \epsilon^{\mu\alpha\beta} [2J_{kl} \partial_\alpha h^l A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_\mu , \\ D_\mu \hat{\Gamma}^\mu &= B_K^\alpha (J_{k\alpha} + \partial_\alpha A_k) , \\ B_K^\alpha &= \epsilon^{\alpha\beta\gamma} J_{\beta\gamma} , \quad J_{k\alpha} = J_{kl} \partial_\alpha s^l , \quad \hat{\epsilon}^{\alpha\beta\gamma} = \epsilon^{\alpha\beta\gamma} \sqrt{g_3} . \end{aligned} \quad (2.6.36)$$

For the extremals of Chern-Simons action one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ . Analogous condition holds true when the constraining contribution to the modified gamma matrices is added.

### 3. Generalized eigenvalue equation for Chern-Simons Dirac action

Consider now the Chern-Simons Dirac equation in more detail assuming that the inclusion of the constraint contribution to the modified gamma matrices does not induce any complications. Assume also extremal property for Chern-Simons action with constraint term and Beltrami flow property.

1. For the extremals the Chern-Simons Dirac operator (constraint term not included) reduces to a one-dimensional Dirac operator

$$D_{C-S} = \hat{\epsilon}^{r\alpha\beta} [2J_{k\alpha} A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_r . \quad (2.6.37)$$

Constraint term implies only a modification of the modified gamma matrices but the form of the operator remains otherwise same when extrema are in question so that one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ .

2. For the extremals of Chern-Simons action the general solution of the modified Chern-Simons Dirac equation ( $\lambda^k = 0$ ) is covariantly constant with respect to the coordinate  $r$ :

$$D_r \Psi = 0 . \quad (2.6.38)$$

The solution to this condition can be written immediately in terms of a non-integrable phase factor  $P \exp(i \int A_r dr)$ , where integration is along curve with constant transversal coordinates. If  $\hat{\Gamma}^v$  is light-like vector field also  $\hat{\Gamma}^v \Psi_0$  defines a solution of  $D_{C-S}$ . This solution corresponds to a zero mode for  $D_{C-S}$  and does not contribute to the Dirac determinant (suggested to give rise to the exponent of Kähler function identified as Kähler action). Note that the dependence of these solutions on transversal coordinates of  $X_l^3$  is arbitrary which conforms with the hydrodynamic picture. The solutions of Chern-Simons-Dirac are obtained by similar integration procedure also when extremals are not in question.

The formal solution associated with a general eigenvalue  $\lambda$  can be constructed by integrating the eigenvalue equation separately along all coordinate curves. This makes sense if  $r$  indeed assigned to possibly light-like flow lines of  $B^\alpha$  or more general Beltrami field possible induced by the constraint term. There are very strong consistency conditions coming from the conditions that  $\Psi$  in the interior is constant along the flow lines of Kähler current and continuous at the ends and throats (call them collectively boundaries), where  $\Psi$  has a non-trivial variation along the flow lines of  $B^\alpha$ .

1. This makes sense only if the flow lines of the Kähler current are transversal to the boundaries so that the spinor modes at boundaries dictate the modes of the spinor field in the interior. Effective 2-dimensionality means that the spinor modes in the interior can be calculated either by starting from the throats or from the ends so that the data at either upper or lower partonic 2-surfaces dictates everything in accordance with zero energy ontology.
2. This gives an infinite number of commuting diagrams stating that the flow-line time evolution along flow lines along wormhole throats from lower partonic 2-surface to the upper one is equivalent with the flow-line time evolution along the lower end of space-time surface to interior, then along interior to the upper end of the space-time surface and then back to the upper partonic 2-surface. If the space-time surface allows a slicing by partonic 2-surfaces these conditions can be assumed for any pair of partonic 2-surfaces connected by Chern-Simons flow evolution.
3. Since the time evolution along interior keeps the spinor field as constant in the proper gauge and since the flow evolutions at the lower and upper ends are in a reverse direction, there is a strong attemptation to assume that the spinor field at the ends of the of the flow lines of Kähler magnetic field are identical apart from a gauge transformation. This leads to a particle-in-box quantization of the values of the pseudo-mass (periodic boundary conditions). These conditions will be assumed in the sequel.

These assumptions lead to the following picture about the generalized eigen modes.

1. By choosing the gauge so that covariant derivative reduces to ordinary derivative and using the constancy of  $\hat{\Gamma}^r$ , the solution of the generalized eigenvalue equation can be written as

$$\begin{aligned} \Psi &= \exp(iL(r)\hat{\Gamma}^r \lambda^k \Gamma_k) \Psi_0 , \\ L(r) &= \int_0^r \frac{1}{\sqrt{\hat{g}^{rr}}} dr . \end{aligned} \quad (2.6.39)$$

$L(r)$  can be regarded as the along flux line as defined by the effective metric defined by modified gamma matrices. If  $\lambda_k$  is linear combination of  $\Gamma^0$  and  $\Gamma^{r_M}$  it anti-commutes with  $\Gamma^r$  which contains only  $CP_2$  gamma matrices so that the pseudo-momentum is a priori arbitrary.

2. When the constraint term taking care of the electric-magnetic duality is included, also  $M^4$  gamma matrices are present. If they are in the orthogonal complement of a preferred plane  $M^2 \subset M^4$ , anti-commutativity is achieved. This assumption cannot be fully justified yet but conforms with the general physical vision. There is an obvious analogy with the condition that polarizations are in a plane orthogonal to  $M^2$ . The condition indeed states that only transversal deformations define quantum fluctuating WCW degrees of freedom contributing to the WCW Kähler metric. In  $M^8-H$  duality the preferred plane  $M^2$  is interpreted as a hyper-complex plane belonging to the tangent space of the space-time surface and defines the plane of non-physical polarizations. Also a generalization of this plane to an integrable distribution of planes  $M^2(x)$  has been proposed and one must consider also now the possibility of a varying plane  $M^2(x)$  for the pseudo-momenta. The scalar function  $\Phi$  appearing in the general solution ansatz for the field equations satisfies massless d'Alembert equation and its gradient defines a local light-like direction at space-time-level and hence a 2-D plane of the tangent space. Maybe the projection of this plane to  $M^4$  could define the preferred  $M^2$ . The minimum condition is that these planes are defined only at the ends of space-time surface and at wormhole throats.
3. If one accepts this hypothesis, one can write

$$\begin{aligned}\Psi &= \left[ \cos(L(r)\lambda) + i \sin(\lambda(r)) \hat{\Gamma}^r \lambda^k \Gamma_k \right] \Psi_0, \\ \lambda &= \sqrt{\lambda_k \lambda^k}.\end{aligned}\tag{2.6.40}$$

4. Boundary conditions should fix the spectrum of masses. If the the flow lines of Kähler current coincide with the flow lines of Kähler magnetic field or more general Beltrami current at wormhole throats one ends up with difficulties since the induced spinor fields must be constant along flow lines and only trivial eigenvalues are possible. Hence it seems that the two Beltrami fields must be transversal. This requires that at the partonic 2-surfaces the value of the induced spinor mode in the interior coincides with its value at the throat. Since the induced spinor fields in interior are constant along flow lines, one must have

$$\exp(i\lambda L_{(max)}) = 1.\tag{2.6.41}$$

This implies that one has essentially particle in a box with size defined by the effective metric

$$\lambda_n = \frac{n2\pi}{L(r_{max})}.\tag{2.6.42}$$

5. This condition cannot however hold true simultaneously for all points of the partonic 2-surfaces since  $L(r_{max})$  depends on the point of the surface. In the most general case one can consider only a subset consisting of the points for which the values of  $L(r_{max})$  are rational multiples of the value of  $L(r_{max})$  at one of the points -call it  $L_0$ . This implies the notion of number theoretical braid. Induced spinor fields are localized to the points of the braid defined by the flow lines of the Kähler magnetic field (or equivalently, any conserved current- this resolves the longstanding issue about the identification of number theoretical braids). The number of the included points depends on measurement resolution characterized somehow by the number rationals which are allowed. Only finite number of harmonics and sub-harmonics of  $L_0$  are possible so that for integer multiples the number of points is finite. If  $n_{max}L_0$  and  $L_0/n_{min}$  are the largest and smallest lengths involved, one can argue that the rationals  $n_{max}/n$ ,  $n = 1, \dots, n_{max}$  and  $n/n_{min}$ ,  $n = 1, \dots, n_{min}$  are the natural ones.

6. One can consider also algebraic extensions for which  $L_0$  is scaled from its reference value by an algebraic number so that the mass scale  $m$  must be scaled up in similar manner. The spectrum comes also now in integer multiples. p-Adic mass calculations predicts mass scales to the inverses of square roots of prime and this raises the expectation that  $\sqrt{n}$  harmonics and sub-harmonics of  $L_0$  might be necessary. Notice however that pseudo-momentum spectrum is in question so that this argument is on shaky grounds.

There is also the question about the allowed values of  $(\lambda_0, \lambda_3)$  for a given value of  $\lambda$ . This issue will be discussed in the next section devoted to the attempt to calculate the Dirac determinant assignable to this spectrum: suffice it to say that integer valued spectrum is the first guess implying that the pseudo-momenta satisfy  $n_0^2 - n_3^2 = n^2$  and therefore correspond to Pythagorean triangles. What is remarkable that the notion of number theoretic braid pops up automatically from the Beltrami flow hypothesis.

### 2.6.7 Possible role of Beltrami flows and symplectic invariance in the description of gauge and gravitational interactions

One of the most recent observations made by people working with twisters is the finding of Monteiro and O'Connell described in the preprint The Kinematic Algebra From the Self-Dual Sector [63]. The claim is that one can obtain supergravity amplitudes by replacing the color factors with kinematic factors which obey formally 2-D symplectic algebra defined by the plane defined by light-like momentum direction and complexified variable in the plane defined by polarizations. One could say that momentum and polarization dependent kinematic factors are in exactly the same role as the factors coming from Yang-Mills couplings. Unfortunately, the symplectic algebra looks rather formal object since the first coordinate is light-like coordinate and second coordinate complex transverse coordinate. It could make sense only in the complexification of Minkowski space.

In any case, this would suggest that the gravitational gauge group (to be distinguished from diffeomorphisms) is symplectic group of some kind having enormous representative power as we know from the fact that the symmetries of practically any physical system are realized in terms of symplectic transformations. According to the authors of [63] one can identify the Lie algebra of symplectic group of sphere with that of  $SU(N)$  at large  $N$  limit in suitable basis. What makes this interesting is that at large  $N$  limit non-planar diagrams which are the problem of twistor Grassmann approach vanish: this is old result of t'Hooft, which initiated the developments leading to AdS/CFT correspondence.

The symplectic group of  $\delta M_{\pm}^4 \times CP_2$  is the isometry algebra of WCW and I have proposed that the effective replacement of gauge group with this group implies the vanishing of non-planar diagrams [84]. The extension of SYM to a theory of also gravitation in TGD framework could make Yangian symmetry exact, resolve the infrared divergences, and the problems caused by non-planar diagrams. It would also imply stringy picture in finite measurement resolution. Also the construction of the non-commutative homology and cohomology in TGD framework led to the lifting of Galois group algebras to their braided variants realized as symplectic flows [85] and to the conjecture that in finite measurement resolution the cohomology obtained in this manner represents WCW ("world of classical worlds") spinor fields (or at least something very essential about them).

It is however difficult to understand how one could generalize the symplectic structure so that also symplectic transformations involving light-like coordinate and complex coordinate of the partonic 2-surface would make sense in some sense. In fact, a more natural interpretation for the kinematic algebra would in terms of volume preserving flows which are also Beltrami flows [48, 55]. This gives a connection with quantum TGD since Beltrami flows define a basic dynamical symmetry for the preferred extremals of Kähler action which might be called Maxwellian phase.

1. Classical TGD is defined by Kähler action which is the analog of Maxwell action with Maxwell field expressed as the projection of  $CP_2$  Kähler form. The field equations are extremely non-linear and only the second topological half of Maxwell equations is satisfied. The remaining equations state conservation laws for various isometry currents. Actually much more general conservation laws are obtained.
2. As a special case one obtains solutions analogous to those for Maxwell equations but there are also other objects such as  $CP_2$  type vacuum extremals providing correlates for elementary particles and string like objects: for these solutions it does not make sense to speak about QFT

in Minkowski space-time. For the Maxwell like solutions linear superposition is lost but a superposition holds true for solutions with the same local direction of polarization and massless four-momentum. This is a very quantal outcome (in accordance with quantum classical correspondence) since also in quantum measurement one obtains final state with fixed polarization and momentum. So called massless extremals (topological light rays) analogous to wave guides containing laser beam and its phase conjugate are solutions of this kind. The solutions are very interesting since no dispersion occurs so that wave packet preserves its form and the radiation is precisely targeted.

3. Maxwellian preferred extremals decompose in Minkowskian space-time regions to regions that can be regarded as classical space-time correlates for massless particles. Massless particles are characterized by polarization direction and light-like momentum direction. Now these directions can depend on position and are characterized by gradients of two scalar functions  $\Phi$  and  $\Psi$ .  $\Phi$  defines light-like momentum direction and the square of the gradient of  $\Phi$  in Minkowski metric must vanish.  $\Psi$  defines polarization direction and its gradient is orthogonal to the gradient of  $\Phi$  since polarization is orthogonal to momentum.
4. The flow has the additional property that the coordinate associated with the flow lines integrates to a global coordinate. Beltrami flow is the term used by mathematicians. Beltrami property means that the condition  $j \wedge dj = 0$  is satisfied. In other words, the current is in the plane defined by its exterior derivative. The above representation obviously guarantees this. Beltrami property allows to assign order parameter to the flow depending only the parameter varying along flow line.

This is essential for the hydrodynamical interpretation of the preferred extremals which relies on the idea that various conservation laws hold along flow lines. For instance, super-conducting phase requires this kind of flow and velocity along flow line is gradient of the order parameter. The breakdown of super-conductivity would mean topologically the loss of the Beltrami flow property. One might say that the space-time sheets in TGD Universe represent analogs of supra flow and this property is spoiled only by the finite size of the sheets. This strongly suggests that the space-time sheets correspond to perfect fluid flows with very low viscosity to entropy ratio and one application is to the observed perfect flow behavior of quark gluon plasma.

5. The current  $J = \Phi \nabla \Psi$  has vanishing divergence if besides the orthogonality of the gradients the functions  $\Psi$  and  $\Phi$  satisfy massless d'Alembert equation. This is natural for massless field modes and when these functions represent constant wave vector and polarization also d'Alembert equations are satisfied. One can actually add to  $\nabla \Psi$  a gradient of an arbitrary function of  $\Phi$  this corresponds to  $U(1)$  gauge invariance and the addition to the polarization vector a vector parallel to light-like four-momentum. One can replace  $\Phi$  by any function of  $\Phi$  so that one has Abelian Lie algebra analogous to  $U(1)$  gauge algebra restricted to functions depending on  $\Phi$  only.

The general Beltrami flow gives as a special case the kinetic flow associated by Monteiro and O'Connell with plane waves. For ordinary plane wave with constant direction of momentum vector and polarization vector one could take  $\Phi = \cos(\phi)$ ,  $\phi = k \cdot m$  and  $\Psi = \epsilon \cdot m$ . This would give a real flow. The kinematical factor in SYM diagrams corresponds to a complexified flow  $\Phi = \exp(i\phi)$  and  $\Psi = \phi + w$ , where  $w$  is complex coordinate for polarization plane or more naturally, complexification of the coordinate in polarization direction. The flow is not unique since gauge invariance allows to modify  $\phi$  term. The complexified flow is volume preserving only in the formal algebraic sense and satisfies the analog of Beltrami condition only in Dolbeault cohomology where  $d$  is identified as complex exterior derivative ( $df = df/dz dz$  for holomorphic functions). In ordinary cohomology it fails. This formal complex flow of course does not define a real diffeomorphism at space-time level: one should replace Minkowski space with its complexification to get a genuine flow.

The finding of Monteiro and O'Connell encourages to think that the proposed more general Abelian algebra pops up also in non-Abelian YM theories. Discretization by braids would actually select single polarization and momentum direction. If the volume preserving Beltrami flows characterize the basic building bricks of radiation solutions of both general relativity and YM theories, it would not be surprising if the kinematic Lie algebra generators would appear in the vertices of YM theory and replace color factors in the transition from YM theory to general relativity. In TGD framework the

construction of vertices at partonic two-surfaces would define local kinematic factors as effectively constant ones.

## 2.7 How to define Dirac determinant?

The basic challenge is to define Dirac determinant hoped to give rise to the exponent of Kähler action associated with the preferred extremal. The reduction to almost topological QFT gives this kind of expression in terms of Chern-Simons action and one might hope of obtaining even more concrete expression from the Chern-Simons Dirac determinant. The calculation of the previous section allowed to calculate the most general spectrum of the modified Dirac operator. If the number of the eigenvalues is infinite as the naive expectation is then Dirac determinant diverges if calculated as the product of the eigenvalues and one must calculate it by using some kind of regularization procedure. Zeta function regularization is the natural manner to do this.

The following arguments however lead to a concrete vision how the regularization could be avoided and a connection with infinite primes. In fact, the manifestly finite option and the option involving zeta function regularization give Kähler functions differing only by a scaling factor and only the manifestly finite option satisfies number theoretical constraints coming from p-adicization. An explicit expression for the Dirac determinant in terms of geometric data of the orbit of the partonic 2-surface emerges.

Arithmetic quantum field theory defined by infinite primes emerges naturally. The lines of the generalized Feynman graphs are characterized by infinite primes and the selection rules correlating the geometries of the lines of the generalized Feynman graphs corresponds to the conservation of the sum of number theoretic momenta  $\log(p_i)$  assignable to sub-braids corresponding to different primes  $p_i$  assignable to the orbit of parton. This conforms with the vision that infinite primes indeed characterize the geometry of light-like 3-surfaces and therefore also of space-time sheets. The eigenvalues of the modified Dirac operator are proportional  $1/\sqrt{p_i}$  where  $p_i$  are the primes appearing in the definition of the p-adic prime and the interpretation as analogs of Higgs vacuum expectation values makes sense and is consistent with p-adic length scale hypothesis and p-adic mass calculations. It must be emphasized that all this is essentially due to single basic hypothesis, namely the reduction of quantum TGD to almost topological QFT guaranteed by the Beltrami ansatz for field equations and by the weak form of electric-magnetic duality.

### 2.7.1 Dirac determinant when the number of eigenvalues is infinite

At first sight the general spectrum looks the only reasonable possibility but if the eigenvalues correlate with the geometry of the partonic surface as quantum classical correspondence suggests, this conclusion might be wrong. The original hope was the number of eigenvalues would be finite so that also determinant would be finite automatically. There were some justifications for this hope in the definition of Dirac determinant based on the dimensional reduction of  $D_K$  as  $D_K = D_{K,3} + D_1$  and the identification of the generalized eigenvalues as those assigned to  $D_{K,3}$  as analogs of energy eigenvalues assignable to the light-like 3-surface. It will be found that number theoretic input could allow to achieve a manifest finiteness in the case of  $D_{C-S}$  and that this option is the only possible one if number theoretic universality is required.

If there are no constraints on the eigenvalue spectrum of  $D_{C-S}$  for a given partonic orbit, the naive definition of the determinant gives an infinite result and one must define Dirac determinant using  $\zeta$  function regularization implying that Kähler function reduces to the derivative of the zeta function  $\zeta_D(s)$  -call it Dirac Zeta- associated with the eigenvalue spectrum.

Consider now the situation when the number of eigenvalues is infinite.

1. In this kind of situation zeta function regularization is the standard manner to define the Dirac determinant. What one does is to assign zeta function to the spectrum- let us call it Dirac zeta function and denote by  $\zeta_D(s)$ - as

$$\zeta_D(s) = \sum_k \lambda_k^{-s} . \quad (2.7.1)$$

If the eigenvalue  $\lambda_k$  has degeneracy  $g_k$  it appears  $g_k$  times in the sum. In the case of harmonic oscillator one obtains Riemann zeta for which sum representation converges only for  $Re(s) \geq 1$ . Riemann zeta can be however analytically continued to the entire complex plane and the idea is that this can be done also in the more general case.

2. By the basic conjecture Kähler function corresponds to the logarithm of the Dirac determinant and equals to the sum of the logarithms of the eigenvalues

$$K = \log\left(\prod \lambda_k\right) = -\frac{d\zeta_D}{ds} \Big|_{s=0} . \quad (2.7.2)$$

The expression on the left hand side diverges if taken as such but the expression on the right had side based on the analytical continuation of the zeta function is completely well-defined and finite quantity. Note that the replacement of eigenvalues  $\lambda_k$  by their powers  $\lambda_k^n$  -or equivalently the increase of the degeneracy by a factor  $n$  - brings in only a factor  $n$  to  $K$ :  $K \rightarrow nK$ .

3. Dirac determinant involves in the minimal situation only the integer multiples of pseudo-mass scale  $\lambda = 2\pi/L_{min}$ . One can consider also rational and even algebraic multiples  $qL_{min} < L_{max}$ ,  $q \geq 1$ , of  $L_{min}$  so that one would have several integer spectra simultaneously corresponding to different braids. Here  $L_{min}$  and  $L_{max}$  are the extrema of the braid strand length determined in terms of the effective metric as  $L = \int (\hat{g}^{rr})^{-1/2} dr$ . The question what multiples are involved will be needed later.
4. Each rational or algebraic multiple of  $L_{min}$  gives to the zeta function a contribution which is of same form so that one has

$$\zeta_D = \sum_q \zeta(\log(qx)s) , \quad x = \frac{L_{min}}{R} , \quad 1 \leq q < \frac{L_{max}}{L_{min}} . \quad (2.7.3)$$

Kähler function can be expressed as

$$K = \sum_n \log(\lambda_n) = -\frac{d\zeta_D(s)}{ds} = -\sum_q \log(qx) \frac{d\zeta(s)}{ds} \Big|_{s=0} , \quad x = \frac{L_{min}}{R} . \quad (2.7.4)$$

What is remarkable that the number theoretical details of  $\zeta_D$  determine only the overall scaling factor of Kähler function and thus the value of Kähler coupling strength, which would be purely number theoretically determined if the hypothesis about the role of infinite primes is correct. Also the value of  $R$  is irrelevant since it does not affect the Kähler metric.

5. The dependence of Kähler function on WCW degrees of freedom would be coded completely by the dependence of the length scales  $qL_{min}$  on the complex coordinates of WCW: note that this dependence is different for each scale. This is reminiscent of the coding of the shape of the drum (or more generally - manifold) by the spectrum of its eigen frequencies. Now Kähler geometry would code for the dependence of the spectrum on the shape of the drum defined by the partonic 2-surface and the 4-D tangent space distribution associated with it.

What happens at the limit of vacuum extremals serves as a test for the identification of Kähler function as Dirac determinant. The weak form of electric magnetic duality implies that all components of the induced Kähler field vanish simultaneously if Kähler magnetic field cancels. In the modified Chern-Simons Dirac equation one obtains  $L = \int (\hat{g}^{rr})^{-1/2} dr$ . The modified gamma matrix  $\hat{\Gamma}^r$  approaches a finite limit when Kähler magnetic field vanishes

$$\hat{\Gamma}^r = \epsilon^{r\beta\gamma} (2J_{\beta k} A_\gamma + J_{\beta\gamma} A_k) \Gamma^k \rightarrow 2\epsilon^{r\beta\gamma} J_{\beta k} \Gamma^k . \quad (2.7.5)$$

The relevant component of the effective metric is  $\hat{g}^{rr}$  and is given by

$$\hat{g}^{rr} = (\hat{\Gamma}^r)^2 = 4\epsilon^{r\beta\gamma}\epsilon^{r\mu\nu}J_{\beta k}J_{\mu}{}^k A_{\gamma}A_{\nu} . \quad (2.7.6)$$

The limit is non-vanishing in general and therefore the eigenvalues remain finite also at this limit as also the parameter  $L_{min} = \int (\hat{g}^{rr})^{-1/2} dr$  defining the minimum of the length of the braid strand defined by Kähler magnetic flux line in the effective metric unless  $\hat{g}^{rr}$  goes to zero everywhere inside the partonic surface. Chern-Simons action and Kähler action vanish for vacuum extremals so that in this case one could require that Dirac determinant approaches to unity in a properly chosen gauge. Dirac determinant should approach to unit for vacuum extremals indeed approaches to unity since there are no finite eigenvalues at the limit  $\hat{g}^{rr} = 0$ .

### 2.7.2 Hyper-octonionic primes

Before detailed discussion of the hyper-octonionic option it is good to consider the basic properties of hyper-octonionic primes.

1. Hyper-octonionic primes are of form

$$\Pi_p = (n_0, n_3, n_1, n_2, \dots, n_7) , \quad \Pi_p^2 = n_0^2 - \sum_i n_i^2 = p \text{ or } p^2 . \quad (2.7.7)$$

2. Hyper-octonionic primes have a standard representation as hyper-complex primes. The Minkowski norm squared factorizes into a product as

$$n_0^2 - n_3^2 = (n_0 + n_3)(n_0 - n_3) . \quad (2.7.8)$$

If one has  $n_3 \neq 0$ , the prime property implies  $n_0 - n_3 = 1$  so that one obtains  $n_0 = n_3 + 1$  and  $2n_3 + 1 = p$  giving

$$(n_0, n_3) = ((p+1)/2, (p-1)/2) . \quad (2.7.9)$$

Note that one has  $(p+1)/2$  odd for  $p \bmod 4 = 1$  and  $(p+1)/2$  even for  $p \bmod 4 = 3$ . The difference  $n_0 - n_3 = 1$  characterizes prime property.

If  $n_3$  vanishes the prime property implies equivalence with ordinary prime and one has  $n_0^2 = p^2$ . These hyper-octonionic primes represent particles at rest.

3. The action of a discrete subgroup  $G(p)$  of the octonionic automorphism group  $G_2$  generates form hyper-complex primes with  $n_3 \neq 0$  further hyper-octonionic primes  $\Pi(p, k)$  corresponding to the same value of  $n_0$  and  $p$  and for these the integer valued projection to  $M^2$  satisfies  $n_0^2 - n_3^2 = n > p$ . It is also possible to have a state representing the system at rest with  $(n_0, n_3) = ((p+1)/2, 0)$  so that the pseudo-mass varies in the range  $[\sqrt{p}, (p+1)/2]$ . The subgroup  $G(n_0, n_3) \subset SU(3)$  leaving invariant the projection  $(n_0, n_3)$  generates the hyper-octonionic primes corresponding to the same value of mass for hyper-octonionic primes with same Minkowskian length  $p$  and pseudo-mass  $\lambda = n \geq \sqrt{p}$ .
4. One obtains two kinds of primes corresponding to the lengths of pseudo-momenta equal to  $p$  or  $\sqrt{p}$ . The first kind of particles are always at rest whereas the second kind of particles can be brought at rest only if one interprets the pseudo-momentum as  $M^2$  projection. This brings in mind the secondary p-adic length scales assigned to causal diamonds (CDs) and the primary p-adic lengths scales assigned to particles.

If the  $M^2$  projections of hyper-octonionic primes with length  $\sqrt{p}$  characterize the allowed basic momenta,  $\zeta_D$  is sum of zeta functions associated with various projections which must be in the limits dictated by the geometry of the orbit of the partonic surface giving upper and lower bounds  $L_{max}$  and  $L_{min}$  on the length  $L$ .  $L_{min}$  is scaled up to  $\sqrt{n_0^2 - n_3^2} L_{min}$  for a given projection  $(n_0, n_3)$ . In general a given  $M^2$  projection  $(n_0, n_3)$  corresponds to several hyper-octonionic primes since  $SU(3)$  rotations give a new hyper-octonionic prime with the same  $M^2$  projection. This leads to an inconsistency unless one has a good explanation for why some basic momentum can appear several times. One might argue that the spinor mode is degenerate due to the possibility to perform discrete color rotations of the state. For hyper complex representatives there is no such problem and it seems favored. In any case, one can look how the degeneracy factors for given projection can be calculated.

1. To calculate the degeneracy factor  $D(n)$  associated with given pseudo-mass value  $\lambda = n$  one must find all hyper-octonionic primes  $\Pi$ , which can have projection in  $M^2$  with length  $n$  and sum up the degeneracy factors  $D(n, p)$  associated with them:

$$\begin{aligned} D(n) &= \sum_p D(n, p) , \\ D(n, p) &= \sum_{n_0^2 - n_3^2 = p} D(p, n_0, n_3) , \\ n_0^2 - n_3^2 &= n , \quad \Pi_p^2(n_0, n_3) = n_0^2 - n_3^2 - \sum_i n_i^2 = n - \sum_i n_i^2 = p . \end{aligned} \quad (2.7.10)$$

2. The condition  $n_0^2 - n_3^2 = n$  allows only Pythagorean triangles and one must find the discrete subgroup  $G(n_0, n_3) \subset SU(3)$  producing hyper-octonions with integer valued components with length  $p$  and components  $(n_0, n_3)$ . The points at the orbit satisfy the condition

$$\sum n_i^2 = p - n . \quad (2.7.11)$$

The degeneracy factor  $D(p, n_0, n_3)$  associated with given mass value  $n$  is the number of elements of in the coset space  $G(n_0, n_3, p)/H(n_0, n_3, p)$ , where  $H(n_0, n_3, p)$  is the isotropy group of given hyper-octonionic prime obtained in this manner. For  $n_0^2 - n_3^2 = p^2$   $D(n_0, n_3, p)$  obviously equals to unity.

### 2.7.3 Three basic options for the pseudo-momentum spectrum

The calculation of the scaling factor of the Kähler function requires the knowledge of the degeneracies of the mass squared eigen values. There are three options to consider.

#### First option: all pseudo-momenta are allowed

If the degeneracy for pseudo-momenta in  $M^2$  is same for all mass values- and formally characterizable by a number  $N$  telling how many 2-D pseudo-momenta reside on mass shell  $n_0^2 - n_3^2 = m^2$ . In this case zeta function would be proportional to a sum of Riemann Zetas with scaled arguments corresponding to scalings of the basic mass  $m$  to  $m/q$ .

$$\zeta_D(s) = N \sum_q \zeta(\log(qx)s) , \quad x = \frac{L_{min}}{R} . \quad (2.7.12)$$

This option provides no idea about the possible values of  $1 \leq q \leq L_{max}/L_{min}$ . The number  $N$  is given by the integral of relativistic density of states  $\int dk/2\sqrt{k^2 + m^2}$  over the hyperbola and is logarithmically divergent so that the normalization factor  $N$  of the Kähler function would be infinite.

### Second option: All integer valued pseudomomenta are allowed

Second option is inspired by number theoretic vision and assumes integer valued components for the momenta using  $m_{max} = 2\pi/L_{min}$  as mass unit. p-Adicization motivates also the assumption that momentum components using  $m_{max}$  as mass scale are integers. This would restrict the choice of the number theoretical braids.

Integer valuedness together with masses coming as integer multiples of  $m_{max}$  implies  $(\lambda_0, \lambda_3) = (n_0, n_3)$  with on mass shell condition  $n_0^2 - n_3^2 = n^2$ . Note that the condition is invariant under scaling. These integers correspond to Pythagorean triangles plus the degenerate situation with  $n_3 = 0$ . There exists a finite number of pairs  $(n_0, n_3)$  satisfying this condition as one finds by expressing  $n_0$  as  $n_0 = n_3 + k$  giving  $2n_3k + k^2 = p^2$  giving  $n_3 < n^2/2, n_0 < n^2/2 + 1$ . This would be enough to have a finite degeneracy  $D(n) \geq 1$  for a given value of mass squared and  $\zeta_D$  would be well defined.  $\zeta_D$  would be a modification of Riemann zeta given by

$$\begin{aligned}\zeta_D &= \sum_q \zeta_1(\log(qx)s) , \quad x = \frac{L_{min}}{R} , \\ \zeta_1(s) &= \sum g_n n^{-s} , \quad g_n \geq 1 .\end{aligned}\tag{2.7.13}$$

For generalized Feynman diagrams this option allows conservation of pseudo-momentum and for loops no divergences are possible since the integral over two-dimensional virtual momenta is replaced with a sum over discrete mass shells containing only a finite number of points. This option looks thus attractive but requires a regularization. On the other hand, the appearance of a zeta function having a strong resemblance with Riemann zeta could explain the finding that Riemann zeta is closely related to the description of critical systems. This point will be discussed later.

### Third option: Infinite primes code for the allowed mass scales

According to the proposal of [70] , [8] the hyper-complex parts of hyper-octonionic primes appearing in their infinite counterparts correspond to the  $M^2$  projections of real four-momenta. This hypothesis suggests a very detailed map between infinite primes and standard model quantum numbers and predicts a universal mass spectrum [70] . Since pseudo-momenta are automatically restricted to the plane  $M^2$ , one cannot avoid the question whether they could actually correspond to the hyper-octonionic primes defining the infinite prime. These interpretations need not of course exclude each other. This option allows several variants and at this stage it is not possible to exclude any of these options.

1. One must choose between two alternatives for which pseudo-momentum corresponds to hyper-complex prime serving as a canonical representative of a hyper-octonionic prime or a projection of hyper-octonionic prime to  $M^2$ .
2. One must decide whether one allows a) only the momenta corresponding to hyper-complex primes, b) also their powers (p-adic fractality), or c) all their integer multiples ("Riemann option").

One must also decide what hyper-octonionic primes are allowed.

1. The first guess is that all hyper-complex/hyper-octonionic primes defining length scale  $\sqrt{p}L_{min} \leq L_{max}$  or  $pL_{min} \leq L_{max}$  are allowed. p-Adic fractality suggests that also the higher p-adic length scales  $p^{n/2}L_{min} < L_{max}$  and  $p^n L_{min} < L_{max}$ ,  $n \geq 1$ , are possible.

It can however happen that no primes are allowed by this criterion. This would mean vanishing Kähler function which is of course also possible since Kähler action can vanish (for instance, for massless extremals). It seems therefore safer to allow also the scale corresponding to the trivial prime  $(n_0, n_3) = (1, 0)$  (1 is formally prime because it is not divisible by any prime different from 1) so that at least  $L_{min}$  is possible. This option also allows only rather small primes unless the partonic 2-surface contains vacuum regions in which case  $L_{max}$  is infinite: in this case all primes would be allowed and the exponent of Kähler function would vanish.

2. The hypothesis that only the hyper-complex or hyper-octonionic primes appearing in the infinite hyper-octonionic prime are possible looks more reasonable since large values of  $p$  would be possible and could be identified in terms of the p-adic length scale hypothesis. All hyper-octonionic primes appearing in infinite prime would be possible and the geometry of the orbit of the partonic 2-surface would define an infinite prime. This would also give a concrete physical interpretation for the earlier hypothesis that hyper-octonionic primes appearing in the infinite prime characterize partonic 2-surfaces geometrically. One can also identify the fermionic and purely bosonic primes appearing in the infinite prime as braid strands carrying fermion number and purely bosonic quantum numbers. This option will be assumed in the following.

### 2.7.4 Expression for the Dirac determinant for various options

The expressions for the Dirac determinant for various options can be deduced in a straightforward manner. Numerically Riemann option and manifestly finite option do not differ much but their number theoretic properties are totally different.

#### Riemann option

All integer multiples of these basic pseudo-momenta would be allowed for Riemann option so that  $\zeta_D$  would be sum of Riemann zetas with arguments scaled by the basic pseudo-masses coming as inverses of the basic length scales for braid strands. For the option involving only hyper-complex primes the formula for  $\zeta_D$  reads as

$$\zeta_D = \zeta(\log(x_{min}s)) + \sum_{i,n} \zeta(\log(x_{i,n}s)) + \sum_{i,n} \zeta(\log(y_{i,n}s)) ,$$

$$x_{i,n} = p_i^{n/2} x_{min} \leq x_{max} , \quad p_i \geq 3 , \quad y_{i,n} = p_i^n x_{min} \leq x_{max} \cdot p_i \geq 2 ,$$
(2.7.14)

$L_{max}$  resp.  $L_{min}$  is the maximal resp. minimal length  $L = \int (\hat{g}^{rr})^{-1/2} dr$  for the braid strand defined by the flux line of the Kähler magnetic field in the effective metric. The contributions correspond to the effective hyper-complex prime  $p_1 = (1, 0)$  and hyper-complex primes with Minkowski lengths  $\sqrt{p}$  ( $p \geq 3$ ) and  $p, p \geq 2$ . If also higher p-adic length scales  $L_n = p^{n/2} L_{min} < L_{max}$  and  $L_n = p^n L_{min} < L_{max}$ ,  $n > 1$ , are allowed there is no further restriction on the summation. For the restricted option only  $L_n$ ,  $n = 0, 2$  is allowed.

The expressions for the Kähler function and its exponent reads as

$$K = k(\log(x_{min}) + \sum_i \log(x_i) + \sum_i \log(y_i)) ,$$

$$exp(K) = \left(\frac{1}{x_{min}}\right)^k \times \prod_i \left(\frac{1}{x_i}\right)^k \times \prod_i \left(\frac{1}{y_i}\right)^k ,$$

$$x_i \leq x_{max} , \quad y_i \leq x_{max} , \quad k = -\frac{d\zeta(s)}{ds} \Big|_{s=0} = \frac{1}{2} \log(2\pi) \simeq .9184 .$$
(2.7.15)

From the point of view of p-adicization program the appearance of strongly transcendental numbers in the normalization factor of  $\zeta_D$  is not a well-come property.

If the scaling of the WCW Kähler metric by  $1/k$  is a legitimate procedure it would allow to get rid of the transcendental scaling factor  $k$  and this scaling would cancel also the transcendental from the exponent of Kähler function. The scaling is not however consistent with the view that Kähler coupling strength determines the normalization of the WCW metric.

This formula generalizes in a rather obvious manner to the cases when one allows  $M^2$  projections of hyper-octonionic primes.

### Manifestly finite options

The options for which one does not allow summation over all integer multiples of the basic momenta characterized by the canonical representatives of hyper-complex primes or their projections to  $M^2$  are manifestly finite. They differ from the Riemann option only in that the normalization factor  $k \simeq .9184$  defined by the derivative Riemann Zeta at origin is replaced with  $k = 1$ . This would mean manifest finiteness of  $\zeta_D$ . Kähler function and its exponent are given by

$$\begin{aligned} K &= k(\log(x_{min}) + \sum_i \log(x_i) + \sum_i \log(y_i)) , \quad x_i \leq x_{max} , \quad y_i \leq x_{max} , \\ exp(K) &= \frac{1}{x_{min}} \times \prod_i \frac{1}{x_i} \times \prod_i \frac{1}{y_i} . \end{aligned} \tag{2.7.16}$$

Numerically the Kähler functions do not differ much since their ratio is .9184. Number theoretically these functions are however completely different. The resulting dependence involves only square roots of primes and is an algebraic function of the lengths  $p_i$  and rational function of  $x_{min}$ . p-Adicization program would require rational values of the lengths  $x_{min}$  in the intersection of the real and p-adic worlds if one allows algebraic extension containing the square roots of the primes involved. Note that in p-adic context this algebraic extension involves two additional square roots for  $p > 2$  if one does not want square root of  $p$ . Whether one should allow for  $R_p$  also extension based on  $\sqrt{p}$  is not quite clear. This would give 8-D extension.

For the more general option allowing all projections of hyper-complex primes to  $M^2$  the general form of Kähler function is same. Instead of pseudo-masses coming as primes and their square roots one has pseudomasses coming as square roots of some integers  $n \leq p$  or  $n \leq p^2$  for each  $p$ . In this case the conservation laws are not so strong.

Note that in the case of vacuum extremals  $x_{min} = \infty$  holds true so that there are no primes satisfying the condition and Kähler function vanishes as it indeed should.

### More concrete picture about the option based on infinite primes

The identification of pseudo-momenta in terms of infinite primes suggests a rather concrete connection between number theory and physics.

1. One could assign the finite hyper-octonionic primes  $\Pi_i$  making the infinite prime to the sub-braids identified as Kähler magnetic flux lines with the same length  $L$  in the effective metric. The primes assigned to the finite part of the infinite prime correspond to single fermion and some number of bosons. The primes assigned to the infinite part correspond to purely bosonic states assignable to the purely bosonic braid strands. Purely bosonic state would correspond to the action of a WCW Hamiltonian to the state.

This correspondence can be expanded to include all quantum numbers by using the pair of infinite primes corresponding to the "vacuum primes"  $X \pm 1$ , where  $X$  is the product of all finite primes [70]. The only difference with respect to the earlier proposal is that physical momenta would be replaced by pseudo-momenta.

2. Different primes  $p_i$  appearing in the infinite prime would correspond to their own sub-braids. For each sub-braid there is a  $N$ -fold degeneracy of the generalized eigen modes corresponding to the number  $N$  of braid strands so that many particle states are possible as required by the braid picture.
3. The correspondence of infinite primes with the hierarchy of Planck constants could allow to understand the fermion-many boson states and many boson states assigned with a given finite prime in terms of many-particle states assigned to  $n_a$  and  $n_b$ -sheeted singular covering spaces of  $CD$  and  $CP_2$  assignable to the two infinite primes. This interpretation requires that only single p-adic prime  $p_i$  is realized as quantum state meaning that quantum measurement always selects a particular p-adic prime  $p_i$  (and corresponding sub-braid) characterizing the p-adicity of the quantum state. This selection of number field behind p-adic physics responsible for cognition looks very plausible.

4. The correspondence between pairs of infinite primes and quantum states [70] allows to interpret color quantum numbers in terms of the states associated with the representations of a finite subgroup of  $SU(3)$  transforming hyper-octonionic primes to each other and preserving the  $M^2$  pseudo-momentum. Same applies to  $SO(3)$ . The most natural interpretation is in terms of wave functions in the space of discrete  $SU(3)$  and  $SO(3)$  transforms of the partonic 2-surface. The dependence of the pseudo-masses on these quantum numbers is natural so that the projection hypothesis finds support from this interpretation.
5. The infinite prime characterizing the orbit of the partonic 2-surface would thus code which multiples of the basic mass  $2\pi/L_{min}$  are possible. Either the  $M^2$  projections of hyper-octonionic primes or their hyper-complex canonical representatives would fix the basic  $M^2$  pseudo-momenta for the corresponding number theoretic braid associated. In the reverse direction the knowledge of the light-like 3-surface, the  $CD$  and  $CP_2$  coverings, and the number of the allowed discrete  $SU(3)$  and  $SU(2)$  rotations of the partonic 2-surface would dictate the infinite prime assignable to the orbit of the partonic 2-surface.

One would also like to understand whether there is some kind of conservation laws associated with the pseudo-momenta at vertices. The arithmetic QFT assignable to infinite primes would indeed predict this kind of conservation laws.

1. For the manifestly finite option the ordinary conservation of pseudo-momentum conservation at vertices is not possible since the addition of pseudo-momenta does not respect the condition  $n_0 - n_3 = 1$ . In fact, this difference in the sum of hyper-complex prime momenta tells how many momenta are present. If one applies the conservation law to the sum of the pseudo-momenta corresponding to different primes and corresponding braids, one can have reactions in which the number of primes involved is conserved. This would give the selection rule  $\sum_1^N p_i = \sum_1^N p_f$ . These reactions have interpretation in terms of the geometry of the 3-surface representing the line of the generalized Feynman diagram.
2. Infinite primes define an arithmetic quantum field theory in which the total momentum defined as  $\sum n_i \log(p_i)$  is a conserved quantity. As matter fact, each prime  $p_i$  would define a separately conserved momentum so that there would be an infinite number of conservation laws. If the sum  $\sum_i \log(p_i)$  is conserved in the vertex, the primes  $p_i$  associated with the incoming particle are shared with the outgoing particles so that also the total momentum is conserved. This looks the most plausible option and would give very powerful number theoretical selection rules at vertices since the collection of primes associated with incoming line would be union of the collections associated with the outgoing lines and also total pseudo-momentum would be conserved.
3. For the both Riemann zeta option and manifestly finite options the arithmetic QFT associated with infinite primes would be realized at the level of pseudo-momenta meaning very strong selection rules at vertices coding for how the geometries of the partonic lines entering the vertex correlate. WCW integration would reduce for the lines of Feynman diagram to a sum over light-like 3-surfaces characterized by  $(x_{min}, x_{max})$  with a suitable weighting factor and the exponent of Kähler function would give an exponential damping as a function of  $x_{min}$ .

### Which option to choose?

One should be able to make two choices. One must select between hyper-complex representations and the projections of hyper-octonionic primes and between the manifestly finite options and the one producing Riemann zeta?

Hyper-complex option seems to be slightly favored over the projection option.

1. The appearance of the scales  $\sqrt{p_i} x_{min}$  and possibly also their  $p^n$  multiples brings in mind p-adic length scales coming as  $\sqrt{p^n}$  multiples of  $CP_2$  length scale. The scales  $p_i x_{min}$  associated with hyper-complex primes reducing to ordinary primes in turn bring in mind the size scales assignable to  $CD$ s. The hierarchy of Planck constants implies also  $\hbar/\hbar_0 = \sqrt{n_a n_b}$  multiples of these length scales but mass scales would not depend on  $n_a$  and  $n_b$  [71]. For large values of  $p$  the pseudo-momenta are almost light-like for hyper-complex option whereas the projection option allows also states at rest.

2. Hyper-complex option predicts that only the p-adic pseudo-mass scales appear in the partition function and is thus favored by the p-adic length scale hypothesis. Projection option predicts also the possibility of the mass scales (not all of them) coming as  $1/\sqrt{n}$ . These mass scales are however not predicted by the hierarchy of Planck constants.
3. The same pseudo-mass scale can appear several times for the projection option. This degeneracy corresponds to the orbit of the hyper-complex prime under the subgroup of  $SU(3)$  respecting integer property. Similar statement holds true in the case of  $SO(3)$ : these groups are assigned to the two infinite primes characterizing parton. The natural assignment of this degeneracy is to the discrete color rotational and rotational degrees associated with the partonic 2-surface itself rather than spinor modes at fixed partonic 2-surface. That the pseudo-mass would depend on color and angular momentum quantum numbers would make sense.

Consider next the arguments in favor of the manifestly finite option.

1. The manifestly finite option is admittedly more elegant than the one based on Riemann zeta and also guarantees that no additional loop summations over pseudo-momenta are present. The strongest support for the manifestly finite option comes from number theoretical universality.
2. One could however argue that the restriction of the pseudo-momenta to a finite number is not consistent with the modified Dirac-Chern-Simons equation. Quantum classical correspondence however implies correlation between the geometry of the partonic orbits and the pseudo-momenta and the summation over all prime valued pseudo-momenta is present but with a weighting factor coming from Kähler function implying exponential suppression.

The Riemann zeta option could be also defended.

1. The numerical difference of the normalization factors of the Kähler function is however only about 8 per cent and quantum field theorists might interpret the replacement the length scales  $x_i$  and  $y_i$  with  $x_i^d$  and  $y_i^d$ ,  $d \simeq .9184$ , in terms of an anomalous dimension of these length scales. Could one say that radiative corrections mean the scaling of the original preferred coordinates so that one could still have consistency with number theoretic universality?
2. Riemann zeta with a non-vanishing argument could have also other applications in quantum TGD. Riemann zeta has interpretation as a partition function and the zeros of partition functions have interpretation in terms of phase transitions. The quantum criticality of TGD indeed corresponds to a phase transition point. There is also experimental evidence that the distribution of zeros of zeta corresponds to the distribution of energies of quantum critical systems in the sense that the energies correspond to the imaginary parts of the zeros of zeta [38].

The first explanation would be in terms of the analogs of the harmonic oscillator coherent states with integer multiple of the basic momentum taking the role of occupation number of harmonic oscillator and the zeros  $s = 1/2 + iy$  of  $\zeta$  defining the values of the complex coherence parameters. TGD inspired strategy for the proof of Riemann hypothesis indeed leads to the identification of the zeros as coherence parameters rather than energies as in the case of Hilbert-Polya hypothesis [63] and the vanishing of the zeta at zero has interpretation as orthogonality of the state with respect to the state defined by a vanishing coherence parameter interpreted as a tachyon. One should demonstrate that the energies of quantum states can correspond to the imaginary parts of the coherence parameters.

Second interpretation could be in terms of quantum critical zero energy states for which the "complex square root of density matrix" defines time-like entanglement coefficients of  $M$ -matrix. The complex square roots of the probabilities defined by the coefficient of harmonic oscillator states (perhaps identifiable in terms of the multiples of pseudo-momentum) in the coherent state defined by the zero of  $\zeta$  would define the  $M$ -matrix in this situation. Energy would correspond also now to the imaginary part of the coherence parameter. The norm of the state would be completely well-defined.

### Representation of configuration Kähler metric in terms of eigenvalues of $D_{C-S}$

A surprisingly concrete connection of the configuration space metric in terms of generalized eigenvalue spectrum of  $D_{C-S}$  results. From the general expression of Kähler metric in terms of Kähler function

$$G_{k\bar{l}} = \partial_k \partial_{\bar{l}} K = \frac{\partial_k \partial_{\bar{l}} \exp(K)}{\exp(K)} - \frac{\partial_k \exp(K)}{\exp(K)} \frac{\partial_{\bar{l}} \exp(K)}{\exp(K)}, \quad (2.7.17)$$

and from the expression of  $\exp(K) = \prod_i \lambda_i$  as the product of finite number of eigenvalues of  $D_{C-S}$ , the expression

$$G_{k\bar{l}} = \sum_i \frac{\partial_k \partial_{\bar{l}} \lambda_i}{\lambda_i} - \frac{\partial_k \lambda_i}{\lambda_i} \frac{\partial_{\bar{l}} \lambda_i}{\lambda_i} \quad (2.7.18)$$

for the configuration space metric follows. Here complex coordinates refer to the complex coordinates of configuration space. Hence the knowledge of the eigenvalue spectrum of  $D_{C-S}(X^3)$  as function of some complex coordinates of configuration space allows to deduce the metric to arbitrary accuracy. If the above arguments are correct the calculation reduces to the calculation of the derivatives of  $\log(\sqrt{p}L_{min}/R)$ , where  $L_{min}$  is the length of the Kähler magnetic flux line between partonic 2-surfaces with respect to the effective metric defined by the anti-commutators of the modified gamma matrices. Note that these length scales have different dependence on WCW coordinates so that one cannot reduce everything to  $L_{min}$ . Therefore one would have explicit representation of the basic building brick of WCW Kähler metric in terms of the geometric data associated with the orbit of the partonic 2-surface.

### The formula for the Kähler action of $CP_2$ type vacuum extremals is consistent with the Dirac determinant formula

The first killer test for the formula of Kähler function in terms of the Dirac determinant based on infinite prime hypothesis is provided by the action of  $CP_2$  type vacuum extremals. One of the first attempts to make quantitative predictions in TGD framework was the prediction for the gravitational constant. The argument went as follows.

1. For dimensional reasons gravitational constant must be proportional to p-adic length scale squared, where  $p$  characterizes the space-time sheet of the graviton. It must be also proportional to the square of the vacuum function for the graviton representing a line of generalized Feynman diagram and thus to the exponent  $\exp(-2K)$  of Kähler action for topologically condensed  $CP_2$  type vacuum extremals with very long projection. If topological condensation does not reduce much of the volume of  $CP_2$  type vacuum extremal, the action is just Kähler action for  $CP_2$  itself. This gives

$$\hbar_0 G = L_p^2 \exp(2L_K(CP_2)) = pR^2 \exp(2L_K(CP_2)). \quad (2.7.19)$$

2. Using as input the constraint  $\alpha_K \simeq \alpha_{em} \sim 1/137$  for Kähler coupling strengths coming from the comparison of the TGD prediction for the rotation velocity of distant galaxies around galactic nucleus and the p-adic mass calculation for the electron mass, one obtained the result

$$\exp(2L_K(CP_2)) = \frac{1}{p \times \prod_{p_i \leq 23} p_i}. \quad (2.7.20)$$

The product contains the product of all primes smaller than 24 ( $p_i \in \{2, 3, 5, 7, 11, 13, 17, 19, 23\}$ ). The expression for the Kähler function would be just of the form predicted by the Dirac determinant formula with  $L_{min}$  replaced with  $CP_2$  length scale. As a matter fact, this was the first indication that particles are characterized by several p-adic primes but that only one of them is "active". As explained, the number theoretical state function reduction explains this.

3. The same formula for the gravitational constant would result for any prime  $p$  but the value of Kähler coupling strength would depend on prime  $p$  logarithmically for this option. I indeed proposed that this formula fixes the discrete evolution of the Kähler coupling strength as function of p-adic prime from the condition that gravitational constant is renormalization group invariant quantity but gave up this hypothesis later. It is wisest to keep an agnostic attitude to this issue.
4. I also made numerous brave attempts to deduce an explicit formula for Kähler coupling strength. The general form of the formula is

$$\frac{1}{\alpha_K} = k \log(K^2), \quad K^2 = p \times 2 \times 3 \times 5 \dots \times 23 \quad . \quad (2.7.21)$$

The problem is the exact value of  $k$  cannot be known precisely and the guesses for its value depend on what one means with number theoretical universality. Should Kähler action be a rational number? Or is it Kähler function which is rational number (it is for the Dirac determinant option in this particular case). Is Kähler coupling strength  $g_K^2/4\pi$  or  $g_K^2$  a rational number? Some of the guesses were  $k = \pi/4$  and  $k = 137/107$ . The facts that the value of Kähler action for the line of a generalized diagram is not exactly  $CP_2$  action and the value of  $\alpha_K$  is not known precisely makes these kind of attempts hopeless in absence of additional ideas.

Also other elementary particles -in particular exchanged bosons- should involve the exponent of Kähler action for  $CP_2$  type vacuum extremal. Since the values of gauge couplings are gigantic as compared to the expression of the gravitational constant the value of Kähler action must be rather small form them.  $CP_2$  type vacuum extremals must be short in the sense that  $L_{min}$  in the effective metric is very short. Note however that the p-adic prime characterizing the particle according to p-adic mass calculations would be large also now. One can of course ask whether this p-adic prime characterizes the gravitational space-time sheets associated with the particle and not the particle itself. The assignment of p-adic mass calculations with thermodynamics at gravitational space-time sheets of the particle would be indeed natural. The value of  $\alpha_K$  would depend on  $p$  in logarithmic manner for this option. The topological condensation of could also eat a lot of  $CP_2$  volume for them.

### Eigenvalues of $D_{C-S}$ as vacuum expectations of Higgs field?

Infinite prime hypothesis implies the analog of p-adic length scale hypothesis but since pseudo-momenta are in question, this need not correspond to the p-adic length scale hypothesis for the actual masses justified by p-adic thermodynamics. Note also that  $L_{min}$  does not correspond to  $CP_2$  length scale. This is actually not a problem since the effective metric is not  $M^4$  metric and one can quite well consider the possibility that  $L_{min}$  corresponds to  $CP_2$  length scale in the induced metric. The reason is that light-like 3- surface is in question the distance along the Kähler magnetic flux line reduces essentially to a distance along the partonic 2-surface having size scale of order  $CP_2$  length for the partonic 2-surfaces identified as wormhole throats. Therefore infinite prime can code for genuine p-adic length scales associated with the light-like 3-surface and quantum states would correspond by number theoretical state function reduction hypothesis to single ordinary prime.

Support for this identification comes also from the expression of gravitational constant deduced from p-adic length scale hypothesis. The result is that gravitational constant is assumed to be proportional to have the expression  $G = L_p^2 \exp(-2S_K(CP_2))$ , where  $p$  characterizes graviton or the space-time sheet mediating gravitational interaction and exponent gives Kähler action for  $CP_2$  type vacuum extremal representing graviton. The argument allows to identify the p-adic prime  $p = M_{127}$  associated with electron (largest Mersenne prime which does not correspond to super-astronomical length scale) as the p-adic prime characterizing also graviton. The exponent of Kähler action is proportional to  $1/p$  which conforms with the general expression for Kähler function. I have considered several identifications of the numerical factor and one of them has been as product of primes  $2 \leq p \leq 23$  assuming that somehow the primes  $\{2, \dots, 23, p\}$  characterize graviton. This guess is indeed consistent with the prediction of the infinite-prime hypothesis.

The first guess inspired by the p-adic mass calculations is that the squares  $\lambda_i^2$  of the eigenvalues of  $D_{C-S}$  could correspond to the conformal weights of ground states. Another natural physical

interpretation of  $\lambda$  is as an analog of the Higgs vacuum expectation. The instability of the Higgs=0 phase would correspond to the fact that  $\lambda = 0$  mode is not localized to any region in which electromagnetic field or induced Kähler field is non-vanishing. By the previous argument one would have order of magnitude estimate  $h_0 = \sqrt{2\pi/L_{min}}$ .

1. The vacuum expectation value of Higgs is only proportional to the scale of  $\lambda$ . Indeed, Higgs and gauge bosons as elementary particles correspond to wormhole contacts carrying fermion and anti-fermion at the two wormhole throats and must be distinguished from the space-time correlate of its vacuum expectation as something proportional to  $\lambda$ . For free fermions the vacuum expectation value of Higgs does not seem to be even possible since free fermions do not correspond to wormhole contacts between two space-time sheets but possess only single wormhole throat (p-adic mass calculations are consistent with this). If fermion suffers topological condensation as indeed assumed to do in interaction region, a wormhole contact is generated and makes possible the generation of Higgs vacuum expectation value.
2. Physical considerations suggest that the vacuum expectation of Higgs field corresponds to a particular eigenvalue  $\lambda_i$  of modified Chern-Simons Dirac operator so that the eigenvalues  $\lambda_i$  would define TGD counterparts for the minima of Higgs potential. For the minimal option one has only a finite number of pseudo-mass eigenvalues inversely proportional  $\sqrt{p}$  so that the identification as a Higgs vacuum expectation is consistent with the p-adic length scale hypothesis. Since the vacuum expectation of Higgs corresponds to a condensate of wormhole contacts giving rise to a coherent state, the vacuum expectation cannot be present for topologically condensed  $CP_2$  type vacuum extremals representing fermions since only single wormhole throat is involved. This raises a hen-egg question about whether Higgs contributes to the mass or whether Higgs is only a correlate for massivation having description using more profound concepts. From TGD point of view the most elegant option is that Higgs does not give rise to mass but Higgs vacuum expectation value accompanies bosonic states and is naturally proportional to  $\lambda_i$ . With this interpretation  $\lambda_i$  could give a contribution to both fermionic and bosonic masses.
3. If the coset construction for super-symplectic and super Kac-Moody algebra implying Equivalence Principle is accepted, one encounters what looks like a problem. p-Adic mass calculations require negative ground state conformal weight compensated by Super Virasoro generators in order to obtain massless states. The tachyonicity of the ground states would mean a close analogy with both string models and Higgs mechanism.  $\lambda_i^2$  is very natural candidate for the ground state conformal weights identified but would have wrong sign. Therefore it seems that  $\lambda_i^2$  can define only a deviation of the ground state conformal weight from negative value and is positive.
4. In accordance with this  $\lambda_i^2$  would give constant contribution to the ground state conformal weight. What contributes to the thermal mass squared is the deviation of the ground state conformal weight from half-odd integer since the negative integer part of the total conformal weight can be compensated by applying Virasoro generators to the ground state. The first guess motivated by cyclotron energy analogy is that the lowest conformal weights are of form  $h_c = -n/2 + \lambda_i^2$  where the negative contribution comes from Super Virasoro representation. The negative integer part of the net conformal weight can be canceled using Super Virasoro generators but  $\Delta h_c$  would give to mass squared a contribution analogous to Higgs contribution. The mapping of the real ground state conformal weight to a p-adic number by canonical identification involves some delicacies.
5. p-Adic mass calculations are consistent with the assumption that Higgs type contribution is vanishing (that is small) for fermions and dominates for gauge bosons. This requires that the deviation of  $\lambda_i^2$  with smallest magnitude from half-odd integer value in the case of fermions is considerably smaller than in the case of gauge bosons in the scale defined by p-adic mass scale  $1/L(k)$  in question. Somehow this difference could relate to the fact that bosons correspond to pairs of wormhole throats.

### **Is there a connection between p-adic thermodynamics, hierarchy of Planck constants, and infinite primes**

The following observations suggest that there might be an intrinsic connection between p-adic thermodynamics, hierarchy of Planck constants, and infinite primes.

1. p-Adic thermodynamics [41] is based on string mass formula in which mass squared is proportional to conformal weight having values which are integers apart from the contribution of the conformal weight of vacuum which can be non-integer valued. The thermal expectation in p-adic thermodynamics is obtained by replacing the Boltzman weight  $\exp(-E/T)$  of ordinary thermodynamics with p-adic conformal weight  $p^{n/T_p}$ , where  $n$  is the value of conformal weight and  $1/T_p = m$  is integer values inverse p-adic temperature. Apart from the ground state contribution and scale factor p-adic mass squared is essentially the expectation value

$$\langle n \rangle = \frac{\sum_n g(n) n p^{\frac{n}{T_p}}}{\sum_n g(n) p^{\frac{n}{T_p}}} . \quad (2.7.22)$$

$g(n)$  denotes the degeneracy of a state with given conformal weight and depends only on the number of tensor factors in the representations of Virasoro or Super-Virasoro algebra. p-Adic mass squared is mapped to its real counterpart by canonical identification  $\sum x_n p^n \rightarrow \sum x_n p^{-n}$ . The real counterpart of p-adic thermodynamics is obtained by the replacement  $p^{-\frac{n}{T_p}}$  and gives under certain additional assumptions in an excellent accuracy the same results as the p-adic thermodynamics.

2. An intriguing observation is that one could interpret p-adic and real thermodynamics for mass squared also in terms of number theoretic thermodynamics for the number theoretic momentum  $\log(p^n) = n \log(p)$ . The expectation value for this differs from the expression for  $\langle n \rangle$  only by the factor  $\log(p)$ .
3. In the proposed characterization of the partonic orbits in terms of infinite primes the primes appearing in infinite prime are identified as p-adic primes. For minimal option the p-adic prime characterizes  $\sqrt{p}$ - or  $p$ - multiple of the minimum length  $L_{min}$  of braid strand in the effective metric defined by modified Chern-Simons gamma matrix. One can consider also  $(\sqrt{p})^n$  and  $p^n$  (p-adic fractality)- and even integer multiples of  $L_{min}$  if they are below  $L_{max}$ . If light-like 3-surface contains vacuum regions arbitrary large  $p$ :s are possible since for these one has  $L_{min} \rightarrow \infty$ . Number theoretic state function reduction implies that only single  $p$  can be realized -one might say "is active"- for a given quantum state. The powers  $p_i^n$  appearing in the infinite prime have interpretation as many particle states with total number theoretic momentum  $n_i \log(p)_i$ . For the finite part of infinite prime one has one fermion and  $n_i - 1$  bosons and for the bosonic part  $n_i$  bosons. The arithmetic QFT associated with infinite primes - in particular the conservation of the number theoretic momentum  $\sum n_i \log(p_i)$  - would naturally describe the correlations between the geometries of light-like 3-surfaces representing the incoming lines of the vertex of generalized Feynman diagram. As a matter fact, the momenta associated with different primes are separately conserved so that one has infinite number of conservation laws.
4. One must assign two infinite primes to given partonic two surface so that one has for a given prime  $p$  two integers  $n_+$  and  $n_-$ . Also the hierarchy of Planck constants assigns to a given page of the Big Book two integers and one has  $\hbar = n_a n_b \hbar_0$ . If one has  $n_a = n_+$  and  $n_b = n_-$  then the reactions in which given initial number theoretic momenta  $n_{\pm, i} \log(p_i)$  is shared between final states would have concrete interpretation in terms of the integers  $n_a, n_b$  characterizing the coverings of incoming and outgoing lines.

Note that one can also consider the possibility that the hierarchy of Planck constants emerges from the basic quantum TGD. Basically due to the vacuum degeneracy of Kähler action the canonical momentum densities correspond to several values of the time derivatives of the imbedding space coordinates so that for a given partonic 2-surface there are several space-time sheets with same conserved quantities defined by isometry currents and Kähler current. This forces the introduction of  $N$ -fold covering of  $CD \times CP_2$  in order to describe the situation. The splitting of the partonic 2-surface into  $N$  pieces implies a charge fractionization during its travel to the upper end of  $CD$ . One can also develop an argument suggesting that the coverings factorize to coverings of  $CD$  and  $CP_2$  so that the number of the sheets of the covering is  $N = n_a n_b$  [35] .

These observations make one wonder whether there could be a connection between p-adic thermodynamics, hierarchy of Planck constants, and infinite primes.

1. Suppose that one accepts the identification  $n_a = n_+$  and  $n_b = n_-$ . Could one perform a further identification of these integers as non-negative conformal weights characterizing physical states so that conservation of the number theoretic momentum for a given p-adic prime would correspond to the conservation of conformal weight. In p-adic thermodynamics this conformal weight is sum of conformal weights of 5 tensor factors of Super-Virasoro algebra. The number must be indeed five and one could assign them to the factors of the symmetry group. One factor for color symmetries and two factors of electro-weak  $SU(2)_L \times U(1)$  are certainly present. The remaining two factors could correspond to transversal degrees of freedom assignable to string like objects but one can imagine also other identifications [41].
2. If this interpretation is correct, a given conformal weight  $n = n_a = n_+$  (say) would correspond to all possible distributions of five conformal weights  $n_i$ ,  $i = 1, \dots, 5$  between the  $n_a$  sheets of covering of  $CD$  satisfying  $\sum_{i=1}^5 n_i = n_a = n_+$ . Single sheet of covering would carry only unit conformal weight so that one would have the analog of fractionization also now and a possible interpretation would be in terms of the instability of states with conformal weight  $n > 1$ . Conformal thermodynamics would also mean thermodynamics in the space of states determined by infinite primes and in the space of coverings.
3. The conformal weight assignable to the  $CD$  would naturally correspond to mass squared but there is also the conformal weight assignable to  $CP_2$  and one can wonder what its interpretation might be. Could it correspond to the expectation of pseudo mass squared characterizing the generalized eigenstates of the modified Dirac operator? Note that one should allow in the spectrum also the powers of hyper-complex primes up to some maximum power  $p^{n_{max}/2} \leq L_{max}/L_{min}$  so that Dirac determinant would be non-vanishing and Kähler function finite. From the point of conformal invariance this is indeed natural.

## 2.8 An attempt to understand preferred extremals of Kähler action

There are pressing motivations for understanding the preferred extremals of Kähler action. For instance, the conformal invariance of string models naturally generalizes to 4-D invariance defined by quantum Yangian of quantum affine algebra (Kac-Moody type algebra) characterized by two complex coordinates and therefore explaining naturally the effective 2-dimensionality [84]. The problem is however how to assign a complex coordinate with the string world sheet having Minkowskian signature of metric. One can hope that the understanding of preferred extremals could allow to identify two preferred complex coordinates whose existence is also suggested by number theoretical vision giving preferred role for the rational points of partonic 2-surfaces in preferred coordinates. The best one could hope is a general solution of field equations in accordance with the hints that TGD is integrable quantum theory.

A lot is known about properties of preferred extremals and just by trying to integrate all this understanding, one might gain new visions. The problem is that all these arguments are heuristic and rely heavily on physical intuition. The following considerations relate to the space-time regions having Minkowskian signature of the induced metric. The attempt to generalize the construction also to Euclidian regions could be very rewarding. Only a humble attempt to combine various ideas to a more coherent picture is in question.

The core observations and visions are following.

1. Hamilton-Jacobi coordinates for  $M^4$  (discussed in this chapter) define natural preferred coordinates for Minkowskian space-time sheet and might allow to identify string world sheets for  $X^4$  as those for  $M^4$ . Hamilton-Jacobi coordinates consist of light-like coordinate  $m$  and its dual defining local 2-plane  $M^2 \subset M^4$  and complex transversal complex coordinates  $(w, \bar{w})$  for a plane  $E_x^2$  orthogonal to  $M_x^2$  at each point of  $M^4$ . Clearly, hyper-complex analyticity and complex analyticity are in question.

2. Space-time sheets allow a slicing by string world sheets (partonic 2-surfaces) labelled by partonic 2-surfaces (string world sheets).
3. The quaternionic planes of octonion space containing preferred hyper-complex plane are labelled by  $CP_2$ , which might be called  $CP_2^{mod}$  [72]. The identification  $CP_2 = CP_2^{mod}$  motivates the notion of  $M^8 - M^4 \times CP_2$  duality [20]. It also inspires a concrete solution ansatz assuming the equivalence of two different identifications of the quaternionic tangent space of the space-time sheet and implying that string world sheets can be regarded as strings in the 6-D coset space  $G_2/SU(3)$ . The group  $G_2$  of octonion automorphisms has already earlier appeared in TGD framework.
4. The duality between partonic 2-surfaces and string world sheets in turn suggests that the  $CP_2 = CP_2^{mod}$  conditions reduce to string model for partonic 2-surfaces in  $CP_2 = SU(3)/U(2)$ . String model in both cases could mean just hypercomplex/complex analyticity for the coordinates of the coset space as functions of hyper-complex/complex coordinate of string world sheet/partonic 2-surface.

The considerations of this section lead to a revival of an old very ambitious and very romantic number theoretic idea.

1. To begin with express octonions in the form  $o = q_1 + Iq_2$ , where  $q_i$  is quaternion and  $I$  is an octonionic imaginary unit in the complement of fixed a quaternionic sub-space of octonions. Map preferred coordinates of  $H = M^4 \times CP_2$  to octonionic coordinate, form an arbitrary octonion analytic function having expansion with real Taylor or Laurent coefficients to avoid problems due to non-commutativity and non-associativity. Map the outcome to a point of  $H$  to get a map  $H \rightarrow H$ . This procedure is nothing but a generalization of Wick rotation to get an 8-D generalization of analytic map.
2. Identify the preferred extremals of Kähler action as surfaces obtained by requiring the vanishing of the imaginary part of an octonion analytic function. Partonic 2-surfaces and string world sheets would correspond to commutative sub-manifolds of the space-time surface and of imbedding space and would emerge naturally. The ends of braid strands at partonic 2-surface would naturally correspond to the poles of the octonion analytic functions. This would mean a huge generalization of conformal invariance of string models to octonionic conformal invariance and an exact solution of the field equations of TGD and presumably of quantum TGD itself.

### 2.8.1 Basic ideas about preferred extremals

#### The slicing of the space-time sheet by partonic 2-surfaces and string world sheets

The basic vision is that space-time sheets are sliced by partonic 2-surfaces and string world sheets. The challenge is to formulate this more precisely at the level of the preferred extremals of Kähler action.

1. Almost topological QFT property means that the Kähler action reduces to Chern-Simons terms assignable to 3-surfaces. This is guaranteed by the vanishing of the Coulomb term in the action density implied automatically if conserved Kähler current is proportional to the instanton current with proportionality coefficient some scalar function.
2. The field equations reduce to the conservation of isometry currents. An attractive ansatz is that the flow lines of these currents define global coordinates. This means that these currents are Beltrami flows [48] so that corresponding 1-forms  $J$  satisfy the condition  $J \wedge dJ = 0$ . These conditions are satisfied if

$$J = \Phi \nabla \Psi$$

hold true for conserved currents. From this one obtains that  $\Psi$  defines global coordinate varying along flow lines of  $J$ .

3. A possible interpretation is in terms of local polarization and momentum directions defined by the scalar functions involved and natural additional conditions are that the gradients of  $\Psi$  and  $\Phi$  are orthogonal:

$$\nabla\Phi \cdot \nabla\Psi = 0 \quad ,$$

and that the  $\Psi$  satisfies massless d'Alembert equation

$$\nabla^2\Psi = 0$$

as a consequence of current conservation. If  $\Psi$  defines a light-like vector field - in other words

$$\nabla\Psi \cdot \nabla\Psi = 0 \quad ,$$

the light-like dual of  $\Phi$  -call it  $\Phi_c$ - defines a light-like like coordinate and  $\Phi$  and  $\Phi_c$  defines a light-like plane at each point of space-time sheet.

If also  $\Phi$  satisfies d'Alembert equation

$$\nabla^2\Phi = 0 \quad ,$$

also the current

$$K = \Psi\nabla\Phi$$

is conserved and its flow lines define a global coordinate in the polarization plane orthogonal to time-like plane defined by local light-like momentum direction.

If  $\Phi$  allows a continuation to an analytic function of the transversal complex coordinate, one obtains a coordinatization of spacetime surface by  $\Psi$  and its dual (defining hyper-complex coordinate) and  $w, \bar{w}$ . Complex analyticity and its hyper-complex variant would allow to provide space-time surface with four coordinates very much analogous with Hamilton-Jacobi coordinates of  $M^4$ .

This would mean a decomposition of the tangent space of space-time surface to orthogonal planes defined by light-like momentum and plane orthogonal to it. If the flow lines of  $J$  defined Beltrami flow it seems that the distribution of momentum planes is integrable.

4. General arguments suggest that the space-time sheets allow a slicing by string world sheets parametrized by partonic 2-surfaces or vice versa. This would mean an intimate connection with the mathematics of string models. The two complex coordinates assignable to the Yangian of affine algebra would naturally relate to string world sheets and partonic 2-surfaces and the highly non-trivial challenge is to identify them appropriately.

#### Hamilton-Jacobi coordinates for $M^4$

The earlier attempts to construct preferred extremals [8] led to the realization that so called Hamilton-Jacobi coordinates  $(m, w)$  for  $M^4$  define its slicing by string world sheets parametrized by partonic 2-surfaces.  $m$  would be pair of light-like conjugate coordinates associated with an integrable distribution of planes  $M^2$  and  $w$  would define a complex coordinate for the integrable distribution of 2-planes  $E^2$  orthogonal to  $M^2$ . There is a great temptation to assume that these coordinates define preferred coordinates for  $M^4$ .

1. The slicing is very much analogous to that for space-time sheets and the natural question is how these slicings relate. What is of special interest is that the momentum plane  $M^2$  can be defined by massless momentum. The scaling of this vector does not matter so that these planes are labelled by points  $z$  of sphere  $S^2$  telling the direction of the line  $M^2 \cap E^3$ , when one assigns rest frame and therefore  $S^2$  with the preferred time coordinate defined by the line connecting the tips of  $CD$ . This direction vector can be mapped to a twistor consisting of a spinor and its conjugate.

The complex scalings of the twistor  $(u, \bar{u}) \rightarrow \lambda u, \bar{u}/\lambda$  define the same plane. Projective twistor like entities defining  $CP_1$  having only one complex component instead of three are in question. This complex number defines with certain prerequisites a local coordinate for space-time sheet and together with the complex coordinate of  $E^2$  could serve as a pair of complex coordinates  $(z, w)$  for space-time sheet. This brings strongly in mind the two complex coordinates appearing in the expansion of the generators of quantum Yangian of quantum affine algebra [84].

2. The coordinate  $\Psi$  appearing in Beltrami flow defines the light-like vector field defining  $M^2$  distribution. Its hyper-complex conjugate would define  $\Psi_c$  and conjugate light-like direction. An attractive possibility is that  $\Phi$  allows analytic continuation to a holomorphic function of  $w$ . In this manner one would have four coordinates for  $M^4$  also for space-time sheet.
3. The general vision is that at each point of space-time surface one can decompose the tangent space to  $M^2(x) \subset M^4 = M_x^2 \times E_x^2$  representing momentum plane and polarization plane  $E^2 \subset E_x^2 \times T(CP_2)$ . The moduli space of planes  $E^2 \subset E^6$  is 8-dimensional and parametrized by  $SO(6)/SO(2) \times SO(4)$  for a given  $E_x^2$ . How can one achieve this selection and what conditions it must satisfy? Certainly the choice must be integrable but this is not the only condition.

### Space-time surfaces as quaternionic surfaces

The idea that number theory determines classical dynamics in terms of associativity condition means that space-time surfaces are in some sense quaternionic surfaces of an octonionic space-time. It took several trials before the recent form of this hypothesis was achieved.

1. Octonionic structure is defined in terms of the octonionic representation of gamma matrices of the imbedding space existing only in dimension  $D = 8$  since octonion units are in one-one correspondence with tangent vectors of the tangent space. Octonionic real unit corresponds to a preferred time axes (and rest frame) identified naturally as that connecting the tips of  $CD$ . What modified gamma matrices mean depends on variational principle for space-time surface. For volume action one would obtain induced gamma matrices. For Kähler action one obtains something different. In particular, the modified gamma matrices do not define vector basis identical with tangent vector basis of space-time surface.
2. Quaternionicity means that the modified gamma matrices defined as contractions of gamma matrices of  $H$  with canonical momentum densities for Kähler action span quaternionic sub-space of the octonionic tangent space [28]. A further condition is that each quaternionic space defined in this manner contains a preferred hyper-complex subspace of octonions.
3. The sub-space defined by the modified gamma matrices does not co-incide with the tangent space of space-time surface in general so that the interpretation of this condition is far from obvious. The canonical momentum densities need not define four independent vectors at given point. For instance, for massless extremals these densities are proportional to light-like vector so that the situation is degenerate and the space in question reduces to 2-D hyper-complex sub-space since light-like vector defines plane  $M^2$ .

The obvious questions are following.

1. Does the analog of tangent space defined by the octonionic modified gammas contain the local tangent space  $M^2 \subset M^4$  for preferred extremals? For massless extremals [8] this condition would be true. The orthogonal decomposition  $T(X^4) = M^2 \oplus_{\perp} E^2$  can be defined at each point if this is true. For massless extremals also the functions  $\Psi$  and  $\Phi$  can be identified.
2. One should answer also the following delicate question. Can  $M^2$  really depend on point  $x$  of space-time?  $CP_2$  as a moduli space of quaternionic planes emerges naturally if  $M^2$  is *same* everywhere. It however seems that one should allow an integrable distribution of  $M_x^2$  such that  $M_x^2$  is same for all points of a given partonic 2-surface.

How could one speak about fixed  $CP_2$  (the imbedding space) at the entire space-time sheet even when  $M_x^2$  varies?

- (a) Note first that  $G_2$  defines the Lie group of octonionic automorphisms and  $G_2$  action is needed to change the preferred hyper-octonionic sub-space. Various  $SU(3)$  subgroups of  $G_2$  are related by  $G_2$  automorphism. Clearly, one must assign to each point of a string world sheet in the slicing parameterizing the partonic 2-surfaces an element of  $G_2$ . One would have Minkowskian string model with  $G_2$  as a target space. As a matter of fact, this string model is defined in the target space  $G_2/SU(3)$  having dimension  $D = 6$  since  $SU(3)$  automorphisms leave given  $SU(3)$  invariant.
  - (b) This would allow to identify at each point of the string world sheet standard quaternionic basis - say in terms of complexified basis vectors consisting of two hyper-complex units and octonionic unit  $q_1$  with "color isospin"  $I_3 = 1/2$  and "color hypercharge"  $Y = -1/3$  and its conjugate  $\bar{q}_1$  with opposite color isospin and hypercharge.
  - (c) The  $CP_2$  point assigned with the quaternionic basis would correspond to the  $SU(3)$  rotation needed to rotate the standard basis to this basis and would actually correspond to the first row of  $SU(3)$  rotation matrix. Hyper-complex analyticity is the basic property of the solutions of the field equations representing Minkowskian string world sheets. Also now the same assumption is highly natural. In the case of string models in Minkowski space, the reduction of the induced metric to standard form implies Virasoro conditions and similar conditions are expected also now. There is no need to introduce action principle -just the hyper-complex analyticity is enough-since Kähler action already defines it.
3. The WZW model inspired approach to the situation would be following. The parametrization corresponds to a map  $g : X^2 \rightarrow G_2$  for which  $g$  defines a flat  $G_2$  connection at string world sheet. WZW type action would give rise to this kind of situation. The transition  $G_2 \rightarrow G_2/SU(3)$  would require that one gauges  $SU(3)$  degrees of freedom by bringing in  $SU(3)$  connection. Similar procedure for  $CP_2 = SU(3)/U(2)$  would bring in  $SU(3)$  valued chiral field and  $U(2)$  gauge field. Instead of introducing these connections one can simply introduce  $G_2/SU(3)$  and  $SU(3)/U(2)$  valued chiral fields. What this observation suggests is that this ansatz indeed predicts gluons and electroweak gauge bosons assignable to string like objects so that the mathematical picture would be consistent with physical intuition.

### The two interpretations of $CP_2$

An old observation very relevant for what I have called  $M^8 - H$  duality [20] is that the moduli space of quaternionic sub-spaces of octonionic space (identifiable as  $M^8$ ) containing preferred hyper-complex plane is  $CP_2$ . Or equivalently, the space of two planes whose addition extends hyper-complex plane to some quaternionic subspace can be parametrized by  $CP_2$ . This  $CP_2$  can be called  $CP_2^{mod}$  to avoid confusion. In the recent case this would mean that the space  $E^2(x) \subset E_x^2 \times T(CP_2)$  is represented by a point of  $CP_2^{mod}$ . On the other hand, the imbedding of space-time surface to  $H$  defines a point of "real"  $CP_2$ . This gives two different  $CP_2$ s.

1. The highly suggestive idea is that the identification  $CP_2^{mod} = CP_2$  (apart from isometry) is crucial for the construction of preferred extremals. Indeed, the projection of the space-time point to  $CP_2$  would fix the local polarization plane completely. This condition for  $E^2(x)$  would be purely local and depend on the values of  $CP_2$  coordinates only. Second condition for  $E^2(x)$  would involve the gradients of imbedding space coordinates including those of  $CP_2$  coordinates.
2. The conditions that the planes  $M_x^2$  form an integrable distribution at space-like level and that  $M_x^2$  is determined by the modified gamma matrices. The integrability of this distribution for  $M^4$  could imply the integrability for  $X^2$ .  $X^4$  would differ from  $M^4$  only by a deformation in degrees of freedom transversal to the string world sheets defined by the distribution of  $M^2$ s.

Does this mean that one can begin from vacuum extremal with constant values of  $CP_2$  coordinates and makes them non-constant but allows to depend only on transversal degrees of freedom? This condition is too strong even for simplest massless extremals for which  $CP_2$  coordinates depend on transversal coordinates defined by  $\epsilon \cdot m$  and  $\epsilon \cdot k$ . One could however allow dependence of  $CP_2$  coordinates on light-like  $M^4$  coordinate since the modification of the induced metric is light-like so that light-like coordinate remains light-like coordinate in this modification of the metric.

Therefore, if one generalizes directly what is known about massless extremals, the most general dependence of  $CP_2$  points on the light-like coordinates assignable to the distribution of  $M_x^2$  would be dependence on either of the light-like coordinates of Hamilton-Jacobi coordinates but not both.

### 2.8.2 What could be the construction recipe for the preferred extremals assuming $CP_2 = CP_2^{mod}$ identification?

The crucial condition is that the planes  $E^2(x)$  determined by the point of  $CP_2 = CP_2^{mod}$  identification and by the tangent space of  $E_x^2 \times CP_2$  are same. The challenge is to transform this condition to an explicit form.  $CP_2 = CP_2^{mod}$  identification should be general coordinate invariant. This requires that also the representation of  $E^2$  as  $(e^2, e^3)$  plane is general coordinate invariant suggesting that the use of preferred  $CP_2$  coordinates -presumably complex Eguchi-Hanson coordinates- could make life easy. Preferred coordinates are also suggested by number theoretical vision. A careful consideration of the situation would be required.

The modified gamma matrices define a quaternionic sub-space analogous to tangent space of  $X^4$  but not in general identical with the tangent space: this would be the case only if the action were 4-volume. I will use the notation  $T_x^m(X^4)$  about the modified tangent space and call the vectors of  $T_x^m(X^4)$  modified tangent vectors. I hope that this would not cause confusion.

#### $CP_2 = CP_2^{mod}$ condition

Quaternionic property of the counterpart of  $T_x^m(X^4)$  allows an explicit formulation using the tangent vectors of  $T_x^m(X^4)$ .

1. The unit vector pair  $(e_2, e_3)$  should correspond to a unique tangent vector of  $H$  defined by the coordinate differentials  $dh^k$  in some natural coordinates used. Complex Eguchi-Hanson coordinates [2] are a natural candidate for  $CP_2$  and require complexified octonionic imaginary units. If octonionic units correspond to the tangent vector basis of  $H$  uniquely, this is possible.
2. The pair  $(e_2, e_3)$  as also its complexification  $(q_1 = e_2 + ie_3, \bar{q}_1 = e_2 - ie_3)$  is expressible as a linear combination of octonionic units  $I_2, \dots, I_7$  should be mapped to a point of  $CP_2^{mod} = CP_2$  in canonical manner. This mapping is what should be expressed explicitly. One should express given  $(e_2, e_3)$  in terms of  $SU(3)$  rotation applied to a standard vector. After that one should define the corresponding  $CP_2$  point by the bundle projection  $SU(3) \rightarrow CP_2$ .
3. The tangent vector pair

$$(\partial_w h^k, \partial_{\bar{w}} h^k)$$

defines second representation of the tangent space of  $E^2(x)$ . This pair should be equivalent with the pair  $(q_1, \bar{q}_1)$ . Here one must be however very cautious with the choice of coordinates. If the choice of  $w$  is unique apart from constant the gradients should be unique. One can use also real coordinates  $(x, y)$  instead of  $(w = x + iy, \bar{w} = x - iy)$  and the pair  $(e_2, e_3)$ . One can project the tangent vector pair to the standard vielbein basis which must correspond to the octonion basis

$$(\partial_x h^k, \partial_y h^k) \rightarrow (\partial_x h^k e_k^A, \partial_y h^k e_k^A) e_A \leftrightarrow (e_2, e_3) ,$$

where the  $e_A$  denote the octonion units in 1-1 correspondence with vielbein vectors. This expression can be compared to the expression of  $(e_2, e_3)$  derived from the knowledge of  $CP_2$  projection.

#### Formulation of quaternionicity condition in terms of octonionic structure constants

One can consider also a formulation of the quaternionic tangent planes in terms of  $(e_2, e_3)$  expressed in terms of octonionic units deducible from the condition that unit vectors obey quaternionic algebra. The expressions for octonionic *resp.* quaternionic structure constants can be found at [22] *resp.* [30].

1. The ansatz is

$$\begin{aligned}
 \{E_k\} &= \{1, I_1, E_2, E_3\} , \\
 E_2 &= E_{2k}e^k \equiv \sum_{k=2}^7 E_{2k}e^k , \quad E_3 = E_{3k}e^k \equiv \sum_{k=2}^7 E_{3k}e^k , \\
 |E_2| &= 1 , \quad |E_3| = 1 .
 \end{aligned} \tag{2.8.1}$$

2. The multiplication table for octonionic units expressible in terms of octonionic triangle [22] gives

$$f^{1kl}E_{2k} = E_{3l} , \quad f^{1kl}E_{3k} = -E_{2l} , \quad f^{klr}E_{2k}E_{3l} = \delta_1^r . \tag{2.8.2}$$

Here the indices are raised by unit metric so that there is no difference between lower and upper indices. Summation convention is assumed. Also the contribution of the real unit is present in the structure constants of third equation but this contribution must vanish.

3. The conditions are linear and quadratic in the coefficients  $E_{2k}$  and  $E_{3k}$  and are expected to allow an explicit solution. The first two conditions define homogenous equations which must allow solution. The coefficient matrix acting on  $(E_2, E_3)$  is of the form

$$\begin{pmatrix} f_1 & 1 \\ -1 & f_1 \end{pmatrix} ,$$

where 1 denotes unit matrix. The vanishing of the determinant of this matrix should be due to the highly symmetric properties of the structure constants. In fact the equations can be written as eigen conditions

$$f_1 \circ (E_2 \pm iE_3) = \mp i(E_2 \pm iE_3) ,$$

and one can say that the structure constants are eigenstates of the hermitian operator defined by  $I_1$  analogous to color hyper charge. Both values of color hyper charged are obtained.

### Explicit expression for the $CP_2 = CP_2^{mod}$ conditions

The symmetry under  $SU(3)$  allows to construct the solutions of the above equations directly.

1. One can introduce complexified basis of octonion units transforming like  $(1, 1, 3, \bar{3})$  under  $SU(3)$ . Note the analogy of triplet with color triplet of quarks. One can write complexified basis as  $(1, e_1, (q_1, q_2, q_3), (\bar{q}_1, \bar{q}_2, \bar{q}_3))$ . The expressions for complexified basis elements are

$$(q_1, q_2, q_3) = \frac{1}{\sqrt{2}}(e_2 + ie_3, e_4 + ie_5, e_6 + ie_7) .$$

These options can be seen to be possible by studying octonionic triangle in which all lines containing 3 units defined associative triple: any pair of octonion units at this kind of line can be used to form pair of complexified unit and its conjugate. In the tangent space of  $M^4 \times CP_2$  the basis vectors  $q_1$ , and  $q_2$  are mixtures of  $E_x^2$  and  $CP_2$  tangent vectors.  $q_3$  involves only  $CP_2$  tangent vectors and there is a temptation to interpret it as the analog of the quark having no color isospin.

2. The quaternionic basis is real and must transform like  $(1, 1, q_1, \bar{q}_1)$ , where  $q_1$  is any quark in the triplet and  $\bar{q}_1$  its conjugate in antitriplet. Having fixed some basis one can perform  $SU(3)$  rotations to get a new basis. The action of the rotation is by  $3 \times 3$  special unitary matrix. The over all phases of its rows do not matter since they induce only a rotation in  $(e_2, e_3)$  plane not

affecting the plane itself. The action of  $SU(3)$  on  $q_1$  is simply the action of its first row on  $(q_1, q_2, q_3)$  triplet:

$$\begin{aligned} q_1 &\rightarrow (Uq)_1 = U_{11}q_1 + U_{12}q_2 + U_{13}q_3 \equiv z_1q_1 + z_2q_2 + z_3q_3 \\ &= z_1(e_2 + ie_3) + z_2(e_4 + ie_5) + z_3(e_6 + ie_7) . \end{aligned} \quad (2.8.3)$$

The triplets  $(z_1, z_2, z_3)$  defining a complex unit vector and point of  $S^5$ . Since overall phase does not matter a point of  $CP_2$  is in question. The new real octonion units are given by the formulas

$$\begin{aligned} e_2 &\rightarrow Re(z_1)e_2 + Re(z_2)e_4 + Re(z_3)e_6 - Im(z_1)e_3 - Im(z_2)e_5 - Im(z_3)e_7 , \\ e_3 &\rightarrow Im(z_1)e_2 + Im(z_2)e_4 + Im(z_3)e_6 + Re(z_1)e_3 + Re(z_2)e_5 + Re(z_3)e_7 . \end{aligned} \quad (2.8.4)$$

For instance the  $CP_2$  coordinates corresponding to the coordinate patch  $(z_1, z_2, z_3)$  with  $z_3 \neq 0$  are obtained as  $(\xi_1, \xi_2) = (z_1/z_3, z_2/z_3)$ .

Using these expressions the equations expressing the conjecture  $CP_2 = CP_2^{mod}$  equivalence can be expressed explicitly as first order differential equations. The conditions state the equivalence

$$(e_2, e_3) \leftrightarrow (\partial_x h^k e_k^A e_A, \partial_y h^k e_k^A e_A) , \quad (2.8.5)$$

where  $e_A$  denote octonion units. The comparison of two pairs of vectors requires normalization of the tangent vectors on the right hand side to unit vectors so that one takes unit vector in the direction of the tangent vector. After this the vectors can be equated. This allows to express the contractions of the partial derivatives with vielbein vectors with the 6 components of  $e_2$  and  $e_3$ . Each condition gives 6+6 first order partial differential equations which are non-linear by the presence of the overall normalization factor for the right hand side. The equations are invariant under scalings of  $(x, y)$ . The very special form of these equations suggests that some symmetry is involved.

It must be emphasized that these equations make sense only in preferred coordinates: ordinary Minkowski coordinates and Hamiltonin-Jacobi coordinates for  $M^4$  and Eguchi-Hanson complex coordinates in which  $SU(2) \times U(1)$  is represented linearly for  $CP_2$ . These coordinates are preferred because they carry deep physical meaning.

### Does TGD boil down to two string models?

It is good to look what have we obtained. Besides Hamilton-Jacobi conditions, and  $CP_2 = CP_2^{mod}$  conditions one has what one might call string model with 6-dimensional  $G_2/SU(3)$  as target space. The orbit of string in  $G_2/SU(3)$  allows to deduce the  $G_2$  rotation identifiable as a point of  $G_2/SU(3)$  defining what one means with standard quaternionic plane at given point of string world sheet. The hypothesis is that hyper-complex analyticity solves these equations.

The conjectured electric-magnetic duality implies duality between string world sheet and partonic 2-surfaces central for the proposed mathematical applications of TGD [36, 37, 70, 85]. This duality suggests that the solutions to the  $CP_2 = CP_2^{mod}$  conditions could reduce to holomorphy with respect to the coordinate  $w$  for partonic 2-surface plus the analogs of Virasoro conditions. The dependence on light-like coordinate would appear as a parametric dependence.

If this were the case, TGD would reduce at least partially to what might be regarded as dual string models in  $G_2/SU(3)$  and  $SU(3)/U(2)$  and also to string model in  $M^4$  and  $X^4$ ! In the previous arguments one ends up to string models in moduli spaces of string world sheets and partonic 2-surfaces. TGD seems to yield an inflation of string models! This not actually surprising since the slicing of space-time sheets by string world sheets and partonic 2-surfaces implies automatically various kinds of maps having interpretation in terms of string orbits.

### 2.8.3 Could octonion analyticity solve the field equations?

The interesting question is what happens in the space-time regions with Euclidian signature of induced metric. In this case it is not possible to introduce light-like plane at each point of the space-time sheet. Nothing however prevents from applying the above described procedure to construct conserved currents whose flow lines define global coordinates. In both cases analytic continuation allows to extend the coordinates to complex coordinates. Therefore one would have two complex functions satisfying Laplace equation and having orthogonal gradients.

1. When  $CP_2$  projection is 4-dimensional, there is strong temptation to assume that these functions could be reduced to complex  $CP_2$  coordinates analogous to the Hamilton-Jacobi coordinates for  $M^4$ . Complex Eguchi-Hanson coordinates transforming linearly under  $U(2) \subset SU(3)$  define the simplest candidates in this respect. Laplace-equations are satisfied automatically since holomorphic functions are in question. The gradients are also orthogonal automatically since the metric is Kähler metric. Note however that one could argue that in inner product the conjugate of the function appears. Any holomorphic map defines new coordinates of this kind. Note that the maps need not be globally holomorphic since  $CP_2$  projection of space-time sheet need not cover the entire  $CP_2$ .
2. For string like objects  $X^4 = X^2 \times Y^2 \subset M^4 \times CP_2$  with Minkowskian signature of the metric the coordinate pair would be hyper-complex coordinate in  $M^4$  and complex coordinate in  $CP_2$ . If  $X^2$  has Euclidian signature of induced metric the coordinate in question would be complex coordinate. The proposal in the case of  $CP_2$  allows all holomorphic functions of the complex coordinates.

There is an objection against this construction. There should be a symmetry between  $M^4$  and  $CP_2$  but this is not the case. Therefore this picture cannot be quite correct.

Could the construction of new preferred coordinates by holomorphic maps generalize as electric-magnetic duality suggests? One can imagine several options, which bring in mind old ideas that what I have christened as "romantic stuff" [72].

1. Should one generalize the holomorphic map to a quaternion analytic map with real Taylor coefficients so that non-commutativity would not produce problems. One would map first  $M^4$  coordinates to quaternions, map these coordinates to new ones by quaternion analytic map defined by a Taylor or even Laurnte expansion with real coefficients, and then map the resulting quaternion valued coordinate back to hyper-quaternion defining four coordinates as fuctions in  $M^4$ . This procedure would be very much analogous to Wick rotation used in quantum field theories. Similar quaternion analytic map be applied also in  $CP_2$  degrees of freedom followed by the map of the quaternion to two complex numbers. This would give additional constraints on the map. This option could be seen as a quaternionic generalization of conformal invariance.

The problem is that one decouples  $M^4$  and  $CP_2$  degrees of freedom completely. These degrees are however coupled in the proposed construction since the  $E^2(x)$  corresponds to subspace of  $E_x^2 \times T(CP_2)$ . Something goes still wrong.

2. This motivates to imagine even more ambitious and even more romantic option realizing the original idea about octonionic generalization of conformal invariance. Assume linear  $M^4 \times CP_2$  coordinates (Eguchi-Hanson coordinates transforming linearly under  $U(2)$  in the case of  $CP_2$ ). Map these to octonionic coordinate  $h$ . Map the octonionic coordinate to itself by an octonionic analytic map defined by Taylor or even Laurent series with real coefficients so that non-commutativity and non-associativity do not cause troubles. Map the resulting octonion valued coordinates back to ordinary  $H$ -coordinates and expressible as functions of original coordinates.

It must be emphasized that this would be nothing but a generalization of Wick rotation and its inverse used routinely in quantum field theories in order to define loop integrals.

#### Could octonion real-analyticity make sense?

Suppose that one -for a fleeting moment- takes octonionic analyticity seriously. For space-time surfaces themselves one should have in some sense quaternionic variant of conformal invariance. What does this mean?

1. Could one regard space-time surfaces analogous to the curves at which the imaginary part of analytic function of complex argument vanishes so that complex analyticity reduces to real analyticity. One can indeed divide octonion to quaternion and its imaginary part to give  $o = q_1 + Iq_2$ :  $q_1$  and  $q_2$  are quaternionic and  $I$  is octonionic imaginary unit in the complement of the quaternionic sub-space. This decomposition actually appears in the standard construction of octonions. Therefore 4-dimensional surfaces at which the imaginary part of octonion valued function vanishes make sense and defined in well-defined sense quaternionic 4-surfaces.

This kind of definition would be in nice accord with the vision about physics as algebraic geometry. Now the algebraic geometry would be extended from complex realm to the octonionic realm since quaternionic surfaces/string world sheets could be regarded as associative/commutative sub-algebras of the algebra of the octonionic real-analytic functions.

2. Could these surfaces correspond to quaternionic 4-surfaces defined in terms of the modified gamma matrices or induced gamma matrices? Contrary to the original expectations it will be found that only induced gamma matrices is a plausible option. This would be an enormous simplification and would mean that the theory is exactly solvable in the same sense as string models are: complex analyticity would be replaced with octonion analyticity. I have considered this option in several variants using the notion of real octonion analyticity [72] but have not managed to build any satisfactory scenario.
3. Hyper-complex and complex conformal symmetries would result by a restriction to hyper-complex *resp.* complex sub-manifolds of the imbedding space defined by string world sheets *resp.* partonic 2-surfaces. The principle forcing this restriction would be commutativity. Yangian of an affine algebra would unify these views to single coherent view [84].

4-D n-point functions of the theory should result from the restriction on partonic 2-surfaces or string world sheets with arguments of n-point functions identified as the ends of braid strands so that a kind of analytic continuation from 2-D to the 4-D case would be in question. The octonionic conformal invariance would be induced by the ordinary conformal invariance in accordance with strong form of General Coordinate Invariance.

4. This algebraic continuation of the ordinary conformal invariance could help to construct also the representations of Yangians of affine Kac-Moody type algebras. For the Yangian symmetry of 1+1 D integrable QFTs the charges are multilocal involving multiple integrals over ordered multiple points of 1-D space. I

In the recent case multiple 1-D space is replaced with a space-like 3-surface at the light-like end of  $CD$ . The point of the 1-D space appearing in the multiple integral are replaced by a partonic 2-surface represented by a collection of punctures. There is a strong temptation to assume that the intermediate points on the line correspond to genuine physical particles and therefore to partonic 2-surfaces at which the signature of the induced metric changes. If so, the 1-D space would correspond to a closed curve connecting punctures of different partonic 2-surfaces representing physical particles and ordered along a loop. The integral over multiple points would correspond to an integral over WCW rather than over fixed back-ground space-time.

1-D space would be replaced with a closed curve going through punctures of a subset of partonic 2-surfaces associated with a space-like 3-surface. If a given partonic surface or a given puncture can contribute only once to the multiple integral the multi-locality is bounded from above and only a finite number of Yangian generators are obtained in this manner unless one allows the number of partonic 2-surfaces and of punctures for them to vary. This variation is physically natural and would correspond to generation of particle pairs by vacuum polarization. Although only punctures would contribute, the Yangian charges would be defined in WCW rather than in fixed space-time. Integral over positions of punctures and possible numbers of them would be actually an integral over WCW. 2-D modular invariance of Yangian charges for the partonic 2-surfaces is a natural constraint.

The question is whether some conformal fields at the punctures of the partonic 2-surfaces appearing in the multiple integral define the basic building bricks of the conserved quantum charges representing the multilocal generators of the Yangian algebra? Note that Wick rotation would be involved.

### What the non-triviality of the moduli space of the octonionic structures means?

The moduli space  $G_2$  of the octonionic structures is essentially the Galois group defined as maps of octonions to itself respecting octonionic sum and multiplication. This raises the question whether octonion analyticity should be generalized in such a manner that the global choice of the octonionic imaginary units - in particular that of preferred commuting complex sub-space- would become local. Physically this would correspond to the choice of momentum plane  $M_x^2$  for a position dependent light-like momentum defining the plane of non-physical polarizations.

This question is inspired by the general solution ansatz based on the slicing of space-time sheets which involves the dependence of the choice of the momentum plane  $M_x^2$  on the point of string world sheet. This dependence is parameterized by a point of  $G_2/SU(3)$  and assumed to be constant along partonic 2-surfaces. These slicings would be naturally associated with the two complex parts  $c_i$  of the quaternionic coordinate  $q_1 = c_1 + Ic_2$  of the space-time sheet.

This dependence is well-defined only for the quaternionic 4-surface defining the space-time surface and can be seen as a local choice of a preferred complex imaginary unit along string world sheets.  $CP_2$  would parametrize the remaining geometric degrees of freedom. Should/could one extend this dependence to entire 8-D imbedding space? This is possible if the 8-D imbedding space allows a slicing by the string world sheets. If the string world sheets correspond to the string world sheets appearing in the slicing of  $M^4$  defined by Hamilton-Jacobi coordinates [8], this slicing indeed exists.

### Zero energy ontology and octonion analyticity

How does this picture relate to zero energy ontology and how partonic 2-surfaces and string world sheets could be identified in this framework?

1. The intersection of the quaternionic four-surfaces with the 7-D light-like boundaries of  $CD$ s is 3-D space-like surface. String world sheets are obtained as 2-D complex surfaces by putting  $c_2 = 0$ , where  $c_2$  is the imaginary part of the quaternion coordinate  $q = c_1 + Ic_2$ . Their intersections with  $CD$  boundaries are generally 1-dimensional and represent space-like strings.
2. Partonic 2-surfaces could correspond to the intersections of  $Re(c_1) = constant$  3-surfaces with the boundaries of  $CD$ . The variation of  $Re(c_1)$  would give a family of (possibly light-like) 3-surfaces whose intersection with the boundaries of  $CD$  would be 2-dimensional. The interpretation  $Re(c_1) = constant$  surfaces as (possibly light-like) orbits of partonic 2-surfaces would be natural. Wormhole throats at which the signature of the induced metric changes (by definition) would correspond to some special value of  $Re(c_1)$ , naturally  $Re(c_1) = 0$ .

What comes first in mind is that partonic 2-surfaces assignable to wormhole throats correspond to co-complex 2-surfaces obtained by putting  $c_1 = 0$  (or  $c_1 = constant$ ) in the decomposition  $q = c_1 + ic_2$ . This option is consistent with the above assumption if  $Im(c_1) = 0$  holds true at the boundaries of  $CD$ . Note that also co-quaternionic surfaces make sense and would have Euclidian signature of the induced metric: the interpretation as counterparts of lines of generalized Feynman graphs might make sense.

3. One can of course wonder whether also the poles of  $c_1$  might be relevant. The most natural idea is that the value of  $Re(c_1)$  varies between 0 and  $\infty$  between the ends of the orbit of partonic 2-surface. This would mean that  $c_1$  has a pole at the other end of  $CD$  (or light-like orbit of partonic 2-surface). In light of this the earlier proposal [70] that zero energy states might correspond to rational functions assignable to infinite primes and that the zeros/poles of these functions correspond to the positive/negative energy part of the state is interesting.

The intersections of string world sheets and partonic 2-surfaces identifiable as the common ends of space-like and time like braid strands would correspond to the points  $q = c_1 + Ic_2 = 0$  and  $q = \infty + Ic_2$ , where  $\infty$  means real infinity. In other words, to the zeros and real poles of quaternion analytic function with real coefficients. In the number theoretic vision especially interesting situations correspond to polynomials with rational number valued coefficients and rational functions formed from these. In this kind of situations the number of zeros and therefore of braid strands is always finite.

### Do induced or modified gamma matrices define quaternionicity?

There are two options to be considered: either induced or modified gamma matrices define quaternionicity.

1. There are several arguments supporting this view that induced gamma matrices define quaternionicity and that quaternionic planes are therefore tangent planes for space-time sheet.
  - (a)  $H - M^8$  correspondence is based on the observation that quaternionic sub-spaces of octonions containing preferred complex sub-space are labelled by points of  $CP_2$ . The integrability of the distribution of quaternionic spaces could follow from the parametrization by points of  $CP_2$  ( $CP_2 = CP_{mod}$  condition). Quaternionic planes would be necessarily tangent planes of space-time surface. Induced gamma matrices correspond naturally to the tangent space vectors of the space-time surface.  
 Here one should however understand the role of the  $M^4$  coordinates. What is the functional form of  $M^4$  coordinates as functions of space-time coordinates or does this matter at all (general coordinate invariance): could one choose the space-time coordinates as  $M^4$  coordinates for surfaces representable as graphs for maps  $M^4 \rightarrow CP_2$ ? What about other cases such as cosmic strings [21]?
  - (b) Could one do entirely without gamma matrices and speak only about induced octonion structure in 8-D tangent space (raising also dimension  $D = 8$  to preferred role) with reduces to quaternionic structure for quaternionic 4-surfaces. The interpretation of quaternionic plane as tangent space would be unavoidable also now. In this approach there would be no question about whether one should identify octonionic gamma matrices as induced gamma matrices or as modified octonionic gamma matrices.
  - (c) If quaternion analyticity is defined in terms of modified gamma matrices defined by the volume action why it would solve the field equations for Kähler action rather than for minimal surfaces? Is the reason that quaternionic and octonionic analyticities defined as generalized differentiability are not possible. The real and imaginary parts of quaternionic real-analytic function with quaternion interpreted as bi-complex number are not analytic functions of two complex variables of either complex variable. In 4-D situation minimal surface property would be too strong a condition whereas Kähler action poses much weaker conditions. Octonionic real-analyticity however poses strong symmetries and suggests effective 2-dimensionality.
2. The following argument suggest that modified gamma matrices cannot define the notion of quaternionic plane.
  - (a) Modified gamma matrices can define sub-spaces of lower dimensionality so that they do not defined a 4-plane. In this case they cannot define  $CP_2$  point so that  $CP_2 = CP_2^{mod}$  identity fails. Massless extremals represents the basic example about this. Hydrodynamic solutions defined in terms of Beltrami flows could represent a more general phase of this kind.
  - (b) Modified gamma matrices are not in general parallel to the space-time surface. The  $CP_2$  part of field equations coming from the variation of Kähler form gives the non-tangential contribution. If the distribution of the quaternionic planes is integrable it defines another space-time surface and this looks rather strange.
  - (c) Integrable quaternionicity can mean only tangent space quaternionicity. For modified gamma matrices this cannot be the case. One cannot assign to the octonion analytic map modified gamma matrices in any natural manner.

The conclusion seems to be that induced gamma matrices or induced octonion structure must define quaternionicity and quaternionic planes are tangent planes of space-time surface and therefore define an integrable distribution. An open question is whether  $CP_2 = CP_2^{mod}$  condition implies the integrability automatically.

### Volume action or Kähler action?

What seems clear is that quaternionicity must be defined by the induced gamma matrices obtained as contractions of canonical momentum densities associated with volume action with imbedding space gamma matrices. Probably equivalent definition is in terms of induced octonion structure. For the believer in strings this would suggest that the volume action is the correct choice. There are however strong objections against this choice.

1. In 2-dimensional case the minimal surfaces allow conformal invariance and one can speak of complex structure in their tangent space. In particular, string world sheets can be regarded as complex 2-surfaces of quaternionic space-time surfaces. In 4-dimensional case the situation is different since quaternionic differentiability fails by non-commutativity. It is quite possible that only very few minimal surfaces (volume action) are quaternionic.
2. The possibility of Beltrami flows is a rather plausible property of quite many preferred extremals of Kähler action. Beltrami flows are also possible for a 4-D minimal surface action. In particular,  $M^4$  translations would define Beltrami flows for which the 1-forms would be gradients of linear  $M^4$  coordinates. If  $M^4$  coordinate can be used one obtains flows in directions of all coordinate axes. Hydrodynamical picture in the strong form therefore fails whereas for Kähler action various isometry currents could be parallel (as they are for massless extremals).
3. For volume action topological QFT property fails as also fails the decomposition of solutions to massless quanta in Minkowskian regions. The same applies to criticality. The crucial vacuum degeneracy responsible for most nice features of Kähler action is absent and also the effective 2-dimensionality and almost topological QFT property are lost since the action does not reduce to 3-D term.

One can however keep Kähler action and define quaternionicity in terms of induced gamma matrices or induced octonion structure. Preferred extremals could be identified as extremals of Kähler action which are also quaternionic 4-surfaces.

1. Preferred extremal property for Kähler action could be much weaker condition than minimal surface property so that much larger set of quaternionic space-time surfaces would be extremals of the Kähler action than of volume action. The reason would be that the rank of energy momentum tensor for Maxwell action tends to be smaller than maximal. This expectation is supported by the vacuum degeneracy, the properties of massless extremals and of  $CP_2$  type vacuum extremals, and by the general hydrodynamical picture.
2. There is also a long list of beautiful properties supporting Kähler action which should be also familiar: effective 2-dimensionality and slicing of space-time surface by string world sheets and partonic 2-surfaces, reduction to almost topological QFT and to abelian Chern-Simons term, weak form of electric-magnetic duality, quantum criticality, spin glass degeneracy, etc...

### Are quaternionicities defined in terms of induced gamma matrices *resp.* octonion real-analytic maps equivalent?

Quaternionicity could be defined by induced gamma matrices or in terms of octonion real-analytic maps. Are these two definitions equivalent and how could one test the equivalence?

1. The calculation technical problem is that space-time surfaces are not defined in terms of imbedding map involving some coordinate choice but in terms of four vanishing conditions for the imaginary part of the octonion real-analytic function expressible as biquaternion valued functions.
2. Integrability to 4-D surface is achieved if there exists a 4-D closed Lie algebra defined by vector fields identifiable as tangent vector fields. This Lie algebra can be generalized to a local 4-D Lie algebra. One cannot however represent octonionic units in terms of 8-D vector fields since the commutators of the latter do not form an associative algebra. Also the representation of 7 octonionic imaginary units as 8-D vector fields is impossible since the algebra in question is non-associative Malcev algebra [20] which can be seen as a Lie algebra over non-associative number

field (one speaks of 7-dimensional cross product [33]). One must use instead of vector fields either octonionic units as such or octonionic gamma "matrices" to represent tangent vectors. The use of octonionic units as such would mean the introduction of the notion of octonionic tangent space structure. That the subalgebra generated by any two octonionic units is associative brings strongly in mind effective 2-dimensionality.

3. The tangent vector fields of space-time surface in the representation using octonionic units can be identified in the following manner. Map can be defined using 8-D octonionic coordinates defined by standard  $M^4$  coordinates or possibly Hamilton-Jacobi coordinates and  $CP_2$  complex coordinates for which  $U(2)$  is represented linearly. Gamma "matrices" for  $H$  using octonionic representation are known in these coordinates. One can introduce the 8 components of the image of a given point under the octonion real-analytic map as new imbedding space coordinates. One can calculate the covariant gamma matrices of  $H$  in these coordinates.

What should check whether the octonionic gamma matrices associated with the four non-vanishing coordinates define quaternionic (and thus associative) algebra in the octonionic basis for the gamma matrices. Also the interpretation as a associative subspace of local Malcev algebra elements is possible and one should check whether if the algebra reduces to a quaternionic Lie-algebra. Local  $SO(2) \times U(1)$  algebra should emerge in this manner.

4. Can one identify quaternionic imaginary units with vector fields generating  $SO(3)$  Lie algebra or its local variant? The Lie algebra of rotation generators defines algebra equivalent with that based on commutars of quaternionic units. Could the slicing of space-time sheet by time axis define local  $SO(3)$  algebra? Light-like momentum direction and momentum direction and its dual define as their sum space-like vector field and together with vector fields defining transversal momentum directions they might generate a local  $SO(3)$  algebra.

#### Questions related to quaternion real-analyticity

There are many poorly understood issues and the following questions represent only some of very many such questions picked up rather randomly.

1. The above considerations are restricted to Minkowskian regions of space-time sheets. What happens in the Euclidian regions? Does the existence of light-like Beltrami field and its dual generalize to the existence of complex vector field and its dual?
2. It would be nice to find a justification for the notion of  $CD$  from basic principles. The condition  $q\bar{q} = 0$  implies  $q = 0$  for quaternions. For hyper-quaternionic subspace of complexified quaternions obtained by Wick rotation it implies  $q\bar{q} = 0$  corresponds the entire light-cone boundary. If n-point functions can be identified identified as products of quaternion valued n-point functions and their quaternionic conjugates, the outcome could be proportional to  $1/q\bar{q}$  having poles at light-cone boundaries or  $CD$  boundaries rather than at single point as in Euclidian realm.
3. This correspondence of points and light-cone boundaries would effectively identify the points at future and past light-like boundaries of  $CD$  along light rays. Could one think that only the 2-sphere at which the upper and lower light-like boundaries of  $CD$  meet remains after this identification. The structure would be homologically very much like  $CP_2$  which is obtained by compactifying  $E^4$  by adding a 2-sphere at infinity. Could this  $CD - CP_2$  correspondence have some deep physical meaning? Do the boundaries of  $CD$  somehow correspond to zeros and/or poles of quaternionic analytic functions in the Minkowskian realm? Could the light-like orbits of partonic 2-surfaces at which the signature of the induced metric changes correspond to similar counterparts of zeros or poles when the quaternion analytic variables is obtained as quaternion real analytic function of  $H$  coordinates regarded as bi-quaternions?
4. Could braids correspond to zeros and poles of an octonion real-analytic function? Consider the partonic 2-surfaces at which the signature of the induced metric changes. The intersections of these surfaces with string world sheets at the ends of  $CDs$ . contain only complex and thus commutative points meaning that the imaginary part of bi-complex number representing quaternionic value of octonion real-analytic function vanishes. Braid ends would thus correspond to the origins of local complex coordinate patches. Finite measurement resolution would be forced

by commutativity condition and correlate directly with the complexity of the partonic 2-surface measured by the minimal number of coordinate patches. Its realization would be as an upper bound on the number of braid strands. A natural expectation would be that only the values of  $n$ -point functions at these points contribute to scattering amplitudes. Number theoretic braids would be realized but in a manner different from the original guess.

### How complex analysis could generalize?

One can make several questions related to the possible generalization of complex analysis to the quaternionic and octonionic situation.

1. Does the notion of analyticity in the sense that derivatives  $df/dq$  and  $df/do$  make sense hold true? The answer is "No": non-commutativity destroys all hopes about this kind of generalization. Octonion and quaternion real-analyticity has however a well-defined meaning.
2. Could the generalization of residue calculus by keeping interaction contours as 1-D curves make sense? Since residue formulas is the outcome of the fact that any analytic function  $g$  can be written as  $g = df/dz$  locally, the answer is "No".
3. Could one generalize of the residue calculus by replacing 1-dimensional curves with 4-D surfaces -possibly quaternionic 4-surfaces? Could one reduce the 4-D integral of quaternion analytic function to a double residue integral? This would be the case if the quaternion real-analytic function of  $q = c_1 + Ic_2$  could be regarded as an analytic function of complex arguments  $c_1$  and  $c_2$ . This is not the case. The product of two octonions decomposed to two quaternions as  $o_i = q_{i1} + Iq_{i2}$ ,  $i = a, b$  reads as

$$o_a o_b = q_{a1} q_{b1} - \bar{q}_{a2} q_{b2} + I(\bar{q}_{a1} q_{b2} - q_{a2} q_{b1}) . \quad (2.8.6)$$

The conjugations result from the anticommutativity of imaginary parts and  $I$ . This formula gives similar formula for quaternions by restriction. As a special cas  $o_a = o_b = q_1 + Iq_2$  one has

$$o^2 = q_1^2 - \bar{q}_2 q_2 + I(\bar{q}_1 q_2 - q_2 q_1)$$

From this it is clear that the real part of an octonion real-analytic function cannot be regarded as quaternion-analytic function unless one assumes that the imaginary part  $q_2$  vanishes. By similar argument real part of quaternion real-analytic function  $q = c_1 + Ic_2$  fails to be analytic unless one restricts the consideration to a surface at which one has  $c_2 = 0$ . These negative results are obviously consistent with the effective 2-dimensionality.

4. One must however notice that physicists use often what might be called analytization trick [3] working if the non-analytic function  $f(x, y) = f(z, \bar{z})$  is differentiable. The trick is to interpret  $z$  and  $\bar{z}$  as independent variables. In the recent case this is rather natural. Wick rotation could be used to transform the integral over the space-time sheet to integral in quaternionic domain. For 4-dimensional integrals of quaternion real-analytic function with integration measure proportional to  $dc_1 d\bar{c}_1 dc_2 d\bar{c}_2$  one could formally define the integral using multiple residue integration with four complex variables. The constraint is that the poles associated with  $c_i$  and  $\bar{c}_i$  are conjugates of each other. Quaternion real-analyticity should guarantee this. This would of course be a *definition* of four-dimensional integral and might work for the 4-D generalization of conformal field theory.

Mandelbrot and Julia sets are fascinating fractals and already now more or less a standard piece of complex analysis. The fact that the iteration of octonion real-analytic map produces a sequence of space-time surfaces and partonic 2-surfaces encourages to ask whether these notions -and more generally, the dynamics based on iteration of analytic functions - might have a higher-dimensional generalization in the proposed framework.

1. The canonical Mandelbrot set corresponds to the set of the complex parameters  $c$  in  $f(z) = z^2 + c$  for which iterates of  $z = 0$  remain finite. In octonionic and quaternionic real-analytic case  $c$  would be real so that one would obtain only the intersection of the Mandelbrot set with real axes and the outcome would be rather uninteresting. This is true quite generally.
2. Julia set corresponds to the boundary of the Fatou set in which the dynamics defined by the iteration of  $f(z)$  by definition behaves in a regular manner. In Julia set the behavior is chaotic. Julia set can be defined as a set of complex plane resulting by taking inverse images of a generic point belonging to the Julia set. For polynomials Julia set is the boundary of the region in which iterates remain finite. In Julia set the dynamics defined by the iteration is chaotic.

Julia set could be interesting also in the recent case since it could make sense for real analytic functions of both quaternions and octonions, and one might hope that the dynamics determined by the iterations of octonion real-analytic function could have a physical meaning as a space-time correlate for quantal self-organization by quantum jump in TGD framework. Single step in iteration would be indeed a very natural space-time correlate for quantum jump. The restriction of octonion analytic functions to string world sheets should produce the counterparts of the ordinary Julia sets since these surfaces are mapped to themselves under iteration and octonion real-analytic functions reduces to ordinary complex real-analytic functions at them. Therefore one might obtain the counterparts of Julia sets in 4-D sense as extensions of ordinary Julia sets. These extensions would be 3-D sets obtained as piles of ordinary Julia sets labelled by partonic 2-surfaces.

## 2.9 In what sense TGD could be an integrable theory?

During years evidence supporting the idea that TGD could be an integrable theory in some sense has accumulated. The challenge is to show that various ideas about what integrability means form pieces of a bigger coherent picture. Of course, some of the ideas are doomed to be only partially correct or simply wrong. Since it is not possible to know beforehand what ideas are wrong and what are right the situation is very much like in experimental physics and it is easy to claim (and has been and will be claimed) that all this argumentation is useless speculation. This is the price that must be paid for real thinking.

Integrable theories allow to solve nonlinear classical dynamics in terms of scattering data for a linear system. In TGD framework this translates to quantum classical correspondence. The solutions of modified Dirac equation define the scattering data. This data should define a real analytic function whose octonionic extension defines the space-time surface as a surface for which its imaginary part in the representation as bi-quaternion vanishes. There are excellent hopes about this thanks to the reduction of the modified Dirac equation to geometric optics.

In the following I will first discuss briefly what integrability means in (quantum) field theories, list some bits of evidence for integrability in TGD framework, discuss once again the question whether the different pieces of evidence are consistent with other and what one really means with various notions. As an outcome I represent what I regard as a more coherent view about integrability of TGD. The notion of octonion analyticity developed in the previous section is essential for the for what follows.

### 2.9.1 What integrable theories are?

The following is an attempt to get some bird's eye of view about the landscape of integrable theories.

#### Examples of integrable theories

Integrable theories are typically non-linear 1+1-dimensional (quantum) field theories. Solitons and various other particle like structures are the characteristic phenomenon in these theories. Scattering matrix is trivial in the sense that the particles go through each other in the scattering and suffer only a phase change. In particular, momenta are conserved. Korteweg-de Vries equation [7] was motivated by the attempt to explain the experimentally discovered shallow water wave preserving its shape and moving with a constant velocity. Sine-Gordon equation [15] describes geometrically constant curvature surfaces and defines a Lorentz invariant non-linear field theory in 1+1-dimensional space-time, which can be applied to Josephson junctions (in TGD inspired quantum biology it is encountered in the

model of nerve pulse [59]). Non-linear Schrödinger equation [12] having applications to optics and water waves represents a further example. All these equations have various variants.

From TGD point of view conformal field theories represent an especially interesting example of integrable theories. (Super-)conformal invariance is the basic underlying symmetry and by its infinite-dimensional character implies infinite number of conserved quantities. The construction of the theory reduces to the construction of the representations of (super-)conformal algebra. One can solve 2-point functions exactly and characterize them in terms of (possibly anomalous) scaling dimensions of conformal fields involved and the coefficients appearing in 3-point functions can be solved in terms of fusion rules leading to an associative algebra for conformal fields. The basic applications are to 2-dimensional critical thermodynamical systems whose scaling invariance generalizes to conformal invariance. String models represent second application in which a collection of super-conformal field theories associated with various genera of 2-surface is needed to describe loop corrections to the scattering amplitudes. Also moduli spaces of conformal equivalence classes become important.

Topological quantum field theories are also examples of integrable theories. Because of its independence on the metric Chern-Simons action is in 3-D case the unique action defining a topological quantum field theory. The calculations of knot invariants (for TGD approach see [36]), topological invariants of 3-manifolds and 4-manifolds, and topological quantum computation (for a model of DNA as topological quantum computer see [26]) represent applications of this approach. TGD as almost topological QFT means that the Kähler action for preferred extremals reduces to a surface term by the vanishing of Coulomb term in action and by the weak form of electric-magnetic duality reduces to Chern-Simons action. Both Euclidian and Minkowskian regions give this kind of contribution.

$\mathcal{N} = 4$  SYM is the a four-dimensional and very nearly realistic candidate for an integral quantum field theory. The observation that twistor amplitudes allow also a dual of the 4-D conformal symmetry motivates the extension of this symmetry to its infinite-dimensional Yangian variant [41]. Also the enormous progress in the construction of scattering amplitudes suggests integrability. In TGD framework Yangian symmetry would emerge naturally by extending the symplectic variant of Kac-Moody algebra from light-cone boundary to the interior of causal diamond and the Kac-Moody algebra from light-like 3-surface representing wormhole throats at which the signature of the induced metric changes to the space-time interior [84].

### About mathematical methods

The mathematical methods used in integrable theories are rather refined and have contributed to the development of the modern mathematical physics. Mention only quantum groups, conformal algebras, and Yangian algebras.

The basic element of integrability is the possibility to transform the non-linear classical problem for which the interaction is characterized by a potential function or its analog to a linear scattering problem depending on time. For instance, for the ordinary Schrödinger function one can solve potential once single solution of the equation is known. This does not work in practice. One can however gather information about the asymptotic states in scattering to deduce the potential. One cannot do without information about bound state energies too.

In TGD framework asymptotic states correspond to partonic 2-surfaces at the two light-like boundaries of  $CD$  (more precisely: the largest  $CD$  involved and defining the IR resolution for momenta). From the scattering data coding information about scattering for various values of energy of the incoming particle one deduced the potential function or its analog.

1. The basic tool is inverse scattering transform known as Gelfand-Marchenko-Levitan (GML) transform described in simple terms in [19].
  - (a) In 1+1 dimensional case the S-matrix characterizing scattering is very simple since the only thing that can take place in scattering is reflection or transmission. Therefore the S-matrix elements describe either of these processes and by unitarity the sum of corresponding probabilities equals to 1. The particle can arrive to the potential either from left or right and is characterized by a momentum. The transmission coefficient can have a pole meaning complex (imaginary in the simplest case) wave vector serving as a signal for the formation of a bound state or resonance. The scattering data are represented by the reflection and transmission coefficients as function of time.

- (b) One can deduce an integral equation for a propagator like function  $K(t, x)$  describing how delta pulse moving with light velocity is scattered from the potential and is expressible in terms of time integral over scattering data with contributions from both scattering states and bound states. The derivation of GML transform [19] uses time reversal and time translational invariance and causality defined in terms of light velocity. After some tricks one obtains the integral equation as well as an expression for the time independent potential as  $V(x) = K(x, x)$ . The argument can be generalized to more complex problems to deduce the GML transform.
2. The so called Lax pair is one manner to describe integrable systems [8]. Lax pair consists of two operators  $L$  and  $M$ . One studies what might be identified as "energy" eigenstates satisfying  $L(x, t)\Psi = \lambda\Psi$ .  $\lambda$  does not depend on time and one can say that the dynamics is associated with  $x$  coordinate whereas as  $t$  is time coordinate parametrizing different variants of eigenvalue problem with the same spectrum for  $L$ . The operator  $M(t)$  does not depend on  $x$  at all and the independence of  $\lambda$  on time implies the condition

$$\partial_t L = [L, M] \ .$$

This equation is analogous to a quantum mechanical evolution equation for an operator induced by time dependent "Hamiltonian"  $M$  and gives the non-linear classical evolution equation when the commutator on the right hand side is a multiplicative operator (so that it does not involve differential operators acting on the coordinate  $x$ ). Non-linear classical dynamics for the time dependent potential emerges as an integrability condition.

One could say that  $M(t)$  introduces the time evolution of  $L(t, x)$  as an automorphism which depends on time and therefore does not affect the spectrum. One has  $L(t, x) = U(t)L(0, x)U^{-1}(t)$  with  $dU(t)/dt = M(t)U(t)$ . The time evolution of the analog of the quantum state is given by a similar equation.

3. A more refined view about Lax pair is based on the observation that the above equation can be generalized so that  $M$  depends also on  $x$ . The generalization of the basic equation for  $M(x, t)$  reads as

$$\partial_t L - \partial_x M - [L, M] = 0 \ .$$

The condition has interpretation as a vanishing of the curvature of a gauge potential having components  $A_x = L, A_t = M$ . This generalization allows a beautiful geometric formulation of the integrability conditions and extends the applicability of the inverse scattering transform. The monodromy of the flat connection becomes important in this approach. Flat connections in moduli spaces are indeed important in topological quantum field theories and in conformal field theories.

4. There is also a connection with the so called Riemann-Hilbert problem [31]. The monodromies of the flat connection define monodromy group and Riemann-Hilbert problem concerns the existence of linear differential equations having a given monodromy group. Monodromy group emerges in the analytic continuation of an analytic function and the action of the element of the monodromy group tells what happens for the resulting many-valued analytic function as one turns around a singularity once ('mono-'). The linear equations obviously relate to the linear scattering problem. The flat connection  $(M, L)$  in turn defines the monodromy group. What is needed is that the functions involved are analytic functions of  $(t, x)$  replaced with a complex or hyper-complex variable. Again Wick rotation is involved. Similar approach generalizes also to higher dimensional moduli spaces with complex structures.

In TGD framework the effective 2-dimensionality raises the hope that this kind of mathematical apparatus could be used. An interesting possibility is that finite measurement resolution could be realized in terms of a gauge group or Kac-Moody type group represented by trivial gauge potential defining a monodromy group for n-point functions. Monodromy invariance would hold for the full n-point functions constructed in terms of analytic n-point functions and their conjugates. The ends of braid strands are natural candidates for the singularities around which monodromies are defined.

### 2.9.2 Why TGD could be integrable theory in some sense?

There are many indications that TGD could be an integrable theory in some sense. The challenge is to see which ideas are consistent with each other and to build a coherent picture where everything finds its own place.

1. 2-dimensionality or at least effective 2-dimensionality seems to be a prerequisite for integrability. Effective 2-dimensionality is suggested by the strong form of General Coordinate Invariance implying also holography and generalized conformal invariance predicting infinite number of conservation laws. The dual roles of partonic 2-surfaces and string world sheets supports a four-dimensional generalization of conformal invariance. Twistor considerations [82] indeed suggest that Yangian invariance and Kac-Moody invariances combine to a 4-D analog of conformal invariance induced by 2-dimensional one by algebraic continuation.
2. Octonionic representation of imbedding space Clifford algebra and the identification of the space-time surfaces as quaternionic space-time surfaces would define a number theoretically natural generalization of conformal invariance. The reason for using gamma matrix representation is that vector field representation for octonionic units does not exist. The problem concerns the precise meaning of the octonionic representation of gamma matrices.

Space-time surfaces could be quaternionic also in the sense that conformal invariance is analytically continued from string curve to 8-D space by octonion real-analyticity. The question is whether the Clifford algebra based notion of tangent space quaternionicity is equivalent with octonionic real-analyticity based notion of quaternionicity.

The notions of co-associativity and co-quaternionicity make also sense and one must consider seriously the possibility that associativity-co-associativity dichotomy corresponds to Minkowskian-Euclidian dichotomy.

3. Field equations define hydrodynamic Beltrami flows satisfying integrability conditions of form  $J \wedge dJ = 0$ .
  - (a) One can assign local momentum and polarization directions to the preferred extremals and this gives a decomposition of Minkowskian space-time regions to massless quanta analogous to the 1+1-dimensional decomposition to solitons. The linear superposition of modes with 4-momenta with different directions possible for free Maxwell action does not look plausible for the preferred extremals of Kähler action. This rather quantal and solitonic character is in accordance with the quantum classical correspondence giving very concrete connection between quantal and classical particle pictures. For 4-D volume action one does not obtain this kind of decomposition. In 2-D case volume action gives superposition of solutions with different polarization directions so that the situation is nearer to that for free Maxwell action and is not like soliton decomposition.
  - (b) Beltrami property in strong sense allows to identify 4 preferred coordinates for the space-time surface in terms of corresponding Beltrami flows. This is possible also in Euclidian regions using two complex coordinates instead of hyper-complex coordinate and complex coordinate. The assumption that isometry currents are parallel to the same light-like Beltrami flow implies hydrodynamic character of the field equations in the sense that one can say that each flow line is analogous to particle carrying some quantum numbers. This property is not true for all extremals (say cosmic strings).
  - (c) The tangent bundle theoretic view about integrability is that one can find a Lie algebra of vector fields in some manifold spanning the tangent space of a lower-dimensional manifolds and is expressed in terms of Frobenius theorem [13]). The gradients of scalar functions defining Beltrami flows appearing in the ansatz for preferred extremals would define these vector fields and the slicing. Partonic 2-surfaces would correspond to two complex conjugate vector fields (local polarization direction) and string world sheets to light-like vector field and its dual (light-like momentum directions). This slicing generalizes to the Euclidian regions.
4. Infinite number of conservation laws is the signature of integrability. Classical field equations follow from the condition that the vector field defined by modified gamma matrices has vanishing

divergence and can be identified an integrability condition for the modified Dirac equation guaranteeing also the conservation of super currents so that one obtains an infinite number of conserved charges.

5. Quantum criticality is a further signal of integrability. 2-D conformal field theories describe critical systems so that the natural guess is that quantum criticality in TGD framework relates to the generalization of conformal invariance and to integrability. Quantum criticality implies that Kähler coupling strength is analogous to critical temperature. This condition does affect classical field equations only via boundary conditions expressed as weak form of electric magnetic duality at the wormhole throats at which the signature of the metric changes.

For finite-dimensional systems the vanishing of the determinant of the matrix defined by the second derivatives of potential is similar signature and applies in catastrophe theory. Therefore the existence of vanishing second variations of Kähler action should characterize criticality and define a property of preferred extremals. The vanishing of second variations indeed leads to an infinite number of conserved currents [28, 8].

### 2.9.3 Questions

There are several questions which are not completely settled yet. Even the question what preferred extremals are is still partially open. In the following I try to de-learn what I have possibly learned during these years and start from scratch to see which assumptions might be un-necessarily strong or even wrong.

### 2.9.4 Could TGD be an integrable theory?

Consider first the abstraction of integrability in TGD framework. Quantum classical correspondence could be seen as a correspondence between linear quantum dynamics and non-linear classical dynamics. Integrability would realize this correspondence. In integrable models such as Sine-Gordon equation particle interactions are described by potential in 1+1 dimensions. This too primitive for the purposes of TGD. The vertices of generalized Feynman diagrams take care of this. At lines one has free particle dynamics so that the situation could be much simpler than in integrable models if one restricts the considerations to the lines or Minkowskian space-time regions surrounding them.

The non-linear dynamics for the space-time sheets representing incoming lines of generalized Feynman diagram should be obtainable from the linear dynamics for the induced spinor fields defined by modified Dirac operator. There are two options.

1. Strong form of the quantum classical correspondence states that each solution for the linear dynamics of spinor fields corresponds to space-time sheet. This is analogous to solving the potential function in terms of a single solution of Schrödinger equation. Coupling of space-time geometry to quantum numbers via measurement interaction term is a proposal for realizing this option. It is however the quantum numbers of positive/negative energy parts of zero energy state which would be visible in the classical dynamics rather than those of induced spinor field modes.
2. Only overall dynamics characterized by scattering data- the counterpart of  $S$ -matrix for the modified Dirac operator- is mapped to the geometry of the space-time sheet. This is much more abstract realization of quantum classical correspondence.
3. Can these two approaches be equivalent? This might be the case since quantum numbers of the state are not those of the modes of induced spinor fields.

What the scattering data could be for the induced spinor field satisfying modified Dirac equation?

1. If the solution of field equation has hydrodynamic character, the solutions of the modified Dirac equation can be localized to light-like Beltrami flow lines of hydrodynamic flow. These correspond to basic solutions and the general solution is a superposition of these. There is no dispersion and the dynamics is that of geometric optics at the basic level. This means geometric optics like character of the spinor dynamics.

Solutions of the modified Dirac equation are completely analogous to the pulse solutions defining the fundamental solution for the wave equation in the argument leading from wave equation with external time independent potential to Marchenko-Gelfand-Levitan equation allowing to identify potential in terms of scattering data. There is however no potential present now since the interactions are described by the vertices of Feynman diagram where the particle lines meet. Note that particle like regions are Euclidian and that this picture applies only to the Minkowskian exteriors of particles.

2. Partonic 2-surfaces at the ends of the line of generalized Feynman diagram are connected by flow lines. Partonic 2-surfaces at which the signature of the induced metric changes are in a special position. Only the imaginary part of the bi-quaternionic value of the octonion valued map is non-vanishing at these surfaces which can be said to be co-complex 2-surfaces. By geometric optics behavior the scattering data correspond to a diffeomorphism mapping initial partonic 2-surface to the final one in some preferred complex coordinates common to both ends of the line.
3. What could be these preferred coordinates? Complex coordinates for  $S^2$  at light-cone boundary define natural complex coordinates for the partonic 2-surface. With these coordinates the diffeomorphism defining scattering data is diffeomorphism of  $S^2$ . Suppose that this map is real analytic so that maps "real axis" of  $S^2$  to itself. This map would be same as the map defining the octonionic real analyticity as algebraic extension of the complex real analytic map. By octonionic analyticity one can make large number of alternative choices for the coordinates of partonic 2-surface.
4. There can be non-uniqueness due to the possibility of  $G_2/SU(3)$  valued map characterizing the local octonionic units. The proposal is that the choice of octonionic imaginary units can depend on the point of string like orbit: this would give string model in  $G_2/SU(3)$ . Conformal invariance for this string model would imply analyticity and helps considerably but would not probably fix the situation completely since the element of the coset space would constant at the partonic 2-surfaces at the ends of  $CD$ . One can of course ask whether the  $G_2/SU(3)$  element could be constant for each propagator line and would change only at the 2-D vertices?

This would be the inverse scattering problem formulated in the spirit of TGD. There could be also dependence of space-time surface on quantum numbers of quantum states but not on individual solution for the induced spinor field since the scattering data of this solution would be purely geometric.

## Chapter 3

# Construction of Quantum Theory: Symmetries

### 3.1 Introduction

This chapter provides a summary about the role of symmetries in the construction of quantum TGD. The discussions are based on the general vision that quantum states of the Universe correspond to the modes of classical spinor fields in the "world of the classical worlds" (WCW) identified as the infinite-dimensional configuration space of light-like 3-surfaces of  $H = M^4 \times CP_2$  (more or less-equivalently, the corresponding 4-surfaces defining generalized Bohr orbits). The following topics are discussed on basis of this vision.

#### 3.1.1 Physics as infinite-dimensional Kähler geometry

1. The basic idea is that it is possible to reduce quantum theory to configuration space geometry and spinor structure. The geometrization of loop spaces inspires the idea that the mere existence of Riemann connection fixes configuration space Kähler geometry uniquely. Accordingly, configuration space can be regarded as a union of infinite-dimensional symmetric spaces labeled by zero modes labeling classical non-quantum fluctuating degrees of freedom.

The huge symmetries of the configuration space geometry deriving from the light-likeness of 3-surfaces and from the special conformal properties of the boundary of 4-D light-cone would guarantee the maximal isometry group necessary for the symmetric space property. Quantum criticality is the fundamental hypothesis allowing to fix the Kähler function and thus dynamics of TGD uniquely. Quantum criticality leads to surprisingly strong predictions about the evolution of coupling constants.

2. Configuration space spinors correspond to Fock states and anti-commutation relations for fermionic oscillator operators correspond to anti-commutation relations for the gamma matrices of the configuration space. Configuration space gamma matrices contracted with Killing vector fields give rise to a super-symplectic algebra which together with Hamiltonians of the configuration space forms what I have used to call super-symplectic algebra.

Super-symplectic degrees of freedom represent completely new degrees of freedom and have no electroweak couplings. In the case of hadrons super-symplectic quanta correspond to what has been identified as non-perturbative sector of QCD: they define TGD correlate for the degrees of freedom assignable to hadronic strings. They are responsible for the most of the mass of hadron and resolve spin puzzle of proton.

3. Besides super-symplectic symmetries there are Super-Kac Moody symmetries assignable to light-like 3-surfaces and together these algebras extend the conformal symmetries of string models to dynamical conformal symmetries instead of mere gauge symmetries. The construction of the representations of these symmetries is one of the main challenges of quantum TGD.

4. Modular invariance is one aspect of conformal symmetries and plays a key role in the understanding of elementary particle vacuum functionals and the description of family replication phenomenon in terms of the topology of partonic 2-surfaces.
5. Modified Dirac equation gives also rise to a hierarchy super-conformal algebras assignable to zero modes. These algebras follow from the existence of conserved fermionic currents. The corresponding deformations of the space-time surface correspond to vanishing second variations of Kähler action and provide a realization of quantum criticality. This led to a breakthrough in the understanding of the modified Dirac action via the addition of a measurement interaction term to the action allowing to obtain among other things stringy propagator and the coding of quantum numbers of super-conformal representations to the geometry of space-time surfaces required by quantum classical correspondence.
6. The effective 2-dimensionality of the space-like 3-surfaces realizing quantum holography can be formulated as a symmetry stating that the replacement of wormhole throat by any light-like 3-surfaces parallel to it in the slicing of the space-time sheet induces only a gauge transformation of WCW Kähler function adding to it a real part of a holomorphic function of complex coordinate of WCW depending also on zero modes. This means that the Kähler metric of WCW remains invariant. It is also postulated that measurement interaction added to the modified Dirac action induces similar gauge symmetry.

### 3.1.2 p-Adic physics as physics of cognition and intentionality

p-Adic mass calculations relying on p-adic length scale hypothesis led to an understanding of elementary particle masses using only super-conformal symmetries and p-adic thermodynamics. The need to fuse real physics and various p-adic physics to single coherent whole led to a generalization of the notion of number obtained by gluing together reals and p-adics together along common rationals and algebraics. The interpretation of p-adic space-time sheets is as correlates for cognition and intentionality. p-Adic and real space-time sheets intersect along common rationals and algebraics and the subset of these points defines what I call number theoretic braid in terms of which both configuration space geometry and S-matrix elements should be expressible. Thus one would obtain number theoretical discretization, which involves no adhoc elements and is inherent to the physics of TGD.

The original idea was that the notion of number theoretic braid could pose strong number theoretic conditions on physics just as p-adic thermodynamics poses on elementary particle mass spectrum. A practically oriented physicist would argue that general braids must be allowed if one wants to calculate something and that number theoretic braids represent only the intersection between the real and various p-adic physics. He could also insist that at the level of WCW various sectors must be realized in a more abstract manner - say as hierarchies of polynomials with coefficients belonging to various extensions or rationals so that one can speak about surfaces common to real and various p-adic sectors. In this view the fusion of various physics would be analogous to the completion of rationals to various number fields.

Perhaps the most dramatic implication relates to the fact that points, which are p-adically infinitesimally close to each other, are infinitely distant in the real sense (recall that real and p-adic imbedding spaces are glued together along rational imbedding space points). This means that any open set of p-adic space-time sheet is discrete and of infinite extension in the real sense. This means that cognition is a cosmic phenomenon and involves always discretization from the point of view of the real topology. The testable physical implication of effective p-adic topology of real space-time sheets is p-adic fractality meaning characteristic long range correlations combined with short range chaos.

Also a given real space-time sheets should correspond to a well-defined prime or possibly several of them. The classical non-determinism of Kähler action should correspond to p-adic non-determinism for some prime(s)  $p$  in the sense that the effective topology of the real space-time sheet is p-adic in some length scale range. p-Adic space-time sheets with same prime should have many common rational points with the real space-time and be easily transformable to the real space-time sheet in quantum jump representing intention-to-action transformation. The concrete model for the transformation of intention to action leads to a series of highly non-trivial number theoretical conjectures assuming that the extensions of p-adics involved are finite-dimensional and can contain also transcendentals.

An ideal realization of the space-time sheet as a cognitive representation results if the  $CP_2$  coordinates as functions of  $M_+^4$  coordinates have the same functional form for reals and various p-adic number

fields and that these surfaces have discrete subset of rational numbers with upper and lower length scale cutoffs as common. The hierarchical structure of cognition inspires the idea that S-matrices form a hierarchy labeled by primes  $p$  and the dimensions of algebraic extensions.

The number-theoretic hierarchy of extensions of rationals appears also at the level of configuration space spinor fields and allows to replace the notion of entanglement entropy based on Shannon entropy with its number theoretic counterpart having also negative values in which case one can speak about genuine information. In this case case entanglement is stable against Negentropy Maximization Principle stating that entanglement entropy is minimized in the self measurement and can be regarded as bound state entanglement. Bound state entanglement makes possible macro-temporal quantum coherence. One can say that rationals and their finite-dimensional extensions define islands of order in the chaos of continua and that life and intelligence correspond to these islands.

TGD inspired theory of consciousness and number theoretic considerations inspired for years ago the notion of infinite primes [70] . It came as a surprise, that this notion might have direct relevance for the understanding of mathematical cognition. The idea is very simple. There is infinite hierarchy of infinite rationals having real norm one but different but finite p-adic norms. Thus single real number (complex number, (hyper-)quaternion, (hyper-)octonion) corresponds to an algebraically infinite-dimensional space of numbers equivalent in the sense of real topology. Space-time and imbedding space points become infinitely structured and single space-time point would represent the Platonia of mathematical ideas. This structure would be completely invisible at the level of real physics but would be crucial for mathematical cognition and explain why we are able to imagine also those mathematical structures which do not exist physically. Space-time could be also regarded as an algebraic hologram. The connection with Brahman=Atman idea is also obvious.

### 3.1.3 Hierarchy of Planck constants and dark matter hierarchy

The work with HFFs combined with experiment The realization for the hierarchy of Planck constants proposed as a solution to the dark matter puzzles leads to a profound generalization of quantum TGD through a generalization of the notion of imbedding space to characterize quantum criticality. The resulting space has a book like structure with various almost-copies of the imbedding space representing the pages of the book meeting at quantum critical sub-manifolds. A particular page of the book can be seen as an n-fold singular covering or factor space of  $CP_2$  or of a causal diamond ( $CD$ ) of  $M^4$  defined as an intersection of the future and past directed light-cones. Therefore the cyclic groups  $Z_n$  appear as discrete symmetry groups.

### 3.1.4 Number theoretical symmetries

TGD as a generalized number theory vision leads to the idea that also number theoretical symmetries are important for physics.

1. There are good reasons to believe that the strands of number theoretical braids can be assigned with the roots of a polynomial with suggests the interpretation corresponding Galois groups as purely number theoretical symmetries of quantum TGD. Galois groups are subgroups of the permutation group  $S_\infty$  of infinitely manner objects acting as the Galois group of algebraic numbers. The group algebra of  $S_\infty$  is HFF which can be mapped to the HFF defined by configuration space spinors. This picture suggest a number theoretical gauge invariance stating that  $S_\infty$  acts as a gauge group of the theory and that global gauge transformations in its completion correspond to the elements of finite Galois groups represented as diagonal groups of  $G \times G \times \dots$  of the completion of  $S_\infty$ .
2. HFFs inspire also an idea about how entire TGD emerges from classical number fields, actually their complexifications. In particular,  $SU(3)$  acts as subgroup of octonion automorphisms leaving invariant preferred imaginary unit. If space-time surfaces are hyper-quaternionic (meaning that the octonionic counterparts of the modified gamma matrices span complex quaternionic sub-algebra of octonions) and contain at each point a preferred plane  $M^2$  of  $M^4$ , one ends up with  $M^8 - H$  duality stating that space-time surfaces can be equivalently regarded as surfaces in  $M^8$  or  $M^4 \times CP_2$ . One can actually generalize  $M^2$  to a two-dimensional Minkowskian sub-manifold of  $M^4$ . One ends up with quantum TGD by considering associative sub-algebras of the local

octonionic Clifford algebra of  $M^8$  or  $H$ . so that TGD could be seen as a generalized number theory.

## 3.2 Symmetries

The most general expectation is that configuration space can be regarded as a union of coset spaces which are infinite-dimensional symmetric spaces with Kähler structure:  $C(H) = \cup_i G/H(i)$ . Index  $i$  labels 3-topology and zero modes. The group  $G$ , which can depend on 3-surface, can be identified as a subgroup of diffeomorphisms of  $\delta M^4_+ \times CP_2$  and  $H$  must contain as its subgroup a group, whose action reduces to  $Diff(X^3)$  so that these transformations leave 3-surface invariant.

The task is to identify plausible candidate for  $G$  and  $H$  and to show that the tangent space of the configuration space allows Kähler structure, in other words that the Lie-algebras of  $G$  and  $H(i)$  allow complexification. One must also identify the zero modes and construct integration measure for the functional integral in these degrees of freedom. Besides this one must deduce information about the explicit form of configuration space metric from symmetry considerations combined with the hypothesis that Kähler function is Kähler action for a preferred extremal of Kähler action. One must of course understand what "preferred" means.

### 3.2.1 General Coordinate Invariance and generalized quantum gravitational holography

The basic motivation for the construction of configuration space geometry is the vision that physics reduces to the geometry of classical spinor fields in the infinite-dimensional configuration space of 3-surfaces of  $M^4_+ \times CP_2$  or of  $M^4 \times CP_2$ . Hermitian conjugation is the basic operation in quantum theory and its geometrization requires that configuration space possesses Kähler geometry. Kähler geometry is coded into Kähler function.

The original belief was that the four-dimensional general coordinate invariance of Kähler function reduces the construction of the geometry to that for the boundary of configuration space consisting of 3-surfaces on  $\delta M^4_+ \times CP_2$ , the moment of big bang. The proposal was that Kähler function  $K(Y^3)$  could be defined as a preferred extremal of so called Kähler action for the unique space-time surface  $X^4(Y^3)$  going through given 3-surface  $Y^3$  at  $\delta M^4_+ \times CP_2$ . For  $Diff^4$  transforms of  $Y^3$  at  $X^4(Y^3)$  Kähler function would have the same value so that  $Diff^4$  invariance and degeneracy would be the outcome. The proposal was that the preferred extremals are absolute minima of Kähler action.

This picture turned out to be too simple.

1. I have already described the recent view about light-like 3-surfaces as generalized Feynman diagrams and space-time surfaces as preferred extremals of Kähler action and will not repeat what has been said.
2. It has also become obvious that the gigantic symmetries associated with  $\delta M^4_\pm \times CP_2 \subset CD \times CP_2$  manifest themselves as the properties of propagators and vertices. Cosmological considerations, Poincare invariance, and the new view about energy favor the decomposition of the configuration space to a union of configuration spaces assignable to causal diamonds  $CD$ s defined as intersections of future and past directed light-cones. The minimum assumption is that  $CD$ s label the sectors of  $CH$ : the nice feature of this option is that the considerations of this chapter restricted to  $\delta M^4_+ \times CP_2$  generalize almost trivially. This option is beautiful because the center of mass degrees of freedom associated with the different sectors of  $CH$  would correspond to  $M^4$  itself and its Cartesian powers.

The definition of the Kähler function requires that the many-to-one correspondence  $X^3 \rightarrow X^4(X^3)$  must be replaced by a bijective correspondence in the sense that  $X^3_l$  as light-like 3-surface is unique among all its  $Diff^4$  translates. This also allows physically preferred "gauge fixing" allowing to get rid of the mathematical complications due to  $Diff^4$  degeneracy. The internal geometry of the space-time sheet must define the preferred 3-surface  $X^3_l$ .

The realization of this vision means a considerable mathematical challenge. The effective metric 2-dimensionality of 3-dimensional light-like surfaces  $X^3_l$  of  $M^4$  implies generalized conformal and symplectic symmetries allowing to generalize quantum gravitational holography from light like boundary so that the complexities due to the non-determinism can be taken into account properly.

### 3.2.2 Light like 3-D causal determinants and effective 2-dimensionality

The light like 3-surfaces  $X_l^3$  of space-time surface appear as 3-D causal determinants. Basic examples are boundaries and elementary particle horizons at which Minkowskian signature of the induced metric transforms to Euclidian one. This brings in a second conformal symmetry related to the metric 2-dimensionality of the 3-D light-like 3-surface. This symmetry is identifiable as TGD counterpart of the Kac Moody symmetry of string models. The challenge is to understand the relationship of this symmetry to configuration space geometry and the interaction between the two conformal symmetries.

1. Field-particle duality is realized. Light-like 3-surfaces  $X_l^3$  -generalized Feynman diagrams - correspond to the particle aspect of field-particle duality whereas the physics in the interior of space-time surface  $X^4(X_l^3)$  would correspond to the field aspect. Generalized Feynman diagrams in 4-D sense could be identified as regions of space-time surface having Euclidian signature.
2. One could also say that light-like 3-surfaces  $X_l^3$  and the space-like 3-surfaces  $X^3$  in the intersections of  $X^4(X_l^3) \cap CD \times CP_2$  where the causal diamond  $CD$  is defined as the intersections of future and past directed light-cones provide dual descriptions.
3. Generalized coset construction implies that the differences of super-symplectic and Super Kac-Moody type Super Virasoro generators annihilated physical states. This implies Equivalence Principle. This construction in turn led to the realization that configuration space for fixed values of zero modes - in particular the values of the induced Kähler form of  $\delta M_{\pm}^4 \times CP_2$  - allows identification as a coset space obtained by dividing the symplectic group of  $\delta M_{\pm}^4 \times CP_2$  with Kac-Moody group, whose generators vanish at  $X^2 = X_l^3 \times \delta M_{\pm}^4 \times CP_2$ . One can say that quantum fluctuating degrees of freedom in a very concrete sense correspond to the local variant of  $S^2 \times CP_2$ .

The analog of conformal invariance in the light-like direction of  $X_l^3$  and in the light-like radial direction of  $\delta M_{\pm}^4$  implies that the data at either  $X^3$  or  $X_l^3$  should be enough to determine configuration space geometry. This implies that the relevant data is contained to their intersection  $X^2$  at least for finite regions of  $X^3$ . This is the case if the deformations of  $X_l^3$  not affecting  $X^2$  and preserving light-likeness corresponding to zero modes or gauge degrees of freedom and induce deformations of  $X^3$  also acting as zero modes. The outcome is effective 2-dimensionality. One must be however cautious in order to not make over-statements. The reduction to 2-D theory in global sense would trivialize the theory and the reduction to 2-D theory must takes places for finite region of  $X^3$  only so one has in well defined sense three-dimensionality in discrete sense. A more precise formulation of this vision is in terms of hierarchy of  $CD$ s containing  $CD$ s containing.... The introduction of sub- $CD$ :s brings in improved measurement resolution and means also that effective 2-dimensionality is realized in the scale of sub- $CD$  only.

One cannot over-emphasize the importance of the effective 2-dimensionality. It indeed simplifies dramatically the earlier formulas for configuration space metric involving 3-dimensional integrals over  $X^3 \subset M_{\pm}^4 \times CP_2$  reducing now to 2-dimensional integrals. Note that  $X^3$  is determined by preferred extremal property of  $X^4(X_l^3)$  once  $X_l^3$  is fixed and one can hope that this mapping is one-to-one.

### 3.2.3 Magic properties of light cone boundary and isometries of configuration space

The special conformal, metric and symplectic properties of the light cone of four-dimensional Minkowski space:  $\delta M_{\pm}^4$ , the boundary of four-dimensional light cone is metrically 2-dimensional(!) sphere allowing infinite-dimensional group of conformal transformations and isometries(!) as well as Kähler structure. Kähler structure is not unique: possible Kähler structures of light cone boundary are parametrized by Lobatchevski space  $SO(3,1)/SO(3)$ . The requirement that the isotropy group  $SO(3)$  of  $S^2$  corresponds to the isotropy group of the unique classical 3-momentum assigned to  $X^4(Y^3)$  defined as a preferred extremum of Kähler action, fixes the choice of the complex structure uniquely. Therefore group theoretical approach and the approach based on Kähler action complement each other.

1. The allowance of an infinite-dimensional group of isometries isomorphic to the group of conformal transformations of 2-sphere is completely unique feature of the 4-dimensional light cone

boundary. Even more, in case of  $\delta M_+^4 \times CP_2$  the isometry group of  $\delta M_+^4$  becomes localized with respect to  $CP_2$ ! Furthermore, the Kähler structure of  $\delta M_+^4$  defines also symplectic structure.

Hence any function of  $\delta M_+^4 \times CP_2$  would serve as a Hamiltonian transformation acting in both  $CP_2$  and  $\delta M_+^4$  degrees of freedom. These transformations obviously differ from ordinary local gauge transformations. This group leaves the symplectic form of  $\delta M_+^4 \times CP_2$ , defined as the sum of light cone and  $CP_2$  symplectic forms, invariant. The group of symplectic transformations of  $\delta M_+^4 \times CP_2$  is a good candidate for the isometry group of the configuration space.

2. The approximate symplectic invariance of Kähler action is broken only by gravitational effects and is exact for vacuum extremals. If Kähler function were exactly invariant under the symplectic transformations of  $CP_2$ ,  $CP_2$  symplectic transformations would correspond to zero modes having zero norm in the Kähler metric of configuration space. This does not make sense since symplectic transformations of  $\delta M^4 \times CP_2$  actually parameterize the quantum fluctuation degrees of freedom.
3. The groups  $G$  and  $H$ , and thus configuration space itself, should inherit the complex structure of the light cone boundary. The diffeomorphisms of  $M^4$  act as dynamical symmetries of vacuum extremals. The radial Virasoro localized with respect to  $S^2 \times CP_2$  could in turn act in zero modes perhaps inducing conformal transformations: note that these transformations lead out from the symmetric space associated with given values of zero modes.

### 3.2.4 Symplectic transformations of $\delta M_+^4 \times CP_2$ as isometries of configuration space

The symplectic transformations of  $\delta M_+^4 \times CP_2$  are excellent candidates for inducing symplectic transformations of the configuration space acting as isometries. There are however deep differences with respect to the Kac Moody algebras.

1. The conformal algebra of the configuration space is gigantic when compared with the Virasoro + Kac Moody algebras of string models as is clear from the fact that the Lie-algebra generator of a symplectic transformation of  $\delta M_+^4 \times CP_2$  corresponding to a Hamiltonian which is product of functions defined in  $\delta M_+^4$  and  $CP_2$  is sum of generator of  $\delta M_+^4$ -local symplectic transformation of  $CP_2$  and  $CP_2$ -local symplectic transformations of  $\delta M_+^4$ . This means also that the notion of local gauge transformation generalizes.
2. The physical interpretation is also quite different: the relevant quantum numbers label the unitary representations of Lorentz group and color group, and the four-momentum labeling the states of Kac Moody representations is not present. Physical states carrying no energy and momentum at quantum level are predicted. The appearance of a new kind of angular momentum not assignable to elementary particles might shed some light to the longstanding problem of baryonic spin (quarks are not responsible for the entire spin of proton). The possibility of a new kind of color might have implications even in macroscopic length scales.
3. The central extension induced from the natural central extension associated with  $\delta M_+^4 \times CP_2$  Poisson brackets is anti-symmetric with respect to the generators of the symplectic algebra rather than symmetric as in the case of Kac Moody algebras associated with loop spaces. At first this seems to mean a dramatic difference. For instance, in the case of  $CP_2$  symplectic transformations localized with respect to  $\delta M_+^4$  the central extension would vanish for Cartan algebra, which means a profound physical difference. For  $\delta M_+^4 \times CP_2$  symplectic algebra a generalization of the Kac Moody type structure however emerges naturally.

The point is that  $\delta M_+^4$ -local  $CP_2$  symplectic transformations are accompanied by  $CP_2$  local  $\delta M_+^4$  symplectic transformations. Therefore the Poisson bracket of two  $\delta M_+^4$  local  $CP_2$  Hamiltonians involves a term analogous to a central extension term symmetric with respect to  $CP_2$  Hamiltonians, and resulting from the  $\delta M_+^4$  bracket of functions multiplying the Hamiltonians. This additional term could give the entire bracket of the configuration space Hamiltonians at the maximum of the Kähler function where one expects that  $CP_2$  Hamiltonians vanish and have a form essentially identical with Kac Moody central extension because it is indeed symmetric with respect to indices of the symplectic group.

### 3.2.5 Does the symmetric space property reduce to coset construction for Super Virasoro algebras?

The idea about symmetric space is extremely beautiful but it took a long time and several false alarms before the time was ripe for identifying the precise form of the Cartan decomposition  $g = t + h$  satisfying the defining conditions

$$g = t + h \quad , \quad [t, t] \subset h \quad , \quad [h, t] \subset t \quad . \quad (3.2.1)$$

The ultimate solution of the puzzle turned out to be amazingly simple and came only after quantum TGD was understood well enough.

Configuration space geometry allows two super-conformal symmetries. The first one corresponds to super-symplectic transformations acting at the level of imbedding space. The second one corresponds to super Kac-Moody symmetry acting as deformations of light-like 3-surfaces respecting their light-likeness. Super Kac-Moody algebra can be regarded as sub-algebra of super-symplectic algebra, and quantum states correspond to the coset representations for these two algebras so that the differences of the corresponding super-Virasoro generators annihilate physical states. This obviously generalizes Goddard-Olive-Kent construction [118]. The physical interpretation is in terms of Equivalence Principle. After having realized this it took still some time to realize that this coset representation and therefore also Equivalence Principle also corresponds to the coset structure of the configuration space!

The first guess would be that  $t$  corresponds to super-symplectic algebra made also local with respect to  $X^3$  and  $h$  corresponds to super Kac-Moody algebra. The experience with finite-dimensional coset spaces would suggest that super Kac-Moody generators interpreted in terms of  $h$  leave the points of configuration space analogous to the origin of say  $CP_2$  invariant and in fact vanish at this point. Therefore super Kac-Moody generators should vanish for those 3-surfaces  $X_l^3$  which correspond to the origin of coset space. The maxima of Kähler function could correspond to this kind of points and could play also an essential role in the integration over configuration space by generalizing the Gaussian integration of free quantum field theories. The dynamical Kac-Moody algebra appearing in p-adic mass calculations and in coset construction would be a larger algebra affecting also  $X^2$ . Thus one must distinguish between the Kac-Moody algebras associated with the coset construction and coset space.

The first guess is not quite correct. The generators of super-symplectic and super Kac-Moody algebra are not completely free functions of  $X^3$  coordinates. The condition that they leave induced  $CP_2$  Kähler form  $J_{\mu\nu}(x)$  of the partonic 2-surfaces  $X^2(v) \subset X_l^3$  ( $v$  is light-like coordinate of  $X_l^3$ ) invariant implies that they depend on the symplectic invariant  $J = \epsilon^{\mu\nu} J_{\mu\nu}(x)$  only.  $J$  obviously takes the role of complex coordinate [17].

### 3.2.6 What effective 2-dimensionality and holography really mean?

Concerning the interpretation of Kac-Moody algebra there are some poorly understood points, which directly relate to what one means with holography.

1. The strongest view about effective 2-dimensionality (holography) is that for preferred extremals the partonic 2-surfaces  $X^2$  at the ends of  $CD$  act as causal determinants fixing  $X_l^3$  in the resolution defined by  $CD$ . A weaker view about holography is that light-like 3-surfaces with fixed ends give rise to same configuration space metric and the deformations of these surfaces by Kac-Moody algebra correspond to zero modes just like the interior degrees of freedom for space-like 3-surface do. Which of these options is the correct one? The same question can be posed in the case of space-like 3-surfaces.
2. The non-trivial action of Kac-Moody algebra in the interior of  $X_l^3$  together with effective 2-dimensionality and holography would encourage the interpretation of Kac-Moody symmetries acting trivially at  $X^2$  as gauge symmetries. Light-like 3-surfaces having fixed partonic 2-surfaces at their ends would be equivalent physically and effective 2-dimensionality and holography would be realized modulo gauge transformations.
3. There are also Kac-Moody generators which do not vanish at the ends of the  $X_l^3$ , and these would act as physical symmetries and their action would reduce at  $X^2$  to symplectic action.

This Kac-Moody algebra should appear in p-adic mass calculations. This seems to be in conflict with the idea that coset construction corresponds to coset space construction. Perhaps strict correspondence is too naive an assumption. Why couldn't one use the larger Kac-Moody algebra in coset construction and smaller Kac-Moody algebra in coset space construction?

4. Gauge symmetry property means that the Kähler metric of the configuration space is same for all gauge equivalent choices of  $X_l^3$  and Kac-Moody deformations correspond to zero modes. Kähler function could differ by a real part of a holomorphic function of configuration space coordinates representing now Kac-Moody transforms of  $X_l^3$ . If Dirac determinant gives the exponent of Kähler function, the eigenvalues of the modified Dirac action can differ only by scalings with are products of holomorphic function of configuration space coordinates and its conjugates labeling different Kac-Moody transforms of  $X_l^3$ . This condition makes sense if one restricts the consideration to the finite number of eigenvalues  $\lambda_k$  assigned to  $D_K$ . The introduction of instanton term transforming the eigenvalues to  $\lambda_k + \sqrt{n}$  would not allow his scaling.

Either one must assume more general spectrum of form  $\lambda_k + \sqrt{n}x_k$  with  $\lambda_k$  and  $x_k$  scaling in identical manner or that  $n = 0$  modes are enough to define Kähler function. The latter option might be correct since the preferred extremal realizes effective 2-dimensionality at space-time level and conformal excitations break it so that they should not contribute to Kähler function. Also number theoretic universality favors this option. One cannot however exclude the first option. It must be admitted that the situation is not completely understood.

### 3.2.7 About the relationship between super-symplectic and super Kac-Moody algebras

The relationship between Kac-Moody and symplectic algebras is now relatively well understood but the physical interpretation of Kac-Moody algebra deserves attention. There are two Kac-Moody algebras: the smaller one leaves partonic 2-surfaces invariant and second one affects also them. Both of them are in dual relation to the symplectic algebra and these relations correspond to coset space construction and coset construction.

TGD inspired quantum measurement theory suggests that the super-symplectic algebra and smaller Kac-Moody algebra correspond to each other like classical and quantal degrees of freedom. Hence smaller Kac-Moody algebra would act in the zero modes of the configuration space metric. In the proposed construction this indeed is the case for Kac-Moody algebra elements leaving partonic 2-surface invariant and appearing in the *coset space construction* but not for those Kac-Moody algebra elements affecting partonic 2-surface and allowing interpretation as sub-algebra of symplectic algebra and appearing in *coset construction*. This interpretation conforms also with the fact that Kac-Moody algebra generates massive excitations in p-adic thermodynamics.

In TGD inspired quantum measurement zero modes correspond to classical non-quantum fluctuating dynamical variables in 1-1 correspondence with quantum fluctuating degrees of freedom like the positions of the pointer of the measurement apparatus with the directions of spin of electron. Hence Kac-Moody algebra would define configuration space coordinates in terms of the map induced by correlation between classical and quantal degrees of freedom induced by entanglement. The choice of gauge selecting one particular light-like 3-surface  $X_l^3$  could have thus interpretation as a map mapping quantum degrees of freedom to classical ones. This choice of gauge could be achieved by the addition of phase factor depending on quantum numbers assigned with the braid strands so that stationary phase approximation would select the preferred 3-surface with fluctuations around them allowed.

The dual relation between super symplectic algebra and bigger Kac-Moody algebra is realized in terms of coset construction. The idea inspired by Olive-Goddard-Kent coset construction is that the generators of Super Virasoro algebra corresponds to the differences of those associated with Super Kac-Moody and super-symplectic algebras. The justification comes from the miraculous geometry of the light cone boundary implying that Super Kac-Moody conformal symmetries of  $X^2$  can be compensated by super-symplectic local radial scalings so that the differences of corresponding Super Virasoro generators annihilate physical states. If the central extension parameters are same, the resulting central extension is trivial. What is done is to construct first a state with a non-positive conformal weight using super-symplectic generators, and then to apply Super-Kac-Moody generators to compensate this conformal weight to get a state with vanishing conformal weight. Mass squared

would however correspond to either Super-Kac Moody or super-symplectic mass. The identity of these masses gives rise to Equivalence Principle as a one manifestation of the coset representation.

### Basic super-conformal symmetries

The identification of explicit representations of super conformal algebras was for a long time plagued by the lack of appropriate formalism. The modified Dirac operator  $D_K$  associated with Kähler action resolves this problem if one accepts the implications of number theoretic compactification supported by what is known about preferred extremals of Kähler action and one can identify the charges associated with symplectic and Kac-Moody algebra as Noether charges. Fermionic generators can in turn be identified from the condition that they anticommute to  $X^2$  local Hamiltonians of corresponding bosonic transformations. In case of Super Virasoro algebra Sugawara construction allows to construct super generators  $G$ .

1. Covariantly constant right handed neutrino is the fundamental generator of dynamical super conformal symmetries and appears in both leptonic and quark-like realizations of gamma matrices.  $\Gamma$  matrices have also Super Kac-Moody counterparts and reduce in special case to symplectic ones. Also super currents whose anti-commutators give products of corresponding Hamiltonians can be defined so that both ordinary product and Poisson bracket give rise to quark and lepton like realizations of super-symmetries. Besides this there are also electric and magnetic representations of the gamma matrices.
2. The zero modes of  $D_K(X^2)$  which do not depend on the light-like radial coordinate of  $X_l^3$  define super conformal symmetries for which any  $c$ -number spinor field generates super conformal symmetry. These symmetries are pure gauge symmetries but also them can be parameterized by Hamiltonians and by functions depending only on the coordinates of the transverse section  $X^2$  so that one obtains also now both function algebra and symplectic algebra localized with respect to  $X^2$ . Similar picture applies in both super-symplectic and super Kac-Moody sector. In particular, one can deduce canonical expressions for the super currents associated with these super symmetries. Since all charge states are possible for the generators of these super symmetries, these super symmetries naturally correspond to those assignable to electro-weak degrees of freedom.
3. The notion of  $X^2$  local super-symmetry makes sense if the choice of coordinates  $x$  for  $X^2$  is specified by the inherent properties of  $X^2$  so that same coordinates  $x$  apply for all surfaces obtained as deformations of  $X^2$ . The regions, where induced Kähler form is non-vanishing define good candidates for coordinate patches. The Hamilton-Jacobi coordinates associated with the decomposition of  $M^4$  are a natural choice. Also geodesic coordinates can be considered. The redundancy related to rotations of coordinate axis around origin can be reduced by choosing second axis so that it connects the origin to nearest point of the number theoretic braid.
4. The diffeomorphisms of light-like coordinate of  $\delta M_{\pm}^4$  and  $X_l^3$  playing the role of conformal transformations. One can construct fermionic representations of as Noether charges associated with modified Dirac action. The problem is however that that super-generators cannot be derived in this manner so that these transformations cannot be regarded as symplectic transformations. The manner to circumvent the difficulty is to construct fermionic super charges  $\Gamma_A$  as gamma matrices for both super symplectic and super Kac-Moody algebras in terms of generators  $j^{Ak}\Gamma_k$  and corresponding Kac-Moody algebra elements  $T^A$  as fermionic super charges. From these operators super generators  $G$  can be constructed by the standard Sugawara construction allowing to interpret operators  $G = T^A\Gamma_A$  as Dirac operators at the level of configuration space. By coset construction the actions of super-symplectic and super Kac-Moody Dirac operators are identical. Internal consistency requires that the Virasoro generators obtained as anticommutator  $L = \{G, G^\dagger\}$  are equal to the Virasoro generators derived as fermionic Noether charges.

### Finite measurement resolution and cutoff in the spectrum of conformal weights

The basic properties of Kähler action imply that the number generalized eigenvalues  $\lambda_i$  of  $D_K(X^2)$  is finite. The interpretation is that the notion of finite measurement resolution is coded by Kähler

action to space-time dynamics. This has also implications for the representations of super-conformal algebras.

1. The fermionic representations of various super-algebras involve only finite number of oscillator operators. Hence some kind of cutoff in the number of states reflecting the finiteness of the measurement resolution is unavoidable. A cutoff reduce integers as labels of the generators of super-conformal algebras to a finite number of integers. Finite field  $G(p, 1)$  for some prime  $p$  would be a natural candidate. Since p-adic integers modulo  $p$  are in question the cutoff could relate closely to effective p-adicity and p-adic length scale-hypothesis.
2. The interpretation of the eigenvalues of the modified Dirac operator as ground state conformal weights raises the question how to represent states with conformal weights  $n + \lambda_i^2$ ,  $n > 0$ . The notion of number theoretic braid allows to circumvent the difficulty. Since canonical anti-commutation relations fail, one must replace the integral representations of super-conformal generators with discrete sums over the points of number theoretic braid, the resulting representations of super-conformal algebras must reduce to representation of finite-dimensional algebras. The cutoff on conformal weight must result from the fact that the higher Virasoro generators are expressible in terms of lower ones. The cutoff is not a problem since  $n < 3$  cutoff for conformal weights gives an excellent accuracy in p-adic mass calculations. A not-very-educated guess but the only one that one can imagine is that for  $p \simeq 2^k$ ,  $n_{max} = k$  defines the cutoff on allowed conformal weights.

### Generalized coset representation

$X^2$  local super-symplectic algebra as super Kac-Moody algebra as sub-algebra. Since  $X^2$  locality corresponds to a full 2-D gauge invariance, one can conclude that SKM is in well defined sense sub-algebra of super-symplectic algebra so that generalized coset construction makes sense and generalizes Equivalence Principle in the sense that not only four-momenta but all analogous quantum numbers associated with SKM and SS algebras are identical.

1. In this framework the ground state conformal weights associated with both super-symplectic and super Kac-Moody algebras can be identified as squares of the eigenvalues  $\lambda_i$  of  $D_K(X^2)$ . This identification together with p-adic mass thermodynamics predicts that  $\lambda_i^2$  gives to mass squared a contribution analogous to the square of Higgs vacuum expectation. This identification would resolve the long-standing problem of identifying the values of these ground state conformal weights for super-conformal algebras and give a direct connection with Higgs mechanism.
2. The identification of SKM as a sub-algebra of super-symplectic algebra becomes more convincing if the light-like coordinate  $r$  allows lifting to a light-like coordinate of  $H$ . This is achieved if  $r$  is identified as coordinate associated with a light-like curve whose tangent at point  $x \in X_l^3$  is light-like vector in  $M^2(x) \subset T(X^4(X^3))$ . With this interpretation of SKM algebra as sub-algebra of super-symplectic algebra becomes natural.
3. The existence of a lifting of  $SS$  and  $SKM$  algebras to entire  $H$  would solve the problems. The lifting problem is obviously non-trivial only in  $M^4$  degrees of freedom. Suppose that the existence of an integrable distribution of planes  $M^2(x)$  and their orthogonal complements  $E^2(x)$  belonging to the tangent space of  $M^4$  projection  $P_{M^4}(X^4(X^3))$  characterizes the preferred extremals with Minkowskian signature of induced metric. In this case the lifting of the super-symplectic and super Kac-Moody algebras to entire  $H$  is possible. The local degrees of freedom contributing to the configuration space metric would belong to the integrable distribution of orthogonal complements  $E^2(x)$  of  $M^2(x)$  having physical interpretation as planes of physical polarizations.

### 3.2.8 Comparison of TGD and stringy views about super-conformal symmetries

The best manner to represent TGD based view about conformal symmetries is by comparison with the conformal symmetries of super string models.

### Basic differences between the realization of super conformal symmetries in TGD and in super-string models

The realization super conformal symmetries in TGD framework differs from that in string models in several fundamental aspects.

1. In TGD framework super-symmetry generators acting as configuration space gamma matrices carry either lepton or quark number. Majorana condition required by the hermiticity of super generators which is crucial for super string models would be in conflict with the conservation of baryon and lepton numbers and is avoided. This is made possible by the realization of bosonic generators represented as Hamiltonians of  $X^2$ -local symplectic transformations rather than vector fields generating them [17]. This kind of representation applies also in Kac-Moody sector since the local transversal isometries localized in  $X_i^3$  and respecting light-likeness condition can be regarded as  $X^2$  local symplectic transformations, whose Hamiltonians generate also isometries. Localization is not complete: the functions of  $X^2$  coordinates multiplying symplectic and Kac-Moody generators are functions of the symplectic invariant  $J = \epsilon^{\mu\nu} J_{\mu\nu}$  so that effective one-dimensionality results but in different sense than in conformal field theories. This realization of super symmetries is what distinguishes between TGD and super string models and leads to a totally different physical interpretation of super-conformal symmetries. The fermionic representations of super-symplectic and super Kac-Moody generators can be identified as Noether charges in standard manner.
2. A long-standing problem of quantum TGD was that stringy propagator  $1/G$  does not make sense if  $G$  carries fermion number. The progress in the understanding of second quantization of the modified Dirac operator made it however possible to identify the counterpart of  $G$  as a c-number valued operator and interpret it as different representation of  $G$  [19].
3. The notion of super-space is not needed at all since Hamiltonians rather than vector fields represent bosonic generators, no super-variant of geometry is needed. The distinction between Ramond and N-S representations important for  $N = 1$  super-conformal symmetry and allowing only ground state weight 0 an  $1/2$  disappears. Indeed, for  $N = 2$  super-conformal symmetry it is already possible to generate spectral flow transforming these Ramond and N-S representations to each other ( $G_n$  is not Hermitian anymore). This means that the interpretation of  $\lambda_i^2$  ( $\lambda_i$  is generalized eigenvalue of  $D_K(X^2)$ ) as ground state conformal weight does not lead to difficulties.
4. If Kähler action defines the modified Dirac operator, the number of spinor modes is finite. One must be here somewhat cautious since bound state in the Coulomb potential associated with electric part of induced electro-weak gauge field might give rise to an infinite number of bound states which eigenvalues converging to a fixed eigenvalue (as in the case of hydrogen atom). Finite number of generalized eigenmodes means that the representations of super-conformal algebras reduces to finite-dimensional ones in TGD framework. Also the notion of number theoretic braid indeed implies this. The physical interpretation is in terms of finite measurement resolution. If Kähler action is complexified to include imaginary part defined by CP breaking instanton term, the number of generalized eigenvalues becomes infinite since conformal excitations are possible. This means breakdown of exact holography and effective 2-dimensionality of 3-surfaces. It seems that the inclusion of instanton term is necessary for several reasons. The notion of finite measurement resolution forces conformal cutoff also now. There are arguments suggesting that only the modes with vanishing conformal weight contribute to the Dirac determinant defining vacuum functional identified as exponent of Kähler function in turn identified as Kähler action for its preferred extremal.
5. What makes spinor field mode a generator of gauge super-symmetry is that is c-number and not an eigenmode of  $D_K(X^2)$  and thus represents non-dynamical degrees of freedom. If the number of eigen modes of  $D_K(X^2)$  is indeed finite means that most of spinor field modes represent super gauge degrees of freedom.

#### The super generators $G$ are not Hermitian in TGD!

The already noticed important difference between TGD based and the usual Super Virasoro representations is that the Super Virasoro generator  $G$  cannot Hermitian in TGD. The reason is that

configuration space gamma matrices possess a well defined fermion number. The hermiticity of the configuration space gamma matrices  $\Gamma$  and of the Super Virasoro current  $G$  could be achieved by posing Majorana conditions on the second quantized H-spinors. Majorana conditions can be however realized only for space-time dimension  $D \bmod 8 = 2$  so that super string type approach does not work in TGD context. This kind of conditions would also lead to the non-conservation of baryon and lepton numbers.

An analogous situation is encountered in super-symmetric quantum mechanics, where the general situation corresponds to super symmetric operators  $S, S^\dagger$ , whose anti-commutator is Hamiltonian:  $\{S, S^\dagger\} = H$ . One can define a simpler system by considering a Hermitian operator  $S_0 = S + S^\dagger$  satisfying  $S_0^2 = H$ : this relation is completely analogous to the ordinary Super Virasoro relation  $GG = L$ . On basis of this observation it is clear that one should replace ordinary Super Virasoro structure  $GG = L$  with  $GG^\dagger = L$  in TGD context.

It took a long time to realize the trivial fact that  $N = 2$  super-symmetry is the standard physics counterpart for TGD super symmetry.  $N = 2$  super-symmetry indeed involves the doubling of super generators and super generators carry  $U(1)$  charge having an interpretation as fermion number in recent context. The so called short representations of  $N = 2$  super-symmetry algebra can be regarded as representations of  $N = 1$  super-symmetry algebra.

Configuration space gamma matrix  $\Gamma_n, n > 0$  corresponds to an operator creating fermion whereas  $\Gamma_n, n < 0$  annihilates antifermion. For the Hermitian conjugate  $\Gamma_n^\dagger$  the roles of fermion and antifermion are interchanged. Only the anti-commutators of gamma matrices and their Hermitian conjugates are non-vanishing. The dynamical Kac Moody type generators are Hermitian and are constructed as bilinears of the gamma matrices and their Hermitian conjugates and, just like conserved currents of the ordinary quantum theory, contain parts proportional to  $a^\dagger a, b^\dagger b, a^\dagger b^\dagger$  and  $ab$  ( $a$  and  $b$  refer to fermionic and antifermionic oscillator operators). The commutators between Kac Moody generators and Kac Moody generators and gamma matrices remain as such.

For a given value of  $m$   $G_n, n > 0$  creates fermions whereas  $G_n, n < 0$  annihilates antifermions. Analogous result holds for  $G_n^\dagger$ . Virasoro generators remain Hermitian and decompose just like Kac Moody generators do. Thus the usual anti-commutation relations for the super Virasoro generators must be replaced with anti-commutations between  $G_m$  and  $G_n^\dagger$  and one has

$$\begin{aligned} \{G_m, G_n^\dagger\} &= 2L_{m+n} + \frac{c}{3}(m^2 - \frac{1}{4})\delta_{m,-n} \quad , \\ \{G_m, G_n\} &= 0 \quad , \\ \{G_m^\dagger, G_n^\dagger\} &= 0 \quad . \end{aligned} \tag{3.2.2}$$

The commutators of type  $[L_m, L_n]$  are not changed. Same applies to the purely kinematical commutators between  $L_n$  and  $G_m/G_m^\dagger$ .

The Super Virasoro conditions satisfied by the physical states are as before in case of  $L_n$  whereas the conditions for  $G_n$  are doubled to those of  $G_n, n < 0$  and  $G_n^\dagger, n > 0$ .

### What could be the counter parts of stringy conformal fields in TGD framework?

The experience with string models would suggest the conformal symmetries associated with the complex coordinates of  $X^2$  as a candidate for conformal super-symmetries. One can imagine two counterparts of the stringy coordinate  $z$  in TGD framework.

1. Super-symplectic and super Kac-Moody symmetries are local with respect to  $X^2$  in the sense that the coefficients of generators depend on the invariant  $J = \epsilon^{\alpha\beta} J_{\alpha\beta} \sqrt{g_2}$  rather than being completely free [17]. Thus the real variable  $J$  replaces complex (or hyper-complex) stringy coordinate and effective 1-dimensionality holds true also now but in different sense than for conformal field theories.
2. The slicing of  $X^2$  by string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$  implied by number theoretical compactification implies string-parton duality and involves the super conformal fermionic gauge symmetries associated with the coordinates  $u$  and  $w$  in the dual dimensional reductions to stringy and partonic dynamics. These coordinates define the natural analogs of stringy coordinate. The effective reduction of  $X^3$  to braid by finite measurement resolution implies the effective reduction of  $X^4(X^3)$  to string world sheet. This implies quite strong resemblance with

string model and allows to understand among other things how Equivalence Principle emerges in TGD framework at space-time level from its quantum counterpart realized in terms of generalized coset representation for super-symplectic and Super Kac-Moody algebras.

3. The conformal fields of string model would reside at  $X^2$  or  $Y^2$  depending on which description one uses and complex (hyper-complex) string coordinate would be identified accordingly.  $Y^2$  could be fixed as a union of stringy world sheets having the strands of number theoretic braids as its ends. The proposed definition of braids is unique and characterizes finite measurement resolution at space-time level.  $X^2$  could be fixed uniquely as the intersection of  $X_l^3$  (the light-like 3-surface at which induced metric of space-time surface changes its signature) with  $\delta M_{\pm}^4 \times CP_2$ . Clearly, wormhole throats  $X_l^3$  would take the role of branes and would be connected by string world sheets defined by number theoretic braids.
4. An alternative identification for TGD parts of conformal fields is inspired by  $M^8 - H$  duality. Conformal fields would be fields in configuration space. The counterpart of  $z$  coordinate could be the hyper-octonionic  $M^8$  coordinate  $m$  appearing as argument in the Laurent series of configuration space Clifford algebra elements.  $m$  would characterize the position of the tip of  $CD$  and the fractal hierarchy of  $CD$ s within  $CD$ s would give a hierarchy of Clifford algebras and thus inclusions of hyper-finite factors of type  $II_1$ . Reduction to hyper-quaternionic field -that is field in  $M^4$  center of mass degrees of freedom- would be needed to obtain associativity. The arguments  $m$  at various level might correspond to arguments of N-point function in quantum field theory.

### 3.3 Number theoretic compactification and $M^8 - H$ duality

This section summarizes the basic vision about number theoretic compactification reducing the classical dynamics to number theory. In strong form  $M^8 - H$  duality boils down to the assumption that space-time surfaces can be regarded either as surfaces of  $H$  or as surfaces of  $M^8$  composed of hyper-quaternionic and co-hyper-quaternionic regions identifiable as regions of space-time possessing Minkowskian *resp.* Euclidian signature of the induced metric.

#### 3.3.1 Basic idea behind $M^8 - M^4 \times CP_2$ duality

The hopes of giving  $M^4 \times CP_2$  hyper-octonionic structure are meager. This circumstance forces to ask whether four-surfaces  $X^4 \subset M^8$  could under some conditions define 4-surfaces in  $M^4 \times CP_2$  indirectly so that the spontaneous compactification of super string models would correspond in TGD to two different manners to interpret the space-time surface. The following arguments suggest that this is indeed the case.

The hard mathematical fact behind number theoretical compactification is that the quaternionic sub-algebras of octonions with fixed complex structure (that is complex sub-space) are parameterized by  $CP_2$  just as the complex planes of quaternion space are parameterized by  $CP_1 = S^2$ . Same applies to hyper-quaternionic sub-spaces of hyper-octonions.  $SU(3)$  would thus have an interpretation as the isometry group of  $CP_2$ , as the automorphism sub-group of octonions, and as color group.

1. The space of complex structures of the octonion space is parameterized by  $S^6$ . The subgroup  $SU(3)$  of the full automorphism group  $G_2$  respects the a priori selected complex structure and thus leaves invariant one octonionic imaginary unit, call it  $e_1$ . Hyper-quaternions can be identified as  $U(2)$  Lie-algebra but it is obvious that hyper-octonions do not allow an identification as  $SU(3)$  Lie algebra. Rather, octonions decompose as  $1 \oplus 1 \oplus 3 \oplus \bar{3}$  to the irreducible representations of  $SU(3)$ .
2. Geometrically the choice of a preferred complex (quaternionic) structure means fixing of complex (quaternionic) sub-space of octonions. The fixing of a hyper-quaternionic structure of hyper-octonionic  $M^8$  means a selection of a fixed hyper-quaternionic sub-space  $M^4 \subset M^8$  implying the decomposition  $M^8 = M^4 \times E^4$ . If  $M^8$  is identified as the tangent space of  $H = M^4 \times CP_2$ , this decomposition results naturally. It is also possible to select a fixed hyper-complex structure, which means a further decomposition  $M^4 = M^2 \times E^2$ .

3. The basic result behind number theoretic compactification and  $M^8 - H$  duality is that hyper-quaternionic sub-spaces  $M^4 \subset M^8$  containing a fixed hyper-complex sub-space  $M^2 \subset M^4$  or its light-like line  $M_{\pm}$  are parameterized by  $CP_2$ . The choices of a fixed hyper-quaternionic basis  $1, e_1, e_2, e_3$  with a fixed complex sub-space (choice of  $e_1$ ) are labeled by  $U(2) \subset SU(3)$ . The choice of  $e_2$  and  $e_3$  amounts to fixing  $e_2 \pm \sqrt{-1}e_3$ , which selects the  $U(2) = SU(2) \times U(1)$  subgroup of  $SU(3)$ .  $U(1)$  leaves 1 invariant and induced a phase multiplication of  $e_1$  and  $e_2 \pm e_3$ .  $SU(2)$  induces rotations of the spinor having  $e_2$  and  $e_3$  components. Hence all possible completions of  $1, e_1$  by adding  $e_2, e_3$  doublet are labeled by  $SU(3)/U(2) = CP_2$ .
4. Space-time surface  $X^4 \subset M^8$  is by the standard definition hyper-quaternionic if the tangent spaces of  $X^4$  are hyper-quaternionic planes. Co-hyper-quaternionicity means the same for normal spaces. The presence of fixed hyper-complex structure means at space-time level that the tangent space of  $X^4$  contains fixed  $M^2$  at each point. Under this assumption one can map the points  $(m, e) \in M^8$  to points  $(m, s) \in H$  by assigning to the point  $(m, e)$  of  $X^4$  the point  $(m, s)$ , where  $s \in CP_2$  characterize  $T(X^4)$  as hyper-quaternionic plane. This definition is not the only one and even the appropriate one in TGD context the replacement of the tangent plane with the 4-D plane spanned by modified gamma matrices defined by Kähler action is a more natural choice. This plane is not parallel to tangent plane in general. In the sequel  $T(X^4)$  denotes the preferred 4-plane which co-incides with tangent plane of  $X^4$  only if the action defining modified gamma matrices is 4-volume.
5. The choice of  $M^2$  can be made also local in the sense that one has  $T(X^4) \supset M^2(x) \subset M^4 \subset H$ . It turns out that strong form of number theoretic compactification requires this kind of generalization. In this case one must be able to fix the convention how the point of  $CP_2$  is assigned to a hyper-quaternionic plane so that it applies to all possible choices of  $M^2 \subset M^4$ . Since  $SO(3)$  hyper-quaternionic rotation relates the hyper-quaternionic planes to each other, the natural assumption is hyper-quaternionic planes related by  $SO(3)$  rotation correspond to the same point of  $CP_2$ . Under this assumption it is possible to map hyper-quaternionic surfaces of  $M^8$  for which  $M^2 \subset M^4$  depends on point of  $X^4$  to  $H$ .

### 3.3.2 Hyper-octonionic Pauli "matrices" and modified definition of hyper-quaternionicity

Hyper-octonionic Pauli matrices suggest an interesting possibility to define precisely what hyper-quaternionicity means at space-time level (for background see [82] ).

1. According to the standard definition space-time surface  $X^4$  is hyper-quaternionic if the tangent space at each point of  $X^4$  in  $X^4 \subset M^8$  picture is hyper-quaternionic. What raises worries is that this definition involves in no manner the action principle so that it is far from obvious that this identification is consistent with the vacuum degeneracy of Kähler action. It also unclear how one should formulate hyper-quaternionicity condition in  $X^4 \subset M^4 \times CP_2$  picture.
2. The idea is to map the modified gamma matrices  $\Gamma^\alpha = \frac{\partial L_K}{\partial h_\alpha^k} \Gamma^k$ ,  $\Gamma_k = e_k^A \gamma_A$ , to hyper-octonionic Pauli matrices  $\sigma^\alpha$  by replacing  $\gamma_A$  with hyper-octonion unit. Hyper-quaternionicity would state that the hyper-octonionic Pauli matrices  $\sigma^\alpha$  obtained in this manner span complexified quaternion sub-algebra at each point of space-time. These conditions would provide a number theoretic manner to select preferred extremals of Kähler action. Remarkably, this definition applies both in case of  $M^8$  and  $M^4 \times CP_2$ .
3. Modified Pauli matrices span the tangent space of  $X^4$  if the action is four-volume because one has  $\frac{\partial L_K}{\partial h_\alpha^k} = \sqrt{g} g^{\alpha\beta} \partial h_\beta^l h_{kl}$ . Modified gamma matrices reduce to ordinary induced gamma matrices in this case: 4-volume indeed defines a super-conformally symmetric action for ordinary gamma matrices since the mass term of the Dirac action given by the trace of the second fundamental form vanishes for minimal surfaces.
4. For Kähler action the hyper-quaternionic sub-space does not coincide with the tangent space since  $\frac{\partial L_K}{\partial h_\alpha^k}$  contains besides the gravitational contribution coming from the induced metric also the "Maxwell contribution" from the induced Kähler form not parallel to space-time surface.

Modified gamma matrices are required by super conformal symmetry for the extremals of Kähler action and they also guarantee that vacuum extremals defined by surfaces in  $M^4 \times Y^2$ ,  $Y^2$  a Lagrange sub-manifold of  $CP_2$ , are trivially hyper-quaternionic surfaces. The modified definition of hyper-quaternionicity does not affect in any manner  $M^8 \leftrightarrow M^4 \times CP_2$  duality allowing purely number theoretic interpretation of standard model symmetries.

A side comment not strictly related to hyper-quaternionicity is in order. The anticommutators of the modified gamma matrices define an effective Riemann metric and one can assign to it the counterparts of Riemann connection, curvature tensor, geodesic line, volume, etc... One would have two different metrics associated with the space-time surface. Only if the action defining space-time surface is identified as the volume in the ordinary metric, these metrics are equivalent. The index raising for the effective metric could be defined also by the induced metric and it is not clear whether one can define Riemann connection also in this case. Could this effective metric have concrete physical significance and play a deeper role in quantum TGD? For instance, AdS-CFT duality leads to ask whether interactions be coded in terms of the gravitation associated with the effective metric.

### 3.3.3 Minimal form of $M^8 - H$ duality

The basic problem in the construction of quantum TGD has been the identification of the preferred extremals of Kähler action playing a key role in the definition of the theory. The most elegant manner to do this is by fixing the 4-D tangent space  $T(X^4(X_i^3))$  of  $X^4(X_i^3)$  at each point of  $X_i^3$  so that the boundary value problem is well defined. What I called number theoretical compactification allows to achieve just this although I did not fully realize this in the original vision. The minimal picture is following.

1. The basic observations are following. Let  $M^8$  be endowed with hyper-octonionic structure. For hyper-quaternionic space-time surfaces in  $M^8$  tangent spaces are by definition hyper-quaternionic. If they contain a preferred plane  $M^2 \subset M^4 \subset M^8$  in their tangent space, they can be mapped to 4-surfaces in  $M^4 \times CP_2$ . The reason is that the hyper-quaternionic planes containing preferred the hyper-complex plane  $M^2$  of  $M_\pm \subset M^2$  are parameterized by points of  $CP_2$ . The map is simply  $(m, e) \rightarrow (m, s(m, e))$ , where  $m$  is point of  $M^4$ ,  $e$  is point of  $E^4$ , and  $s(m, 2)$  is point of  $CP_2$  representing the hyperquaternionic plane. The inverse map assigns to each point  $(m, s)$  in  $M^4 \times CP_2$  point  $m$  of  $M^4$ , undetermined point  $e$  of  $E^4$  and 4-D plane. The requirement that the distribution of planes containing the preferred  $M^2$  or  $M_\pm$  corresponds to a distribution of planes for 4-D surface is expected to fix the points  $e$ . The physical interpretation of  $M^2$  is in terms of plane of non-physical polarizations so that gauge conditions have purely number theoretical interpretation.
2. In principle, the condition that  $T(X^4)$  contains  $M^2$  can be replaced with a weaker condition that either of the two light-like vectors of  $M^2$  is contained in it since already this condition assigns to  $T(X^4)$   $M^2$  and the map  $H \rightarrow M^8$  becomes possible. Only this weaker form applies in the case of massless extremals [8] as will be found.
3. The original idea was that hyper-quaternionic 4-surfaces in  $M^8$  containing  $M^2 \subset M^4$  in their tangent space could correspond to preferred extremals of Kähler action. This condition does not seem to be consistent with what is known about the extremals of Kähler action. The weaker form of the hypothesis is that hyper-quaternionicity holds only for 4-D tangent spaces of  $X_i^3 \subset H = M^4 \times CP_2$  identified as wormhole throats or boundary components lifted to 3-surfaces in 8-D tangent space  $M^8$  of  $H$ . The minimal hypothesis would be that only  $T(X^4(X_i^3))$  at  $X_i^3$  is associative that is hyper-quaternionic for fixed  $M^2$ .  $X_i^3 \subset M^8$  and  $T(X^4(X_i^3))$  at  $X_i^3$  can be mapped to  $X_i^3 \subset H$  if tangent space contains also  $M_\pm \subset M^2$  or  $M^2 \subset M^4 \subset M^8$  itself having interpretation as preferred hyper-complex plane. This condition is not satisfied by all surfaces  $X_i^3$  as is clear from the fact that the inverse map involves local  $E^4$  translation. The requirements that the distribution of hyper-quaternionic planes containing  $M^2$  corresponds to a distribution of 4-D tangent planes should fix the  $E^4$  translation to a high degree.
4. A natural requirement is that the image of  $X_i^3 \subset H$  in  $M^8$  is light-like. The condition that the determinant of induced metric vanishes gives an additional condition reducing the number of

free parameters by one. This condition cannot be formulated as a condition on  $CP_2$  coordinate characterizing the hyper-quaternionic plane. Since  $M^4$  projections are same for the two representations, this condition is satisfied if the contributions from  $CP_2$  and  $E^4$  and projections to the induced metric are identical:  $s_{kl}\partial_\alpha s^k\partial_\beta s^l = e_{kl}\partial_\alpha e^k\partial_\beta e^l$ . This condition means that only a subset of light-like surfaces of  $M^8$  are realized physically. One might argue that this is as it must be since the volume of  $E^4$  is infinite and that of  $CP_2$  finite: only an infinitesimal portion of all possible light-like 3-surfaces in  $M^8$  can have  $H$  counterparts. The conclusion would be that number theoretical compactification is 4-D isometry between  $X^4 \subset H$  and  $X^4 \subset M^8$  at  $X_l^3$ . This unproven conjecture is unavoidable.

5.  $M^2 \subset T(X^4(X_l^3))$  condition fixes  $T(X^4(X_l^3))$  in the generic case by extending the tangent space of  $X_l^3$ , and the construction of configuration space spinor structure fixes boundary conditions completely by additional conditions necessary when  $X_l^3$  corresponds to a light-like 3 surfaces defining wormhole throat at which the signature of induced metric changes. What is especially beautiful that only the data in  $T(X^4(X_l^3))$  at  $X_l^3$  is needed to calculate the vacuum functional of the theory as Dirac determinant: the only remaining conjecture (strictly speaking un-necessary but realistic looking) is that this determinant gives exponent of Kähler action for the preferred extremal and there are excellent hopes for this by the structure of the basic construction.

The basic criticism relates to the condition that light-like 3-surfaces are mapped to light-like 3-surfaces guaranteed by the condition that  $M^8 - H$  duality is isometry at  $X_l^3$ .

### 3.3.4 Strong form of $M^8 - H$ duality

The proposed picture is the minimal one. One can of course ask whether the original much stronger conjecture that the preferred extrema of Kähler action correspond to hyper-quaternionic surfaces could make sense in some form. One can also wonder whether one could allow the choice of the plane  $M^2$  of non-physical polarization to be local so that one would have  $M^2(x) \subset M^4 \subset M^4 \times E^4$ , where  $M^4$  is fixed hyper-quaternionic sub-space of  $M^8$  and identifiable as  $M^4$  factor of  $H$ .

1. If  $M^2$  is same for all points of  $X_l^3$ , the inverse map  $X_l^3 \subset H \rightarrow X_l^3 \subset M^8$  is fixed apart from possible non-uniqueness related to the local translation in  $E^4$  from the condition that hyper-quaternionic planes represent light-like tangent 4-planes of light-like 3-surfaces. The question is whether not only  $X_l^3$  but entire four-surface  $X^4(X_l^3)$  could be mapped to the tangent space of  $M^8$ . By selecting suitably the local  $E^4$  translation one might hope of achieving the achieving this. The conjecture would be that the preferred extrema of Kähler action are those for which the distribution integrates to a distribution of tangent planes.
2. There is however a problem. What is known about extremals of Kähler action is not consistent with the assumption that fixed  $M^2$  of  $M_\pm \subset M^2$  is contained in the tangent space of  $X^4$ . This suggests that one should relax the condition that  $M^2 \subset M^4 \subset M^8$  is a fixed hyper-complex plane associated with the tangent space or normal space  $X^4$  and allow  $M^2$  to vary from point to point so that one would have  $M^2 = M^2(x)$ . In  $M^8 \rightarrow H$  direction the justification comes from the observation (to be discussed below) that it is possible to uniquely fix the convention assigning  $CP_2$  point to a hyper-quaternionic plane containing varying hyper-complex plane  $M^2(x) \subset M^4$ . Number theoretic compactification fixes naturally  $M^4 \subset M^8$  so that it applies to any  $M^2(x) \subset M^4$ . Under this condition the selection is parameterized by an element of  $SO(3)/SO(2) = S^2$ . Note that  $M^4$  projection of  $X^4$  would be at least 2-dimensional in hyper-quaternionic case. In co-hyper-quaternionic case  $E^4$  projection would be at least 2-D.  $SO(2)$  would act as a number theoretic gauge symmetry and the  $SO(3)$  valued chiral field would approach to constant at  $X_l^3$  invariant under global  $SO(2)$  in the case that one keeps the assumption that  $M^2$  is fixed ad  $X_l^3$ .
3. This picture requires a generalization of the map assigning to hyper-quaternionic plane a point of  $CP_2$  so that this map is defined for all possible choices of  $M^2 \subset M^4$ . Since the  $SO(3)$  rotation of the hyper-quaternionic unit defining  $M^2$  rotates different choices parameterized by  $S^2$  to each other, a natural assumption is that the hyper-quaternionic planes related by  $SO(3)$  rotation correspond to the same point of  $CP_2$ . Denoting by  $M^2$  the standard representative of  $M^2$ , this means that for the map  $M^8 \rightarrow H$  one must perform  $SO(3)$  rotation of hyper-quaternionic plane

taking  $M^2(x)$  to  $M^2$  and map the rotated plane to  $CP_2$  point. In  $M^8 \rightarrow H$  case one must first map the point of  $CP_2$  to hyper-quaternionic plane and rotate this plane by a rotation taking  $M^2(x)$  to  $M^2$ .

4. In this framework local  $M^2$  can vary also at the surfaces  $X_l^3$ , which considerably relaxes the boundary conditions at wormhole throats and light-like boundaries and allows much more general variety of light-like 3-surfaces since the basic requirement is that  $M^4$  projection is at least 1-dimensional. The physical interpretation would be that a local choice of the plane of non-physical polarizations is possible everywhere in  $X^4(X_l^3)$ . This does not seem to be in any obvious conflict with physical intuition.

These observations provide support for the conjecture that (classical)  $S^2 = SO(3)/SO(2)$  conformal field theory might be relevant for (classical) TGD.

1. General coordinate invariance suggests that the theory should allow a formulation using any light-like 3-surface  $X^3$  inside  $X^4(X_l^3)$  besides  $X_l^3$  identified as union of wormhole throats and boundary components. For these surfaces the element  $g(x) \in SO(3)$  would vary also at partonic 2-surfaces  $X^2$  defined as intersections of  $\delta CD \times CP_2$  and  $X^3$  (here  $CD$  denotes causal diamond defined as intersection of future and past directed light-cones). Hence one could have  $S^2 = SO(3)/SO(2)$  conformal field theory at  $X^2$  (regarded as quantum fluctuating so that also  $g(x)$  varies) generalizing to WZW model for light-like surfaces  $X^3$ .
2. The presence of  $E^4$  factor would extend this theory to a classical  $E^4 \times S^2$  WZW model bringing in mind string model with 6-D Euclidian target space extended to a model of light-like 3-surfaces. A further extension to  $X^4$  would be needed to integrate the WZW models associated with 3-surfaces to a full 4-D description. General Coordinate Invariance however suggests that  $X_l^3$  description is enough for practical purposes.
3. The choices of  $M^2(x)$  in the interior of  $X_l^3$  is dictated by dynamics and the first optimistic conjecture is that a classical solution of  $SO(3)/SO(2)$  Wess-Zumino-Witten model obtained by coupling  $SO(3)$  valued field to a covariantly constant  $SO(2)$  gauge potential characterizes the choice of  $M^2(x)$  in the interior of  $M^8 \supset X^4(X_l^3) \subset H$  and thus also partially the structure of the preferred extremal. Second optimistic conjecture is that the Kähler action involving also  $E^4$  degrees of freedom allows to assign light-like 3-surface to light-like 3-surface.
4. The best that one can hope is that  $M^8 - H$  duality could allow to transform the extremely non-linear classical dynamics of TGD to a generalization of WZW-type model. The basic problem is to understand how to characterize the dynamics of  $CP_2$  projection at each point.

In  $H$  picture there are two basic types of vacuum extremals:  $CP_2$  type extremals representing elementary particles and vacuum extremals having  $CP_2$  projection which is at most 2-dimensional Lagrange manifold and representing say hadron. Vacuum extremals can appear only as limiting cases of preferred extremals which are non-vacuum extremals. Since vacuum extremals have so decisive role in TGD, it is natural to require that this notion makes sense also in  $M^8$  picture. In particular, the notion of vacuum extremal makes sense in  $M^8$ .

This requires that Kähler form exist in  $M^8$ .  $E^4$  indeed allows full  $S^2$  of covariantly constant Kähler forms representing quaternionic imaginary units so that one can identify Kähler form and construct Kähler action. The obvious conjecture is that hyper-quaternionic space-time surface is extremal of this Kähler action and that the values of Kähler actions in  $M^8$  and  $H$  are identical. The elegant manner to achieve this, as well as the mapping of vacuum extremals to vacuum extremals and the mapping of light-like 3-surfaces to light-like 3-surfaces is to assume that  $M^8 - H$  duality is Kähler isometry so that induced Kähler forms are identical.

This picture contains many speculative elements and some words of warning are in order.

1. Light-likeness conjecture would boil down to the hypothesis that  $M^8 - H$  correspondence is Kähler isometry so that the metric and Kähler form of  $X^4$  induced from  $M^8$  and  $H$  would be identical. This would guarantee also that Kähler actions for the preferred extremal are identical. This conjecture is beautiful but strong.
2. The slicing of  $X^4(X_l^3)$  by light-like 3-surfaces is very strong condition on the classical dynamics of Kähler action and does not make sense for pieces of  $CP_2$  type vacuum extremals.

### Minkowskian-Euclidian $\leftrightarrow$ associative-co-associative

The 8-dimensionality of  $M^8$  allows to consider both associativity (hyper-quaternionicity) of the tangent space and associativity of the normal space- let us call this co-associativity of tangent space- as alternative options. Both options are needed as has been already found. Since space-time surface decomposes into regions whose induced metric possesses either Minkowskian or Euclidian signature, there is a strong temptation to propose that Minkowskian regions correspond to associative and Euclidian regions to co-associative regions so that space-time itself would provide both the description and its dual.

The proposed interpretation of conjectured associative-co-associative duality relates in an interesting manner to p-adic length scale hypothesis selecting the primes  $p \simeq 2^k$ ,  $k$  positive integer as preferred p-adic length scales.  $L_p \propto \sqrt{p}$  corresponds to the p-adic length scale defining the size of the space-time sheet at which elementary particle represented as  $CP_2$  type extremal is topologically condensed and is of order Compton length.  $L_k \propto \sqrt{k}$  represents the p-adic length scale of the worm-hole contacts associated with the  $CP_2$  type extremal and  $CP_2$  size is the natural length unit now. Obviously the quantitative formulation for associative-co-associative duality would be in terms  $p \rightarrow k$  duality.

### Are the known extremals of Kähler action consistent with the strong form of $M^8 - H$ duality

It is interesting to check whether the known extremals of Kähler action [8] are consistent with strong form of  $M^8 - H$  duality assuming that  $M^2$  or its light-like ray is contained in  $T(X^4)$  or normal space.

1.  $CP_2$  type vacuum extremals correspond cannot be hyper-quaternionic surfaces but co-hyper-quaternionicity is natural for them. In the same manner canonically imbedded  $M^4$  can be only hyper-quaternionic.
2. String like objects are associative since tangent space obviously contains  $M^2(x)$ . Objects of form  $M^1 \times X^3 \subset M^4 \times CP_2$  do not have  $M^2$  either in their tangent space or normal space in  $H$ . So that the map from  $H \rightarrow M^8$  is not well defined. There are no known extremals of Kähler action of this type. The replacement of  $M^1$  random light-like curve however gives vacuum extremal with vanishing volume, which need not mean physical triviality since fundamental objects of the theory are light-like 3-surfaces.
3. For canonically imbedded  $CP_2$  the assignment of  $M^2(x)$  to normal space is possible but the choice of  $M^2(x) \subset N(CP_2)$  is completely arbitrary. For a generic  $CP_2$  type vacuum extremals  $M^4$  projection is a random light-like curve in  $M^4 = M^1 \times E^3$  and  $M^2(x)$  can be defined uniquely by the normal vector  $n \in E^3$  for the local plane defined by the tangent vector  $dx^\mu/dt$  and acceleration vector  $d^2x^\mu/dt^2$  assignable to the orbit.
4. Consider next massless extremals. Let us fix the coordinates of  $X^4$  as  $(t, z, x, y) = (m^0, m^2, m^1, m^2)$ . For simplest massless extremals  $CP_2$  coordinates are arbitrary functions of variables  $u = k \cdot m = t - z$  and  $v = \epsilon \cdot m = x$ , where  $k = (1, 1, 0, 0)$  is light-like vector of  $M^4$  and  $\epsilon = (0, 0, 1, 0)$  a polarization vector orthogonal to it. Obviously, the extremals defines a decomposition  $M^4 = M^2 \times E^2$ . Tangent space is spanned by the four  $H$ -vectors  $\nabla_\alpha h^k$  with  $M^4$  part given by  $\nabla_\alpha m^k = \delta_\alpha^k$  and  $CP_2$  part by  $\nabla_\alpha s^k = \partial_u s^k k_\alpha + \partial_v s^k \epsilon_\alpha$ .

The normal space cannot contain  $M^4$  vectors since the  $M^4$  projection of the extremal is  $M^4$ . To realize hyper-quaternionic representation one should be able to from these vector two vectors of  $M^2$ , which means linear combinations of tangent vectors for which  $CP_2$  part vanishes. The vector  $\partial_t h^k - \partial_z h^k$  has vanishing  $CP_2$  part and corresponds to  $M^4$  vector  $(1, -1, 0, 0)$  fix assigns to each point the plane  $M^2$ . To obtain  $M^2$  one would need  $(1, 1, 0, 0)$  too but this is not possible. The vector  $\partial_y h^k$  is  $M^4$  vector orthogonal to  $\epsilon$  but  $M^2$  would require also  $(1, 0, 0, 0)$ . The proposed generalization of massless extremals allows the light-like line  $M_\pm$  to depend on point of  $M^4$  [8], and leads to the introduction of Hamilton-Jacobi coordinates involving a local decomposition of  $M^4$  to  $M^2(x)$  and its orthogonal complement with light-like coordinate lines having interpretation as curved light rays.  $M^2(x) \subset T(X^4)$  assumption fails also for vacuum extremals of form  $X^1 \times X^3 \subset M^4 \times CP_2$ , where  $X^1$  is light-like random curve. In the latter case, vacuum property follows from the vanishing of the determinant of the induced metric.

5. The deformations of string like objects to magnetic flux quanta are basic conjectural extremals of Kähler action and the proposed picture supports this conjecture. In hyper-quaternionic case the assumption that local 4-D plane of  $X^3$  defined by modified gamma matrices contains  $M^2(x)$  but that  $T(X^3)$  does not contain it, is very strong. It states that  $T(X^4)$  at each point can be regarded as a product  $M^2(x) \times T^2$ ,  $T^2 \subset T(CP_2)$ , so that hyper-quaternionic  $X^4$  would be a collection of Cartesian products of infinitesimal 2-D planes  $M^2(x) \subset M^4$  and  $T^2(x) \subset CP_2$ . The extremals in question could be seen as local variants of string like objects  $X^2 \times Y^2 \subset M^4 \times CP_2$ , where  $X^2$  is minimal surface and  $Y^2$  holomorphic surface of  $CP_2$ . One can say that  $X^2$  is replaced by a collection of infinitesimal pieces of  $M^2(x)$  and  $Y^2$  with similar pieces of homologically non-trivial geodesic sphere  $S^2(x)$  of  $CP_2$ , and the Cartesian products of these pieces are glued together to form a continuous surface defining an extremal of Kähler action. Field equations would pose conditions on how  $M^2(x)$  and  $S^2(x)$  can depend on  $x$ . This description applies to magnetic flux quanta, which are the most important must-be extremals of Kähler action.

### Geometric interpretation of strong $M^8 - H$ duality

In the proposed framework  $M^8 - H$  duality would have a purely geometric meaning and there would be nothing magical in it.

1.  $X^4(X_l^3) \subset H$  could be seen as a curve representing the orbit of a light-like 3-surface defining a 4-D surface. The question is how to determine the notion of tangent vector for the orbit of  $X_l^3$ . Intuitively tangent vector is a one-dimensional arrow tangential to the curve at point  $X_l^3$ . The identification of the hyper-quaternionic surface  $X^4(X_l^3) \subset M^8$  as tangent vector conforms with this intuition.
2. One could argue that  $M^8$  representation of space-time surface is kind of chart of the real space-time surface obtained by replacing real curve by its tangent line. If so, one cannot avoid the question under which conditions this kind of chart is faithful. An alternative interpretation is that a representation making possible to realize number theoretical universality is in question.
3. An interesting question is whether  $X^4(X_l^3)$  as orbit of light-like 3-surface is analogous to a geodesic line -possibly light-like- so that its tangent vector would be parallel translated in the sense that  $X^4(X^3)$  for any light-like surface at the orbit is same as  $X^4(X_l^3)$ . This would give justification for the possibility to interpret space-time surfaces as a geodesic of configuration space: this is one of the first -and practically forgotten- speculations inspired by the construction of configuration space geometry. The light-likeness of the geodesic could correspond at the level of  $X^4$  the possibility to decompose the tangent space to a direct sum of two light-like spaces and 2-D transversal space producing the foliation of  $X^4$  to light-like 3-surfaces  $X_l^3$  along light-like curves.
4.  $M^8 - H$  duality would assign to  $X_l^3$  classical orbit and its tangent vector at  $X_l^3$  as a generalization of Bohr orbit. This picture differs from the wave particle duality of wave mechanics stating that once the position of particle is known its momentum is completely unknown. The outcome is however the same: for  $X_l^3$  corresponding to wormhole throats and light-like boundaries of  $X^4$ , canonical momentum densities in the normal direction vanish identically by conservation laws and one can say that the analog of  $(q, p)$  phase space as the space carrying wave functions is replaced with the analog of subspace consisting of points  $(q, 0)$ . The dual description in  $M^8$  would not be analogous to wave functions in momentum space but to those in the space of unique tangents of curves at their initial points.

### The Kähler and spinor structures of $M^8$

If one introduces  $M^8$  as dual of  $H$ , one cannot avoid the idea that hyper-quaternionic surfaces obtained as images of the preferred extremals of Kähler action in  $H$  are also extremals of  $M^8$  Kähler action with same value of Kähler action. As found, this leads to the conclusion that the  $M^8 - H$  duality is Kähler isometry. Coupling of spinors to Kähler potential is the next step and this in turn leads to the introduction of spinor structure so that quantum TGD in  $H$  should have full  $M^8$  dual.

There are strong physical constraints on  $M^8$  dual and they could kill the hypothesis. The basic constraint to the spinor structure of  $M^8$  is that it reproduces basic facts about electro-weak interactions. This includes neutral electro-weak couplings to quarks and leptons identified as different  $H$ -chiralities and parity breaking.

1. By the flatness of the metric of  $E^4$  its spinor connection is trivial.  $E^4$  however allows full  $S^2$  of covariantly constant Kähler forms so that one can accommodate free independent Abelian gauge fields assuming that the independent gauge fields are orthogonal to each other when interpreted as realizations of quaternionic imaginary units.
2. One should be able to distinguish between quarks and leptons also in  $M^8$ , which suggests that one introduce spinor structure and Kähler structure in  $E^4$ . The Kähler structure of  $E^4$  is unique apart from  $SO(3)$  rotation since all three quaternionic imaginary units and the unit vectors formed from them allow a representation as an antisymmetric tensor. Hence one must select one preferred Kähler structure, that is fix a point of  $S^2$  representing the selected imaginary unit. It is natural to assume different couplings of the Kähler gauge potential to spinor chiralities representing quarks and leptons: these couplings can be assumed to be same as in case of  $H$ .
3. Electro-weak gauge potential has vectorial and axial parts. Em part is vectorial involving coupling to Kähler form and  $Z^0$  contains both axial and vector parts. The free Kähler forms could thus allow to produce  $M^8$  counterparts of these gauge potentials possessing same couplings as their  $H$  counterparts. This picture would produce parity breaking in  $M^8$  picture correctly.
4. Only the charged parts of classical electro-weak gauge fields would be absent. This would conform with the standard thinking that charged classical fields are not important. The predicted classical  $W$  fields is one of the basic distinctions between TGD and standard model and in this framework. A further prediction is that this distinction becomes visible only in situations, where  $H$  picture is necessary. This is the case at high energies, where the description of quarks in terms of  $SU(3)$  color is convenient whereas  $SO(4)$  QCD would require large number of  $E^4$  partial waves. At low energies large number of  $SU(3)$  color partial waves are needed and the convenient description would be in terms of  $SO(4)$  QCD. Proton spin crisis might relate to this.
5. Also super-symmetries of quantum TGD crucial for the construction of configuration space geometry force this picture. In the absence of coupling to Kähler gauge potential all constant spinor fields and their conjugates would generate super-symmetries so that  $M^8$  would allow  $N = 8$  super-symmetry. The introduction of the coupling to Kähler gauge potential in turn means that all covariantly constant spinor fields are lost. Only the representation of all three neutral parts of electro-weak gauge potentials in terms of three independent Kähler gauge potentials allows right-handed neutrino as the only super-symmetry generator as in the case of  $H$ .
6. The  $SO(3)$  element characterizing  $M^2(x)$  is fixed apart from a local  $SO(2)$  transformation, which suggests an additional  $U(1)$  gauge field associated with  $SO(2)$  gauge invariance and representable as Kähler form corresponding to a quaternionic unit of  $E^4$ . A possible identification of this gauge field would be as a part of electro-weak gauge field.

### $M^8$ dual of configuration space geometry and spinor structure?

If one introduces  $M^8$  spinor structure and preferred extremals of  $M^8$  Kähler action, one cannot avoid the question whether it is possible or useful to formulate the notion of configuration space geometry and spinor structure for light-like 3-surfaces in  $M^8$  using the exponent of Kähler action as vacuum functional.

1. The isometries of the configuration space in  $M^8$  and  $H$  formulations would correspond to symplectic transformation of  $\delta M_{\pm}^4 \times E^4$  and  $\delta M_{\pm}^4 \times CP_2$  and the Hamiltonians involved would belong to the representations of  $SO(4)$  and  $SU(3)$  with 2-dimensional Cartan sub-algebras. In  $H$  picture color group would be the familiar  $SU(3)$  but in  $M^8$  picture it would be  $SO(4)$ . Color confinement in both  $SU(3)$  and  $SO(4)$  sense could allow these two pictures without any inconsistency.

2. For  $M^4 \times CP_2$  the two spin states of covariantly constant right handed neutrino and antineutrino spinors generate super-symmetries. This super-symmetry plays an important role in the proposed construction of configuration space geometry. As found, this symmetry would be present also in  $M^8$  formulation so that the construction of  $M^8$  geometry should reduce more or less to the replacement of  $CP_2$  Hamiltonians in representations of  $SU(3)$  with  $E^4$  Hamiltonians in representations of  $SO(4)$ . These Hamiltonians can be taken to be proportional to functions of  $E^4$  radius which is  $SO(4)$  invariant and these functions bring in additional degree of freedom.
3. The construction of Dirac determinant identified as a vacuum functional can be done also in  $M^8$  picture and the conjecture is that the result is same as in the case of  $H$ . In this framework the construction is much simpler due to the flatness of  $E^4$ . In particular, the generalized eigen modes of the Dirac operator  $D_K(Y_l^3)$  restricted to the  $X_l^3$  correspond to a situation in which one has fermion in induced Maxwell field mimicking the neutral part of electro-weak gauge field in  $H$  as far as couplings are considered. Induced Kähler field would be same as in  $H$ . Eigen modes are localized to regions inside which the Kähler magnetic field is non-vanishing and apart from the fact that the metric is the effective metric defined in terms of canonical momentum densities via the formula  $\hat{\Gamma}^\alpha = \partial L_K / \partial h_\alpha^k \Gamma_k$  for effective gamma matrices. This in fact, forces the localization of modes implying that their number is finite so that Dirac determinant is a product over finite number eigenvalues. It is clear that  $M^8$  picture could dramatically simplify the construction of configuration space geometry.
4. The eigenvalue spectra of the transversal parts of  $D_K$  operators in  $M^8$  and  $H$  should be identical. This motivates the question whether it is possible to achieve a complete correspondence between  $H$  and  $M^8$  pictures also at the level of spinor fields at  $X^3$  by performing a gauge transformation eliminating the classical  $W$  gauge boson field altogether at  $X_l^3$  and whether this allows to transform the modified Dirac equation in  $H$  to that in  $M^8$  when restricted to  $X_l^3$ . That something like this might be achieved is supported by the fact that in Coulombic gauge the component of gauge potential in the light-like direction vanishes so that the situation is effectively 2-dimensional and holonomy group is Abelian.

#### Why $M^8 - H$ duality is useful?

Skeptics could of course argue that  $M^8 - H$  duality produces only an inflation of unproven conjectures. There are however strong reasons for  $M^8 - H$  duality: both theoretical and physical.

1. The map of  $X_l^3 \subset H \rightarrow X_l^3 \subset M^8$  and corresponding map of space-time surfaces would allow to realize number theoretical universality.  $M^8 = M^4 \times E^4$  allows linear coordinates as natural coordinates in which one can say what it means that the point of imbedding space is rational/algebraic. The point of  $X^4 \subset H$  is algebraic if it is mapped to an algebraic point of  $M^8$  in number theoretic compactification. This of course restricts the symmetry groups to their rational/algebraic variants but this does not have practical meaning. Number theoretic compactification could in fact be motivated by the number theoretical universality.
2.  $M^8 - H$  duality could provide much simpler description of preferred extremals of Kähler action since the Kähler form in  $E^4$  has constant components. If the spinor connection in  $E^4$  is combination of the three Kähler forms mimicking neutral part of electro-weak gauge potential, the eigenvalue spectrum for the modified Dirac operator would correspond to that for a fermion in  $U(1)$  magnetic field defined by an Abelian magnetic field whereas in  $M^4 \times CP_2$  picture  $U(2)_{ew}$  magnetic fields would be present.
3.  $M^8 - H$  duality provides insights to low energy hadron physics.  $M^8$  description might work when  $H$ -description fails. For instance, perturbative QCD which corresponds to  $H$ -description fails at low energies whereas  $M^8$  description might become perturbative description at this limit. Strong  $SO(4) = SU(2)_L \times SU(2)_R$  invariance is the basic symmetry of the phenomenological low energy hadron models based on conserved vector current hypothesis (CVC) and partially conserved axial current hypothesis (PCAC). Strong  $SO(4) = SU(2)_L \times SU(2)_R$  relates closely also to electro-weak gauge group  $SU(2)_L \times U(1)$  and this connection is not well understood in QCD description.  $M^8 - H$  duality could provide this connection. Strong  $SO(4)$  symmetry would emerge as a low energy dual of the color symmetry. Orbital  $SO(4)$  would correspond to strong

$SU(2)_L \times SU(2)_R$  and by flatness of  $E^4$  spin like  $SO(4)$  would correspond to electro-weak group  $SU(2)_L \times U(1)_R \subset SO(4)$ . Note that the inclusion of coupling to Kähler gauge potential is necessary to achieve respectable spinor structure in  $CP_2$ . One could say that the orbital angular momentum in  $SO(4)$  corresponds to strong isospin and spin part of angular momentum to the weak isospin.

### 3.3.5 $M^8 - H$ duality and low energy hadron physics

The description of  $M^8 - H$  at the configuration space level can be applied to gain a view about color confinement and its dual for electro-weak interactions at short distance limit. The basic idea is that  $SO(4)$  and  $SU(3)$  provide provide dual descriptions of quark color using  $E^4$  and  $CP_2$  partial waves and low energy hadron physics corresponds to a situation in which  $M^8$  picture provides the perturbative approach whereas  $H$  picture works at high energies. The basic prediction is that  $SO(4)$  should appear as dynamical symmetry group of low energy hadron physics and this is indeed the case.

Consider color confinement at the long length scale limit in terms of  $M^8 - H$  duality.

1. At high energy limit only lowest color triplet color partial waves for quarks dominate so that QCD description becomes appropriate whereas very higher color partial waves for quarks and gluons are expected to appear at the confinement limit. Since configuration space degrees of freedom begin to dominate, color confinement limit transcends the descriptive power of QCD.
2. The success of  $SO(4)$  sigma model in the description of low lying hadrons would directly relate to the fact that this group labels also the  $E^4$  Hamiltonians in  $M^8$  picture. Strong  $SO(4)$  quantum numbers can be identified as orbital counterparts of right and left handed electro-weak isospin coinciding with strong isospin for lowest quarks. In sigma model pion and sigma boson form the components of  $E^4$  valued vector field or equivalently collection of four  $E^4$  Hamiltonians corresponding to spherical  $E^4$  coordinates. Pion corresponds to  $S^3$  valued unit vector field with charge states of pion identifiable as three Hamiltonians defined by the coordinate components. Sigma is mapped to the Hamiltonian defined by the  $E^4$  radial coordinate. Excited mesons corresponding to more complex Hamiltonians are predicted.
3. The generalization of sigma model would assign to quarks  $E^4$  partial waves belonging to the representations of  $SO(4)$ . The model would involve also 6  $SO(4)$  gluons and their  $SO(4)$  partial waves. At the low energy limit only lowest representations would be important whereas at higher energies higher partial waves would be excited and the description based on  $CP_2$  partial waves would become more appropriate.
4. The low energy quark model would rely on quarks moving  $SO(4)$  color partial waves. Left *resp.* right handed quarks could correspond to  $SU(2)_L$  *resp.*  $SU(2)_R$  triplets so that spin statistics problem would be solved in the same manner as in the standard quark model.
5. Family replication phenomenon is described in TGD framework the same manner in both cases so that quantum numbers like strangeness and charm are not fundamental. Indeed, p-adic mass calculations allowing fractally scaled up versions of various quarks allow to replace Gell-Mann mass formula with highly successful predictions for hadron masses [51].

To my opinion these observations are intriguing enough to motivate a concrete attempt to construct low energy hadron physics in terms of  $SO(4)$  gauge theory.

### 3.3.6 The notion of number theoretical braid

Braids -not necessary number theoretical- provide a realization discretization as a space-time correlate for the finite measurement resolution. The notion of braid was inspired by the idea about quantum TGD as almost topological quantum field theory. Although the original form of this idea has been buried, the notion of braid has survived: in the decomposition of space-time sheets to string world sheets, the ends of strings define representatives for braid strands at light-like 3-surfaces.

The notion of number theoretic universality inspired the much more restrictive notion of number theoretic braid requiring that the points in the intersection of the braid with the partonic 2-surface correspond to rational or at most algebraic points of  $H$  in preferred coordinates fixed by symmetry

considerations. The challenge has been to find a unique identification of the number theoretic braid or at least of the end points of the braid. The following consideration suggest that the number theoretic braids are not a useful notion in the generic case but make sense and are needed in the intersection of real and p-adic worlds which is in crucial role in TGD based vision about living matter [44].

It is only the braiding that matters in topological quantum field theories used to classify braids. Hence braid should require only the fixing of the end points of the braids at the intersection of the braid at the light-like boundaries of  $CDs$  and the braiding equivalence class of the braid itself. Therefore it is enough to specify the topology of the braid and the end points of the braid in accordance with the attribute "number theoretic". Of course, the condition that all points of the strand of the number theoretic braid are algebraic is impossible to satisfy.

The situation in which the equations defining  $X^2$  make sense both in real sense and p-adic sense using appropriate algebraic extension of p-adic number field is central in the TGD based vision about living matter [44]. The reason is that in this case the notion of number entanglement theoretic entropy having negative values makes sense and entanglement becomes information carrying. This motivates the identification of life as something in the intersection of real and p-adic worlds. In this situation the identification of the ends of the number theoretic braid as points belonging to the intersection of real and p-adic worlds is natural. These points -call them briefly algebraic points- belong to the algebraic extension of rationals needed to define the algebraic extension of p-adic numbers. This definition however makes sense also when the equations defining the partonic 2-surfaces fail to make sense in both real and p-adic sense. In the generic case the set of points satisfying the conditions is discrete. For instance, according to Fermat's theorem the set of rational points satisfying  $X^n + Y^n = Z^n$  reduces to the point  $(0, 0, 0)$  for  $n = 3, 4, \dots$ . Hence the constraint might be quite enough in the intersection of real and p-adic worlds where the choice of the algebraic extension is unique.

One can however criticize this proposal.

1. One must fix the the number of points of the braid and outside the intersection and the non-uniqueness of the algebraic extension makes the situation problematic. Physical intuition suggests that the points of braid define carriers of quantum numbers assignable to second quantized induced spinor fields so that the total number of fermions antifermions would define the number of braids. In the intersection the highly non-trivial implication is that this number cannot exceed the number of algebraic points.
2. In the generic case one expects that even the smallest deformation of the partonic 2-surface can change the number of algebraic points and also the character of the algebraic extension of rational numbers needed. The restriction to rational points is not expected to help in the generic case. If the notion of number theoretical braid is meant to be practical, must be able to decompose WCW to open sets inside which the numbers of algebraic points of braid at its ends are constant. For real topology this is expected to be impossible and it does not make sense to use p-adic topology for WCW whose points do not allow interpretation as p-adic partonic surfaces.
3. In the intersection of real and p-adic worlds which corresponds to a discrete subset of WCW, the situation is different. Since the coefficients of polynomials involved with the definition of the partonic 2-surface must be rational or at most algebraic, continuous deformations are not possible so that one avoids the problem.
4. This forces to ask the reason why for the number theoretic braids. In the generic case they seem to produce only troubles. In the intersection of real and p-adic worlds they could however allow the construction of the elements of  $M$ -matrix describing quantum transitions changing p-adic to real surfaces and vice versa as realizations of intentions and generation of cognitions. In this the case it is natural that only the data from the intersection of the two worlds are used. In [44] I have sketched the idea about number theoretic quantum field theory as a description of intentional action and cognition.

There is also the the problem of fixing the interior points of the braid modulo deformations not affecting the topology of the braid.

1. Infinite number of non-equivalent braidings are possible. Should one allow all possible braidings for a fixed light-like 3-surface and say that their existence is what makes the dynamics essentially

three-dimensional even in the topological sense? In this case there would be no problems with the condition that the points at both ends of braid are algebraic.

2. Or should one try to characterize the braiding uniquely for a given partonic 2-surfaces and corresponding 4-D tangent space distributions? The slicing of the space-time sheet by partonic 2-surfaces and string world sheets suggests that the ends of string world sheets could define the braid strands in the generic context when there is no algebraicity condition involved. This could be taken as a very natural manner to fix the topology of braid but leave the freedom to choose the representative for the braid. In the intersection of real and p-adic worlds there is no good reason for the end points of strands in this case to be algebraic at both ends of the string world sheet. One can however start from the braid defined by the end points of string world sheets, restrict the end points to be algebraic at the end with a smaller number of algebraic points and then perform a topologically non-trivial deformation of the braid so that also the points at the other end are algebraic? Non-trivial deformations need not be possible for all possible choices of algebraic braid points at the other end of braid and different choices of the set of algebraic points would give rise to different braidings. A further constraint is that only the algebraic points at which one has assign fermion or antifermion are used so that the number of braid points is not always maximal.
3. One can also ask whether one should perform the gauge fixing for the strands of the number theoretic braid using algebraic functions making sense both in real and p-adic context. This question does not seem terribly relevant since since it is only the topology of the braid that matters.

### 3.3.7 Connection with string model and Equivalence Principle at space-time level

Coset construction allows to generalize Equivalence Principle and understand it at quantum level. This is however not quite enough: a precise understanding of Equivalence Principle is required also at the classical level. Also the mechanism selecting via stationary phase approximation a preferred extremal of Kähler action providing a correlation between quantum numbers of the particle and geometry of the preferred extremals is still poorly understood.

#### Is stringy action principle coded by the geometry of preferred extremals?

It seems very difficult to deduce Equivalence Principle as an identity of gravitational and inertial masses identified as Noether charges associated with corresponding action principles. Since string model is an excellent theory of quantum gravitation, one can consider a less direct approach in which one tries to deduce a connection between classical TGD and string model and hope that the bridge from string model to General Relativity is easier to build. Number theoretical compactification gives good hopes that this kind of connection exists.

1. Number theoretic compactification implies that the preferred extremals of Kähler action have the property that one can assign to each point of  $M^4$  projection  $P_{M^4}(X^4(X_l^3))$  of the preferred extremal  $M^2(x)$  identified as the plane of non-physical polarizations and also as the plane in which local massless four-momentum lies.
2. If the distribution of the planes  $M^2(x)$  is integrable, one can slice  $P_{M^4}(X^4(X_l^3))$  to string world-sheets. The intersection of string world sheets with  $X^3 \subset \delta M_{\pm}^4 \times CP_2$  corresponds to a light-like curve having tangent in local tangent space  $M^2(x)$  at light-cone boundary. This is the first candidate for the definition of number theoretic braid. Second definition assumes  $M^2$  to be fixed at  $\delta CD$ : in this case the slicing is parameterized by the sphere  $S^2$  defined by the light rays of  $\delta M_{\pm}^4$ .
3. One can assign to the string world sheet -call it  $Y^2$  - the standard area action

$$S_G(Y^2) = \int_{Y^2} T \sqrt{g_2} d^2 y \ , \quad (3.3.1)$$

where  $g_2$  is either the induced metric or only its  $M^4$  part. The latter option looks more natural since  $M^4$  projection is considered.  $T$  is string tension.

4. The naivest guess would be  $T = 1/\hbar G$  apart from some numerical constant but one must be very cautious here since  $T = 1/L_p^2$  apart from a numerical constant is also a good candidate if one accepts the basic argument identifying  $G$  in terms of p-adic length  $L_p$  and Kähler action for two pieces of  $CP_2$  type vacuum extremals representing propagating graviton. The formula reads  $G = L_p^2 \exp(-2a S_K(CP_2))$ ,  $a \leq 1$  [3, 27]. The interaction strength which would be  $L_p^2$  without the presence of  $CP_2$  type vacuum extremals is reduced by the exponential factor coming from the exponent of Kähler function of configuration space.
5. One would have string model in either  $CD \times CP_2$  or  $CD \subset M^4$  with the constraint that stringy world sheet belongs to  $X^4(X_l^3)$ . For the extremals of  $S_G(Y^2)$  gravitational four-momentum defined as Noether charge is conserved. The extremal property of string world sheet need not however be consistent with the preferred extremal property. This constraint might bring in coupling of gravitons to matter. The natural guess is that graviton corresponds to a string connecting wormhole contacts. The strings could also represent formation of gravitational bound states when they connect wormhole contacts separated by a large distance. The energy of the string is roughly  $E \sim \hbar T L$  and for  $T = 1/\hbar G$  gives  $E \sim L/G$ . Macroscopic strings are not allowed except as models of black holes. The identification  $T \sim 1/L_p^2$  gives  $E \sim \hbar L/L_p^2$ , which does not favor long strings for large values of  $\hbar$ . The identification  $G_p = L_p^2/\hbar_0$  gives  $T = 1/\hbar G_p$  and  $E \sim \hbar_0 L/L_p^2$ , which makes sense and allows strings with length not much longer than p-adic length scale. Quantization - that is the presence of configuration space degrees of freedom - would bring in massless gravitons as deformations of string whereas strings would carry the gravitational mass.
6. The exponent  $\exp(iS_G)$  can appear as a phase factor in the definition of quantum states for preferred extremals.  $S_G$  is not however enough. One can assign also to the points of number theoretic braid action describing the interaction of a point like current  $Q dx^\mu/ds$  with induced gauge potentials  $A_\mu$ . The corresponding contribution to the action is

$$S_{braid} = \int_{braid} i \text{Tr} \left( Q \frac{dx^\mu}{ds} A_\mu \right) dx . \quad (3.3.2)$$

In stationary phase approximation subject to the additional constraint that a preferred extremal of Kähler action is in question one obtains the desired correlation between the geometry of preferred extremal and the quantum numbers of elementary particle. This interaction term carries information only about the charges of elementary particle. It is quite possible that the interaction term is more complex: for instance, it could contain spin dependent terms (Stern-Gerlach experiment).

7. The constraint coming from preferred extremal property of Kähler action can be expressed in terms of Lagrange multipliers

$$S_c = \int_{Y^2} \lambda^k D_\alpha \left( \frac{\partial L_K}{\partial \alpha^k} \right) \sqrt{g_2} d^2 y . \quad (3.3.3)$$

8. The action exponential reads as

$$\exp(iS_G + S_{braid} + S_c) . \quad (3.3.4)$$

The resulting field equations couple stringy  $M^4$  degrees of freedom to the second variation of Kähler action with respect to  $M^4$  coordinates and involve third derivatives of  $M^4$  coordinates at the right hand side. If the second variation of Kähler action with respect to  $M^4$  coordinates vanishes, free string results. This is trivially the case if a vacuum extremal of Kähler action is in question.

9. An interesting question is whether the preferred extremal property boils down to the condition that the second variation of Kähler action with respect to  $M^4$  coordinates or actually all coordinates vanishes so that gravitonic string is free. As a matter of fact, the stronger condition is required that the Noether currents associated with the modified Dirac action are conserved. The physical interpretation would be in terms of quantum criticality which is the basic conjecture about the dynamics of quantum TGD. This is clear from the fact that in 1-D system criticality means that the potential  $V(x) = ax + bx^2 + \dots$  has  $b = 0$ . In field theory criticality corresponds to the vanishing of the term  $m^2\phi^2/2$  so that massless situation corresponds to massless theory and criticality and long range correlations. For more than one dynamical variable there is a hierarchy of criticalities corresponding to the gradual reduction of the rank of the matrix of the matrix defined by the second derivatives of  $V(x)$  and this gives rise to a classification of criticalities. Maximum criticality would correspond to the total vanishing of this matrix. In infinite-D case this hierarchy is infinite.

### What does the equality of gravitational and inertial masses mean?

Consider next the question in what form Equivalence Principle could be realized in this framework.

1. Coset construction inspires the conjecture that gravitational and inertial four-momenta are identical. Also some milder form of it would make sense. What is clear is that the construction of preferred extremal involving the distribution of  $M^2(x)$  implies that conserved four-momentum associated with Kähler action can be expressed formally as stringy four-momentum. The integral of the conserved inertial momentum current over  $X^3$  indeed reduces to an integral over the curve defining string as one integrates over other two degrees of freedom. It would not be surprising if a stringy expression for four-momentum would result but with string tension depending on the point of string and possibly also on the component of four-momentum. If the dependence of string tension on the point of string and on the choice of the stringy world sheet is slow, the interpretation could be in terms of coupling constant evolution associated with the stringy coordinates. An alternative interpretation is that string tension corresponds to a scalar field. A quite reasonable option is that for given  $X_i^3$   $T$  defines a scalar field and that the observed  $T$  corresponds to the average value of  $T$  over deformations of  $X_i^3$ .
2. The minimum option is that Kähler mass is equal to the sum gravitational masses assignable to strings connecting points of wormhole throat or two different wormhole throats. This hypothesis makes sense even for wormhole contacts having size of order Planck length.
3. The condition that gravitational mass equals to the inertial mass (rest energy) assigned to Kähler action is the most obvious condition that one can imagine. The breaking of Poincaré invariance to Lorentz invariance with respect to the tip of  $CD$  supports this form of Equivalence Principle. This would predict the value of the ratio of the parameter  $R^2T$  and p-adic length scale hypothesis would allow only discrete values for this parameter.  $p \simeq 2^k$  following from the quantization of the temporal distance  $T(n)$  between the tips of  $CD$  as  $T(n) = 2^n T_0$  would suggest string tension  $T_n = 2^n R^2$  apart from a numerical factor.  $G_p \propto 2^n R^2/\hbar_0$  would emerge as a prediction of the theory.  $G$  can be seen either as a prediction or RG invariant input parameter fixed by quantum criticality. The arguments related to p-adic coupling constant evolution suggest  $R^2/\hbar_0 G = 3 \times 2^{23}$  [3, 27].
4. The scalar field property of string tension should be consistent with the vacuum degeneracy of Kähler action. For instance, for the vacuum extremals of Kähler action stringy action is non-vanishing. The simplest possibility is that one includes the integral of the scalar  $J^{\mu\nu} J_{\mu\nu}$  over the degrees transversal to  $M^2$  to the stringy action so that string tension vanishes for vacuum extremals. This would be nothing but dimensional reduction of 4-D theory to a 2-D theory using the slicing of  $X^4(X_i^3)$  to partonic 2-surfaces and stringy world sheets. For cosmic strings Kähler action reduces to stringy action with string tension  $T \propto 1/g_K^2 R^2$  apart from a numerical constant. If one wants consistency with  $T \propto 1/L_p^2$ , one must have  $T \propto 1/g_K^2 2^n R^2$  for the cosmic strings deformed to Kähler magnetic flux tubes. This looks rather plausible if the thickness of deformed string in  $M^4$  degrees of freedom is given by p-adic length scale.

### 3.4 Does modified Dirac action define the fundamental action principle?

Although quantum criticality in principle predicts the possible values of Kähler coupling strength, one might hope that there exists even more fundamental approach involving no coupling constants and predicting even quantum criticality and realizing quantum gravitational holography. The Dirac determinant associated with the modified Dirac action is an excellent candidate in this respect.

The original working hypothesis was that Dirac determinant defines the vacuum functional of the theory having interpretation as the exponent of Kähler function of world of classical worlds (WCW) expressible and that Kähler function reduces to Kähler action for a preferred extremal of Kähler action.

#### 3.4.1 What are the basic equations of quantum TGD?

A good place to start is to ask what might the basic equations of quantum TGD. There are two kinds of equations at the level of space-time surfaces.

1. Purely classical equations define the dynamics of the space-time sheets as preferred extremals of Kähler action. Preferred extremals are quantum critical in the sense that second variation vanishes for critical deformations representing zero modes. This condition guarantees that corresponding fermionic currents are conserved. There is infinite hierarchy of these currents and they define fermionic counterparts for zero modes. Space-time sheets can be also regarded as hyper-quaternionic surfaces. What these statements precisely mean has become clear only during this year. A rigorous proof for the equivalence of these two identifications is still lacking.
2. The purely quantal equations are associated with the representations of various super-conformal algebras and with the modified Dirac equation. The requirement that there are deformations of the space-time surface -actually infinite number of them- giving rise to conserved fermionic charges implies quantum criticality at the level of Kähler action in the sense of critical deformations. The precise form of the modified Dirac equation is not however completely fixed without further input. Quantal equations involve also generalized Feynman rules for  $M$ -matrix generalizing  $S$ -matrix to a "complex square root" of density matrix and defined by time-like entanglement coefficients between positive and negative energy parts of zero energy states is certainly the basic goal of quantum TGD.
3. The notion of weak electric-magnetic duality generalizing the notion of electric-magnetic duality [28] , [9] leads to a detailed understanding of how TGD reduces to almost topological quantum field theory [28] , [9] . If Kähler current defines Beltrami flow [48] it is possible to find a gauge in which Coulomb contribution to Kähler action vanishes so that it reduces to Chern-Simons term. If light-like 3-surfaces and ends of space-time surface are extremals of Chern-Simons action also effective 2-dimensionality is realized. The condition that the theory reduces to almost topological QFT and the hydrodynamical character of field equations leads to a detailed ansatz for the general solution of field equations and also for the solutions of the modified Dirac equation relying on the notion of Beltrami flow for which the flow parameter associated with the flow lines defined by a conserved current extends to a global coordinate. This makes the theory in well-defined sense completely integrable. Direct connection with massless theories emerges: every conserved Beltrami currents corresponds to a pair of scalar functions with the first one satisfying massless d'Alembert equation in the induced metric. The orthogonality of the gradients of these functions allows interpretation in terms of polarization and momentum directions. The Beltrami flow property can be also seen as one aspect of quantum criticality since the conserved currents associated with critical deformations define this kind of pairs.
4. The hierarchy of Planck constants provides also a fresh view to the quantum criticality. The original justification for the hierarchy of Planck constants came from the indications that Planck constant could have large values in both astrophysical systems involving dark matter and also in biology. The realization of the hierarchy in terms of the singular coverings and possibly also factor spaces of  $CD$  and  $CP_2$  emerged from consistency conditions. It however seems that TGD actually predicts this hierarchy of covering spaces. The extreme non-linearity of

the field equations defined by Kähler action means that the correspondence between canonical momentum densities and time derivatives of the imbedding space coordinates is 1-to-many. This leads naturally to the introduction of the covering space of  $CD \times CP_2$ , where  $CD$  denotes causal diamond defined as intersection of future and past directed light-cones.

At the level of WCW there is the generalization of the Dirac equation which can be regarded as a purely classical Dirac equation. The modified Dirac operators associated with quarks and leptons carry fermion number but the Dirac equations are well-defined. An orthogonal basis of solutions of these Dirac operators define in zero energy ontology a basis of zero energy states. The  $M$ -matrices defining entanglement between positive and negative energy parts of the zero energy state define what can be regarded as analogs of thermal S-matrices. The  $M$ -matrices associated with the solution basis of the WCW Dirac equation define by their orthogonality unitary  $U$ -matrix between zero energy states. This matrix finds the proper interpretation in TGD inspired theory of consciousness. WCW Dirac equation as the analog of super-Virasoro conditions for the "gamma fields" of superstring models defining super counterparts of Virasoro generators was the main focus during earlier period of quantum TGD but has not received so much attention lately and will not be discussed in this chapter.

### 3.4.2 Quantum criticality and modified Dirac action

The precise mathematical formulation of quantum criticality has remained one of the basic challenges of quantum TGD. The question leading to a considerable progress in the problem was simple: Under what conditions the modified Dirac action allows to assign conserved fermionic currents with the deformations of the space-time surface? The answer was equally simple: These currents exist only if these deformations correspond to vanishing second variations of Kähler action - which is what criticality is. The vacuum degeneracy of Kähler action strongly suggests that the number of critical deformations is always infinite and that these deformations define an infinite inclusion hierarchy of super-conformal algebras. This inclusion hierarchy would correspond to a fractal hierarchy of breakings of super-conformal symmetry generalizing the symmetry breaking hierarchies of gauge theories. These super-conformal inclusion hierarchies would realize the inclusion hierarchies for hyper-finite factors of type  $II_1$ .

#### Quantum criticality and fermionic representation of conserved charges associated with second variations of Kähler action

It is rather obvious that TGD allows a huge generalizations of conformal symmetries. The development of the understanding of conservation laws has been slow. Modified Dirac action provides excellent candidates for quantum counterparts of Noether charges. Unfortunately, the isometry charges vanish for Cartan algebras. The only manner to obtain non-trivial isometry charges is to add a direct coupling to the charges in Cartan algebra as will be found later. This addition involves Chern-Simons Dirac action so that the original intuition guided by almost TQFT idea was not wrong after all.

1. *Conservation of the fermionic current requires the vanishing of the second variation of Kähler action*

1. The modified Dirac action assigns to a deformation of the space-time surface a conserved charge expressible as bilinears of fermionic oscillator operators only if the first variation of the modified Dirac action under this deformation vanishes. The vanishing of the first variation for the modified Dirac action is equivalent with the vanishing of the second variation for the Kähler action. This can be seen by the explicit calculation of the second variation of the modified Dirac action and by performing partial integration for the terms containing derivatives of  $\Psi$  and  $\bar{\Psi}$  to give a total divergence representing the difference of the charge at upper and lower boundaries of the causal diamond plus a four-dimensional integral of the divergence term defined as the integral of the quantity

$$\begin{aligned} \Delta S_D &= \bar{\Psi} \Gamma^k D_\alpha J_k^\alpha \Psi , \\ J_k^\alpha &= \frac{\partial^2 L_K}{\partial h_\alpha^k \partial h_\beta^l} \delta h_\beta^k + \frac{\partial^2 L_K}{\partial h_\alpha^k \partial h^l} \delta h^l . \end{aligned} \quad (3.4.1)$$

Here  $h_{\beta}^k$  denote partial derivative of the imbedding space coordinate with respect to space-time coordinates. This term must vanish:

$$D_{\alpha} J_k^{\alpha} = 0 \ .$$

The condition states the vanishing of the second variation of Kähler action. This can of course occur only for preferred deformations of  $X^4$ . One could consider the possibility that these deformations vanish at light-like 3-surfaces or at the boundaries of CD. Note that covariant divergence is in question so that  $J_k^{\alpha}$  does not define conserved classical charge in the general case.

2. It is essential that the modified Dirac equation holds true so that the modified Dirac action vanishes: this is needed to cancel the contribution to the second variation coming from the determinant of the induced metric. The condition that the modified Dirac equation is satisfied for the deformed space-time surface requires that also  $\Psi$  suffers a transformation determined by the deformation. This gives

$$\delta\Psi = -\frac{1}{D} \times \Gamma^k J_k^{\alpha} \Psi \ . \quad (3.4.2)$$

Here  $1/D$  is the inverse of the modified Dirac operator defining the counterpart of the fermionic propagator.

3. The fermionic conserved currents associated with the deformations are obtained from the standard conserved fermion current

$$J^{\alpha} = \bar{\Psi} \Gamma^{\alpha} \Psi \ . \quad (3.4.3)$$

Note that this current is conserved only if the space-time surface is extremal of Kähler action: this is also needed to guarantee Hermiticity and same form for the modified Dirac equation for  $\Psi$  and its conjugate as well as absence of mass term essential for super-conformal invariance [32, 35]. Note also that ordinary divergence rather only covariant divergence of the current vanishes.

The conserved currents are expressible as sums of three terms. The first term is obtained by replacing modified gamma matrices with their increments in the deformation keeping  $\Psi$  and its conjugate constant. Second term is obtained by replacing  $\Psi$  with its increment  $\delta\Psi$ . The third term is obtained by performing same operation for  $\delta\bar{\Psi}$ .

$$J^{\alpha} = \bar{\Psi} \Gamma^k J_k^{\alpha} \Psi + \bar{\Psi} \hat{\Gamma}^{\alpha} \delta\Psi + \delta\bar{\Psi} \hat{\Gamma}^{\alpha} \Psi \ . \quad (3.4.4)$$

These currents provide a representation for the algebra defined by the conserved charges analogous to a fermionic representation of Kac-Moody algebra [16].

4. Also conserved super charges corresponding to super-conformal invariance are obtained. The first class of super currents are obtained by replacing  $\Psi$  or  $\bar{\Psi}$  right-handed neutrino spinor or its conjugate in the expression for the conserved fermion current and performing the above procedure giving two terms since nothing happens to the covariantly constant right handed-neutrino spinor. Second class of conserved currents is defined by the solutions of the modified Dirac equation interpreted as c-number fields replacing  $\Psi$  or  $\bar{\Psi}$  and the same procedure gives three terms appearing in the super current.

5. The existence of vanishing of second variations is analogous to criticality in systems defined by a potential function for which the rank of the matrix defined by second derivatives of the potential function vanishes at criticality. Quantum criticality becomes the prerequisite for the existence of quantum theory since fermionic anti-commutation relations in principle can be fixed from the condition that the algebra in question is equivalent with the algebra formed by the vector fields defining the deformations of the space-time surface defining second variations. Quantum criticality in this sense would also select preferred extremals of Kähler action as analogs of Bohr orbits and the spectrum of preferred extremals would be more or less equivalent with the expected existence of infinite-dimensional symmetry algebras.

### 2. About the general structure of the algebra of conserved charges

Some general comments about the structure of the algebra of conserved charges are in order.

1. Any Cartan algebra of the isometry group  $P \times SU(3)$  (there are two types of them for  $P$  corresponding to linear and cylindrical Minkowski coordinates) defines critical deformations (one could require that the isometries respect the geometry of  $CD$ ). The corresponding charges are conserved but vanish since the corresponding conjugate coordinates are cyclic for the Kähler metric and Kähler form so that the conserved current is proportional to the gradient of a Killing vector field which is constant in these coordinates. Therefore one cannot represent isometry charges as fermionic bilinears. Four-momentum and color quantum numbers are defined for Kähler action as classical conserved quantities but this is probably not enough. This can be seen as a problem.
  - (a) Four-momentum and color Cartan algebra emerge naturally in the representations of super-conformal algebras. In the case of color algebra the charges in the complement of the Cartan algebra can be constructed in standard manner as extension of those for the Cartan algebra using free field representation of Kac-Moody algebras. In string theories four-momentum appears linearly in bosonic Kac-Moody generators and in Sugawara construction [118] of super Virasoro generators as bilinears of bosonic Kac-Moody generators and fermionic super Kac-Moody generators [16]. Also now quantized transversal parts for  $M^4$  coordinates could define a second quantized field having interpretation as an operator acting on spinor fields of WCW. The angle coordinates conjugate to color isospin and hyper charge take the role of  $M^4$  coordinates in case of  $CP_2$ .
  - (b) Somehow one should be able to feed the information about the super-conformal representation of the isometry charges to the modified Dirac action by adding to it a term coupling fermionic current to the Cartan charges in general coordinate invariant and isometry invariant manner. As will be shown later, this is possible. The interpretation is as measurement interaction guaranteeing also the stringy character of the fermionic propagators. The values of the couplings involved are fixed by the condition of quantum criticality assumed in the sense that Kähler function of WCW suffers only a  $U(1)$  gauge transformation  $K \rightarrow K + f + \bar{f}$ , where  $f$  is a holomorphic function of WCW coordinates depending also on zero modes.
  - (c) The simplest addition involves the modified gamma matrices defined by a Chern-Simon term at the light-like wormhole throats and is sum of Chern-Simons Dirac action and corresponding coupling term linear in Cartan charges assignable to the partonic 2-surfaces at the ends of the throats. Hence the modified Dirac equation in the interior of the space-time sheet is not affected and nothing changes as far as quantum criticality in interior is considered.
2. The action defined by four-volume gives a first glimpse about what one can expect. In this case modified gamma matrices reduce to the induced gamma matrices. Second variations satisfy d'Alembert type equation in the induced metric so that the analogs of massless fields are in question. Mass term is present only if some dimensions are compact. The vanishing of excitations at light-like boundaries is a natural boundary condition and might well imply that the solution spectrum could be empty. Hence it is quite possible that four-volume action leads to a trivial theory.

3. For the vacuum extremals of Kähler action the situation is different. There exists an infinite number of second variations and the classical non-determinism suggests that deformations vanishing at the light-like boundaries exist. For the canonical imbedding of  $M^4$  the equation for second variations is trivially satisfied. If the  $CP_2$  projection of the vacuum extremal is one-dimensional, the second variation contains a non-vanishing term and an equation analogous to massless d'Alembert equation for the increments of  $CP_2$  coordinates is obtained. Also for the vacuum extremals of Kähler action with 2-D  $CP_2$  projection all terms involving induced Kähler form vanish and the field equations reduce to d'Alembert type equations for  $CP_2$  coordinates. A possible interpretation is as the classical analog of Higgs field. For the deformations of non-vacuum extremals this would suggest the presence of terms analogous to mass terms: these kind of terms indeed appear and are proportional to  $\delta s^k$ .  $M^4$  degrees of freedom decouple completely and one obtains QFT type situation.
4. The physical expectation is that at least for the vacuum extremals the critical manifold is infinite-dimensional. The notion of finite measurement resolution suggests infinite hierarchies of inclusions of hyper-finite factors of type  $II_1$  possibly having interpretation in terms of inclusions of the super conformal algebras defined by the critical deformations.
5. The properties of Kähler action give support for this expectation. The critical manifold is infinite-dimensional in the case of vacuum extremals. Canonical imbedding of  $M^4$  would correspond to maximal criticality analogous to that encountered at the tip of the cusp catastrophe. The natural guess would be that as one deforms the vacuum extremal the previously critical degrees of freedom are transformed to non-critical ones. The dimension of the critical manifold could remain infinite for all preferred extremals of the Kähler action. For instance, for cosmic string like objects any complex manifold of  $CP_2$  defines cosmic string like objects so that there is a huge degeneracy is expected also now. For  $CP_2$  type vacuum extremals  $M^4$  projection is arbitrary light-like curve so that also now infinite degeneracy is expected for the deformations.

### 3. Critical super algebra and zero modes

The relationship of the critical super-algebra to configuration space geometry is interesting.

1. The vanishing of the second variation plus the identification of Kähler function as a Kähler action for preferred extremals means that the critical variations are orthogonal to all deformations of the space-time surface with respect to the configuration space metric and thus correspond to zero modes. This conforms with the fact that configuration space metric vanishes identically for canonically imbedded  $M^4$ . Zero modes do not seem to correspond to gauge degrees of freedom so that the super-conformal algebra associated with the zero modes has genuine physical content.
2. Since the action of  $X^4$  local Hamiltonians of  $\delta M^4 \times CP_2$  corresponds to the action in quantum fluctuating degrees of freedom, critical deformations cannot correspond to this kind of Hamiltonians.
3. The notion of finite measurement resolution suggests that the degrees of freedom which are below measurement resolution correspond to vanishing gauge charges. The sub-algebras of critical super-conformal algebra for which charges annihilate physical states could correspond to this kind of gauge algebras.
4. The conserved super charges associated with the vanishing second variations cannot give configuration space metric as their anti-commutator. This would also lead to a conflict with the effective 2-dimensionality stating that the configuration space line-element is expressible as sum of contribution coming from partonic 2-surfaces as also with fermionic anti-commutation relations.

### 4. Connection with quantum criticality

The vanishing of the second variation for some deformations means that the system is critical, in the recent case quantum critical. Basic example of criticality is bifurcation diagram for cusp catastrophe. For some mysterious reason I failed to realize that quantum criticality realized as the vanishing of

the second variation makes possible a more or less unique identification of preferred extremals and considered alternative identifications such as absolute minimization of Kähler action which is just the opposite of criticality. Both the super-symmetry of  $D_K$  and conservation Dirac Noether currents for modified Dirac action have thus a connection with quantum criticality.

1. Finite-dimensional critical systems defined by a potential function  $V(x^1, x^2, \dots)$  are characterized by the matrix defined by the second derivatives of the potential function and the rank of system classifies the levels in the hierarchy of criticalities. Maximal criticality corresponds to the complete vanishing of this matrix. Thom's catastrophe theory classifies these hierarchies, when the numbers of behavior and control variables are small (smaller than 5). In the recent case the situation is infinite-dimensional and the criticality conditions give additional field equations as existence of vanishing second variations of Kähler action.
2. The vacuum degeneracy of Kähler action allows to expect that this kind infinite hierarchy of criticalities is realized. For a general vacuum extremal with at most 2-D  $CP_2$  projection the matrix defined by the second variation vanishes because  $J_{\alpha\beta} = 0$  vanishes and also the matrix  $(J_k^\alpha + J_k^\alpha)(J_l^\beta + J_l^\beta)$  vanishes by the antisymmetry  $J_k^\alpha = -J_k^\alpha$ . Recall that the formulation of Equivalence Principle in string picture demonstrated that the reduction of stringy dynamics to that for free strings requires that second variation with respect to  $M^4$  coordinates vanish. This condition would guarantee the conservation of fermionic Noether currents defining gravitational four-momentum and other Poincare quantum numbers but not those for gravitational color quantum numbers. Encouragingly, the action of  $CP_2$  type vacuum extremals having random light-like curve as  $M^4$  projection have vanishing second variation with respect to  $M^4$  coordinates (this follows from the vanishing of Kähler energy momentum tensor, second fundamental form, and Kähler gauge current). In this case however the momentum is vanishing.
3. Conserved bosonic and fermionic Noether charges would characterize quantum criticality. In particular, the isometries of the imbedding space define conserved currents represented in terms of the fermionic oscillator operators if the second variations defined by the infinitesimal isometries vanish for the modified Dirac action. For vacuum extremals the dimension of the critical manifold is infinite: maybe there is hierarchy of quantum criticalities for which this dimension decreases step by step but remains always infinite. This hierarchy could closely relate to the hierarchy of inclusions of hyper-finite factors of type  $II_1$ . Also the conserved charges associated with Super-symplectic and Super Kac-Moody algebras would require infinite-dimensional critical manifold defined by the spectrum of second variations.
4. Phase transitions are characterized by the symmetries of the phases involved with the transitions, and it is natural to expect that dynamical symmetries characterize the hierarchy of quantum criticalities. The notion of finite quantum measurement resolution based on the hierarchy of Jones inclusions indeed suggests the existence of a hierarchy of dynamical gauge symmetries characterized by gauge groups in ADE hierarchy [27] with degrees of freedom below the measurement resolution identified as gauge degrees of freedom.
5. A breakthrough in understanding of the criticality was the discovery that the realization that the hierarchy of singular coverings of  $CD \times CP_2$  needed to realize the hierarchy of Planck constants could correspond directly to a similar hierarchy of coverings forced by the factor that classical canonical momentum densities correspond to several values of the time derivatives of the imbedding space coordinates led to a considerable progress if the understanding of the relationship between criticality and hierarchy of Planck constants [35], [7]. Therefore the problem which led to the geometrization program of quantum TGD, also allowed to reduce the hierarchy of Planck constants introduced on basis of experimental evidence to the basic quantum TGD. One can say that the 3-surfaces at the ends of  $CD$  resp. wormhole throats are critical in the sense that they are unstable against splitting to  $n_b$  resp.  $n_a$  surfaces so that one obtains space-time surfaces which can be regarded as surfaces in  $n_a \times n_b$  fold covering of  $CD \times CP_2$ . This allows to understand why Planck constant is effectively replaced with  $n_a n_b \hbar_0$  and explains charge fractionization.

### Preferred extremal property as classical correlate for quantum criticality, holography, and quantum classical correspondence

The Noether currents assignable to the modified Dirac equation are conserved only if the first variation of the modified Dirac operator  $D_K$  defined by Kähler action vanishes. This is equivalent with the vanishing of the second variation of Kähler action -at least for the variations corresponding to dynamical symmetries having interpretation as dynamical degrees of freedom which are below measurement resolution and therefore effectively gauge symmetries.

The vanishing of the second variation in interior of  $X^4(X_l^3)$  is what corresponds exactly to quantum criticality so that the basic vision about quantum dynamics of quantum TGD would lead directly to a precise identification of the preferred extremals. Something which I should have noticed for more than decade ago! The question whether these extremals correspond to absolute minima remains however open.

The vanishing of second variations of preferred extremals -at least for deformations representing dynamical symmetries, suggests a generalization of catastrophe theory of Thom, where the rank of the matrix defined by the second derivatives of potential function defines a hierarchy of criticalities with the tip of bifurcation set of the catastrophe representing the complete vanishing of this matrix. In the recent case this theory would be generalized to infinite-dimensional context. There are three kind of variables now but quantum classical correspondence (holography) allows to reduce the types of variables to two.

1. The variations of  $X^4(X_l^3)$  vanishing at the intersections of  $X^4(X_l^3)$  with the light-like boundaries of causal diamonds  $CD$  would represent behavior variables. At least the vacuum extremals of Kähler action would represent extremals for which the second variation vanishes identically (the "tip" of the multi-furcation set).
2. The zero modes of Kähler function would define the control variables interpreted as classical degrees of freedom necessary in quantum measurement theory. By effective 2-dimensionality (or holography or quantum classical correspondence) meaning that the configuration space metric is determined by the data coming from partonic 2-surfaces  $X^2$  at intersections of  $X_l^3$  with boundaries of  $CD$ , the interiors of 3-surfaces  $X^3$  at the boundaries of  $CD$ s in rough sense correspond to zero modes so that there is indeed huge number of them. Also the variables characterizing 2-surface, which cannot be complexified and thus cannot contribute to the Kähler metric of configuration space represent zero modes. Fixing the interior of the 3-surface would mean fixing of control variables. Extremum property would fix the 4-surface and behavior variables if boundary conditions are fixed to sufficient degree.
3. The complex variables characterizing  $X^2$  would represent third kind of variables identified as quantum fluctuating degrees of freedom contributing to the configuration space metric. Quantum classical correspondence requires 1-1 correspondence between zero modes and these variables. This would be essentially holography stating that the 2-D "causal boundary"  $X^2$  of  $X^3(X^2)$  codes for the interior. Preferred extremal property identified as criticality condition would realize the holography by fixing the values of zero modes once  $X^2$  is known and give rise to the holographic correspondence  $X^2 \rightarrow X^3(X^2)$ . The values of behavior variables determined by extremization would fix then the space-time surface  $X^4(X_l^3)$  as a preferred extremal.
4. Clearly, the presence of zero modes would be absolutely essential element of the picture. Quantum criticality, quantum classical correspondence, holography, and preferred extremal property would all represent more or less the same thing. One must of course be very cautious since the boundary conditions at  $X_l^3$  involve normal derivative and might bring in delicacies forcing to modify the simplest heuristic picture.
5. There is a possible connection with the notion of self-organized criticality [14] introduced to explain the behavior of systems like sand piles. Self-organization in these systems tends to lead "to the edge". The challenge is to understand how system ends up to a critical state, which by definition is unstable. Mechanisms for this have been discovered and based on phase transitions occurring in a wide range of parameters so that critical point extends to a critical manifold. In TGD Universe quantum criticality suggests a universal mechanism of this kind. The criticality for the preferred extremals of Kähler action would mean that classically all systems are critical

in well-defined sense and the question is only about the degree of criticality. Evolution could be seen as a process leading gradually to increasingly critical systems. One must however distinguish between the criticality associated with the preferred extremals of Kähler action and the criticality caused by the spin glass like energy landscape like structure for the space of the maxima of Kähler function.

### 3.4.3 Handful of problems with a common resolution

Theory building could be compared to pattern recognition or to a solving a crossword puzzle. It is essential to make trials, even if one is aware that they are probably wrong. When stares long enough to the letters which do not quite fit, one suddenly realizes what one particular crossword must actually be and it is soon clear what those other crosswords are. In the following I describe an example in which this analogy is rather concrete. Let us begin by listing the problems.

1. The condition that modified Dirac action allows conserved charges leads to the condition that the symmetries in question give rise to vanishing second variations of Kähler action. The interpretation is as quantum criticality and there are good arguments suggesting that the critical symmetries define an infinite-dimensional super-conformal algebra forming an inclusion hierarchy related to a sequence of symmetry breakings closely related to a hierarchy of inclusions of hyper-finite factors of types  $II_1$  and  $III_1$ . This means an enormous generalization of the symmetry breaking patterns of gauge theories.

There is however a problem. For the translations of  $M^4$  and color hyper charge and isospin (more generally, any Cartan algebra of  $P \times SU(3)$ ) the resulting fermionic charges vanish. The trial for the crossword in absence of nothing better would be the following argument. By the abelianity of these charges the vanishing of quantal representation of four-momentum and color Cartan charges is not a problem and that classical representation of these charges or their super-conformal representation is enough.

2. Modified Dirac equation is satisfied in the interior of space-time surface always. This means that one does not obtain off-mass shell propagation at all in 4-D sense. Effective 2-dimensionality suggests that off mass shell propagation takes place along wormhole throats. The reduction to almost topological QFT with Kähler function reducing to Chern-Simons type action implied by the weak form of electric-magnetic duality and a proper gauge choice for the induced Kähler gauge potential implies effective 3-dimensionality at classical level. This inspires the question whether Chern-Simons type action resulting from an instanton term could define the modified gamma matrices appearing in the 3-D modified Dirac action associated with wormhole throats and the ends of the space-time sheet at the boundaries of  $CD$ .

The assumption that modified Dirac equation is satisfied also at the ends and wormhole throats would realize effective 2-dimensionality as conditions on the boundary values of the 4-D Dirac equation but would not allow off mass shell propagation. Therefore one could argue that effective 2-dimensionality in this sense holds true only for incoming and outgoing particles.

The reduction of Kähler action to Chern-Simons term together with effective 2-dimensionality suggests that Kähler function corresponds to an extremum of this action with a constraint term due to the weak form of electric-magnetic duality. Without this term the extrema of Chern-Simons action have 2-D  $CP_2$  projection not consistent with the weak form of electric-magnetic duality. The extrema are not maxima of Kähler function: they are obtained by varying with respect to tangent space data of the partonic 2-surfaces. Lagrange multiplier term induces also to the modified gamma matrices a contribution which is of the same general form as for any general coordinate invariant action.

3. Quantum classical correspondence requires that the geometry of the space-time sheet should correlate with the quantum numbers characterizing positive (negative) energy part of the quantum state. One could argue that by multiplying WCW spinor field by a suitable phase factor depending on the charges of the state, the correspondence follows from stationary phase approximation. This crossword looks unconvincing. A more precise connection between quantum and classical is required.

4. In quantum measurement theory classical macroscopic variables identified as degrees of freedom assignable to the interior of the space-time sheet correlate with quantum numbers. Stern Gerlach experiment is an excellent example of the situation. The generalization of the imbedding space concept by replacing it with a book like structure implies that imbedding space geometry at given page and for given causal diamond ( $CD$ ) carries information about the choice of the quantization axes (preferred plane  $M^2$  of  $M^4$  resp. geodesic sphere of  $CP_2$  associated with singular covering/factor space of  $CD$  resp.  $CP_2$ ). This is a big step but not enough. Modified Dirac action as such does not seem to provide any hint about how to achieve this correspondence. One could even wonder whether dissipative processes or at least the breaking of  $T$  and  $CP$  characterizing the outcome of quantum jump sequence should have space-time correlate. How to achieve this?

Each of these problems makes one suspect that something is lacking from the modified Dirac action: there should exist an elegant manner to feed information about quantum numbers of the state to the modified Dirac action in turn determining vacuum functional as an exponent Kähler function identified as Kähler action for the preferred extremal assumed to be dictated by quantum criticality and equivalently by hyper-quaternionicity.

This observation leads to what might be the correct question. Could a general coordinate invariant and Poincare invariant modification of the modified Dirac action consistent with the vacuum degeneracy of Kähler action allow to achieve this information flow somehow? In the following one manner to achieve this modification is discussed. It must be however emphasized that I have considered many alternatives and the one discussed below finds its justification only from the fact that it is the simplest one found hitherto.

#### The identification of the measurement interaction term

The idea is simple: add to the modified Dirac action a term which is analogous to the Dirac action in  $M^4 \times CP_2$ . One can consider two options according to whether the term is assigned with interior or with a 3-D light-like 3-surface and last years have been continual argumentation about which option is the correct one.

1. The additional term would be essentially the analog of the ordinary Dirac action at the imbedding space level.

$$\begin{aligned}
 S_{int} &= \sum_A Q_A \int \bar{\Psi} g^{AB} j_{B\alpha} \hat{\Gamma}^\alpha \Psi \sqrt{g} d^4x \ , \\
 g_{AB} &= j_A^k h_{kl} j_B^l \ , \quad g^{AB} g_{BC} = \delta_C^A \ , \\
 j_{B\alpha} &= j_B^k h_{kl} \partial_\alpha h^l \ .
 \end{aligned} \tag{3.4.5}$$

The sum is over isometry charges  $Q_A$  interpreted as quantal charges and  $j^{Ak}$  denotes the Killing vector field of the isometry.  $g^{AB}$  is the inverse of the tensor  $g_{AB}$  defined by the local inner products of Killing vectors fields in  $M^4$  and  $CP_2$ . The space-time projections of the Killing vector fields  $j_{B\alpha}$  have interpretation as classical color gauge potentials in the case of  $SU(3)$ . In  $M^4$  degrees of freedom and for Cartan algebra of  $SU(3)$   $j_{B\alpha}$  reduce to the gradients of linear  $M^4$  coordinates in case of translations. Modified gamma matrices could be assigned to Kähler action or its instanton term or with Chern-Simons action.

2. The added term containing quantal charges must make sense in the modified Dirac equation. This requires that the physical state is an eigenstate of momentum and color charges. This allows only color hyper-charge and color isospin so that there is no hope of obtaining exactly the stringy formula for the propagator. The modified Dirac operator is given by

$$\begin{aligned}
 D &= D + D_{int} = \hat{\Gamma}^\alpha D_\alpha + \hat{\Gamma}^\alpha \sum_A Q_A g^{AB} j_{B\alpha} \\
 &= \hat{\Gamma}^\alpha (D_\alpha + \partial_\alpha \phi) \ , \quad \partial_\alpha \phi = \sum_A Q_A g^{AB} j_{B\alpha} \ .
 \end{aligned} \tag{3.4.6}$$

The conserved fermionic isometry currents are

$$J^{A\alpha} = \sum_B Q_B \bar{\Psi} g^{BC} j_C^k h_{kl} j_A^l \hat{\Gamma}^\alpha \Psi = Q_A \bar{\Psi} \hat{\Gamma}^\alpha \Psi . \quad (3.4.7)$$

Here the sum is restricted to a Cartan sub-algebra of Poincare group and color group.

3. An important restriction is that by four-dimensionality of  $M^4$  and  $CP_2$  the rank of  $g_{AB}$  is 4 so that  $g^{AB}$  exists only when one considers only four conserved charges. In the case of  $M^4$  this is achieved by a restriction to translation generators  $Q_A = p_A$ .  $g_{AB}$  reduces to Minkowski metric and Killing vector fields are constants. The Cartan sub-algebra could be however replaced by any four commuting charges in the case of Poincare algebra (second one corresponds to time translation plus translation, boost and rotation in given direction). In the case of  $SU(3)$  one must restrict the consideration either to  $U(2)$  sub-algebra or its complement.  $CP_2 = SU(3)/SU(2)$  decomposition would suggest the complement as the correct choice. One can indeed build the generators of  $U(2)$  as commutators of the charges in the complement. On the other hand, Cartan algebra is enough in free field construction of Kac-Moody algebras.
4. What is remarkable that for the Cartan algebra of  $M^4 \times SU(3)$  the measurement interaction term is equivalent with the addition of gauge part  $\partial_\alpha \phi$  of the induced Kähler gauge potential  $A_\alpha$ . This property might hold true for any measurement interaction term. This also suggests that the change in Kähler function is only the transformation  $A_\alpha \rightarrow A_\alpha + \partial_\alpha \phi$ ,  $\partial_\alpha \phi = \sum_A Q_A g^{AB} j_{B\alpha}$ .
5. Recall that the  $\phi$  for  $U(1)$  gauge transformations respecting the vanishing of the Coulomb interaction term of Kähler action [35], [7] the current  $j_K^\alpha \phi$  is conserved, which implies that the change of the Kähler action is trivial. These properties characterize the gauge transformations respecting the gauge in which Coulombic interaction term of the Kähler action vanishes so that Kähler action reduces to 3-dimensional generalized Chern-Simons term if the weak form of electric-magnetic duality holds true guaranteeing among other things that the induced Kähler field is not too singular at the wormhole throats [35], [7]. The scalar function assignable to the measurement interaction terms does not have this property and this is what is expected since it must change the value of the Kähler function and therefore affect the preferred extremal.

Concerning the precise form of the modified Dirac action the basic clue comes from the observation that the measurement interaction term corresponds to the addition of a gauge part to the induced  $CP_2$  Kähler gauge potential  $A_\alpha$ . The basic question is what part of the action one assigns the measurement interaction term.

1. One could define the measurement interaction term using either the four-dimensional instanton term or its reduction to Chern-Simons terms. The part of Dirac action defined by the instanton term in the interior does not reduce to a 3-D form unless the Dirac equation defined by the instanton term is satisfied: this cannot be true. Hence Chern-Simons term is the only possibility. The classical field equations associated with the Chern-Simons term cannot be assumed since they would imply that the  $CP_2$  projection of the wormhole throat and space-like 3-surface are 2-dimensional. This might hold true for space-like 3-surfaces at the ends of  $CD$  and incoming and outgoing particles but not for off mass shell particles. This is however not a problem since  $D_\alpha \hat{\Gamma}_{C-S}^\alpha$  for the modified gamma matrices for Chern-Simons action does not contain second derivatives. This is due to the topological character of this term. For Kähler action second derivatives are present and this forces extremal property of Kähler action in the modified Dirac Kähler action so that classical physics results as a consistency condition.
2. If one assigns measurement interaction term to both  $D_K$  and  $D_{C-S}$  the measurement interaction corresponds to a mere gauge transformation for  $AS_\alpha$  and is trivial. Therefore it seems that one must choose between  $D_K$  or  $D_{C-S}$ . At least formally the measurement interaction term associated with  $D_K$  is gauge equivalent with its negative  $D_{C-S}$ . The addition of the measurement interaction to  $D_K$  changes the basis for the 4-D induced spinors by the phase  $\exp(-iQK\phi)$  and therefore also the basis for the generalized eigenstates of  $D_{C-S}$  and this brings in effectively the measurement interaction term affecting the Dirac determinant.

3. The definition of Dirac determinant should be in terms of Chern-Simons action induced by the instanton term and identified as a product of the generalized eigenvalues of this operator. The modified Dirac equation for  $\Psi$  is consistent with that for its conjugate if the coefficient of the instanton term is real and one uses the Dirac action  $\bar{\Psi}(D^\rightarrow - D^\leftarrow)\Psi$  giving modified Dirac equation as

$$D_{C-S}\Psi + \frac{1}{2}(D_\alpha \hat{\Gamma}_{C-S}^\alpha)\Psi = 0 . \quad (3.4.8)$$

As noticed, the divergence of gamma matrices does not contain second derivatives in the case of Chern-Simons action. In the case of Kähler action they occur unless field equations equivalent with the vanishing of the divergence term are satisfied.

Also the fermionic current is conserved in this case, which conforms with the idea that fermions flow along the light-like 3-surfaces. If one uses the action  $\bar{\Psi}D^\rightarrow\Psi$ ,  $\bar{\Psi}$  does not satisfy the Dirac equation following from the variational principle and fermion current is not conserved. Also if the Chern-Simons term is imaginary - as a naive idea about dissipation would suggest- the Dirac equation fails to be consistent with the conjugation.

4. Off mass shell states appear in the lines of the generalized Feynman diagrams and for these  $D_{C-S}$  cannot annihilate the spinor field. The generalized eigen modes of  $D_{C-S}$  should be such that one obtains the counterpart of Dirac propagator which is purely algebraic and does not therefore depend on the coordinates of the throat. This is satisfied if the generalized eigenvalues are expressible in terms of covariantly constant combinations of gamma matrices and here only  $M^4$  gamma matrices are possible. Therefore the eigenvalue equation reads as

$$D\Psi = \lambda^k \gamma_k \Psi , \quad D = D_{C-S} + D_\alpha \hat{\Gamma}_{C-S}^\alpha , \quad D_{C-S} = \hat{\Gamma}_{C-S}^\alpha D_\alpha . \quad (3.4.9)$$

Here the covariant derivatives  $D_\alpha$  contain the measurement interaction term as an apparent gauge term. Covariant constancy allows to take the square of this equation and one has

$$(D^2 + [D, \lambda^k \gamma_k])\Psi = \lambda^k \lambda_k \Psi . \quad (3.4.10)$$

The commutator term is analogous to magnetic moment interaction. The generalized eigenvalues correspond to  $\lambda = \sqrt{\lambda^k \lambda_k}$  and Dirac determinant is defined as a product of the eigenvalues.  $\lambda$  is completely analogous to mass. For incoming lines this mass would vanish so that all incoming particles irrespective their actual quantum numbers would be massless in this sense and the propagator is indeed that for a massless particle. Note that the eigen modes define the boundary values for the solutions of  $D_K \Psi = 0$  so that the values of  $\lambda$  indeed define the counterpart of the momentum space.

This transmutation of massive particles to effectively massless ones might make possible the application of the twistor formalism as such in TGD framework [82].  $N = 4$  SUSY is one of the very few gauge theory which might be UV finite but it is definitely unphysical due to the masslessness of the basic quanta. Could the resolution of the interpretational problems be that the four-momenta appearing in this theory do not directly correspond to the observed four-momenta?

## Objections

The alert reader has probably raised several critical questions. Doesn't the need to solve  $\lambda_k$  as functions of incoming quantum numbers plus the need to construct the measurement interactions makes the practical application of the theory hopelessly difficult? Could the resulting pseudo-momentum  $\lambda_k$  correspond to the actual four-momentum? Could one drop the measurement interaction term altogether and assume that the quantum classical correspondence is through the identification of the eigenvalues as the four-momenta of the on mass shell particles propagating at the wormhole throats? Could one indeed assume that the momenta have a continuous spectrum and thus do not depend on the boundary conditions at all? Usually the thinking is just the opposite and in the general case would lead to singular eigen modes.

1. Only the information about four-momentum would be fed into the space-time geometry. TGD however allows much more general measurement interaction terms and it would be very strange if the space-time geometry would not correlate also with the other quantum numbers. Mass formulas would of course contain information also about other quantum numbers so that this claim is not quite justified.
2. Number theoretic considerations and also the construction of octonionic variant of Dirac equation [70] , [8] force the conclusion that the spectrum of pseudo four-momentum is restricted to a preferred plane  $M^2$  of  $M^4$  and this excludes the interpretation of  $\lambda^k$  as a genuine four-momentum. It also improves the hopes that the sum over pseudo-momenta does not imply divergences.
3. Dirac determinant would depend on the mass spectrum only and could not be identified as exponent of Kähler function. Note that the original guideline was the dream about stringy propagators. This is achieved for  $\lambda_A \lambda^A = n$  in suitable units. This spectrum would of course also imply that Dirac determinant defined in terms of  $\zeta$  function regularization is independent of the space-time surface and could not be identified with the exponent of Kähler function. One must of course take the identification of exponent of Kähler function as Dirac determinant as an additional conjecture which is not necessary for the calculation of Kähler function if the weak form of electric-magnetic duality is accepted.
4. All particles would behave as massless particles and this would not be consistent with the proposed Feynman diagrammatics inspired by zero energy ontology. Since wormhole throats carry on mass shell particles with positive or negative energy so that the net momentum can be also space-like propagators diverge for massless particles. One might overcome this problem by assuming small thermal mass (from p-adic thermodynamics [48] ) and this is indeed assumed to reduce the number of generalized Feynman diagrams contributing to a given reaction to finite number.

Second objection of the skeptic reader relates to the delicacies of  $U(1)$  gauge invariance. The modified Dirac action seems to break gauge symmetries and this breaking of gauge symmetry is absolutely essential for the dependence of the Dirac determinant on the quantum numbers. It however seems that this breaking of gauge invariance is only apparent.

1. One must distinguish between genuine  $U(1)$  gauge transformations carried out for the induced Kähler gauge potential  $A_\alpha$  and apparent gauge transformations of the Kähler gauge potential  $A_k$  of  $S^2 \times CP_2$  induced by symplectic transformations deforming the space-time surface and affect also induced metric. This delicacy of  $U(1)$  gauge symmetry explains also the apparent breaking of  $U(1)$  gauge symmetry of Chern-Simons Dirac action due to the presence of explicit terms  $A_k$  and  $A_\alpha$ .
2.  $CP_2$  Kähler gauge potential is obtained in complex coordinates from Kähler function as  $(K_{\xi^i}, K_{\bar{\xi}^i}) = (\partial_{\xi^i} K, -\partial_{\bar{\xi}^i} K)$ . Gauge transformations correspond to the additions  $K \rightarrow K + f + \bar{f}$ , where  $f$  is a holomorphic function. Kähler gauge potential has a unique gauge in which the Kähler function of  $CP_2$  is  $U(2)$  invariant and contains no holomorphic part. Hence  $A_k$  is defined in a preferred gauge and is a gauge invariant quantity in this sense. Same applies to  $S^2$  part of the Kähler potential if present.

3.  $A_\alpha$  should be also gauge invariant under gauge transformation respecting the vanishing of Coulombic interaction energy. The allowed gauge transformations  $A_\alpha \rightarrow A_\alpha + \partial_\alpha \phi$  must satisfy  $D_\alpha(j_K^\alpha \phi) = 0$ . If the scalar function  $\phi$  reduces to constant at the wormhole throats and at the ends of the space-time surface  $D_{C-S}$  is gauge invariant. The gauge transformations for which  $\phi$  does not satisfy this condition are identified as representations of critical deformations of space-time surface so that the change of  $A_\alpha$  would code for this kind of deformation and indeed affect the modified Dirac operator and Kähler function (the change would be due to the change of zero modes).

### Some details about the modified Dirac equation defined by Chern-Simons action

First some general comments about  $D_{C-S}$  are in order.

1. Quite generally, there is vacuum avoidance in the sense that  $\Psi$  must vanish in the regions where the modified gamma matrices vanish. A physical analogy for the system consider is a charged particle in an external magnetic field. The effective metric defined by the anti-commutators of the modified gamma matrices so that standard intuitions might not help much. What one would naively expect would be analogs of bound states in magnetic field localized into regions inside which the magnetic field is non-vanishing.
2. If only  $CP_2$  Kähler form appears in the Kähler action, the modified Dirac action defined by the Chern-Simons term is non-vanishing only when the dimension of the  $CP_2$  projection of the 3-surface is  $D(CP_2) \geq 2$  and the induced Kähler field is non-vanishing. This conforms with the properties of Kähler action. The solutions of the modified Dirac equation with a vanishing eigenvalue  $\lambda$  would naturally correspond to incoming and outgoing particles.
3.  $D(CP_2) \leq 2$  is apparently inconsistent with the weak form of electric-magnetic duality requiring  $D(CP_2) = 3$ . The conclusion is wrong: the variations of Chern-Simons action are subject to the constraint that electric-magnetic duality holds true expressible in terms of Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x . \quad (3.4.11)$$

This gives a constraint force to the field equations and also a dependence on the induced 4-metric so that one has only almost topological QFT. This term also guarantees the  $M^4$  part of WCW Kähler metric is non-trivial. The condition that the ends of space-time sheet and wormhole throats are extrema of Chern-Simons action subject to the electric-magnetic duality constraint is strongly suggested by the effective 2-dimensionality.

4. Electric-magnetic duality constraint gives an additional term to the Dirac action determined by the Lagrange multiplier term. This term gives an additional contribution to the modified gamma matrices having the same general form as coming from Kähler action and Chern-Simons action. In the following this term will not be considered. For the extremals it only affects the modified gamma matrices and leaves the general form of solutions unchanged.

In absence of the constraint from the weak form of electric-magnetic duality the explicit expression of  $D_{C-S}$  is given by

$$\begin{aligned} D &= \hat{\Gamma}^\mu D_\mu + \frac{1}{2} D_\mu \hat{\Gamma}^\mu , \\ \hat{\Gamma}^\mu &= \frac{\partial L_{C-S}}{\partial_\mu h^k} \Gamma_k = \epsilon^{\mu\alpha\beta} [2J_{kl} \partial_\alpha h^l A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_\mu , \\ D_\mu \hat{\Gamma}^\mu &= B_K^\alpha (J_{k\alpha} + \partial_\alpha A_k) , \\ B_K^\alpha &= \epsilon^{\alpha\beta\gamma} J_{\beta\gamma} , \quad J_{k\alpha} = J_{kl} \partial_\alpha s^l , \quad \hat{\epsilon}^{\alpha\beta\gamma} = \epsilon^{\alpha\beta\gamma} \sqrt{g_3} . \end{aligned} \quad (3.4.12)$$

Note  $\hat{\epsilon}^{\alpha\beta\gamma}$  = does not depend on the induced metric.

The extremals of Chern-Simons action without constraint term satisfy

$$B_K^\alpha (J_{kl} + \partial_l A_k) \partial_\alpha h^l = 0, \quad B_K^\alpha = \epsilon^{\alpha\beta\gamma} J_{\beta\gamma}. \quad (3.4.13)$$

For a non-vanishing Kähler magnetic field  $B^\alpha$  these equations hold true when  $CP_2$  projection is 2-dimensional. This implies a vanishing of Chern-Simons action in absence of the constraint term realizing electric-magnetic duality, which is therefore absolutely essential in order for having a non-vanishing WCW metric.

Consider now the situation in more detail.

1. Suppose that one can assign a global coordinate to the flow lines of the Kähler magnetic field. In this case one might hope that ordinary intuitions about motion in constant magnetic field might be helpful. The repetition of the discussion of [35], [7] leads to the condition  $B \wedge dB = 0$  implying that a Beltrami flow for which current flows along the field lines and Lorentz forces vanishes is in question. This need not be the generic case.
2. With this assumption the modified Dirac operator reduces to a one-dimensional Dirac operator

$$D = \hat{\epsilon}^{r\alpha\beta} [2J_{kl} \partial_\alpha h^l A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_r. \quad (3.4.14)$$

3. The general solutions of the modified Dirac equation is covariantly constant with respect to the coordinate  $r$ :

$$D_r \Psi = 0. \quad (3.4.15)$$

The solution to this condition can be written immediately in terms of a non-integrable phase factor  $P \exp(i \int A_r dr)$ , where integration is along curve with constant transversal coordinates. If  $\hat{\Gamma}^v$  is light-like vector field also  $\hat{\Gamma}^v \Psi_0$  defines a solution of  $D_{C-S}$ . This solution corresponds to a zero mode for  $D_{C-S}$  and does not contribute to the Dirac determinant. Note that the dependence of these solutions on transversal coordinates of  $X_l^3$  is arbitrary.

4. The formal solution associated with a general eigenvalue can be constructed by integrating the eigenvalue equation separately along all coordinate curves. This makes sense if  $r$  indeed assigned to light-like curves indeed defines a global coordinate. What is strange that there is no correlation between the behaviors with respect longitudinal coordinate and transversal coordinates. System would be like a collection of totally uncorrelated point like particles reflecting the flow of the current along flux lines. It is difficult to say anything about the spectrum of the generalized eigenvalues in this case: it might be that the boundary conditions at the ends of the flow lines fix the allowed values of  $\lambda$ . Clearly, the Beltrami flow property is what makes this case very special.

### A connection with quantum measurement theory

It is encouraging that isometry charges and also other charges could make themselves visible in the geometry of space-time surface as they should by quantum classical correspondence. This suggests an interpretation in terms of quantum measurement theory.

1. The interpretation resolves the problem caused by the fact that the choice of the commuting isometry charges is not unique. Cartan algebra corresponds naturally to the measured observables. For instance, one could choose the Cartan algebra of Poincare group to consist of energy and momentum, angular momentum and boost (velocity) in particular direction as generators of the Cartan algebra of Poincare group. In fact, the choices of a preferred plane  $M^2 \subset M^4$  and geodesic sphere  $S^2 \subset CP_2$  allowing to fix the measurement sub-algebra to a high degree are implied by the replacement of the imbedding space with a book like structure forced by the hierarchy of Planck constants. Therefore the hierarchy of Planck constants seems to be required by quantum measurement theory. One cannot overemphasize the importance of this connection.

2. One can add similar couplings of the net values of the measured observables to the currents whose existence and conservation is guaranteed by quantum criticality. It is essential that one maps the observables to Cartan algebra coupled to critical current characterizing the observable in question. The coupling should have interpretation as a replacement of the induced Kähler gauge potential with its gauge transform. Quantum classical correspondence encourages the identification of the classical charges associated with Kähler action with quantal Cartan charges. This would support the interpretation in terms of a measurement interaction feeding information to classical space-time physics about the eigenvalues of the observables of the measured system. The resulting field equations remain second order partial differential equations since the second order partial derivatives appear only linearly in the added terms.
3. What about the space-time correlates of electro-weak charges? The earlier proposal explains this correlation in terms of the properties of quantum states: the coupling of electro-weak charges to Chern-Simons term could give the correlation in stationary phase approximation. It would be however very strange if the coupling of electro-weak charges with the geometry of the space-time sheet would not have the same universal description based on quantum measurement theory as isometry charges have.
  - (a) The hint as how this description could be achieved comes from a long standing un-answered question motivated by the fact that electro-weak gauge group identifiable as the holonomy group of  $CP_2$  can be identified as  $U(2)$  subgroup of color group. Could the electro-weak charges be identified as classical color charges? This might make sense since the color charges have also identification as fermionic charges implied by quantum criticality. Or could electro-weak charges be only represented as classical color charges by mapping them to classical color currents in the measurement interaction term in the modified Dirac action? At least this question might make sense.
  - (b) It does not make sense to couple both electro-weak and color charges to the same fermion current. There are also other fundamental fermion currents which are conserved. All the following currents are conserved.

$$\begin{aligned}
 J^\alpha &= \bar{\Psi} O \hat{\Gamma}^\alpha \Psi \\
 O &\in \{1, J \equiv J_{kl} \Sigma^{kl}, \Sigma_{AB}, \Sigma_{AB} J\} .
 \end{aligned}
 \tag{3.4.16}$$

Here  $J_{kl}$  is the covariantly constant  $CP_2$  Kähler form and  $\Sigma_{AB}$  is the (also covariantly) constant sigma matrix of  $M^4$  (flatness is absolutely essential).

- (c) Electromagnetic charge can be expressed as a linear combination of currents corresponding to  $O = 1$  and  $O = J$  and vectorial isospin current corresponds to  $J$ . It is natural to couple of electromagnetic charge to the the projection of Killing vector field of color hyper charge and coupling it to the current defined by  $O_{em} = a + bJ$ . This allows to interpret the puzzling finding that electromagnetic charge can be identified as anomalous color hyper-charge for induced spinor fields made already during the first years of TGD. There exist no conserved axial isospin currents in accordance with CVC and PCAC hypothesis which belong to the basic stuff of the hadron physics of old days.
- (d) Color charges would couple naturally to lepton and quark number current and the  $U(1)$  part of electro-weak charges to the  $n = 1$  multiple of quark current and  $n = 3$  multiple of the lepton current (note that leptons *resp.* quarks correspond to  $t = 0$  *resp.*  $t = \pm 1$  color partial waves). If electro-weak *resp.* couplings to  $H$ -chirality are proportional to 1 *resp.*  $\Gamma_9$ , the fermionic currents assigned to color and electro-weak charges can be regarded as independent. This explains why the possibility of both vectorial and axial couplings in 8-D sense does not imply the doubling of gauge bosons.
- (e) There is also an infinite variety of conserved currents obtained as the quantum critical deformations of the basic fermion currents identified above. This would allow in principle to couple an arbitrary number of observables to the geometry of the space-time sheet by mapping them to Cartan algebras of Poincare and color group for a particular conserved quantum critical current. Quantum criticality would therefore make possible classical space-time correlates of observables necessary for quantum measurement theory.

- (f) The coupling constants associated with the deformations would appear in the couplings. Quantum criticality ( $K \rightarrow K + f + \bar{f}$  condition) should predict the spectrum of these couplings. In the case of momentum the coupling would be proportional to  $\sqrt{G/\hbar_0} = kR/\hbar_0$  and  $k \sim 2^{11}$  should follow from quantum criticality. p-Adic coupling constant evolution should follow from the dependence on the scale of  $CD$  coming as powers of 2.
4. Quantum criticality implies fluctuations in long length and time scales and it is not surprising that quantum criticality is needed to produce a correlation between quantal degrees of freedom and macroscopic degrees of freedom. Note that quantum classical correspondence can be regarded as an abstract form of entanglement induced by the entanglement between quantum charges  $Q_A$  and fermion number type charges assignable to zero modes.
  5. Space-time sheets can have an arbitrary number of wormhole contacts so that the interpretation in terms of measurement theory coupling short and long length scales suggests that the measurement interaction terms are localizable at the wormhole throats. This would favor Chern-Simons term or possibly instanton term if reducible to Chern-Simons terms. The breaking of CP and T might relate to the fact that state function reductions performed in quantum measurements indeed induce dissipation and breaking of time reversal invariance.
  6. The experimental arrangement quite concretely splits the quantum state to a quantum superposition of space-time sheets such that each eigenstate of the measured observables in the superposition corresponds to different space-time sheet already before the realization of state function reduction. This relates interestingly to the question whether state function reduction really occurs or whether only a branching of wave function defined by WCW spinor field takes place as in multiverse interpretation in which different branches correspond to different observers. TGD inspired theory consciousness requires that state function reduction takes place. Maybe multiversalist might be able to find from this picture support for his own beliefs.
  7. One can argue that "free will" appears not only at the level of quantum jumps but also as the possibility to select the observables appearing in the modified Dirac action dictating in turn the Kähler function defining the Kähler metric of WCW representing the "laws of physics". This need not to be the case. The choice of  $CD$  fixes  $M^2$  and the geodesic sphere  $S^2$ : this does not fix completely the choice of the quantization axis but by isometry invariance rotations and color rotations do not affect Kähler function for given  $CD$  and for a given type of Cartan algebra. In  $M^4$  degrees of freedom the possibility to select the observables in two manners corresponding to linear and cylindrical Minkowski coordinates could imply that the resulting Kähler functions are different. The corresponding Kähler metrics do not differ if the real parts of the Kähler functions associated with the two choices differ by a term  $f(Z) + \bar{f}(\bar{Z})$ , where  $Z$  denotes complex coordinates of WCW, the Kähler metric remains the same. The function  $f$  can depend also on zero modes. If this is the case then one can allow in given CD superpositions of WCW spinor fields for which the measurement interactions are different. This condition is expected to pose non-trivial constraints on the measurement action and quantize coupling parameters appearing in it.

### New view about gravitational mass and matter antimatter asymmetry

The physical interpretation of the additional term in the modified Dirac action might force quite a radical revision of the ideas about matter and antimatter.

1. The term  $p_A \partial_\alpha m^A$  contracted with the fermion current is analogous to a gauge potential coupling to fermion number. Since the additional terms in the modified Dirac operator induce stringy propagation, a natural interpretation of the coupling to the induced spinor fields is in terms of gravitation. One might perhaps say that the measurement of four momentum induces gravitational interaction. Besides momentum components also color charges take the role of gravitational charges. As a matter fact, any observable takes this role via coupling to the projections of Killing vector fields of Cartan algebra. The analogy of color interactions with gravitational interactions is indeed one of the oldest ideas in TGD.

2. The coupling to four-momentum is through fermion number (both quark number and lepton number). For states with a vanishing fermion number isometry charges therefore vanish. In this framework matter antimatter asymmetry would be due to the fact that matter (antimatter) corresponds to positive (negative) energy parts of zero energy states for massive systems so that the contributions to the net gravitational four-momentum are of same sign. Could antimatter be unobservable to us because it resides at negative energy space-time sheets? As a matter fact, I proposed already years ago that gravitational mass is essentially the magnitude of the inertial mass but gave up this idea.
3. Bosons do not couple at all to gravitation if they are purely local bound states of fermion and anti-fermion at the same space-time sheet (say represented by generators of super Kac-Moody algebra). Therefore the only possible identification of gauge bosons is as wormhole contacts. If the fermion and anti-fermion at the opposite throats of the contact correspond to positive and negative energy states the net gravitational energy receives a positive contribution from both sheets. If both correspond to positive (negative) energy the contributions to the net four-momentum have opposite signs. It is not yet clear which identification is the correct one.

### 3.4.4 Generalized eigenvalues of $D_{C-S}$ and General Coordinate Invariance

The fixing of light-like 3-surface to be the wormhole throat at which the signature of induced metric changes from Minkowskian to Euclidian corresponds to a convenient fixing of gauge. General Coordinate Invariance however requires that any light-like surface  $Y_l^3$  parallel to  $X_l^3$  in the slicing is equally good choice. In particular, it should give rise to same Kähler metric but not necessarily the same exponent of Kähler function identified as the product of the generalized eigenvalues of  $D_{C,S}$  at  $Y_l^3$ .

General Coordinate Invariance requires that the components of Kähler metric of configuration space defined in terms of Kähler function as

$$G_{k\bar{l}} = \partial_k \partial_{\bar{l}} K = \sum_i \partial_k \partial_{\bar{l}} \lambda_i$$

remain invariant under this flow. Here complex coordinate are of course associated with the configuration space. This is the case if the flow corresponds to the addition of sum of holomorphic function  $f(z)$  and its conjugate  $\bar{f}(z)$  which is anti-holomorphic function to  $K$ . This boils down to the scaling of eigenvalues  $\lambda_i$  by

$$\lambda_i \rightarrow \exp(f_i(z) + \overline{f_i(z)}) \lambda_i . \quad (3.4.17)$$

If the eigenvalues are interpreted as vacuum conformal weights, general coordinate transformations correspond to a spectral flow scaling the eigenvalues in this manner. This in turn would induce spectral flow of ground state conformal weights if the squares of  $\lambda_i$  correspond to ground state conformal weights.

## 3.5 Super-conformal symmetries at space-time and configuration space level

The physical interpretation and detailed mathematical understanding of super-conformal symmetries has developed rather slowly and has involved several side tracks. In the following I try to summarize the basic picture with minimal amount of formulas with the understanding that the statement "Noether charge associated with geometrically realized Kac-Moody symmetry" is enough for the reader to write down the needed formula explicitly.

### 3.5.1 Configuration space as a union of symmetric spaces

In finite-dimensional context globally symmetric spaces are of form  $G/H$  and connection and curvature are independent of the metric, provided it is left invariant under  $G$ . The hope is that same holds true in infinite-dimensional context. The most one can hope of obtaining is the decomposition  $C(H) = \cup_i G/H_i$  over orbits of  $G$ . One could allow also symmetry breaking in the sense that  $G$  and  $H$  depend

on the orbit:  $C(H) = \cup_i G_i/H_i$  but it seems that  $G$  can be chosen to be same for all orbits. What is essential is that these groups are infinite-dimensional. The basic properties of the coset space decomposition give very strong constraints on the group  $H$ , which certainly contains the subgroup of  $G$ , whose action reduces to diffeomorphisms of  $X^3$ .

### Consequences of the decomposition

If the decomposition to a union of coset spaces indeed occurs, the consequences for the calculability of the theory are enormous since it suffices to find metric and curvature tensor for single representative 3-surface on a given orbit (contravariant form of metric gives propagator in perturbative calculation of matrix elements as functional integrals over the configuration space). The representative surface can be chosen to correspond to the maximum of Kähler function on a given orbit and one obtains perturbation theory around this maximum (Kähler function is not isometry invariant).

The task is to identify the infinite-dimensional groups  $G$  and  $H$  and to understand the zero mode structure of the configuration space. Almost twenty (seven according to long held belief!) years after the discovery of the candidate for the Kähler function defining the metric, it became finally clear that these identifications follow quite nicely from  $Diff^4$  invariance and  $Diff^4$  degeneracy as well as special properties of the Kähler action.

The guess (not the first one!) would be following.  $G$  corresponds to the symplectic transformations of  $\delta M_{\pm}^4 \times CP_2$  leaving the induced Kähler form invariant. If  $G$  acts as isometries the values of Kähler form at partonic 2-surfaces (remember effective 2-dimensionality) are zero modes and configuration space allows slicing to symplectic orbits of the partonic 2-surface with fixed induced Kähler form. Quantum fluctuating degrees of freedom would correspond to symplectic group and to the fluctuations of the induced metric. The group  $H$  dividing  $G$  would in turn correspond to the Kac-Moody symmetries respecting light-likeness of  $X_l^3$  and acting in  $X_l^3$  but trivially at the partonic 2-surface  $X^2$ . This coset structure was originally discovered via coset construction for super Virasoro algebras of super-symplectic and super Kac-Moody algebras and realizes Equivalence Principle at quantum level.

### Configuration space isometries as a subgroup of $Diff(\delta M_{\pm}^4 \times CP_2)$

The reduction to light cone boundary leads to the identification of the isometry group as some subgroup of for the group  $G$  for the diffeomorphisms of  $\delta M_{\pm}^4 \times CP_2$ . These diffeomorphisms indeed act in a natural manner in  $\delta CH$ , the the space of 3-surfaces in  $\delta M_{\pm}^4 \times CP_2$ . Configuration space is expected to decompose to a union of the coset spaces  $G/H_i$ , where  $H_i$  corresponds to some subgroup of  $G$  containing the transformations of  $G$  acting as diffeomorphisms for given  $X^3$ . Geometrically the vector fields acting as diffeomorphisms of  $X^3$  are tangential to the 3-surface.  $H_i$  could depend on the topology of  $X^3$  and since  $G$  does not change the topology of 3-surface each 3-topology defines separate orbit of  $G$ . Therefore, the union involves sum over all topologies of  $X^3$  plus possibly other 'zero modes'. Different topologies are naturally glued together since singular 3-surfaces intermediate between two 3-topologies correspond to points common to the two sectors with different topologies.

### 3.5.2 Isometries of configuration space geometry as symplectic transformations of $\delta M_{\pm}^4 \times CP_2$

During last decade I have considered several candidates for the group  $G$  of isometries of the configuration space as the sub-algebra of the subalgebra of  $Diff(\delta M_{\pm}^4 \times CP_2)$ . To begin with let us write the general decomposition of  $diff(\delta M_{\pm}^4 \times CP_2)$ :

$$diff(\delta M_{\pm}^4 \times CP_2) = S(CP_2) \times diff(\delta M_{\pm}^4) \oplus S(\delta M_{\pm}^4) \times diff(CP_2) . \quad (3.5.1)$$

Here  $S(X)$  denotes the scalar function basis of space  $X$ . This Lie-algebra is the direct sum of light cone diffeomorphisms made local with respect to  $CP_2$  and  $CP_2$  diffeomorphisms made local with respect to light cone boundary.

The idea that entire diffeomorphism group would act as isometries looks unrealistic since the theory should be more or less equivalent with topological field theory in this case. Consider now the various candidates for  $G$ .

1. The fact that symplectic transformations of  $CP_2$  and  $M_+^4$  diffeomorphisms are dynamical symmetries of the vacuum extremals suggests the possibility that the diffeomorphisms of the light cone boundary and symplectic transformations of  $CP_2$  could leave Kähler function invariant and thus correspond to zero modes. The symplectic transformations of  $CP_2$  localized with respect to light cone boundary acting as symplectic transformations of  $CP_2$  have interpretation as local color transformations and are a good candidate for the isometries. The fact that local color transformations are not even approximate symmetries of Kähler action is not a problem: if they were exact symmetries, Kähler function would be invariant and zero modes would be in question.
2.  $CP_2$  local conformal transformations of the light cone boundary act as isometries of  $\delta M_+^4$ . Besides this there is a huge group of the symplectic symmetries of  $\delta M_+^4 \times CP_2$  if light cone boundary is provided with the symplectic structure. Both groups must be considered as candidates for groups of isometries.  $\delta M_+^4 \times CP_2$  option exploits fully the special properties of  $\delta M_+^4 \times CP_2$ , and one can develop simple argument demonstrating that  $\delta M_+^4 \times CP_2$  symplectic invariance is the correct option. Also the construction of configuration space gamma matrices as super-symplectic charges supports  $\delta M_+^4 \times CP_2$  option.

This picture remained same for a long time. The discovery that Kac-Moody algebra consisting of  $X^2$  local symmetries generated by Hamiltonians of isometry sub-algebra of symplectic algebra forced to challenge this picture and ask whether also  $X^2$ -local transformations of symplectic group could be involved.

1. The basic condition is that the  $X^2$  local transformation acts leaves induced Kähler form invariant apart from diffeomorphism. Denote the infinitesimal generator of  $X^2$  local symplectomorphism by  $\Phi_A(x)j^{Ak}$ , where  $A$  labels Hamiltonians in the sum and by  $j^\alpha$  the generator of  $X^2$  diffeomorphism.
2. The invariance of  $J = \epsilon^{\alpha\beta} J_{\alpha\beta} \sqrt{g_2}$  modulo diffeomorphism under the infinitesimal symplectic transformation gives

$$\{H^A, \Phi_A\} \equiv \partial_\alpha H^A \epsilon^{\alpha\beta} \partial_\beta \Phi_A = \partial_\alpha J j^\alpha . \quad (3.5.2)$$

3. Note that here the Poisson bracket is not defined by  $J^{\alpha\beta}$  but  $\epsilon^{\alpha\beta}$  defined by the induced metric. Left hand side reflects the failure of symplectomorphism property due to the dependence of  $\Phi_A(x)$  on  $X^2$  coordinate which and comes from the gradients of  $\delta M^4 \times CP_2$  coordinates in the expression of the induced Kähler form. Right hand side corresponds to the action of infinitesimal diffeomorphism.
4. Let us assume that one can restrict the consideration to single Hamiltonian so that the transformation is generated by  $\Phi(x)H_A$  and that to each  $\Phi(x)$  there corresponds a diffeomorphism of  $X^2$ , which is a symplectic transformation of  $X^2$  with respect to symplectic form  $\epsilon^{\alpha\beta}$  and generated by Hamiltonian  $\Psi(x)$ . This transforms the invariance condition to

$$\{H^A, \Phi\} \equiv \partial_\alpha H^A \epsilon^{\alpha\beta} \partial_\beta \Phi = \partial_\alpha J \epsilon^{\alpha\beta} \partial_\beta \Psi_A = \{J, \Psi_A\} . \quad (3.5.3)$$

This condition can be solved identically by assuming that  $\Phi_A$  and  $\Psi$  are proportional to arbitrary smooth function of  $J$ :

$$\Phi = f(J) , \quad \Psi_A = -f(J)H_A . \quad (3.5.4)$$

Therefore the  $X^2$  local symplectomorphisms of  $H$  reduce to symplectic transformations of  $X^2$  with Hamiltonians depending on single coordinate  $J$  of  $X^2$ . The analogy with conformal invariance for which transformations depend on single coordinate  $z$  is obvious. As far as the anti-commutation relations for induced spinor fields are considered this means that  $J = \text{constant}$  curves behave as points. For extrema of  $J$  appearing as candidates for points of number theoretic braids  $J = \text{constant}$  curves reduce to points.

5. From the structure of the conditions it is easy to see that the transformations generate a Lie-algebra. For the transformations  $\Phi_A^1 H^A$   $\Phi_A^2 H^A$  the commutator is

$$\Phi_A^{[1,2]} = f_A^{BC} \Phi_B \Phi_C, \quad (3.5.5)$$

where  $f_A^{BC}$  are the structure constants for the symplectic algebra of  $\delta M_{\pm}^4 \times CP_2$ . From this form it is easy to check that Jacobi identities are satisfied. The commutator has same form as the commutator of gauge algebra generators. BRST gauge symmetry is perhaps the nearest analog of this symmetry. In the case of isometries these transforms realized local color gauge symmetry in TGD sense.

6. If space-time surface allows a slicing to light-like 3-surfaces  $Y_l^3$  parallel to  $X_l^3$ , these conditions make sense also for the partonic 2-surfaces defined by the intersections of  $Y_l^3$  with  $\delta M_{\pm}^4 \times CP_2$  and "parallel" to  $X^2$ . The local symplectic transformations also generalize to their local variants in  $X_l^3$ . Light-likeness of  $X_l^3$  means effective metric 2-dimensionality so that 2-D Kähler metric and symplectic form as well as the invariant  $J = \epsilon^{\alpha\beta} J_{\alpha\beta}$  exist. A straightforward calculation shows that the the notion of local symplectic transformation makes sense also now and formulas are exactly the same as above.

### 3.5.3 SUSY algebra defined by the anticommutation relations of fermionic oscillator operators and WCW local Clifford algebra elements as chiral super-fields

Whether TGD allows space-time supersymmetry has been a long-standing question. Majorana spinors appear in  $N = 1$  super-symmetric QFTs- in particular minimally super-symmetric standard model (MSSM). Majorana-Weyl spinors appear in M-theory and super string models. An undesirable consequence is chiral anomaly in the case that the numbers of left and right handed spinors are not same. For  $D = 11$  and  $D = 10$  these anomalies cancel which led to the breakthrough of string models and later to M-theory. The probable reason for considering these dimensions is that standard model does not predict right-handed neutrino (although neutrino mass suggests that right handed neutrino exists) so that the numbers of left and right handed Weyl-spinors are not the same.

In TGD framework the situation is different. Covariantly constant right-handed neutrino spinor acts as a super-symmetry in  $CP_2$ . One might think that right-handed neutrino in a well-defined sense disappears from the spectrum as a zero mode so that the number of right and left handed chiralities in  $M^4 \times CP_2$  would not be same. For light-like 3-surfaces covariantly constant right-handed neutrino does not however solve the counterpart of Dirac equation for a non-vanishing four-momentum and color quantum numbers of the physical state. Therefore it does not disappear from the spectrum anymore and one expects the same number of right and left handed chiralities.

In TGD framework the separate conservation of baryon and lepton numbers excludes Majorana spinors and also the the Minkowski signature of  $M^4 \times CP_2$  makes them impossible. The conclusion that TGD does not allow super-symmetry is however wrong. For  $\mathcal{N} = 2N$  Weyl spinors are indeed possible and if the number of right and left handed Weyl spinors is same super-symmetry is possible. In 8-D context right and left-handed fermions correspond to quarks and leptons and since color in TGD framework corresponds to  $CP_2$  partial waves rather than spin like quantum number, also the numbers of quark and lepton-like spinors are same.

The physical picture suggest a new kind of approach to super-symmetry in the sense that the anticommutations of fermionic oscillator operators associated with the modes of the induced spinor fields define a structure analogous to SUSY algebra. This means that  $\mathcal{N} = 2N$  SUSY with large  $N$  is in question allowing spins higher than two and also large fermion numbers. Recall that  $\mathcal{N} \leq 32$  is implied by the absence of spins higher than two and the number of real spinor components is  $N = 32$  also in TGD. The situation clearly differs from that encountered in super-string models and SUSYs and the large value of  $N$  allows to expect very powerful constraints on dynamics irrespective of the fact that SUSY is broken. Right handed neutrino modes define a sub-algebra for which the SUSY is only slightly broken by the absence of weak interactions and one could also consider a theory containing a

large number of  $\mathcal{N} = 2$  super-multiplets corresponding to the addition of right-handed neutrinos and antineutrinos at the wormhole throat.

Masslessness condition is essential for super-symmetry and at the fundamental level it could be formulated in terms of modified gamma matrices using octonionic representation and assuming that they span local quaternionic sub-algebra at each point of the space-time sheet. SUSY algebra has standard interpretation with respect to spin and isospin indices only at the partonic 2-surfaces so that the basic algebra should be formulated at these surfaces. Effective 2-dimensionality would require that partonic 2-surfaces can be taken to be ends of any light-like 3-surface  $Y_l^3$  in the slicing of the region surrounding a given wormhole throat.

### Super-algebra associated with the modified gamma matrices

Anti-commutation relations for fermionic oscillator operators associated with the induced spinor fields are naturally formulated in terms of the modified gamma matrices. Super-conformal symmetry suggests that the anti-commutation relations for the fermionic oscillator operators at light-like 3-surfaces or at their ends are most naturally formulated as anti-commutation relations for SUSY algebra. The resulting anti-commutation relations would fix the quantum TGD.

$$\begin{aligned} \{a_{n\alpha}^\dagger, a_{n\beta}\} &= D_{mn} D_{\alpha\beta} \ , \\ D &= (p^\mu + \sum_a Q_a^\mu) \hat{\sigma}^\mu \ . \end{aligned} \quad (3.5.6)$$

Here  $p^\mu$  and  $Q_a^\mu$  are space-time projections of momentum and color charges in Cartan algebra. Their action is purely algebraic. The anti-commutations are nothing but a generalization of the ordinary equal-time anticommutation relations for fermionic oscillator operators to a manifestly covariant form. The matrix  $D_{m,n}$  is expected to reduce to a diagonal form with a proper normalization of the oscillator operators. The experience with extended SUSY algebra suggest that the anti-commutators could contain additional central term proportional to  $\delta_{\alpha\beta}$ .

One can consider basically two different options concerning the definition of the super-algebra.

1. If the super-algebra is defined at the 3-D ends of the intersection of  $X^4$  with the boundaries of  $CD$ , the modified gamma matrices appearing in the operator  $D$  appearing in the anti-commutator are associated with Kähler action. If the generalized masslessness condition  $D^2 = 0$  holds true -as suggested already earlier- one can hope that no explicit breaking of super-symmetry takes place and elegant description of massive states as effectively massless states making also possible generalization of twistor is possible. One must however notice that also massive representatives of SUSY exist.
2. SUSY algebra could be also defined at 2-D ends of light-like 3-surfaces.

According to considerations of [28] these options are equivalent for a large class of space-time sheets. If the effective 3-dimensionality realized in the sense that the effective metric defined by the modified gamma matrices is degenerate, propagation takes place along 3-D light-like 3-surfaces. This condition definitely fails for string like objects.

One can realize the local Clifford algebra also by introducing theta parameters in the standard manner and the expressing a collection of local Clifford algebra element with varying values of fermion numbers (function of  $CD$  and  $CP_2$  coordinates) as a chiral super-field. The definition of a chiral super field requires the introduction of super-covariant derivatives. Standard form for the anti-commutators of super-covariant derivatives  $D_\alpha$  make sense only if they do not affect the modified gamma matrices. This is achieved if  $p_k$  acts on the position of the tip of  $CD$  (rather than internal coordinates of the space-time sheet).  $Q_a$  in turn must act on  $CP_2$  coordinates of the tip.

### Super-fields associated with WCW Clifford algebra

WCW local Clifford algebra elements possess definite fermion numbers and it is not physically sensible to super-pose local Clifford algebra elements with different fermion numbers. The extremely elegant formulation of super-symmetric theories in terms of super-fields encourages to ask whether the local

Clifford algebra elements could allow expansion in terms of complex theta parameters assigned to various fermionic oscillator operator in order to obtain formal superposition of elements with different fermion numbers. One can also ask whether the notion of chiral super field might make sense.

The obvious question is whether it makes sense to assign super-fields with the modified gamma matrices.

1. Modified gamma matrices are not covariantly constant but this is not a problem since the action of momentum generators and color generators is purely algebraic space-time coordinates.
2. One can define the notion of chiral super-field also at the fundamental level. Chiral super-field would be continuation of the local Clifford algebra of associated with  $CD$  to a local Clifford algebra element associated with the union of  $CD$ s. This would allow elegant description of cm degrees of freedom, which are the most interesting as far as QFT limit is considered.
3. Kähler function of WCW as a function of complex coordinates could be extended to a chiral super-field defined in quantum fluctuation degrees of freedom. It would depend on zero modes too. Does also the latter dependence allow super-space continuation? Coefficients of powers of theta would correspond to fermionic oscillator operators. Does this function define the propagators of various states associated with light-like 3-surface? Configuration space complex coordinates would correspond to the modes of induced spinor field so that super-symmetry would be realized very concretely.

### 3.5.4 Identification of Kac-Moody symmetries

The Kac-Moody algebra of symmetries acting as symmetries respecting the light-likeness of 3-surfaces plays a crucial role in the identification of quantum fluctuating configuration space degrees of freedom contributing to the metric.

#### Identification of Kac-Moody algebra

The generators of bosonic super Kac-Moody algebra leave the light-likeness condition  $\sqrt{g_3} = 0$  invariant. This gives the condition

$$\delta g_{\alpha\beta} \text{Cof}(g^{\alpha\beta}) = 0 , \quad (3.5.7)$$

Here  $\text{Cof}$  refers to matrix cofactor of  $g_{\alpha\beta}$  and summation over indices is understood. The conditions can be satisfied if the symmetries act as combinations of infinitesimal diffeomorphisms  $x^\mu \rightarrow x^\mu + \xi^\mu$  of  $X^3$  and of infinitesimal conformal symmetries of the induced metric

$$\delta g_{\alpha\beta} = \lambda(x)g_{\alpha\beta} + \partial_\mu g_{\alpha\beta} \xi^\mu + g_{\mu\beta} \partial_\alpha \xi^\mu + g_{\alpha\mu} \partial_\beta \xi^\mu . \quad (3.5.8)$$

#### Ansatz as an $X^3$ -local conformal transformation of imbedding space

Write  $\delta h^k$  as a super-position of  $X^3$ -local infinitesimal diffeomorphisms of the imbedding space generated by vector fields  $J^A = j^{A,k} \partial_k$ :

$$\delta h^k = c_A(x) j^{A,k} . \quad (3.5.9)$$

This gives

$$\begin{aligned} c_A(x) [D_k j_l^A + D_l j_k^A] \partial_\alpha h^k \partial_\beta h^l + 2\partial_\alpha c_A h_{kl} j^{A,k} \partial_\beta h^l \\ = \lambda(x)g_{\alpha\beta} + \partial_\mu g_{\alpha\beta} \xi^\mu + g_{\mu\beta} \partial_\alpha \xi^\mu + g_{\alpha\mu} \partial_\beta \xi^\mu . \end{aligned} \quad (3.5.10)$$

If an  $X^3$ -local variant of a conformal transformation of the imbedding space is in question, the first term is proportional to the metric since one has

$$D_k j_l^A + D_l j_k^A = 2h_{kl} . \quad (3.5.11)$$

The transformations in question includes conformal transformations of  $H_{\pm}$  and isometries of the imbedding space  $H$ .

The contribution of the second term must correspond to an infinitesimal diffeomorphism of  $X^3$  reducible to infinitesimal conformal transformation  $\psi^{\mu}$ :

$$2\partial_{\alpha} c_A h_{kl} j^{A,k} \partial_{\beta} h^l = \xi^{\mu} \partial_{\mu} g_{\alpha\beta} + g_{\mu\beta} \partial_{\alpha} \xi^{\mu} + g_{\alpha\mu} \partial_{\beta} \xi^{\mu} . \quad (3.5.12)$$

### A rough analysis of the conditions

One could consider a strategy of fixing  $c_A$  and solving solving  $\xi^{\mu}$  from the differential equations. In order to simplify the situation one could assume that  $g_{ir} = g_{rr} = 0$ . The possibility to cast the metric in this form is plausible since generic 3-manifold allows coordinates in which the metric is diagonal.

1. The equation for  $g_{rr}$  gives

$$\partial_r c_A h_{kl} j^{A,k} \partial_r h^k = 0 . \quad (3.5.13)$$

The radial derivative of the transformation is orthogonal to  $X^3$ . No condition on  $\xi^{\alpha}$  results. If  $c_A$  has common multiplicative dependence on  $c_A = f(r)d_A$  by a one obtains

$$d_A h_{kl} j^{A,k} \partial_r h^k = 0 . \quad (3.5.14)$$

so that  $J^A$  is orthogonal to the light-like tangent vector  $\partial_r h^k$   $X^3$  which is the counterpart for the condition that Kac-Moody algebra acts in the transversal degrees of freedom only. The condition also states that the components  $g_{ri}$  is not changed in the infinitesimal transformation.

It is possible to choose  $f(r)$  freely so that one can perform the choice  $f(r) = r^n$  and the notion of radial conformal weight makes sense. The dependence of  $c_A$  on transversal coordinates is constrained by the transversality condition only. In particular, a common scale factor having free dependence on the transversal coordinates is possible meaning that  $X^3$ - local conformal transformations of  $H$  are in question.

2. The equation for  $g_{ri}$  gives

$$\partial_r \xi^i = \partial_r c_A h_{kl} j^{A,k} h^{ij} \partial_j h^k . \quad (3.5.15)$$

The equation states that  $g_{ri}$  are not affected by the symmetry. The radial dependence of  $\xi^i$  is fixed by this differential equation. No condition on  $\xi^r$  results. These conditions imply that the local gauge transformations are dynamical with the light-like radial coordinate  $r$  playing the role of the time variable. One should be able to fix the transformation more or less arbitrarily at the partonic 2-surface  $X^2$ .

3. The three independent equations for  $g_{ij}$  give

$$\xi^{\alpha} \partial_{\alpha} g_{ij} + g_{kj} \partial_i \xi^k + g_{ki} \partial_j \xi^k = \partial_i c_A h_{kl} j^{A,k} \partial_j h^l . \quad (3.5.16)$$

These are 3 differential equations for 3 functions  $\xi^{\alpha}$  on 2 independent variables  $x^i$  with  $r$  appearing as a parameter. Note however that the derivatives of  $\xi^r$  do not appear in the equation.

At least formally equations are not over-determined so that solutions should exist for arbitrary choices of  $c_A$  as functions of  $X^3$  coordinates satisfying the orthogonality conditions. If this is the case, the Kac-Moody algebra can be regarded as a local algebra in  $X^3$  subject to the orthogonality constraint.

This algebra contains as a subalgebra the analog of Kac-Moody algebra for which all  $c_A$  except the one associated with time translation and fixed by the orthogonality condition depends on the radial coordinate  $r$  only. The larger algebra decomposes into a direct sum of representations of this algebra.

### Commutators of infinitesimal symmetries

The commutators of infinitesimal symmetries need not be what one might expect since the vector fields  $\xi^\mu$  are functionals  $c_A$  and of the induced metric and also  $c_A$  depends on induced metric via the orthogonality condition. What this means that  $j^{A,k}$  in principle acts also to  $\phi_B$  in the commutator  $[c_A J^A, c_B J^B]$ .

$$[c_A J^A, c_B J^B] = c_A c_B J^{[A,B]} + J^A \circ c_B J^B - J^B \circ c_A J^A, \quad (3.5.17)$$

where  $\circ$  is a short hand notation for the change of  $c_B$  induced by the effect of the conformal transformation  $J^A$  on the induced metric.

Luckily, the conditions in the case  $g_{rr} = g_{ir} = 0$  state that the components  $g_{rr}$  and  $g_{ir}$  of the induced metric are unchanged in the transformation so that the condition for  $c_A$  resulting from  $g_{rr}$  component of the metric is not affected. Also the conditions coming from  $g_{ir} = 0$  remain unchanged. Therefore the commutation relations of local algebra apart from constraint from transversality result.

The commutator algebra of infinitesimal symmetries should also close in some sense. The orthogonality to the light-like tangent vector creates here a problem since the commutator does not obviously satisfy this condition automatically. The problem can be solved by following the recipes of non-covariant quantization of string model.

1. Make a choice of gauge by choosing time translation  $P^0$  in a preferred  $M^4$  coordinate frame to be the preferred generator  $J^{A_0} \equiv P^0$ , whose coefficient  $\Phi_{A_0} \equiv \Psi(P^0)$  is solved from the orthogonality condition. This assumption is analogous with the assumption that time coordinate is non-dynamical in the quantization of strings. The natural basis for the algebra is obtained by allowing only a single generator  $J^A$  besides  $P^0$  and putting  $d_A = 1$ .
2. This prescription must be consistent with the well-defined radial conformal weight for the  $J^A \neq P^0$  in the sense that the proportionality of  $d_A$  to  $r^n$  for  $J^A \neq P^0$  must be consistent with commutators.  $SU(3)$  part of the algebra is of course not a problem. From the Lorentz vector property of  $P^k$  it is clear that the commutators resulting in a repeated commutation have well-defined radial conformal weights only if one restricts  $SO(3, 1)$  to  $SO(3)$  commuting with  $P^0$ . Also  $D$  could be allowed without losing well-defined radial conformal weights but the argument below excludes it. This picture conforms with the earlier identification of the Kac-Moody algebra.

Conformal algebra contains besides Poincare algebra and the dilation  $D = m^k \partial_{m^k}$  the mutually commuting generators  $K^k = (m^r m_r \partial_{m^k} - 2m^k m^l \partial_{m^l})/2$ . The commutators involving added generators are

$$\begin{aligned} [D, K^k] &= -K^k, & [D, P^k] &= P^k, \\ [K^k, K^l] &= 0, & [K^k, P^l] &= m^{kl} D - M^{kl}. \end{aligned} \quad (3.5.18)$$

From the last commutation relation it is clear that the inclusion of  $K^k$  would mean loss of well-defined radial conformal weights.

3. The coefficient  $dm^0/dr$  of  $\Psi(P^0)$  in the equation

$$\Psi(P^0) \frac{dm^0}{dr} = -J^{Ak} h_{kl} \partial_r h^l$$

is always non-vanishing due to the light-likeness of  $r$ . Since  $P^0$  commutes with generators of  $SO(3)$  (but not with  $D$  so that it is excluded!), one can *define* the commutator of two generators as a commutator of the remaining part and identify  $\Psi(P^0)$  from the condition above.

4. Of course, also the more general transformations act as Kac-Moody type symmetries but the interpretation would be that the sub-algebra plays the same role as  $SO(3)$  in the case of Lorentz group: that is gives rise to generalized spin degrees of freedom whereas the entire algebra divided by this sub-algebra would define the coset space playing the role of orbital degrees of freedom. In fact, also the Kac-Moody type symmetries for which  $c_A$  depends on the transversal coordinates of  $X^3$  would correspond to orbital degrees of freedom. The presence of these orbital degrees of freedom arranging super Kac-Moody representations into infinite multiplets labeled by function basis for  $X^2$  means that the number of degrees of freedom is much larger than in string models.
5. It is possible to replace the preferred time coordinate  $m^0$  with a preferred light-like coordinate. There are good reasons to believe that orbifold singularity for phases of matter involving non-standard value of Planck constant corresponds to a preferred light-ray going through the tip of  $\delta M_{\pm}^4$ . Thus it would be natural to assume that the preferred  $M^4$  coordinate varies along this light ray or its dual. The Kac-Moody group  $SO(3) \times E^3$  respecting the radial conformal weights would reduce to  $SO(2) \times E^2$  as in string models.  $E^2$  would act in tangent plane of  $S_{\pm}^2$  along this ray defining also  $SO(2)$  rotation axis.

### Hamiltonians

The action of these transformations on Kähler action is well-defined and one can deduce the conserved quantities having identification as configuration space Hamiltonians. Hamiltonians also correspond to closed 2-forms. The condition that the Hamiltonian reduces to a dual of closed 2-form is satisfied because  $X^2$ -local conformal transformations of  $M_{\pm}^4 \times CP_2$  are in question ( $X^2$ -locality does not imply any additional conditions).

### The action of Kac-Moody algebra on spinors and fermionic representations of Kac-Moody algebra

One can imagine two interpretations for the action of generalized Kac-Moody transformations on spinors.

1. The basic goal is to deduce the fermionic Noether charge associated with the bosonic Kac-Moody symmetry and this can be done by a standard recipe. The first contribution to the charge comes from the transformation of modified gamma matrices appearing in the modified Dirac action associated with fermions. Second contribution comes from spinor rotation.
2. Both  $SO(3)$  and  $SU(3)$  rotations have a standard action as spin rotation and electro-weak rotation allowing to define the action of the Kac-Moody algebra  $J^A$  on spinors.

### How central extension term could emerge?

The central extension term of Kac-Moody algebra could correspond to a symplectic extension which can emerge from the freedom to add a constant term to Hamiltonians as in the case of super-symplectic algebra. The expression of the Hamiltonians as closed forms could allow to understand how the central extension term emerges.

In principle one can construct a representation for the action of Kac-Moody algebra on fermions a representations as a fermionic bilinear and the central extension of Kac-Moody algebra could emerge in this construction just as it appears in Sugawara construction.

### About the interpretation of super Kac-Moody symmetries

Also the light like 3-surfaces  $X_l^3$  of  $H$  defining elementary particle horizons at which Minkowskian signature of the metric is changed to Euclidian and boundaries of space-time sheets can act as causal determinants, and thus contribute to the configuration space metric. In this case the symmetries correspond to the isometries of the imbedding space localized with respect to the complex coordinate

of the 2-surface  $X^2$  determining the light like 3-surface  $X_l^3$  so that Kac-Moody type symmetry results. Also the condition  $\sqrt{g_3} = 0$  for the determinant of the induced metric seems to define a conformal symmetry associated with the light like direction.

If is enough to localize only the  $H$ -isometries with respect to  $X_l^3$ , the purely bosonic part of the Kac-Moody algebra corresponds to the isometry group  $M^4 \times SO(3, 1) \times SU(3)$ . The physical interpretation of these symmetries is not so obvious as one might think. The point is that one can generalize the formulas characterizing the action of infinitesimal isometries on spinor fields of finite-dimensional Kähler manifold to the level of the configuration space. This gives rise to bosonic generators containing also a sigma-matrix term bilinear in fermionic oscillator operators. This representation need not be equivalent with the purely fermionic representations provided by induced Dirac action. Thus one has two groups of local color charges and the challenge is to find a physical interpretation for them.

The following arguments support one possible identification.

1. The hint comes from the fact that  $U(2)$  in the decomposition  $CP_2 = SU(3)/U(2)$  corresponds in a well-defined sense electro-weak algebra identified as a holonomy algebra of the spinor connection. Hence one could argue that the  $U(2)$  generators of either  $SU(3)$  algebra might be identifiable as generators of local  $U(2)_{ew}$  gauge transformations whereas non-diagonal generators would correspond to Higgs field. This interpretation would conform with the idea that Higgs field is a genuine scalar field rather than a composite of fermions.
2. Since  $X_l^3$ -local  $SU(3)$  transformations represented by fermionic currents are characterized by central extension they would naturally correspond to the electro-weak gauge algebra and Higgs bosons. This is also consistent with the fact that both leptons and quarks define fermionic Kac Moody currents.
3. The fact that only quarks appear in the gamma matrices of the configuration space supports the view that action of the generators of  $X_l^3$ -local color transformations on configuration space spinor fields represents local color transformations. If the action of  $X_l^3$ -local  $SU(3)$  transformations on configuration space spinor fields has trivial central extension term the identification as a representation of local color symmetries is possible.

The topological explanation of the family replication phenomenon is based on an assignment of 2-dimensional boundary to a 3-surface characterizing the elementary particle. The precise identification of this surface has remained open and one possibility is that the 2-surface  $X^2$  defining the light light-like surface associated with an elementary particle horizon is in question. This assumption would conform with the notion of elementary particle vacuum functionals defined in the zero modes characterizing different conformal equivalences classes for  $X^2$ .

### The relationship of the Super-Kac Moody symmetry to the standard super-conformal invariance

Super-Kac Moody symmetry can be regarded as  $N = 4$  complex super-symmetry with complex  $H$ -spinor modes of  $H$  representing the 4 physical helicities of 8-component leptonic and quark like spinors acting as generators of complex dynamical super-symmetries. The super-symmetries generated by the covariantly constant right handed neutrino appear with *both*  $M^4$  helicities: it however seems that covariantly constant neutrino does not generate any global super-symmetry in the sense of particle-sparticle mass degeneracy. Only righthanded neutrino spinor modes (apart from covariantly constant mode) appear in the expressions of configuration space gamma matrices forming a subalgebra of the full super-algebra.

$N = 2$  real super-conformal algebra is generated by the energy momentum tensor  $T(z)$ ,  $U(1)$  current  $J(z)$ , and super generators  $G^\pm(z)$  carrying  $U(1)$  charge. Now  $U(1)$  current would correspond to right-handed neutrino number and super generators would involve contraction of covariantly constant neutrino spinor with second quantized induced spinor field. The further facts that  $N = 2$  algebra is associated naturally with Kähler geometry, that the partition functions associated with  $N = 2$  super-conformal representations are modular invariant, and that  $N = 2$  algebra defines so called chiral ring defining a topological quantum field theory [55], lend a further support for the belief that  $N = 2$  super-conformal algebra acts in super-symplectic degrees of freedom.

The values of  $c$  and conformal weights for  $N = 2$  super-conformal field theories are given by

$$\begin{aligned}
c &= \frac{3k}{k+2} , \\
\Delta_{l,m}(NS) &= \frac{l(l+2) - m^2}{4(k+2)} , \quad l = 0, 1, \dots, k , \\
q_m &= \frac{m}{k+2} , \quad m = -l, -l+2, \dots, l-2, l .
\end{aligned} \tag{3.5.19}$$

$q_m$  is the fractional value of the  $U(1)$  charge, which would now correspond to a fractional fermion number. For  $k = 1$  one would have  $q = 0, 1/3, -1/3$ , which brings in mind anyons.  $\Delta_{l=0, m=0} = 0$  state would correspond to a massless state with a vanishing fermion number. Note that  $SU(2)_k$  Wess-Zumino model has the same value of  $c$  but different conformal weights. More information about conformal algebras can be found from the appendix of [55].

For Ramond representation  $L_0 - c/24$  or equivalently  $G_0$  must annihilate the massless states. This occurs for  $\Delta = c/24$  giving the condition  $k = 2[l(l+2) - m^2]$  (note that  $k$  must be even and that  $(k, l, m) = (4, 1, 1)$  is the simplest non-trivial solution to the condition). Note the appearance of a fractional vacuum fermion number  $q_{vac} = \pm c/12 = \pm k/4(k+2)$ . I have proposed that NS and Ramond algebras could combine to a larger algebra containing also lepto-quark type generators but this not necessary.

The conformal algebra defined as a direct sum of Ramond and NS  $N = 4$  complex sub-algebras associated with quarks and leptons might further extend to a larger algebra if lepto-quark generators acting effectively as half odd-integer Virasoro generators can be allowed. The algebra would contain spin and electro-weak spin as fermionic indices. Poincare and color Kac-Moody generators would act as symplectically extended isometry generators on configuration space Hamiltonians expressible in terms of Hamiltonians of  $X_l^3 \times CP_2$ . Electro-weak and color Kac-Moody currents have conformal weight  $h = 1$  whereas  $T$  and  $G$  have conformal weights  $h = 2$  and  $h = 3/2$ .

The experience with  $N = 4$  complex super-conformal invariance suggests that the extended algebra requires the inclusion of also second quantized induced spinor fields with  $h = 1/2$  and their super-partners with  $h = 0$  and realized as fermion-antifermion bilinears. Since  $G$  and  $\Psi$  are labeled by  $2 \times 4$  spinor indices, super-partners would correspond to  $2 \times (3 + 1) = 8$  massless electro-weak gauge boson states with polarization included. Their inclusion would make the theory highly predictive since induced spinor and electro-weak fields are the fundamental fields in TGD.

### 3.5.5 Coset space structure for configuration space as a symmetric space

The key ingredient in the theory of symmetric spaces is that the Lie-algebra of  $G$  has the following decomposition

$$\begin{aligned}
g &= h + t , \\
[h, h] &\subset h , \quad [h, t] \subset t , \quad [t, t] \subset h .
\end{aligned}$$

In present case this has highly nontrivial consequences. The commutator of *any* two infinitesimal generators generating nontrivial deformation of 3-surface belongs to  $h$  and thus vanishing norm in the configuration space metric at the point which is left invariant by  $H$ . In fact, this same condition follows from Ricci flatness requirement and guarantees also that  $G$  acts as isometries of the configuration space. This generalization is supported by the properties of the unitary representations of Lorentz group at the light cone boundary and by number theoretical considerations.

The algebras suggesting themselves as candidates are symplectic algebra of  $\delta M^\pm \times CP_2$  and Kac-Moody algebra mapping light-like 3-surfaces to light-like 3-surfaces to be discussed in the next section.

The identification of the precise form of the coset space structure is however somewhat delicate.

1. The essential point is that both symplectic and Kac-Moody algebras allow representation in terms of  $X_l^3$ -local Hamiltonians. The general expression for the Hamilton of Kac-Moody algebra is

$$H = \sum \Phi_A(x) H^A . \tag{3.5.20}$$

Here  $H^A$  are Hamiltonians of  $SO(3) \times SU(3)$  acting in  $\delta X_l^3 \times CP_2$ . For symplectic algebra any Hamiltonian is allowed. If  $x$  corresponds to any point of  $X_l^3$ , one must assume a slicing of the causal diamond  $CD$  by translates of  $\delta M_{\pm}^4$ .

2. For symplectic generators the dependence of form on  $r^\Delta$  on light-like coordinate of  $\delta X_l^3 \times CP_2$  is allowed.  $\Delta$  is complex parameter whose modulus squared is interpreted as conformal weight.  $\Delta$  is identified as analogous quantum number labeling the modes of induced spinor field.
3. One can wonder whether the choices of the  $r_M = \text{constant}$  sphere  $S^2$  is the only choice. The Hamiltonin-Jacobi coordinate for  $X_{X_l^3}^4$  suggest an alternative choice as  $E^2$  in the decomposition of  $M^4 = M^2(x) \times E^2(x)$  required by number theoretical compactification and present for known extremals of Kähler action with Minkowskian signature of induced metric. In this case  $SO(3)$  would be replaced with  $SO(2)$ . It however seems that the radial light-like coordinate  $u$  of  $X^4(X_l^3)$  would remain the same since any other curve along light-like boundary would be space-like.
4. The vector fields for representing Kac-Moody algebra must vanish at the partonic 2-surface  $X^2 \subset \delta M_{\pm}^4 \times CP_2$ . The corresponding vector field must vanish at each point of  $X^2$ :

$$j^k = \sum \Phi_A(x) J^{kl} H_l^A = 0 . \quad (3.5.21)$$

This means that the vector field corresponds to  $SO(2) \times U(2)$  defining the isotropy group of the point of  $S^2 \times CP_2$ .

This expression could be deduced from the idea that the surfaces  $X^2$  are analogous to origin of  $CP_2$  at which  $U(2)$  vector fields vanish. Configuration space at  $X^2$  could be also regarded as the analog of the origin of local  $S^2 \times CP_2$ . This interpretation is in accordance with the original idea which however was given up in the lack of proper realization. The same picture can be deduced from braiding in which case the Kac-Moody algebra corresponds to local  $SO(2) \times U(2)$  for each point of the braid at  $X^2$ . The condition that Kac-Moody generators with positive conformal weight annihilate physical states could be interpreted by stating effective 2-dimensionality in the sense that the deformations of  $X_l^3$  preserving its light-likeness do not affect the physics. Note however that Kac-Moody type Virasoro generators do not annihilate physical states.

5. Kac-Moody algebra generator must leave induced Kähler form invariant at  $X^2$ . This is of course trivial since the action leaves each point invariant. The conditions of Cartan decomposition are satisfied. The commutators of the Kac-Moody vector fields with symplectic generators are non-vanishing since the action of symplectic generator on Kac-Moody generator restricted to  $X^2$  gives a non-vanishing result belonging to the symplectic algebra. Also the commutators of Kac-Moody generators are Kac-Moody generators.

### 3.5.6 The relationship between super-symplectic and Super Kac-Moody algebras, Equivalence Principle, and justification of p-adic thermodynamics

The relationship between super-symplectic algebra ( $SS$ ) acting at light-cone boundary and Super Kac-Moody algebra ( $SKM$ ) acting on light-like 3-surfaces has remained somewhat enigmatic due to the lack of physical insights. This is not the only problem. The question to precisely what extent Equivalence Principle (EP) remains true in TGD framework and what might be the precise mathematical realization of EP is waiting for an answer. Also the justification of p-adic thermodynamics for the scaling generator  $L_0$  of Virasoro algebra -in obvious conflict with the basic wisdom that this generator should annihilate physical states- is lacking. It seems that these three problems could have a common solution.

#### New vision about the relationship between $SSV$ and $SKMV$

Consider now the new vision about the relationship between  $SSV$  and  $SKMV$ .

1. The isometries of  $H$  assignable with  $SKM$  are also symplectic transformations [17] (note that I have used the attribute "canonical" instead of "symplectic" previously). Hence might consider the possibility that  $SKM$  could be identified as a subalgebra of  $SS$ . If this makes sense, a generalization of the coset construction obtained by replacing finite-dimensional Lie group with infinite-dimensional symplectic group suggests itself. The differences of  $SSV$  and  $SKMV$  elements would annihilate physical states and commute/anticommute with  $SKMV$ . Also the generators  $O_n$ ,  $n > 0$ , for both algebras would annihilate the physical states so that the differences of the elements would annihilate automatically physical states for  $n > 0$ .
2. The super-generator  $G_0$  contains the Dirac operator  $D$  of  $H$ . If the action of  $SSV$  and  $SKMV$  Dirac operators on physical states are identical then cm of degrees of freedom disappear from the differences  $G_0(SCV) - G_0(SKMV)$  and  $L_0(SCV) - L_0(SKMV)$ . One could interpret the identical action of the Dirac operators as the long sought-for precise realization of Equivalence Principle (EP) in TGD framework. EP would state that the total inertial four-momentum and color quantum numbers assignable to  $SS$  (imbedding space level) are equal to the gravitational four-momentum and color quantum numbers assignable to  $SKM$  (space-time level). Note that since super-symplectic transformations correspond to the isometries of the "world of classical worlds" the assignment of the attribute "inertial" to them is natural.

### Consistency with p-adic thermodynamics

The consistency with p-adic thermodynamics provides a strong reality test and has been already used as a constraint in attempts to understand the super-conformal symmetries in partonic level.

1. In physical states the p-adic thermal expectation value of the  $SKM$  and  $SS$  conformal weights would be non-vanishing and identical and mass squared could be identified equivalently either as the expectation value of  $SKM$  or  $SS$  scaling generator  $L_0$ . There would be no need to give up Super Virasoro conditions for  $SCV - SKMV$ .
2. There is consistency with p-adic mass calculations for hadrons [51] since the non-perturbative  $SS$  contributions and perturbative  $SKM$  contributions to the mass correspond to space-time sheets labeled by different p-adic primes. The earlier statement that  $SS$  is responsible for the dominating non-perturbative contributions to the hadron mass transforms to a statement reflecting  $SS - SKM$  duality. The perturbative quark contributions to hadron masses can be calculated most conveniently by using p-adic thermodynamics for  $SKM$  whereas non-perturbative contributions to hadron masses can be calculated most conveniently by using p-adic thermodynamics for  $SS$ . Also the proposal that the exotic analogs of baryons resulting when baryon loses its valence quarks [45] remains intact in this framework.
3. The results of p-adic mass calculations depend crucially on the number  $N$  of tensor factors contributing to the Super-Virasoro algebra. The required number is  $N = 5$  and during years I have proposed several explanations for this number. It seems that holonomic contributions that is electro-weak and spin contributions must be regarded as contributions separate from those coming from isometries.  $SKM$  algebras in electro-weak degrees and spin degrees of freedom, would give  $2+1=3$  tensor factors corresponding to  $U(2)_{ew} \times SU(2)$ .  $SU(3)$  and  $SO(3)$  (or  $SO(2) \subset SO(3)$  leaving the intersection of light-like ray with  $S^2$  invariant) would give 2 additional tensor factors. Altogether one would indeed have 5 tensor factors.

There are some further questions which pop up in mind immediately.

1. Why mass squared corresponds to the thermal expectation value of the net conformal weight? This option is forced among other things by Lorentz invariance but it is not possible to provide a really satisfactory answer to this question yet. In the coset construction there is no reason to require that the mass squared equals to the integer value conformal weight for  $SKM$  algebra. This allows the possibility that mass squared has same value for states with different values of  $SKM$  conformal weights appearing in the thermal state and equals to the average of the conformal weight.

2. The coefficient of proportionality can be however deduced from the observation that the mass squared values for  $CP_2$  Dirac operator correspond to definite values of conformal weight in p-adic mass calculations. It is indeed possible to assign to partonic 2-surface  $X^2 CP_2$  partial waves correlating strongly with the net electro-weak quantum numbers of the parton so that the assignment of ground state conformal weight to  $CP_2$  partial waves makes sense.
3. In the case of  $M^4$  degrees of freedom it is strictly speaking not possible to talk about momentum eigen states since translations take parton out of  $\delta H_+$ . This would suggest that 4-momentum must be assigned with the tip of the light-cone containing the particle but this is not consistent with zero energy ontology. Hence it seems that one must restrict the translations of  $X_l^3$  to time like translations in the direction of geometric future at  $\delta M_+^4 \times CP_2$ . The decomposition of the partonic 3-surface  $X_l^3$  to regions  $X_{l,i}^3$  carrying non-vanishing induced Kähler form and the possibility to assign  $M^2(x) \subset M^4$  to the tangent space of  $X^4(X_l^3)$  at points of  $X_l^3$  suggests that the points of number theoretic braid to which oscillator operators can be assigned can carry four-momentum in the plane defined by  $M^2(x)$ . One could assume that the four-momenta assigned with points in given region  $X_l^3$  are collinear but even this restriction is not necessary.
4. The additivity of conformal weight means additivity of mass squared at parton level and this has been indeed used in p-adic mass calculations. This implies the conditions

$$\left(\sum_i p_i\right)^2 = \sum_i m_i^2 \quad (3.5.22)$$

The assumption  $p_i^2 = m_i^2$  makes sense only for massless partons moving collinearly. In the QCD based model of hadrons only longitudinal momenta and transverse momentum squared are used as labels of parton states, which together with the presence of preferred plane  $M^2$  would suggest that one has

$$\begin{aligned} p_{i,\parallel}^2 &= m_i^2, \\ -\sum_i p_{i,\perp}^2 + 2\sum_{i,j} p_i \cdot p_j &= 0. \end{aligned} \quad (3.5.23)$$

The masses would be reduced in bound states:  $m_i^2 \rightarrow m_i^2 - (p_T^2)_i$ . This could explain why massive quarks can behave as nearly massless quarks inside hadrons.

### How it is possible to have negative conformal weights for ground states?

p-Adic mass calculations require negative conformal weights for ground states [41]. The only elegant solution of the problems caused by this requirement seems to be p-adic: the conformal weights are positive in the real sense but as p-adic numbers their dominating part is negative integer (in the real sense), which can be compensated by the conformal weights of Super Virasoro generators.

1. If  $\pm\lambda_i^2$  as such corresponds to a ground state conformal weight and if  $\lambda_i$  is real the ground state conformal weight positive in the real sense. In complex case (instanton term) the most natural formula is  $h = \pm|\lambda|^2$ .
2. The first option is based on the understanding of conformal excitations in terms of CP breaking instanton term added to the modified Dirac operator. In this case the conformal weights are identified as  $h = n - |\lambda_k|^2$  and the minus sign comes from the Euclidian signature of the effective metric for the modified Dirac operator. Ground state conformal weight would be non-vanishing for non-zero modes of  $D(X_l^3)$ . Massless bosons produce difficulties unless one has  $h = |\lambda_i(1) - \lambda_i(2)|^2$ , where  $i = 1, 2$  refers to the two wormhole throats. In this case the difference can vanish and its non-vanishing would be due to the symmetric breaking. This scenario is assumed in p-adic mass calculations. Fermions are predicted to be always massive since zero modes of  $D(X^2)$  represent super gauge degrees of freedom.

3. In the context of p-adic thermodynamics a loop hole opens allowing  $\lambda_i$  to be real. In spirit of rational physics suppose that one has in natural units  $h = \lambda_i^2 = xp^2 - n$ , where  $x$  is integer. This number is positive and large in the real sense. In p-adic sense the dominating part of this number is  $-n$  and can be compensated by the net conformal weight  $n$  of Super Virasoro generators acting on the ground state.  $xp^2$  represents the small Higgs contribution to the mass squared proportional to  $(xp^2)_R \simeq x/p^2$  ( $_R$  refers to canonical identification). By the basic features of the canonical identification  $p > x \simeq p$  should hold true for gauge bosons for which Higgs contribution dominates. For fermions  $x$  should be small since p-adic mass calculations are consistent with the vanishing of Higgs contribution to the fermion mass. This would lead to the earlier conclusion that  $xp^2$  and hence  $B_K$  is large for bosons and small for fermions and that the size of fermionic (bosonic) wormhole throat is large (small). This kind of picture is consistent with the p-adic modular arithmetics and suggests by the cutoff for conformal weights implied by the fact that both the number of fermionic oscillator operators and the number of points of number theoretic braid are finite. This solution is however tricky and does not conform with number theoretical universality.

### 3.6 Trying to understand $N = 4$ super-conformal symmetry

The original idea was that  $N = 4$  super-conformal symmetry is a symmetry generated by the solutions of the modified Dirac equation for the second quantized induced spinor fields. Later I was ended up with this symmetry by considering the general structure of these algebras interpreted in TGD framework. In the following the latter approach is discussed in detail.

Needless to say, a lot remains to be understood. One of the problems is that my understanding of  $N = 4$  super-conformal symmetry at technical level is rather modest. There are also profound differences between these two kinds of super conformal symmetries. In TGD framework super generators carry quark or lepton number, super-symplectic and super Kac-Moody generators are identified as Hamiltonians rather than vector fields, and symplectic group is infinite-dimensional whereas the Lie groups associated with Kac-Moody algebras are finite-dimensional. On the other hand, finite measurement resolution implies discretization and cutoff in conformal weight. Therefore the naive attempt to re-interpret results of standard super-conformal symmetry to TGD framework might lead to erratic conclusions.

$N > 0$  super-conformal algebras contain besides super Virasoro generators also other types of generators and this raises the question whether it might be possible to find an algebra coding the basic quantum numbers of the induced spinor fields.

There are several variants of  $N = 4$  SCAs and they correspond to the Kac-Moody algebras  $SU(2)$  (small SCA),  $SU(2) \times SU(2) \times U(1)$  (large SCA) and  $SU(2) \times U(1)^4$ . Rasmussen has found also a fourth variant based on  $SU(2) \times U(1)$  Kac-Moody algebra [105]. It seems that only minimal and maximal  $N = 4$  SCAs can represent realistic options. The reduction to almost topological string theory in critical phase is probably lost for other than minimal SCA but could result as an appropriate limit for other variants.

It must be emphasized that the discussion of this section is not based on the recent view about generalization of space-time supersymmetry to TGD framework in which fermionic oscillator operators define an infinite-dimensional super-symmetry algebra with anticommutators fixed by the measurement interaction term of the modified Dirac action [28]. Therefore the direction connection with quantum TGD remains loose.

#### 3.6.1 Large $N = 4$ SCA

Large  $N = 4$  SCA is described in the following in detail since it might be a natural algebra in TGD framework.

##### The structure of large $N = 4$ SCA algebra

Large  $N = 4$  super-conformal symmetry with  $SU(2)_+ \times SU(2)_- \times U(1)$  inherent Kac-Moody symmetry correspond to a fundamental partonic super-conformal symmetry in TGD framework.

A concise discussion of this symmetry with explicit expressions of commutation and anticommutation relations can be found in [105]. The representations of SCA are characterized by three central extension parameters for Kac-Moody algebras but only two of them are independent and given by

$$\begin{aligned} k_{\pm} &\equiv k(SU(2)_{\pm}) , \\ k_1 &\equiv k(U(1)) = k_+ + k_- . \end{aligned} \quad (3.6.1)$$

The central extension parameter  $c$  is given as

$$c = \frac{6k_+k_-}{k_+ + k_-} . \quad (3.6.2)$$

and is rational valued as required.

A much studied  $N = 4$  SCA corresponds to the special case

$$\begin{aligned} k_- &= 1 , \quad k_+ = k + 1 , \quad k_1 = k + 2 , \\ c &= \frac{6(k+1)}{k+2} . \end{aligned} \quad (3.6.3)$$

$c = 0$  would correspond to  $k_+ = 0, k_- = 1, k_1 = 1$ . For  $k_+ > 0$  one has  $k_1 = k_+ + k_- \neq k_+$ .

### About unitary representations of large $N = 4$ SCA

The unitary representations of large  $N = 4$  SCA are briefly discussed in [73]. The representations are labeled by the ground state conformal weight  $h$ ,  $SU(2)$  spins  $l_+, l_-$ , and  $U(1)$  charge  $u$ . Besides the inherent Kac-Moody algebra there is also "external" Kac-Moody group  $G$  involved and could correspond in TGD framework to the symplectic algebra associated with  $\delta H_{\pm} = \delta M_{\pm}^4 \times CP_2$  or to Kac-Moody group respecting light-likeness of light-like 3-surfaces.

Unitarity constraints apply completely generally irrespective of  $G$  so that one can apply them also in TGD framework. There are two kinds of unitary representations.

1. Generic/long/massive representations which are generated from vacuum state as usual. In this case there are no null vectors.
2. Short or massless representations have a null vector. The expression for the conformal weight  $h_{short}$  of the null vector reads in terms of  $l_+, l_-$  and  $k_+, k_-$  as

$$h_{short} = \frac{1}{k_+ + k_-} (k_- l_+ + k_+ l_- + (l_+ - l_-)^2 + u^2) . \quad (3.6.4)$$

Unitarity demands that both short and long representations lie at or above  $h \geq h_{short}$  and that spins lie in the range  $l_{\pm} = 0, 1/2, \dots, (k_{\pm} - 1)/2$ .

Interesting examples of  $N = 4$  SCA are provided by WZW coset models  $\mathcal{W} \times U(1)$ , where  $\mathcal{W}$  is WZW model associated with a quaternionic (Wolf) space. Examples based on classical groups are  $\mathcal{W} = G/H = SU(n)/SU(n-1) \times U(1)$ ,  $SO(n)/SO(n-4) \times SU(2)$ , and  $Sp(2n)/Sp(2n-2)$ . For  $n = 3$  first series gives  $CP_2$  whereas second series gives for  $n = 4$   $SO(4)/SU(2) = SU(2)$ . In this case one has  $k_+ = \kappa + 1$ , and  $k_- = \hat{c}_G$ , where  $\kappa$  is the level of the bosonic current algebra for  $G$  and  $\hat{c}_G$  is its dual Coxeter number.

### 3.6.2 Overall view about how different $N = 4$ SCAs could emerge in TGD framework

The basic idea is simple  $N = 4$  fermion states obtained as different combinations of spin and isospin for given  $H$ -chirality of imbedding space spinor correspond to  $N = 4$  multiplet. In case of leptons the holonomy group of  $S^2 \times CP_2$  for given spinor chirality is  $SU(2)_R \times SU(2)_R$  or  $SU(2)_L \times SU(2)_R$  depending on  $M^4$  chirality of the spinor. In case of quark one has  $SU(2)_L \times SU(2)_L$  or  $SU(2)_R \times SU(2)_R$ . The coupling to Kähler gauge potential adds to the group  $U(1)$  factor so that large  $N = 4$  SCA is obtained. For covariantly constant right handed neutrino electro-weak part of holonomy group drops away as also  $U(1)$  factor so that one obtains  $SU(2)_L$  or  $SU(2)_R$  and small  $N = 4$  SCA.

#### How maximal $N = 4$ SCA could emerge in TGD framework?

Consider the Kac-Moody algebra  $SU(2) \times SU(2) \times U(1)$  associated with the maximal  $N = 4$  SCA. Besides Kac-Moody currents it contains 4 spin 1/2 fermions having an identification as quantum counterparts of leptonic spinor fields. The interpretation of the first  $SU(2)$  is as rotations as rotations leaving invariant the sphere  $S^2 \subset \delta M_{\pm}^4$ .  $U(2)$  has interpretation as electro-weak gauge group and as maximal linearly realized subgroup of  $SU(3)$ . This algebra acts naturally as symmetries of the 8-component spinors representing super partners of quaternions.

The algebra involves the integer value central extension parameters  $k_+$  and  $k_-$  associated with the two  $SU(2)$  algebras as parameters. The value of  $U(1)$  central extension parameter  $k$  is given by  $k = k_+ + k_-$ . The value of central extension parameter  $c$  is given by

$$c = 6k_- \frac{x}{1+x} < 6k_+ \quad , \quad x = \frac{k_+}{k_-} \quad .$$

$c$  can have all non-negative rational values  $m/n$  for positive values of  $k_{\pm}$  given by  $k_+ = rm, k_- = (6nr - 1)m$ . Unitarity might pose further restrictions on the values of  $c$ . At the limit  $k_- = k, k_+ \rightarrow \infty$  the algebra reduces to the minimal  $N = 4$  SCA with  $c = 6k$  since the contributions from the second  $SU(2)$  and  $U(1)$  to super Virasoro currents vanish at this limit.

#### How small $N = 4$ SCA could emerge in TGD framework?

Consider the TGD based interpretation of the small  $N = 4$  SCA.

1. The group  $SU(2)$  associated with the small  $N = 4$  SCA and acting as rotations of covariantly constant right-handed neutrino spinors allows also an interpretation as a group  $SO(3)$  leaving invariant the sphere  $S^2$  of the light-cone boundary identified as  $r_M = m^0 = \text{constant}$  surface defining generalized Kähler and symplectic structures in  $\delta M_{\pm}^4$ . Electro-weak degrees of freedom are obviously completely frozen so that  $SU(2)_- \times U(1)$  factor indeed drops out.
2. The choice of the preferred coordinate system should have a physical justification. The interpretation of  $SO(3)$  as the isotropy group of the rest system defined by the total four-momentum assignable to the 3-surface containing partonic 2-surfaces is supported by the quantum classical correspondence. The subgroup  $U(1)$  of  $SU(2)$  acts naturally as rotations around the axis defined by the light ray from the tip of  $M_{\pm}^4$  orthogonal to  $S^2$ . For  $c = 0, k = 0$  case these groups define local gauge symmetries. In the more general case local gauge invariance is broken whereas global invariance remains as it should.

In  $M^2 \times E^2$  decomposition  $E^2$  corresponds to the tangent space of  $S^2$  at a given point and  $M^2$  to the plane orthogonal to it. The natural assumption is that the right handed neutrino spinor is annihilated by the momentum space Dirac operator corresponding to the light-like momentum defining  $M^2 \times E^2$  decomposition.

3. For covariantly constant right handed neutrinos the dynamics would be essentially that defined by a topological quantum field theory and this kind of almost trivial dynamics is indeed associated with small  $N = 4$  SCA.

1. *Why  $N = 4$  super-conformal symmetry would be so nice?*

$N = 2$  super-conformal invariance has been claimed to imply the vanishing of all amplitudes with more than 3 external legs for closed critical  $N = 2$  strings having  $c = 6, k = 1$  which is proposed to correspond to  $n \rightarrow \infty$  limit [49, 92]. Only the partition function and  $2 \leq N \leq 3$  scattering amplitudes would be non-vanishing. The argument of [49] relies on the imbedding of  $N = 2$  super-conformal field theory to  $N = 4$  topological string theory whereas in [92] the Ward identities for additional unbroken symmetries associated with the chiral ring accompanying  $N = 2$  super-symmetry [55] are utilized. In fact,  $N = 4$  topological string theory allows also imbeddings of  $N = 1$  super strings [49].

The properties of  $c = 6$  critical theory allowing only integral valued  $U(1)$  charges and fermion numbers would conform nicely with what we know about the perturbative electro-weak physics of leptons and gauge bosons.  $c = 1, k = 1$  sector with  $N = 2$  super-conformal symmetry would involve genuinely stringy physics since all  $N$ -point functions would be non-vanishing and the earlier hypothesis that strong interactions can be identified as electro-weak interactions which have become strong inspired by HO-H duality [72] could find a concrete realization.

In  $c = 6$  phase  $N = 2$ -vertices the loop corrections coming from the presence of higher lepton genera in amplitude could be interpreted as topological mixing forced by unitarity implying in turn leptonic CKM mixing for leptons. The non-triviality of 3-point amplitudes would in turn be enough to have a stringy description of particle number changing reactions, such as single photon brehmstrahlung. The amplitude for the emission of more than one brehmstrahlung photons from a given lepton would vanish. Obviously the connection with quantum field theory picture would be extremely tight and imbeddability to a topological  $N = 4$  quantum field theory could make the theory to a high degree exactly solvable.

## 2. Objections

There are also several reasons for why one must take the idea about the usefulness of  $c = 6$  super-conformal strings from the point of view of TGD with an extreme caution.

1. Stringy diagrams have quite different interpretation in TGD framework. The target space for these theories has dimension four and metric signature (2,2) or (0,4) and the vanishing theorems hold only for (2,2) signature. In lepton sector one might regard the covariantly constant complex right-handed neutrino spinors as generators of  $N = 2$  real super-symmetries but in quark sector there are no super-symmetries.
2. The spectrum looks unrealistic: all degrees of freedom are eliminated by symmetries except single massless scalar field so that one can wonder what is achieved by introducing the extremely heavy computational machinery of string theories. This argument relies on the assumption that time-like modes correspond to negative norm so that the target space reduces effectively to a 2-dimensional Euclidian sub-space  $E^2$  so that only the vibrations in directions orthogonal to the string in  $E^2$  remain. The situation changes if one assigns negative conformal weights and negative energies to the time like excitations. In the generalized coset representation used to construct physical states this is indeed assumed.
3. The central charge has only values  $c = 6k$ , where  $k$  is the central extension parameter of  $SU(2)$  algebra [43] so that it seems impossible to realize the genuinely rational values of  $c$  which should correspond to the series of Jones inclusions. One manner to circumvent the problem would be the reduction to  $N = 2$  super-conformal symmetry.
4.  $SU(2)$  Kac-Moody algebra allows to introduce only 2-component spinors naturally whereas super-quaternions allow quantum counterparts of 8-component spinors.

The  $N = 2$  super-conformal algebra automatically extends to the so called small  $N = 4$  algebra with four super-generators  $G_{\pm}$  and their conjugates [49]. In TGD framework  $G_{\pm}$  degeneracy corresponds to the two spin directions of the covariantly constant right handed neutrinos and the conjugate of  $G_{\pm}$  is obtained by charge conjugation of right handed neutrino. From these generators one can build up a right-handed  $SU(2)$  algebra.

Hence the  $SU(2)$  Kac-Moody of the small  $N = 4$  algebra corresponds to the three imaginary quaternionic units and the  $U(1)$  of  $N = 2$  algebra to ordinary imaginary unit. Energy momentum tensor  $T$  and  $SU(2)$  generators would correspond to quaternionic units.  $G_{\pm}$  to their super counterparts and their conjugates would define their "square roots".

### What about $N = 4$ SCA with $SU(2) \times U(1)$ Kac-Moody algebra?

Rasussen [105] has discovered an  $N = 4$  super-conformal algebra containing besides Virasoro generators and 4 Super-Virasoro generators  $SU(2) \times U(1)$  Kac-Moody algebra and two spin 1/2 fermions and a scalar.

The first identification of  $SU(2) \times U(1)$  is as electro-weak algebra for a given spin state. Second and more natural identification is as the algebra defined by rotation group and electromagnetic or Kähler charge acting on given charge state of fermion and naturally resulting in electro-weak symmetry breaking. Scalar might relate to Higgs field which is  $M^4$  scalar but  $CP_2$  vector.

There are actually two versions about Rasmussen's article [105]: in the first version the author talks about  $SU(2) \times U(1)$  Kac-Moody algebra and in the second one about  $SL(2) \times U(1)$  Kac-Moody algebra.

These variants could correspond in TGD framework to two different inclusions of hyper-finite factors of type  $II_1$ .

1. The first inclusion could be defined by  $G = SL(2, R) \subset SO(3, 1)$  acting on  $M^4$  part of H-spinors (or alternatively, as Lorentz group inducing motions in the plane  $E^2$  orthogonal to a light-like ray from the origin of light-cone  $M^4_+$ ). Physically the inclusion would mean that Lorentz degrees of freedom are frozen in the physical measurement. This leaves electro-weak group  $SU(2)_L \times U(1)$  as the group acting on H-spinors.
2. The second inclusion would be defined by the electro-weak group  $SU(2)_L$  so that Kac-Moody algebra  $SL(2, R) \times U(1)$  remains dynamical.

### 3.6.3 How large $N = 4$ SCA could emerge in quantum TGD?

The discovery of the formulation of TGD as a  $N = 4$  almost topological super-conformal QFT with light-like partonic 3-surfaces identified as basic dynamical objects increased considerably the understanding of super-conformal symmetries and their breaking in TGD framework.  $N = 4$  super-conformal algebra corresponds to the maximal algebra with  $SU(2) \times U(2)$  Kac-Moody algebra as inherent fermionic Kac-Moody algebra.

Concerning the interpretation the first guess would be that  $SU(2)_+$  and  $SU(2)_-$  correspond to vectorial spinor rotations in  $M^4$  and  $CP_2$  and  $U(1)$  to Kähler charge or electromagnetic charge. For given imbedding space chirality (lepton/quark) and  $M^4$  chirality  $SU(2)$  groups are completely fixed.

#### Identification of super generators

Consider first the fermionic generators of the super Kac-Moody algebra.

1. Assume that the modified Dirac operator decomposition  $D = D(Y^2) + D(X^2) = D(Y^1) + D(X^1) + D(X^2)$  reflecting the dual slicings of space-time surfaces to string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$ .
2.  $Y^1$  represents light-like direction and also string connecting braid strands at same component of  $X^3_i$  or at two different components of  $X^3_i$ . Modified Dirac equation implies that the charges

$$\int_{X^3_i} \bar{\Psi}_{\lambda_k, n} \hat{\Gamma}^v \Psi \quad (3.6.5)$$

define conserved super charges in time direction associated with  $Y^1$  and carrying quark or lepton number. Here  $\Psi_{\lambda_k, n}$  corresponds to  $n$ :th conformal excitation of  $\Psi_{\lambda_k}$  and  $\lambda_k$  is a generalized eigenvalue of  $D(X^2)$ , whose modulus squared has interpretation as ground state conformal weight. In the case of ordinary Dirac equation essentially fermionic oscillator operators would be in question.

3. The zero modes of  $D(X^2)$  define a sub-algebra which represents super gauge symmetries. In particular, covariantly constant right handed neutrinos define this kind of super gauge super-symmetries.  $N = 2$  super-conformal symmetry would correspond in TGD framework to covariantly constant complex right handed neutrino spinors with two spin directions forming a right handed doublet and would be exact and act only in the leptonic sector relating configuration space Hamiltonians and super-Hamiltonians. This algebra extends to the so called small  $N = 4$  algebra if one introduces the conjugates of the right handed neutrino spinors. This symmetry is exact if only leptonic chirality is present in theory or if free quarks carry leptonic charges.

A physically attractive realization of the braids - and more generally- of slicings of space-time surface by 3-surfaces and string world sheets, is discussed in [36] by starting from the observation that TGD defines an almost topological QFT of braids, braid cobordisms, and 2-knots. The boundaries of the string world sheets at the space-like 3-surfaces at boundaries of  $CD$ s and wormhole throats would define space-like and time-like braids uniquely.

The idea relies on a rather direct translation of the notions of singular surfaces and surface operators used in gauge theory approach to knots [129] to TGD framework. It leads to the identification of slicing by three-surfaces as that induced by the inverse images of  $r = \text{constant}$  surfaces of  $CP_2$ , where  $r$  is  $U(2)$  invariant radial coordinate of  $CP_2$  playing the role of Higgs field vacuum expectation value in gauge theories.  $r = \infty$  surfaces correspond to geodesic spheres and define analogs of fractionally magnetically charged Dirac strings identifiable as preferred string world sheets. The union of these sheets labelled by subgroups  $U(2) \subset SU(3)$  would define the slicing of space-time surface by string world sheets. The choice of  $U(2)$  relates directly to the choice of quantization axes for color quantum numbers characterizing  $CD$  and would have the choice of braids and string world sheets as a space-time correlate.

### Identification of Kac-Moody generators

Consider next the generators of inherent Kac-Moody algebras for  $SU(2) \times SU(L) \times U(1)$  and freely chosen group  $G$ .

1. Generators of Kac-Moody algebra associated with isometries correspond Noether currents associated with the infinitesimal action of Kac-Moody algebra to the induced spinor fields. Local  $SO(3) \times SU(3)$  algebra is in question and excitations should have dependence on the coordinate  $u$  in direction of  $Y^1$ . The most natural guess is that this algebra corresponds to the Kac-Moody algebra for group  $G$ .
2. The natural candidate for the inherent Kac-Moody algebra is the holonomy algebra associated with  $S^2 \times CP_2$ . This algebra should correspond to a broken symmetry. The generalized eigen modes of  $D(X^2)$  labeled by  $\lambda_k$  should form the representation space in this case. If Kac-Moody symmetry were not broken these representations would correspond a degeneracy associated with given value of  $\lambda_k$ . Electro-weak symmetry breaking is however present and coded already into the geometry of  $CP_2$ . Also  $SO(3)$  symmetry is broken due to the presence of classical electro-weak magnetic fields. The broken symmetries could be formulated in terms of initial values of generalized eigen modes at  $X^2$  defining either end of  $X^3$ . One can rotate these initial values by spinor rotations. Symmetry breaking would mean that the modes obtained by a rotation by angle  $\phi = \pi$  from a mode with fixed eigenvalue  $\lambda_k$  have different eigenvalues. Four states would be obtained for a given imbedding space chirality (quark or lepton). One expects that an analog of cyclotron spectrum with cutoff results with each cyclotron state split to four states with different eigenvalues  $\lambda_k$ . Kac-Moody generators could be expressed as matrices acting in the space spanned by the eigen modes.

### Consistency with p-adic mass calculations

The consistency with p-adic mass calculations provides a strong guide line in attempts to interpret  $N = 4$  SCA. The basis ideas of p-adic mass calculations are following.

1. Fermionic partons move in color partial waves in their cm degrees of freedom. This gives to conformal weight a vacuum contribution equal to the  $CP_2$  contribution to mass squared. The

contribution depends on electro-weak isospin and equals  $h_c(U) = 2$  and  $h_c(D) = 3$  for quarks and one has  $h_c(\nu) = 1$  and  $h_c(L) = 2$ .

2. The ground state can correspond also to non-negative value of  $L_0$  for SKMV algebra which gives rise to a thermal degeneracy of massless states. p-Adic mass calculations require  $(h_{gr}(D), h_{gr}(U)) = (0, -1,)$  and  $(h_{gr}(L), h_{gr}(\nu)) = (-1, -2)$  so that the super-symplectic operator  $O_c$  screening the anomalous color charge has conformal weight  $h_c = -3$  for all fermions.

The simplest interpretation is that the free parameter  $h$  appearing in the representations of the SCA corresponds to the conformal weight due to the color partial wave so that the correlation with electromagnetic charge would indeed emerge but from the correlation of color partial waves and electro-weak quantum numbers.

The requirement that ground states are null states with respect to the SCV associated with the radial light-like coordinate of  $\delta M_{\pm}^4$  gives an additional consistency condition and  $h_c = -3$  should satisfy this condition. p-Adic mass calculations do not pose non-trivial conditions on  $h$  for option 1) if one makes the identification  $u = Q_{em}$  since one has  $h_{short} < 1$  for all values of  $k_+ + k_-$ . Therefore both options 1) and 2) can be considered.

### About symmetry breaking for large $N = 4$ SCA

Partonic formulation predicts that large  $N = 4$  SCA is a broken symmetry, and the first guess is that breaking occurs via several steps. First a "small"  $N = 4$  SCA with Kac-Moody group  $SU(2)_+ \times U(1)$ , where  $SU(2)_+$  corresponds to ordinary rotations on spinor with fixed helicity, would result in electro-weak symmetry breaking. The next step break spin symmetry would lead to  $N = 2$  SCA and the final step to  $N = 0$  SCA. Several symmetry breaking scenarios are possible.

1. The interpretation of  $SU(2)_+$  in terms of right- or left- handed spin rotations and  $U(1)$  as electromagnetic gauge group conforms with the general vision about electro-weak symmetry breaking in non-stringy phase. The interpretation certainly makes sense for covariantly constant right handed neutrinos for which spin direction is free. For left handed charged electro-weak bosons the action of right-handed spinor rotations is trivial so that the interpretation would make sense also now.
2. The next step in the symmetry breaking sequence would be  $N = 2$  SCA with electromagnetic Kac-Moody algebra as inherent Kac-Moody algebra  $U(1)$ .

### 3.6.4 Relationship to super string models, M theory and WZW model

In hope of achieving more precise understanding one can try to understand the relationship of  $N = 4$  super conformal symmetry as it might appear in TGD to super strings, M theory and WZW model.

#### Relationship to super-strings and M-theory

The (4,4) signature characterizing  $N = 4$  SCA topological field theory is not a problem since in TGD framework the target space becomes a fictive concept defined by the Cartan algebra. Both  $M^4 \times CP_2$  decomposition of the imbedding space and space-time dimension are crucial for the 2+2+2+2 structure of the Cartan algebra, which together with the notions of the configuration space and generalized coset representation formed from super Kac-Moody and super-symplectic algebras guarantees  $N = 4$  super-conformal invariance.

Including the 2 gauge degrees of freedom associated with  $M^2$  factor of  $M^4 = M^2 \times E^2$  the critical dimension becomes  $D = 10$  and including the radial degree of light-cone boundary the critical dimension becomes  $D = 11$  of M-theory. Hence the fictive target space associated with the vertex operator construction corresponds to a flat background of super-string theory and flat background of M-theory with one light-like direction. From TGD point view the difficulties of these approaches are due to the un-necessary assumption that the fictive target space defined by the Cartan algebra corresponds to the physical imbedding space. The flatness of the fictive target space forces to introduce the notion of spontaneous compactification and dynamical imbedding space and this in turn leads to the notion of landscape.

### Consistency with critical dimension of super-string models and M-theory

Mass squared is identified as the conformal weight of the positive energy component of the state rather than as a contribution to the conformal weight canceling the total conformal weight. Also the Lorentz invariance of the p-adic thermodynamics requires this. As a consequence, the pseudo 4-momentum  $p$  assignable to  $M^4$  super Kac-Moody algebra could be always light-like or even tachyonic.

Super-symplectic algebra would generate the negative conformal weight of the ground state required by the p-adic mass calculations and super-Kac Moody algebra would generate the non-negative net conformal weight identified as mass squared. In this interpretation SKM and SC degrees of freedom are independent and correspond to opposite signs for conformal weights.

The construction is consistent with p-adic mass calculations [41, 50] and the critical dimension of super-string models.

1. Five Super Virasoro sectors are predicted as required by the p-adic mass calculations (the predicted mass spectrum depends only on the number of tensor factors). Super-symplectic algebra gives  $Can(CP_2)$  and  $Can(S^2)$ . In SKM sector one has  $SU(2)_L$ ,  $U(1)$ , local  $SU(3)$ ,  $SO(2)$  and  $E^2$  so that 5 sectors indeed result.
2. The Cartan algebras involved of SC is 2-dimensional and that of SKM is 7-dimensional so that 10-dimensional Cartan algebra results. This means that vertex operator construction implies generation of 10-dimensional target space which in super-string framework would be identified as imbedding space. Note however that these dimensions have Euclidian signature unlike in super-string models. SKM algebra allows also the option  $SO(3) \times E(3)$  in  $M^4$  degrees of freedom: this would mean that SKM Cartan algebra is 10-dimensional and the whole algebra 11-dimensional.

### $N = 4$ super-conformal symmetry and WZW models

One can question the naive idea that the basic structure  $G_{int} = SU(2) \times U(2)$  structure of  $N = 4$  SCA generalizes as such to the recent framework.

1.  $N = 4$  SCA is originally associated with Majorana spinors.  $N = 4$  algebra can be transformed from a real form to complex form with 2 complex fermions and their conjugates corresponding to complex  $H$ -spinors of definite chirality having spin and weak isospin. At least at formal level the complexification of  $N = 4$  SCA algebra seems to make sense and might be interpreted as a direct sum of two  $N = 4$  SCAs and complexified quaternions. Central charge would remain  $c = 6k_+k_-/(k_+ + k_-)$  if naive complexification works. The fact that Kac-Moody algebra of spinor rotations is  $G_{int} = SO(4) \times SO(4) \times U(1)$  is naturally assignable naturally to spinors of  $H$  suggests that it represents a natural generalization of  $SO(4) \times U(1)$  algebra to inherent Kac-Moody algebra.
2. One might wonder whether the complex form of  $N = 4$  algebra could result from  $N = 8$  SCA by posing the associativity condition.
3. The article of Gunaydin [81] about the representations of  $N = 4$  super-conformal algebras realized in terms of Goddard-Kent-Olive construction and using gauged Wess-Zumino-Witten models forces however to question the straightforward translation of results about  $N = 4$  SCA to TGD framework and it must be admitted that the situation is something confusing. Of course, there is no deep reason to believe that WZW models are appropriate in TGD framework.
  - (a) Gauged WZW models are constructed using super-space formalism which is not natural in TGD framework. The coset space  $CP_2 \times U(2)$  where  $U(2)$ , could be identified as sub-algebra of color algebra or possibly as electro-weak algebra provides one such realization. Also the complexification of the  $N = 4$  algebra is something new.
  - (b) The representation involves 5-grading by the values of color isospin for  $SU(3)$  and makes sense as a coset space realization for  $G/H \times U(1)$  if  $H$  is chosen in such a manner that  $G/H \times SU(2)$  is quaternionic space. For  $SU(3)$  one has  $H = U(1)$  identifiable in terms of color hyper charge  $CP_2$  is indeed quaternionic space. For  $SU(2)$  5-grading degenerates since spin 1/2 Lie-algebra generators are absent and  $H$  is trivial group. In  $M^4$  degrees of gauged WZW model would be trivial.

- (c)  $N = 4$  SCA results as an extension of  $N = 2$  SCA using so called Freudenthal triple system.  $N = 2$  SCA has realization in terms of  $G/H \times U(1)$  gauged WZW theory whereas the extension to  $N = 4$  SCA gives  $G \times U(1)/H$  gauged WZW model: note that  $SU(3) \times U(1)/H$  does not have an obvious interpretation in TGD framework. The Kac-Moody central extension parameters satisfy the constraint  $k_+ = k+1$  and  $k_- = \hat{g}-1$ , where  $k$  is the central extension parameter for  $G$ . For  $G = SU(3)$  one obtains  $k_- = 1$  and  $c = 6(k+1)/(k+2)$ .  $H = U(1)$  corresponding to color hyper-charge and  $U(1)$  for  $N = 2$  algebra corresponds to color isospin. The group  $U(1)$  appearing in  $SU(3) \times U(1)$  might be interpreted in terms of fermion number or Kähler charge.
- (d) What looks somewhat puzzling is that the generators of second  $SU(2)$  algebra carry fermion number  $F = 4I_3$ . Note however that the sigma matrices of configuration space with fermion number  $\pm 2$  are non-vanishing since corresponding gamma matrices anti-commute. Second strange feature is that fermionic generators correspond to 3+3 super-coordinates of the flag-manifold  $SU(3)/U(1) \times U(1)$  plus 2 fermions and their conjugates. Perhaps the coset realization in  $CP_2$  degrees of freedom is not appropriate in TGD framework and that one should work directly with the realization based on second quantized induced spinor fields.

### 3.6.5 The interpretation of the critical dimension $D = 4$ and the objection related to the signature of the space-time metric

The first task is to show that  $D = 4$  ( $D = 8$ ) as critical dimension of target space for  $N = 2$  ( $N = 4$ ) super-conformal symmetry makes sense in TGD framework and that the signature  $(2,2)$  ( $(4,4)$ ) of the metric of the target space is not a fatal flaw. The lifting of TGD to twistor space seems the most promising manner to bring in  $(2,2)$  signature. One must of course remember that super-conformal symmetry in TGD sense differs from that in the standard sense so that one must be very cautious with comparisons at this level.

#### Space-time as a target space for partonic string world sheets?

Since partonic 2-surfaces are sub-manifolds of 4-D space-time surface, it would be natural to interpret space-time surface as the target space for  $N = 2$  super-conformal string theory so that space-time dimension would find a natural explanation. Different Bohr orbit like solutions of the classical field equations could be the TGD counterpart for the dynamic target space metric of M-theory. Since partonic two-surfaces belong to 3-surface  $X_V^3$ , the correlations caused by the vacuum functional would imply non-trivial scattering amplitudes with  $CP_2$  type extremals as pieces of  $X_V^3$  providing the correlate for virtual particles. Hence the theory could be physically realistic in TGD framework and would conform with perturbative character for the interactions of leptons.  $N = 2$  super-conformal theory would of course not describe everything. This algebra seems to be still too small and the question remains how the functional integral over the configuration space degrees of freedom is carried out. It will be found that  $N = 4$  super-conformal algebra results neatly when super Kac-Moody and super-symplectic degrees of freedom are combined.

#### The interpretation of the critical signature

The basic problem with this interpretation is that the signature of the induced metric cannot be  $(2,2)$  which is essential for obtaining the cancelation for  $N = 2$  SCA imbedded to  $N = 4$  SCA with critical dimension  $D = 8$  and signature  $(4,4)$ . When super-generators carry fermion number and do not reduce to ordinary gamma matrices for vanishing conformal weights, there is no need to pose the condition of the metric signature. The  $(4,4)$  signature of the target space metric is not so serious limitation as it looks if one is ready to consider the target space appearing in the calculation of N-point functions as a fictive notion.

The resolution of the problems relies on two observations.

1. The super Kac-Moody and super-symplectic Cartan algebras have dimension  $D = 2$  in both  $M^4$  and  $CP_2$  degrees of freedom giving total effective dimension  $D = 8$ .
2. The generalized coset construction to be discussed in the sequel allows to assign opposite signatures of metric to super Kac-Moody Cartan algebra and corresponding super-symplectic Cartan

algebra so that the desired signature (4,4) results. Altogether one has 8-D effective target space with signature (4,4) characterizing  $N = 4$  super-conformal topological strings. Hence the number of physical degrees of freedom is  $D_{phys} = 8$  as in super-string theory. Including the non-physical  $M^2$  degrees of freedom, one has critical dimension  $D = 10$ . If also the radial degree of freedom associated with  $\delta M_{\pm}^4$  is taken into account, one obtains  $D = 11$  as in M-theory.

### Small $N = 4$ SCA as sub-algebra of $N = 8$ SCA in TGD framework?

A possible interpretation of the small  $N = 4$  super-conformal algebra would be quaternionic sub-SCA of the non-associative octonionic SCA. The  $N = 4$  algebra associated with a fixed fermionic chirality would represent the fermionic counterpart for the restriction to the hyper-quaternionic submanifold of  $HO$  and  $N = 2$  algebra in the further restriction to commutative sub-manifold of  $HO$  so that this algebra would naturally appear at the parton level. Super-affine version of the quaternion algebra can be constructed straightforwardly as a special case of corresponding octonionic algebra [42]. The construction implies 4 fermion spin doublets corresponding and unit quaternion naturally corresponds to right handed neutrino spin doublet. The interpretation is as leptonic spinor fields appearing in Sugawara representation of Super Virasoro algebra.

A possible octonionic generalization of Super Virasoro algebra would involve 4 doublets  $G_{\pm}^{(i)}$ ,  $i = 1, \dots, 4$  of super-generators and their conjugates having interpretation as  $SO(8)$  spinor and its conjugate.  $G_{\pm}^{(i)}$  and their conjugates  $\overline{G}_{\pm}^{(i)}$  would anti-commute to  $SO(8)$  vector octet having an interpretation as a super-affine algebra defined by the octonionic units: this would conform nicely with  $SO(8)$  triality.

One could say that the energy momentum tensor  $T$  extends to an octonionic energy momentum tensor  $T$  as real component and affine generators as imaginary components: the real part would have conformal weight  $h = 2$  and imaginary parts conformal weight  $h = 1$  in the proposed constructions reflecting the special role of real numbers. The ordinary gamma matrices appearing in the expression of  $G$  in Sugawara construction should be represented by units of complexified octonions to achieve non-associativity. This construction would differ from that of [42] in that  $G$  fields would define an  $SO(8)$  octet in the proposed construction: HO-H duality would however suggest that these constructions are equivalent.

One can consider two possible interpretations for  $G_{\pm}^{(i)}$  and corresponding analogs of super Kac-Moody generators in TGD framework.

1. Leptonic right handed neutrino spinors correspond to  $G_{\pm}^{(i)}$  generating quaternionic units and quark like left-handed neutrino spinors with leptonic charges to the remaining non-associative octonionic units. The interpretation in terms of so called mirror symmetry would be natural. What is clear the direct sum of  $N = 4$  SCAs corresponding to the Kac-Moody group  $SU(2) \times SU(2)$  would be exact symmetry if free quarks and leptons carry integer charges. One might however hope of getting also  $N = 8$  super-conformal algebra. The problem with this interpretation is that  $SO(8)$  transformations would in general mix states with different fermion numbers. The only way out would be the allowance of mixtures of right-handed neutrinos of both chiralities and also of their conjugates which looks an ugly option.

In any case, the well-definedness of the fermion number would require the restriction to  $N = 4$  algebra. Obviously this restriction would be a super-symmetric version for the restriction to 4-D quaternionic- or co-quaternionic sub-manifold of  $H$ .

2. One can ask whether  $G_{\pm}^{(i)}$  and their conjugates could be interpreted as components of leptonic H-spinor field. This would give 4 doublets plus their conjugates and mean  $N = 16$  super-symmetry by generalizing the interpretation of  $N = 4$  super-symmetry. In this case fermion number conservation would not forbid the realization of  $SO(8)$  rotations. Super-conformal variant of complexified octonionic algebra obtained by adding a commuting imaginary unit would result. This option cannot be excluded since in TGD framework complexified octonions and quaternions play a key role. The fact that only right handed neutrinos generate associative super-symmetries would mean that the remaining components  $G_{\pm}^{(i)}$  and their conjugates could be used to construct physical states.  $N = 8$  super-symmetry would thus break down to small  $N = 4$  symmetry for purely number theoretic reasons and the geometry of  $CP_2$  would reflect this breaking.

The objection is that the remaining fermion doublets do not allow covariantly constant modes at the level of imbedding space. They could however allow these modes as induced H-spinors in some special cases which is however not enough and this option can be considered only if one accepts breaking of the super-conformal symmetry from beginning. The conclusion is that the  $N = 8$  or even  $N = 16$  algebra might appear as a spectrum generating algebra allowing elegant coding of the primary fermionic fields of the theory.

### 3.6.6 How could exotic Kac-Moody algebras emerge from Jones inclusions?

Also other Kac-Moody algebras than those associated with the basic symmetries of quantum TGD could emerge from Jones inclusions. The interpretation would be the TGD is able to mimic various conformal field theories. The discussion is restricted to Jones inclusions defined by discrete groups acting in  $CP_2$  degrees of freedom in TGD framework but the generalization to the case of  $M^4$  degrees of freedom is straightforward.

#### $\mathcal{M} : \mathcal{N} = \beta < 4$ case

The first situation corresponds to  $\mathcal{M} : \mathcal{N} = \beta < 4$  for which a finite subgroup  $G \subset SU(2)_L$  defines Jones inclusion  $\mathcal{N}^G \subset \mathcal{M}^G$ , with  $G$  commuting with the Clifford algebra elements creating physical states.  $\mathcal{N}$  corresponds to a subalgebra of the entire infinite-dimensional Clifford algebra  $Cl$  for which one 8-D Clifford algebra factor identifiable as Clifford algebra of the imbedding space is replaced with Clifford algebra of  $M^4$ .

Each  $M^4$  point corresponds to  $G$  orbit in  $CP_2$  and the order of maximal cyclic subgroup of  $G$  defines the integer  $n$  defining the quantum phase  $q = \exp(i\pi/n)$ . In this case the points in the covering give rise to a representation of  $G$  defining multiplets for Kac-Moody group  $\hat{G}$  assignable to  $G$  via the ADE diagram characterizing  $G$  using McKay correspondence. Partonic boundary component defines the Riemann surface in which the conformal field theory with Kac Moody symmetry is defined. The formula  $n = k + h_{\hat{G}}$  would determine the value of Kac-Moody central extension parameter  $k$ . The singletness of fermionic oscillator operators with respect to  $G$  would be compensated by the emergence of representations of  $G$  realized in the covering of  $M^4$ .

#### $\mathcal{M} : \mathcal{N} = \beta = 4$ case

Second situation corresponds to  $\beta = 4$ . In this case the inclusions are classified by extended ADE diagrams assignable to Kac Moody algebras. The interpretation  $n = k + h_G$  assigning the quantum phase to  $SU(2)$  Kac Moody algebra corresponds to the Jones inclusion  $\mathcal{N}^{\hat{G}} \subset \mathcal{M}^{\hat{G}}$  of configuration space spinors for  $\hat{G} = SU(2)_L$  with index  $\mathcal{M} : \mathcal{N} = 4$  and trivial quantum phase  $q = 1$ . The Clifford algebra elements in question would be products of fermionic oscillator operators having vanishing  $SU(2)_L$  quantum numbers but arbitrary  $U(1)_R$  quantum numbers if the identification  $\hat{G} = SU(2)_L$  is correct. Thus only right handed fermions carrying homological magnetic charge would be allowed and obviously these fermions must behave like massless particles so that  $\beta < 4$  could be interpreted in terms of massivation. The ends of cosmic strings  $X^2 \times S^2 \subset M^4 \times CP_2$  would represent an example of this phase having only Abelian electro-weak interactions.

According to the proposal of [83] the finite subgroup  $G \subset SU(2)$  defining the quantum phase emerges from the effective decomposition of the geodesic sphere  $S^2 \subset CP_2$  to a lattice having  $S^2/G$  as the unit cell. The discrete wave functions in the lattice would give rise to  $SU(2)_L \supset G$ -multiplets defining the Kac Moody representations and  $S^2/G$  would represent the 2-dimensional Riemann surface in which the conformal theory in question would be defined. Quantum phases would correspond to the holonomy of  $S^2/G$ . Therefore the singletness in fermionic degrees of freedom would be compensated by the emergence of  $G$ -multiplets in lattice degrees of freedom.

### 3.6.7 Are both quark and lepton like chiralities needed/possible?

Before the formulation of quantum TGD based on the identification of light-like 3-surfaces as a representation of parton orbits emerged, one had to consider two different physical realizations of  $N = 4$  super-conformal symmetry. The original option for which leptons and quarks correspond to different

H-chiralities of the induced spinor field is consistent with the partonic picture and definitely favored so that this subsection can be regarded as an interesting side track.

On the other hand, only lepton like chiralities are needed if one can accept a possible instability of proton. This option is mathematically the minimal but it is not at all clear whether the  $SU(3)$  associated with  $A_2$  characterizing Jones inclusion can correspond to color  $SU(3)$ . One can go further and ask whether it is even possible to have both chiralities.

### Option I: $N = 4$ SCA and fractionally charged quarks

Quarks generate super-affinization of quaternions, which involves in no manner the Kähler charge of quarks but for fractional quark charges only SCA in the leptonic sector is possible since covariant constancy fails. At the fundamental level one the spectrum generating algebra for quarks would thus emerge and they could appear as primary fields of  $N = 4$  conformal field theory. Configuration space gamma matrices could be uniquely constructed in terms of the leptonic oscillator operators since they could correspond to super-generators of super-Kac-Moody algebra. Furthermore, if the solutions of the modified Dirac equation generate super-conformal symmetries, it might be possible to have super-conformal symmetry acting also in the quark sector.

A possible manner to understand quarks is as a phase with  $N = 2$  super-conformal symmetry with  $U(1)$  Kac-Moody algebra. Using just the requirement that the charges in the  $k = 1, c = 1$  phase for  $N = 2$  super-conformal symmetry are proportional to factor  $1/3$ , one can conclude that this phase can contain ordinary quarks and fractionally charged leptons whose charge results from the phase factors depending on the sheet of the 3-fold covering of  $CP_2$ . Also phases with  $n > 3$  are possible and require fractionization of both quark and lepton charges. For quarks the condition  $n \bmod 3 = 0$  must be satisfied in this case.

### Option II: $N = 4$ SCA and quarks as fractionally charged leptons

For the simplest option realizing  $N = 4$  SCA only leptons are fundamental particles and quarks would be leptons in the anyonic  $k = 1, c = 1, n = 3$  phase of the theory. This option would resolve elegantly the problem whether one should construct configuration space gamma matrices using leptonic or quark like gamma matrices. Fermion number fractionization might in principle allow the decay of proton to positron plus pion as in GUTs. This decay might be however excluded for purely mathematical reasons. Indeed, the worlds corresponding to different values of  $q = \exp(i\pi/n)$  could communicate only via exchanges of bosons having a vanishing fermion number.

In the interactions between leptons and quarks the gauge bosons would penetrate to the space-time sheets corresponding to the hadrons. In  $k = 1$  phase weak interactions would become strong since arbitrarily high parton vertices would become possible and strong interactions could be simply electro-weak interactions which have become strong in the anyonic phases as HO-H duality strongly suggests [72]. By the same duality strong interactions would have dual descriptions as non-perturbative electro-weak interactions and as color interactions.

There are objections against this picture.

1. p-Adic mass calculations rely strongly on the fact that free quarks have fractional charges and move in  $CP_2$  partial waves and it would be pity to lose the nice results of these calculations.
2. This option requires that the  $SU(3)$  associated with  $A_2$  characterizing  $n = 3$  Jones inclusion produces states equivalent with triality 1 partial waves for quarks in order to reproduce the results of p-adic mass calculations. This does not seem to be the case although one can understand how effective triality 1 states result by considering 3-fold coverings of  $CP_2$  points by  $M^4$  points defined by the space-time surfaces in question. The essential point is that  $2\pi$  rotation in  $CP_2$  phase angle leads to a different  $M^4$  point than original and  $6\pi$  rotation brings back to the original point. This might not be however enough.

### Option III: Integer charged leptons and quarks

For the third option  $N = 4$  superconformal symmetry can be realized in both lepton and quark sector but by the previous arguments  $N = 8$  SCA is not possible. Both imbedding space chiralities would possess leptonic quantum numbers and would be allowed as fundamental fermions. At the level of

configuration space the choice of either chirality to realize the configuration space gamma matrices would correspond to the selection of quark or lepton like chirality. This presumably leads to problems with continuity unless the two chiralities correspond to completely disjoint parts of the configuration space.

Finding an explanation for the experimental absence of the free integer charged quarks is the basic challenge met by the advocate of integer charged free quarks. A possible explanation could rely on the fact that also gauge bosons would be doubled. There are two options.

1. The two kinds of gauge bosons couple to only single H-chirality. One can indeed argue that if one allows at given space-time sheet only quark or lepton like chirality then it is not possible to have quantum superpositions of fermion-antifermion pairs of opposite chiralities at a given space-time sheet so that bosons would couple to either quark or lepton like chirality. This would mean that leptons and free quarks would have no electro-weak interactions. Even gravitational interaction would be absent. This would however imply that ordinary hadrons should consist of fractionally charged leptons so that second chirality would not appear at all in known or experimentally testable physics.
2. An option allowing ordinary hadrons to consist of genuine quarks is that the couplings of these two bosons are vectorial and axial with respect to H-chirality (the simplest option) and left-right permutation occurs for electro-weak couplings. This would induce a breaking of the chiral symmetry at the level of  $H$  just as the ordinary weak interactions do at the level of  $M^4$  and the masses of integer charged quarks could differ from those of genuine leptons.

If H-vectorial and H-axial gauge bosons have same coupling strengths and masses, the diagrams representing exchanges of vectorial and axial gauge bosons would interfere to zero so that free leptons and quarks would not see each other at all. This should be true in  $(c = 6, n = \infty)$  phase. This could be the case for even gravitons. On the other hand, the interactions between free quarks and hadronic quarks would be possible and would make free quarks visible so that this option seems to produce more problems than to solve them.

In  $(c = 1, k = 1, n = 3)$  phase leptons and quarks should interact and this is achieved if the masses and couplings of H-vectorial or H-axial electro-weak bosons are different in this phase. It is far from clear whether this picture can be consistent with what is known about lepton-hadron interactions.

### Common features of the options I and II

Consider now the common features of options I and II which on basis of the previous arguments look the only realistic ones.

1. For both options only  $c = 6$  would correspond to the integer charged world and hadrons would be represented by primary fields in this phase. Hadrons would correspond to  $k = 1, c = 1$  representation for the reduced  $N = 2$  conformal symmetry. Elementary fermions inside hadrons would correspond to the lowest  $n = 3$  Jones inclusion having  $k = 1$  which indeed corresponds to  $A_2$  Dynkin diagram and thus  $SU(3)$ . Ordinary leptons and quarks (whether fractionally charged leptons or not) would thus live in different  $CP_2$ :s (recall that the generalized imbedding space has fan like structure with different  $M^4 \times CP_2$ :s meeting along  $M^4$ ). This would explain the impossibility to observe free fractionally charged quarks.

Anyonic color triplet leptons and fractionally charged quarks would live at the three branches of the covering of  $CP_2$ . The observation that leptonic spinors possess anomalous color hyper-charge identifiable as lepton number and that this charge corresponds to weak hyper-charge explains why the electromagnetic charge of lepton can be fractionized but not its weak isospin.

2. An infinite hierarchy of states with fractionally charged fermions would be predicted with charges of form  $m/n$  appearing as dark matter so that the counterparts of quarks would represent only the simplest Jones inclusion. For quarks one would have  $n = k + 2 \pmod{3} = 0$ . The invisibility of free fractionally charged fermions would be equivalent with the invisibility of dark matter with scaled up value of  $CP_2$  Planck constant in both options. For option I the phase transition transforming leptons to quarks and vice versa would require three leptons per quark in order to achieve conservation of fermion number.

3. I have already proposed the idea that antimatter is dark matter [64] and the obvious possibility is that matter-antimatter asymmetry corresponds to the transformation of  $n$  anti-leptons to baryon like entities consisting of  $n$  fractionally charged leptons inside which they behave like dark matter. For option II anti-leptons would correspond to baryons and antimatter would be directly observable.

### Lepton-hadron interactions for various options

The interactions between leptons and quarks and their fractionally charged counterparts can be also understood. The following arguments favor option I and II over option III.

1. Quite generally, the  $CP_2$  type extremal representing virtual electroweak boson must tunnel between two  $CP_2$ :s in the fan formed by  $M^4 \times CP_2$ :s glued together along  $M^4$  and in this process transform to hadronic weak boson. This means that also strong interactions between leptons and hadrons are generated but these interactions could be seen as secondary strong interactions occurring inside hadron in any case via the decay of photon to quark pair in turn interacting strongly with other partons.

The coupling constant characterizing the tunneling must be such that correct results for electro-weak interactions between quarks and leptons are obtained in the lowest order. The notion of vector meson dominance meaning that weak bosons transform to strongly interacting mesons with same electro-weak quantum numbers conforms with this picture.

2. For option II the lowest order contributions to electro-weak interactions inside hadrons could be identified as direct lepton-quark interaction and there are no obvious problems involved.
3. For option I gauge bosons must couple to both chiralities in order to make possible the interaction between leptons and quarks. This is possible and the prediction is that gauge bosons should appear as H-vectorial and H-axial variants or their mixtures. A doubling of ordinary vector bosons is predicted. This however does not have any dramatic effects if ordinary gauge bosons correspond to H-vectorial gauge bosons and axial ones are heavy enough. Nothing new is predicted for situation in which leptons do not penetrate inside hadrons. A lepton penetrating into hadron must suffer an anyonization and becomes fractionally charged and decomposes into a triplet of leptons with fractional fermion number. This implies that lepton has strong interactions with quarks.
4. For option III the understanding of the interactions between leptons and hadrons consisting of genuine quarks becomes a highly non-trivial problem for several reasons.
  - (a) The hypothesis that only fermions of fixed chirality are possible at a given space-time sheet would exclude the possibility of non-trivial interactions between leptons and hadrons. If one gives up this assumption the doubling of electro-weak interactions gives however hopes for describing the interactions. The non-observability of free quarks in  $c = 6$  phase is guaranteed if the masses and couplings of H-vectorial and -axial bosons are identical in this phase. To have interactions in  $k = 1$  phase, these couplings and masses must be different. This would look nice at first since one could hope of explaining strong interactions in terms of this symmetry breaking.
  - (b) However, if H-vectorial and -axial couplings are different inside hadrons, the expectation is that the resulting low energy lepton-hadron electro-weak interactions are quite different from what they are known to be experimentally. The most natural guess suggested by the masslessness of gluons is that all (say) H-axial weak bosons are massless inside hadrons. However, if both H-vectorial and -axial photons are massless there would be no electromagnetic coupling between quarks and leptons and hadrons would look like em neutral particles at low energies.
  - (c) The coupling constant characterizing this tunneling should have a value making possible to reproduce the standard model picture about lepton-quark scattering. If only (say) H-vectorial ew bosons can tunnel to hadron and the amplitude  $A$  for the tunneling equals to  $A = 2$  it gives amplitude equal to  $V - V + A - A = 2V - V$  between leptons then quark-lepton scattering can be reproduced correctly. This kind of transformation is however not described by a unitary S-matrix.

### New view about strong interactions

The proposed picture suggests the identification of strong interactions as electro-weak interactions which have become strong in  $k = 1$  anyonic phase. HO-H duality leads to the same proposal [72].

#### 1. Strong interactions as electro-weak interactions in a non-perturbative phase?

Consider the situation in  $k = 1, c = 1$  hadronic sector at the sheets of 3-fold covering of  $M^4$  at which fractionally charged fermions reside. It is an experimental fact that their electro-weak interactions allow a perturbative description. One would however obtain all higher order stringy diagrams allowed by rational conformal field theories. This looks like a paradox but one can consider the possibility that electro-weak interactions give rise also to strong interactions.

For all options the non-vanishing of higher n-point functions in  $k = 1, c = 1$  phase would give rise to an additional non-perturbative contribution to electro-weak interactions having a natural interpretation as strong interactions. Weak isospin and hypercharge could be interpreted also as strong isospin and hyper-charge as is indeed found to be the case experimentally. Conserved vector current hypothesis and partially conserved axial current hypothesis of the old-fashioned hadron physics indeed support this kind of duality.

For option I one can consider the possibility that H-axial bosons define the dual counterparts of gluons and are massless. H-axial electro-weak interactions would give rise also to strong interactions between quarks and anyonic leptons inside hadrons. The idea that color interactions have dual description as H-axial electro-weak interactions is admittedly rather seductive.

For option III different masses and couplings of H-vectorial and H-axial bosons inside hadrons would allow to interpret strong interactions as (say) axial weak interactions. The simplest option would be that H-axial weak bosons are massless so that strong isospin and hyper-charge would correspond to their H-axial variants. The problems relating to the interaction between leptons and hadrons have been already mentioned: for instance, em interactions between leptons and quarks would vanish if they vanish in  $c = 6$  phase.

#### 2. HO-H duality and equivalence with QCD type description

One can ask how QCD type description emerges if strong interactions are non-perturbative electro-weak interactions (option II) or H-axial counterparts of them (option I). In [72] I have discussed a possible duality suggested by the fact that space-time surfaces can be regarded as 4-surfaces in hyper-octonionic  $H = M^8$  or in  $H = M^4 \times CP_2$ . In the first picture spinors would be octonionic spinors and correspond to two leptonic singlets and color triplet and its conjugate: there would be no trace about spin and electro-weak quantum numbers besides electro-weak hyper charge.

The absence of spin in HO description could provide a resolution of the spin puzzle of proton (quarks do not seem to contribute to the spin of proton). In H picture spinors would carry only electro-weak quantum numbers and spin besides anomalous color hypercharge. The question is whether quark like spinors in HO are equivalent with leptonic spinors in H and whether the descriptions based on (possibly) doubled electro-weak and color interactions are equivalent for many-sheeted coverings.

## 3.7 Generalization of the notion of imbedding space

This section summarizes the attempt to understand how the hierarchy of Planck constants is realized at the level of imbedding space and what quantum criticality for phase transitions changing Planck constant means.

### 3.7.1 Generalization of the notion of imbedding space

The original idea was that the proposed modification of the imbedding space could explain naturally phenomena like quantum Hall effect involving fractionization of quantum numbers like spin and charge. This does not however seem to be the case.  $G_a \times G_b$  implies just the opposite if these quantum numbers are assigned with the symmetries of the imbedding space. For instance, quantization unit for orbital angular momentum becomes  $n_a$  where  $Z_{n_a}$  is the maximal cyclic subgroup of  $G_a$ .

One can however imagine of obtaining fractionization at the level of imbedding space for space-time sheets, which are analogous to multi-sheeted Riemann surfaces (say Riemann surfaces associated with  $z^{1/n}$  since the rotation by  $2\pi$  understood as a homotopy of  $M^4$  lifted to the space-time sheet

is a non-closed curve. Continuity requirement indeed allows fractionization of the orbital quantum numbers and color in this kind of situation.

### Both covering spaces and factor spaces are possible

The observation above stimulates the question whether it might be possible in some sense to replace  $H$  or its factors by their multiple coverings.

1. This is certainly not possible for  $M^4$ ,  $CP_2$ , or  $H$  since their fundamental groups are trivial. On the other hand, the fixing of quantization axes implies a selection of the sub-space  $H_4 = M^2 \times S^2 \subset M^4 \times CP_2$ , where  $S^2$  is a geodesic sphere of  $CP_2$ .  $\hat{M}^4 = M^4 \setminus M^2$  and  $\hat{CP}_2 = CP_2 \setminus S^2$  have fundamental group  $Z$  since the codimension of the excluded sub-manifold is equal to two and homotopically the situation is like that for a punctured plane. The exclusion of these sub-manifolds defined by the choice of quantization axes could naturally give rise to the desired situation.
2.  $H_4$  represents a straight cosmic string. Quantum field theory phase corresponds to Jones inclusions with Jones index  $\mathcal{M} : \mathcal{N} < 4$ . Stringy phase would by previous arguments correspond to  $\mathcal{M} : \mathcal{N} = 4$ . Also these Jones inclusions are labeled by finite subgroups of  $SO(3)$  and thus by  $Z_n$  identified as a maximal Abelian subgroup.

One can argue that cosmic strings are not allowed in QFT phase. This would encourage the replacement  $\hat{M}^4 \times \hat{CP}_2$  implying that surfaces in  $M^4 \times S^2$  and  $M^2 \times CP_2$  are not allowed. In particular, cosmic strings and  $CP_2$  type extremals with  $M^4$  projection in  $M^2$  and thus light-like geodesic without zitterbewegung essential for massivation are forbidden. This brings in mind instability of Higgs=0 phase.

3. The covering spaces in question would correspond to the Cartesian products  $\hat{M}^4_{n_a} \times \hat{CP}_{2n_b}$  of the covering spaces of  $\hat{M}^4$  and  $\hat{CP}_2$  by  $Z_{n_a}$  and  $Z_{n_b}$  with fundamental group is  $Z_{n_a} \times Z_{n_b}$ . One can also consider extension by replacing  $M^2$  and  $S^2$  with its orbit under  $G_a$  (say tetrahedral, octahedral, or icosahedral group). The resulting space will be denoted by  $\hat{M}^4 \hat{\times} G_a$  resp.  $\hat{CP}_2 \hat{\times} G_b$ .
4. One expects the discrete subgroups of  $SU(2)$  emerge naturally in this framework if one allows the action of these groups on the singular sub-manifolds  $M^2$  or  $S^2$ . This would replace the singular manifold with a set of its rotated copies in the case that the subgroups have genuinely 3-dimensional action (the subgroups which corresponds to exceptional groups in the ADE correspondence). For instance, in the case of  $M^2$  the quantization axes for angular momentum would be replaced by the set of quantization axes going through the vertices of tetrahedron, octahedron, or icosahedron. This would bring non-commutative homotopy groups into the picture in a natural manner.
5. Also the orbifolds  $\hat{M}^4/G_a \times \hat{CP}_2/G_b$  can be allowed as also the spaces  $\hat{M}^4/G_a \times (\hat{CP}_2 \hat{\times} G_b)$  and  $(\hat{M}^4 \hat{\times} G_a) \times \hat{CP}_2/G_b$ . Hence the previous framework would generalize considerably by the allowance of both coset spaces and covering spaces.

There are several non-trivial questions related to the details of the gluing procedure and phase transition as motion of partonic 2-surface from one sector of the imbedding space to another one.

1. How the gluing of copies of imbedding space at  $M^2 \times CP_2$  takes place? It would seem that the covariant metric of  $M^4$  factor proportional to  $\hbar^2$  must be discontinuous at the singular manifold since only in this manner the idea about different scaling factor of  $M^4$  metric can make sense. This is consistent with the identical vanishing of Chern-Simons action in  $M^2 \times S^2$ .
2. One might worry whether the phase transition changing Planck constant means an instantaneous change of the size of partonic 2-surface in  $M^4$  degrees of freedom. This is not the case. Light-likeness in  $M^2 \times S^2$  makes sense only for surfaces  $X^1 \times D^2 \subset M^2 \times S^2$ , where  $X^1$  is light-like geodesic. The requirement that the partonic 2-surface  $X^2$  moving from one sector of  $H$  to another one is light-like at  $M^2 \times S^2$  irrespective of the value of Planck constant requires that  $X^2$  has single point of  $M^2$  as  $M^2$  projection. Hence no sudden change of the size  $X^2$  occurs.

3. A natural question is whether the phase transition changing the value of Planck constant can occur purely classically or whether it is analogous to quantum tunneling. Classical non-vacuum extremals of Chern-Simons action have two-dimensional  $CP_2$  projection to homologically non-trivial geodesic sphere  $S_I^2$ . The deformation of the entire  $S_I^2$  to homologically trivial geodesic sphere  $S_{II}^2$  is not possible so that only combinations of partonic 2-surfaces with vanishing total homology charge (Kähler magnetic charge) can in principle move from sector to another one, and this process involves fusion of these 2-surfaces such that  $CP_2$  projection becomes single homologically trivial 2-surface. A piece of a non-trivial geodesic sphere  $S_I^2$  of  $CP_2$  can be deformed to that of  $S_{II}^2$  using 2-dimensional homotopy flattening the piece of  $S^2$  to curve. If this homotopy cannot be chosen to be light-like, the phase transitions changing Planck constant take place only via quantum tunneling. Obviously the notions of light-like homotopies (cobordisms) and classical light-like homotopies (cobordisms) are very relevant for the understanding of phase transitions changing Planck constant.

### Do factor spaces and coverings correspond to the two kinds of Jones inclusions?

What could be the interpretation of these two kinds of spaces?

1. Jones inclusions appear in two varieties corresponding to  $\mathcal{M} : \mathcal{N} < 4$  and  $\mathcal{M} : \mathcal{N} = 4$  and one can assign a hierarchy of subgroups of  $SU(2)$  with both of them. In particular, their maximal Abelian subgroups  $Z_n$  label these inclusions. The interpretation of  $Z_n$  as invariance group is natural for  $\mathcal{M} : \mathcal{N} < 4$  and it naturally corresponds to the coset spaces. For  $\mathcal{M} : \mathcal{N} = 4$  the interpretation of  $Z_n$  has remained open. Obviously the interpretation of  $Z_n$  as the homology group defining covering would be natural.
2.  $\mathcal{M} : \mathcal{N} = 4$  should correspond to the allowance of cosmic strings and other analogous objects. Does the introduction of the covering spaces bring in cosmic strings in some controlled manner? Formally the subgroup of  $SU(2)$  defining the inclusion is  $SU(2)$  would mean that states are  $SU(2)$  singlets which is something non-physical. For covering spaces one would however obtain the degrees of freedom associated with the discrete fiber and the degrees of freedom in question would not disappear completely and would be characterized by the discrete subgroup of  $SU(2)$ .  
For anyons the non-trivial homotopy of plane brings in non-trivial connection with a flat curvature and the non-trivial dynamics of topological QFTs. Also now one might expect similar non-trivial contribution to appear in the spinor connection of  $\hat{M}^2 \hat{\times} G_a$  and  $\hat{CP}_2 \hat{\times} G_b$ . In conformal field theory models non-trivial monodromy would correspond to the presence of punctures in plane.
3. For factor spaces the unit for quantum numbers like orbital angular momentum is multiplied by  $n_a$  resp.  $n_b$  and for coverings it is divided by this number. These two kind of spaces are in a well defined sense obtained by multiplying and dividing the factors of  $\hat{H}$  by  $G_a$  resp.  $G_b$  and multiplication and division are expected to relate to Jones inclusions with  $\mathcal{M} : \mathcal{N} < 4$  and  $\mathcal{M} : \mathcal{N} = 4$ , which both are labeled by a subset of discrete subgroups of  $SU(2)$ .
4. The discrete subgroups of  $SU(2)$  with fixed quantization axes possess a well defined multiplication with product defined as the group generated by forming all possible products of group elements as elements of  $SU(2)$ . This product is commutative and all elements are idempotent and thus analogous to projectors. Trivial group  $G_1$ , two-element group  $G_2$  consisting of reflection and identity, the cyclic groups  $Z_p$ ,  $p$  prime, and tetrahedral, octahedral, and icosahedral groups are the generators of this algebra.

By commutativity one can regard this algebra as an 11-dimensional module having natural numbers as coefficients ("rig"). The trivial group  $G_1$ , two-element group  $G_2$  generated by reflection, and tetrahedral, octahedral, and icosahedral groups define 5 generating elements for this algebra. The products of groups other than trivial group define 10 units for this algebra so that there are 11 units altogether. The groups  $Z_p$  generate a structure analogous to natural numbers acting as analog of coefficients of this structure. Clearly, one has effectively 11-dimensional commutative algebra in 1-1 correspondence with the 11-dimensional "half-lattice"  $N^{11}$  ( $N$  denotes natural numbers). Leaving away reflections, one obtains  $N^7$ . The projector representation suggests a connection with Jones inclusions. An interesting question concerns the possible Jones

inclusions assignable to the subgroups containing infinitely manner elements. Reader has of course already asked whether dimensions 11, 7 and their difference 4 might relate somehow to the mathematical structures of M-theory with 7 compactified dimensions. One could introduce generalized configuration space spinor fields in the configuration space labeled by sectors of  $H$  with given quantization axes. By introducing Fourier transform in  $N^{11}$  one would formally obtain an infinite-component field in 11-D space.

5. How do the Planck constants associated with factors and coverings relate? One might argue that Planck constant defines a homomorphism respecting the multiplication and division (when possible) by  $G_i$ . If so, then Planck constant in units of  $\hbar_0$  would be equal to  $n_a/n_b$  for  $\hat{H}/G_a \times G_b$  option and  $n_b/n_a$  for  $\hat{H} \hat{\times} (G_a \times G_b)$  with obvious formulas for hybrid cases. This option would put  $M^4$  and  $CP_2$  in a very symmetric role and allow much more flexibility in the identification of symmetries associated with large Planck constant phases.

### 3.7.2 Phase transitions changing the value of Planck constant

There are two basic kinds of phase transitions changing the value of Planck constant inducing a leakage between sectors of imbedding space. There are three cases to consider corresponding to

1. leakage in  $M^4$  degrees of freedom changing  $G_a$ : the critical manifold is  $R_+ \times CP_2$ ;
2. leakage in  $CP_2$  degrees of freedom changing  $G_b$ : the critical manifold is  $\delta M_+^4 \times S_{II}^2$ ;
3. leakage in both degrees of freedom changing both  $G_a$  and  $G_b$ : the critical manifold is  $R_+ \times S_{II}^2$ . This is the non-generic case

For transitions of type 2) and 3)  $X^2$  must go through vacuum extremal in the classical picture about transition.

Covering space can also change to a factor space in both degrees of freedom or vice versa and in this case  $G$  can remain unchanged as a group although its interpretation changes.

The phase transitions satisfy also strong group theoretical constraints. For the transition  $G_1 \rightarrow G_2$  either  $G_1 \subset G_2$  or  $G_2 \subset G_1$  must hold true. For maximal cyclic subgroups  $Z_n$  associated with quantization axes this means that  $n_1$  must divide  $n_2$  or vice versa. Hence a nice number theoretic view about transitions emerges.

One can classify the points of critical manifold according to the degree of criticality. Obviously the maximally critical points corresponds to fixed points of  $G_i$  that its points  $z = 0, \infty$  of the spheres  $S_r^2$  and  $S_{II}^2$ . In the case of  $\delta M_+^4$  the points  $z = 0$  and  $\infty$  correspond to the light-like rays  $R_+$  in opposite directions. This ray would define the quantization direction of angular momentum. Quantum phase transitions changing the value of  $M^4$  Planck constant could occur anywhere along this ray (partonic 2-surface would have 1-D projection along this ray). At the level of cosmology this would bring in a preferred direction. Light-cone dip, the counterpart of big bang, is the maximally quantum critical point since it remains invariant under entire group  $SO(3, 1)$ .

Interesting questions relate to the groups generated by finite discrete subgroups of  $SO(3)$ . As noticed the groups generated as products of groups leaving  $R_+$  invariant and three genuinely 3-D groups are infinite discrete subgroups of  $SO(3)$  and could also define Jones inclusions. In this case orbifold is replaced with orbifold containing infinite number of rotated versions of  $R_+$ . These phases could be important in elementary particle length scales or in early cosmology.

### 3.7.3 Could the dynamics of Kähler action predict the hierarchy of Planck constants?

The original justification for the hierarchy of Planck constants came from the indications that Planck constant could have large values in both astrophysical systems involving dark matter and also in biology. The realization of the hierarchy in terms of the singular coverings and possibly also factor spaces of  $CD$  and  $CP_2$  emerged from consistency conditions. The formula for the Planck constant involves heuristic guess work and physical plausibility arguments. There are good arguments in favor of the hypothesis that only coverings are possible. Only a finite number of pages of the Big Book correspond to a given value of Planck constant, biological evolution corresponds to a gradual

dispersion to the pages of the Big Book with larger Planck constant, and a connection with the hierarchy of infinite primes and p-adicization program based on the mathematical realization of finite measurement resolution emerges.

One can however ask whether this hierarchy could emerge directly from the basic quantum TGD rather than as a separate hypothesis. The following arguments suggest that this might be possible. One finds also a precise geometric interpretation of preferred extremal property interpreted as criticality in zero energy ontology.

### 1-1 correspondence between canonical momentum densities and time derivatives fails for Kähler action

The basic motivation for the geometrization program was the observation that canonical quantization for TGD fails. To see what is involved let us try to perform a canonical quantization in zero energy ontology at the 3-D surfaces located at the light-like boundaries of  $CD \times CP_2$ .

1. In canonical quantization canonical momentum densities  $\pi_k^0 \equiv \pi_k = \partial L_K / \partial(\partial_0 h^k)$ , where  $\partial_0 h^k$  denotes the time derivative of imbedding space coordinate, are the physically natural quantities in terms of which to fix the initial values: once their value distribution is fixed also conserved charges are fixed. Also the weak form of electric-magnetic duality given by  $J^{03} \sqrt{g_4} = 4\pi\alpha_K J_{12}$  and a mild generalization of this condition to be discussed below can be interpreted as a manner to fix the values of conserved gauge charges (not Noether charges) to their quantized values since Kähler magnetic flux equals to the integer giving the homology class of the (wormhole) throat. This condition alone need not characterize criticality, which requires an infinite number of deformations of  $X^4$  for which the second variation of the Kähler action vanishes and implies infinite number conserved charges. This in fact gives hopes of replacing  $\pi_k$  with these conserved Noether charges.
2. Canonical quantization requires that  $\partial_0 h^k$  in the energy is expressed in terms of  $\pi_k$ . The equation defining  $\pi_k$  in terms of  $\partial_0 h^k$  is however highly non-linear although algebraic. By taking squares the equations reduces to equations for rational functions of  $\partial_0 h^k$ .  $\partial_0 h^k$  appears in contravariant and covariant metric at most quadratically and in the induced Kähler electric field linearly and by multiplying the equations by  $\det(g_4)^3$  one can transform the equations to a polynomial form so that in principle  $\partial_0 h^k$  can be obtained as a solution of polynomial equations.
3. One can always eliminate one half of the coordinates by choosing 4 imbedding space coordinates as the coordinates of the spacetime surface so that the initial value conditions reduce to those for the canonical momentum densities associated with the remaining four coordinates. For instance, for space-time surfaces representable as map  $M^4 \rightarrow CP_2$   $M^4$  coordinates are natural and the time derivatives  $\partial_0 s^k$  of  $CP_2$  coordinates are multivalued. One would obtain four polynomial equations with  $\partial_0 s^k$  as unknowns. In regions where  $CP_2$  projection is 4-dimensional -in particular for the deformations of  $CP_2$  vacuum extremals the natural coordinates are  $CP_2$  coordinates and one can regard  $\partial_0 m^k$  as unknowns. For the deformations of cosmic strings, which are of form  $X^4 = X^2 \times Y^2 \subset M^4 \times CP_2$ , one can use coordinates of  $M^2 \times S^2$ , where  $S^2$  is geodesic sphere as natural coordinates and regard as unknowns  $E^2$  coordinates and remaining  $CP_2$  coordinates.
4. One can imagine solving one of the four polynomials equations for time derivatives in terms of other obtaining  $N$  roots. Then one would substitute these roots to the remaining 3 conditions to obtain algebraic equations from which one solves then second variable. Obviously situation is very complex without additional symmetries. The criticality of the preferred extremals might however give additional conditions allowing simplifications. The reasons for giving up the canonical quantization program was following. For the vacuum extremals of Kähler action  $\pi_k$  are however identically vanishing and this means that there is an infinite number of value distributions for  $\partial_0 h^k$ . For small deformations of vacuum extremals one might however hope a finite number of solutions to the conditions and thus finite number of space-time surfaces carrying same conserved charges.

If one assumes that physics is characterized by the values of the conserved charges one must treat the the many-valuedness of  $\partial_0 h^k$ . The most obvious guess is that one should replace the space of space-like 4-surfaces corresponding to different roots  $\partial_0 h^k = F^k(\pi_l)$  with four-surfaces in the covering

space of  $CD \times CP_2$  corresponding to different branches of the many-valued function  $\partial_0 h^k = F(\pi_i)$  co-inciding at the ends of  $CD$ .

**Do the coverings forces by the many-valuedness of  $\partial_0 h^k$  correspond to the coverings associated with the hierarchy of Planck constants?**

The obvious question is whether this covering space actually corresponds to the covering spaces associated with the hierarchy of Planck constants. This would conform with quantum classical correspondence. The hierarchy of Planck constants and hierarchy of covering spaces was introduced to cure the failure of the perturbation theory at quantum level. At classical level the multivaluedness of  $\partial_0 h^k$  means a failure of perturbative canonical quantization and forces the introduction of the covering spaces. The interpretation would be that when the density of matter becomes critical the space-time surface splits to several branches so that the density at each branches is sub-critical. It is of course not at all obvious whether the proposed structure of the Big Book is really consistent with this hypothesis and one also consider modifications of this structure if necessary. The manner to proceed is by making questions.

1. The proposed picture would give only single integer characterizing the covering. Two integers assignable to  $CD$  and  $CP_2$  degrees of freedom are however needed. How these two coverings could emerge?
  - (a) One should fix also the values of  $\pi_k^n = \partial L_K / \partial h_n^k$ , where  $n$  refers to space-like normal coordinate at the wormhole throats. If one requires that charges do not flow between regions with different signatures of the metric the natural condition is  $\pi_k^n = 0$  and allows also multi-valued solution. Since wormhole throats carry magnetic charge and since weak form of electric-magnetic duality is assumed, one can assume that  $CP_2$  projection is four-dimensional so that one can use  $CP_2$  coordinates and regard  $\partial_0 m^k$  as un-knows. The basic idea about topological condensation in turn suggests that  $M^4$  projection can be assumed to be 4-D inside space-like 3-surfaces so that here  $\partial_0 s^k$  are the unknowns. At partonic 2-surfaces one would have conditions for both  $\pi_k^0$  and  $\pi_k^n$ . One might hope that the numbers of solutions are finite for preferred extremals because of their symmetries and given by  $n_a$  for  $\partial_0 m^k$  and by  $n_b$  for  $\partial_0 s^k$ . The optimistic guess is that  $n_a$  and  $n_b$  corresponds to the numbers of sheets for singular coverings of  $CD$  and  $CP_2$ . The covering could be visualized as replacement of space-time surfaces with space-time surfaces which have  $n_a n_b$  branches.  $n_b$  branches would degenerate to single branch at the ends of diagrams of the generated Feynman graph and  $n_a$  branches would degenerate to single one at wormhole throats.
  - (b) This picture is not quite correct yet. The fixing of  $\pi_k^0$  and  $\pi_k^n$  should relate closely to the effective 2-dimensionality as an additional condition perhaps crucial for criticality. One could argue that both  $\pi_k^0$  and  $\pi_k^n$  must be fixed at  $X^3$  and  $X_l^3$  in order to effectively bring in dynamics in two directions so that  $X^3$  could be interpreted as a an orbit of partonic 2-surface in space-like direction and  $X_l^3$  as its orbit in light-like direction. The additional conditions could be seen as gauge conditions made possible by symplectic and Kac-Moody type conformal symmetries. The conditions for  $\pi_k^0$  would give  $n_b$  branches in  $CP_2$  degrees of freedom and the conditions for  $\pi_k^n$  would split each of these branches to  $n_a$  branches.
  - (c) The existence of these two kinds of conserved charges (possibly vanishing for  $\pi_k^n$ ) could relate also very closely to the slicing of the space-time sheets by string world sheets and partonic 2-surfaces.
2. Should one then treat these branches as separate space-time surfaces or as a single space-time surface? The treatment as a single surface seems to be the correct thing to do. Classically the conserved changes would be  $n_a n_b$  times larger than for single branch. Kähler action need not (but could!) be same for different branches but the total action is  $n_a n_b$  times the average action and this effectively corresponds to the replacement of the  $\hbar_0 / g_K^2$  factor of the action with  $\hbar / g_K^2$ ,  $r \equiv \hbar / \hbar_0 = n_a n_b$ . Since the conserved quantum charges are proportional to  $\hbar$  one could argue that  $r = n_a n_b$  tells only that the charge conserved charge is  $n_a n_b$  times larger than without multi-valuedness.  $\hbar$  would be only effectively  $n_a n_b$  fold. This is of course poor man's argument but might catch something essential about the situation.

3. How could one interpret the condition  $J^{03}\sqrt{g_4} = 4\pi\alpha_K J_{12}$  and its generalization to be discussed below in this framework? The first observation is that the total Kähler electric charge is by  $\alpha_K \propto 1/(n_a n_b)$  same always. The interpretation would be in terms of charge fractionization meaning that each branch would carry Kähler electric charge  $Q_K = ng_K/n_a n_b$ . I have indeed suggested explanation of charge fractionization and quantum Hall effect based on this picture.
4. The vision about the hierarchy of Planck constants involves also assumptions about imbedding space metric. The assumption that the  $M^4$  covariant metric is proportional to  $\hbar^2$  follows from the physical idea about  $\hbar$  scaling of quantum lengths as what Compton length is. One can always introduce scaled  $M^4$  coordinates bringing  $M^4$  metric into the standard form by scaling up the  $M^4$  size of  $CD$ . It is not clear whether the scaling up of  $CD$  size follows automatically from the proposed scenario. The basic question is why the  $M^4$  size scale of the critical extremals must scale like  $n_a n_b$ ? This should somehow relate to the weak self-duality conditions implying that Kähler field at each branch is reduced by a factor  $1/r$  at each branch. Field equations should possess a dynamical symmetry involving the scaling of  $CD$  by integer  $k$  and  $J^{0\beta}\sqrt{g_4}$  and  $J^{n\beta}\sqrt{g_4}$  by  $1/k$ . The scaling of  $CD$  should be due to the scaling up of the  $M^4$  time interval during which the branched light-like 3-surface returns back to a non-branched one.
5. The proposed view about hierarchy of Planck constants is that the singular coverings reduce to single-sheeted coverings at  $M^2 \subset M^4$  for  $CD$  and to  $S^2 \subset CP_2$  for  $CP_2$ . Here  $S^2$  is any homologically trivial geodesic sphere of  $CP_2$  and has vanishing Kähler form. Weak self-duality condition is indeed consistent with any value of  $\hbar$  and implies that the vacuum property for the partonic 2-surface implies vacuum property for the entire space-time sheet as holography indeed requires. This condition however generalizes. In weak self-duality conditions the value of  $\hbar$  is free for any 2-D Lagrangian sub-manifold of  $CP_2$ .

The branching along  $M^2$  would mean that the branches of preferred extremals always collapse to single branch when their  $M^4$  projection belongs to  $M^2$ . Magnetically charged light-light-like throats cannot have  $M^4$  projection in  $M^2$  so that self-duality conditions for different values of  $\hbar$  do not lead to inconsistencies. For spacelike 3-surfaces at the boundaries of  $CD$  the condition would mean that the  $M^4$  projection becomes light-like geodesic. Straight cosmic strings would have  $M^2$  as  $M^4$  projection. Also  $CP_2$  type vacuum extremals for which the random light-like projection in  $M^4$  belongs to  $M^2$  would represent this of situation. One can ask whether the degeneration of branches actually takes place along any string like object  $X^2 \times Y^2$ , where  $X^2$  defines a minimal surface in  $M^4$ . For these the weak self-duality condition would imply  $\hbar = \infty$  at the ends of the string. It is very plausible that string like objects feed their magnetic fluxes to larger space-times sheets through wormhole contacts so that these conditions are not encountered.

### Connection with the criticality of preferred extremals

Also a connection with quantum criticality and the criticality of the preferred extremals suggests itself. Criticality for the preferred extremals must be a property of space-like 3-surfaces and light-like 3-surfaces with degenerate 4-metric and the degeneration of the  $n_a n_b$  branches of the space-time surface at the its ends and at wormhole throats is exactly what happens at criticality. For instance, in catastrophe theory roots of the polynomial equation giving extrema of a potential as function of control parameters co-incide at criticality. If this picture is correct the hierarchy of Planck constants would be an outcome of criticality and of preferred extremal property and preferred extremals would be just those multi-branched space-time surfaces for which branches co-incide at the the boundaries of  $CD \times CP_2$  and at the throats.

## Chapter 4

# Construction of Quantum Theory: *M*-matrix

### 4.1 Introduction

During years I have spent a lot of time and effort in attempts to imagine various options for the construction of *S*-matrix, and it seems that there are quite many strong constraints, which might lead to a more or less unique final result if some young analytically blessed brain decided to transform these assumptions to concrete calculational recipes.

The realization that configuration space spinors correspond to von Neumann algebras known as hyper-finite factors of type  $II_1$  meant [83, 27] a turning point also in the attempts to construct *S*-matrix. A sequence of trials and errors led rapidly to the generalization of the quantum measurement theory and re-interpretation of *S*-matrix elements as entanglement coefficients of zero energy states in accordance with the zero energy ontology applied already earlier in TGD inspired cosmology [22]. Zero energy ontology motivated the replacement of the term '*S*-matrix' with '*M*-matrix'. This led to the discovery that rather stringy formulas for *M*-matrix elements emerge in TGD framework.

The purpose of this chapter is to collect to single chapter various general ideas about the construction of *M*-matrix scattered in the chapters of books about TGD and often drowned into details and plagued by side tracks. My hope is that this chapter might provide a kind of bird's eye of view and help the reader to realize how fascinating and profound and near to physics the mathematics of hyper-finite factors is. I do not pretend of having handle about the huge technical complexities and can only recommend the works of von Neumann [75, 124, 106, 71], Tomita [120], [38, 64, 27], the work of Powers and Araki and Woods which served as starting point for the work of Connes [62, 61], the work of Jones [89], and other leading figures in the field. What is my main contribution is fresh physical interpretation of this mathematics which also helps to make mathematical conjectures. The book of Connes [62] available in web provides an excellent overall view about von Neumann algebras and non-commutative geometry.

#### 4.1.1 The recent progress in Quantum TGD and identification of *M*-matrix

My original intention was to summarize the basic principles of Quantum TGD first. The problem is however where to start from since everything is so tightly interwoven that linear representation proceeding from principles to consequences seems impossible. Therefore it might be a good idea to try to give a summary with emphasis on what has happened during the few months in turn of 2008 to 2009 assuming that the reader is familiar with the basic concepts discussed in previous chapters. This summary gives also a bird's eye of view about what I believe *M*-matrix to be. Later this picture is used to answer the questions raised in the earlier version of this chapter.

#### Zero energy ontology

One of the key notions underlying the recent developments is zero energy ontology.

1. Zero energy ontology leads naturally to the identification of light-like 3-surfaces interpreted as a generalization of Feynman diagrams as the most natural dynamical objects (equivalent with space-like 3-surface by holography).
2. The fractal hierarchy of causal diamonds ( $CD$ ) with light like boundaries of  $CD$  interpreted as carriers of positive and negative energy parts of zero energy state emerges naturally. If the scales of  $CD$ s come as powers of 2, p-adic length scale hypothesis follows as a consequence.
3. The identification of  $M$ -matrix as time-like entanglement coefficients between zero energy states identified as the product of positive square root of the density matrix and unitary  $S$ -matrix emerges naturally and leads to the unification of thermodynamics and quantum theory.
4. The identification of  $M$ -matrix in terms of Connes tensor product means that the included algebra  $\mathcal{N} \subset \mathcal{M}$  acts effectively like complex numbers and does not affect the physical state. The interpretation is that  $\mathcal{N}$  corresponds to zero energy states in size scales smaller than the measurement resolution and thus the insertion of this kind of zero energy state should not have any observable effects. The uniqueness of Connes tensor product gives excellent hopes that the  $M$ -matrix could be unique apart from the square root of of density matrix.
5. The unitary  $U$ -matrix between zero energy states assignable to quantum jump has nothing to do with  $S$ -matrix measured in particle physics experiments. A possible interpretation is in terms of consciousness theory. For instance,  $U$ -matrix could make sense even for p-adic-to-real transitions interpreted as transformations of intentions to actions making sense since zero energy state is generated ('Everything is creatable from vacuum' is the basic principle of zero energy ontology) [44]. One can express  $U$ -matrix as a collection of  $M$ -matrices labeled by zero energy states and unitarity conditions for  $U$ -matrix boil down to orthogonality conditions for the zero energy states defined by  $M$ -matrices.

### The notion of finite measurement resolution

The notion of finite measurement resolution as a basic dynamical principle of quantum TGD might be seen by a philosophically minded reader as the epistemological counterpart of zero energy ontology.

1. As far as length scale resolution is considered, finite measurement resolution implies that only  $CD$ s above some size scale are allowed. This is not an approximation but a property of zero energy state so that zero energy states realize finite measurement resolution in their structure. One might perhaps say that quantum states represent only the information that we can become conscious of.
2. In the case of angle resolution the hierarchy of Planck constants accompanied by a hierarchy of algebraic extensions of rationals by roots of unity, and realized in terms of the book like structures assigned with  $CD$  and  $CP_2$ , is a natural outcome of this thinking.
3. Number theoretic braids implying discretization at parton level can be seen as a space-time correlate for the finite measurement resolution. Zero energy states should contain in their construction only information assignable to the points of the braids. Note however that there is also information about tangent space of space-time surface at these points so that the theory does not reduce to a genuinely discrete theory. Each choice of  $M^2$  and geodesic spheres defines a selection of quantization axis and different choice of the number theoretic braid. Hence discreteness does not reduce to that resulting from the assumption that space-time as the arena of dynamics is discrete but reflects the limits to what we can measure, perceive, and cognize in continuous space-time. Zero energy state corresponds to wave-function in the space of these choices realized as the union of copies of the page  $CD \times CP_2$ . Quantum measurement must induce a localization to single point in this space unless one is ready to take seriously the notion of quantum multiverse.
4. Finite measurement resolution allows a realization in terms of inclusions  $\mathcal{N} \subset \mathcal{M}$  of hyper-finite factors of type  $II_1$  (HFFs) about which the configuration space Clifford algebra provides standard example. Also the factor spaces  $\mathcal{M}/\mathcal{N}$  are suggestive and should correspond to quantum variants of HFFs with a finite quantum dimension. p-Adic coupling constant evolution can be

understood in this framework and corresponds to the inclusions of HFFs realized as inclusions of spaces of zero energy states with two different scale cutoffs.

### Number theoretical compactification and $M^8 - H$ duality

The closely related notions of number theoretical compactification and  $M^8 - H$  duality have had a decisive impact on the understanding of the mathematical structure of quantum TGD.

1. The hypothesis is that TGD allows two equivalent descriptions using either  $M^8$ - the space of hyper-octonions- or  $H = M^4 \times CP_2$  as imbedding space so that standard model symmetries have a number theoretic interpretation. The underlying philosophy is that the world of classical worlds and thus  $H$  is unique so that the symmetries of  $H$  should be something very special. Number theoretical symmetries indeed fulfil this criterion.
2. In  $M^8$  description space-time surfaces decompose to hyper-quaternionic and co-hyperquaternionic regions. The map assigning to  $X^4 \subset M^8$  the image in  $X^4 \subset H$  must be a isometry and also preserve the induced Kähler form so that the Kähler action has same value in the two spaces. The isometry groups of  $E^4$  and  $CP_2$  are different, and the interpretation is that the low energy description of hadrons in terms of  $SO(4)$  symmetry and high energy description in terms of  $SU(3)$  gauge group reflect this duality.
3. Number theoretic compactification implies very detailed conjectures about the preferred extremals of Kähler action implying dual slicings of the  $M^4$  projection of space-time surface to string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$  for Minkowskian signature of induced metric. This occurs for the known extremals of Kähler action of this kind [8] . These slicings allow to understand how Equivalence Principle emerges via its stringy variant in TGD framework through dimensional reduction. The tangent spaces of  $Y^2$  and  $X^2$  define local planes of physical and un-physical polarizations and  $M^2$  defines also the plane for the four-momentum assignable to the braid strand so that gauge symmetries are purely number theoretical interpretation.
4. Also a slicing of  $X^4(X_l^3)$  to light-like 3-surfaces  $Y_l^3$  parallel to  $X_l^3$  giving equivalent space-time representations of partonic dynamics is predicted. This implies holography meaning an effective reduction of space-like 3-surfaces to 2-D surfaces. Number theoretical compactification leads also to a dramatic progress in the construction of quantum TGD in terms of the second quantized induced spinor fields. The holography seems however to be not quite simple as one might think first. Kac-Moody symmetries respecting the light-likeness of  $X_l^3$  and leaving  $X^2$  fixed act as gauge transformations and all light-like 3-surfaces with fixed ends and related by Kac-Moody symmetries would be geometrically equivalent in the sense that configuration space Kähler metric is identical for them. These transformations would also act as zero modes of Kähler action.
5. A physically attractive realization of the braids - and more generally- of slicings of space-time surface by 3-surfaces and string world sheets, is discussed in [36] by starting from the observation that TGD defines an almost topological QFT of braids, braid cobordisms, and 2-knots. The boundaries of the string world sheets at the space-like 3-surfaces at boundaries of  $CD$ s and wormhole throats would define space-like and time-like braids uniquely.

The idea relies on a rather direct translation of the notions of singular surfaces and surface operators used in gauge theory approach to knots [129] to TGD framework. It leads to the identification of slicing by three-surfaces as that induced by the inverse images of  $r = \text{constant}$  surfaces of  $CP_2$ , where  $r$  is  $U(2)$  invariant radial coordinate of  $CP_2$  playing the role of Higgs field vacuum expectation value in gauge theories.  $r = \infty$  surfaces correspond to geodesic spheres and define analogs of fractionally magnetically charged Dirac strings identifiable as preferred string world sheets. The union of these sheets labelled by subgroups  $U(2) \subset SU(3)$  would define the slicing of space-time surface by string world sheets. The choice of  $U(2)$  relates directly to the choice of quantization axes for color quantum numbers characterizing  $CD$  and would have the choice of braids and string world sheets as a space-time correlate.

### Configuration space spinor structure

The construction of configuration space spinor structure in terms of second quantized induced spinor fields is certainly the most important step made hitherto towards explicit formulas for  $M$ -matrix elements.

1. Number theoretical compactification ( $M^8 - H$  duality) states that space-time surfaces can be equivalently regarded as 4-dimensional surfaces of either  $H = M^4 \times CP_2$  or of 8-D Minkowski space  $M^8$ , and consisting of hyper-quaternionic and co-hyper-quaternionic regions identified as regions with Minkowskian and Euclidian signatures of induced metric. Duality preserves induced metric and Kähler form. This duality poses very strong constraints on the geometry of the preferred extremals of Kähler action implying dual slicings of the space-time surface by string worlds sheets and partonic 2-surfaces as also by light-like 1-surfaces and light-like 3-surfaces. These predictions are consistent with what is known about the extremals of Kähler action. The predictions of number theoretical compactification lead to dramatic progress in the construction of configuration space spinor structure and geometry. One consequence is dimensional reduction of space-time surface to string world sheet allowing to understand how the space-time correlate for Equivalence Principle is realized in TGD framework (its quantum counterpart emerges from coset construction for super-symplectic and super Kac-Moody algebras).
2. The construction of configuration space geometry and spinor structure in terms of induced spinor fields leads to the conclusion that finite measurement resolution is an intrinsic property of quantum states basically due to the vacuum degeneracy of Kähler action. This gives a justification for the notion of number theoretic braid effectively replacing light-like 3-surfaces. Hence the infinite-dimensional configuration space is replaced with a finite-dimensional space  $(\delta M_{\pm}^4 \times CP_2)^n / S_n$ . A possible interpretation is that the finite fermionic oscillator algebra for given partonic 2-surface  $X^2$  represents the factor space  $\mathcal{M}/\mathcal{N}$  identifiable as quantum variant of Clifford algebra.  $(\delta M_{\pm}^4 \times CP_2)^n / S_n$  would represent its bosonic analog.
3. The isometries of the configuration space corresponds to  $X^2$  local symplectic transformations  $\delta M_{\pm}^4 \times CP_2$  depending only on the value of the invariant  $\epsilon^{\mu\nu} J_{\mu\nu}$ , where  $J_{\mu\nu}$  can correspond to the Kähler form induced from  $\delta M_{\pm}^4$  or  $CP_2$ . This group parameterizes quantum fluctuating degrees of freedom. Zero modes correspond to coordinates which cannot be made complex, in particular to the values of the induced symplectic form which thus behaves as a classical field so that configuration space allows a slicing by the classical field patterns  $J_{\mu\nu}(x)$  representing zero modes.
4. By the effective 2-dimensionality of light-like 3-surfaces  $X_l^3$  (holography) the interiors of light-like 3-surfaces are analogous to gauge degrees of freedom and partially parameterized by Kac-Moody group respecting the light-likeness of 3-surfaces. Quantum classical correspondence suggests that gauge fixing in Kac-Moody degrees of freedom takes place and implies correlation between the quantum numbers of the physical state and  $X_l^3$  or equivalently any light-like 3-surface  $Y_l^3$  parallel to  $X_l^3$ . There would be no path integral over  $X_l^3$  and only functional integral defined by configuration space geometry over partonic 2-surfaces.
5. The condition that the Noether currents assignable to the modified Dirac equation are conserved requires that space-time surfaces correspond to extremals for which second variation of Kähler action vanishes. A milder condition is that the rank of the matrix defined by the second variation of Kähler action is less than maximal. Preferred extremals of Kähler action can be identified as this kind of 4-surface and the interpretation is in terms of quantum criticality.
6. The inverse of the modified Dirac operator does not define stringy propagator since it does not depend on the quantum numbers of the state of super-conformal representation. The solution of the problem is provided by the addition of measurement interaction term to the modified Dirac action and assignable to wormhole throats or equivalently any light-like 3-surface parallel to them into the slicing of space-time sheet: this condition defines additional symmetry modifying Kähler function and Kähler action in such a manner that Kähler metric is not affected. Measurement interaction term implies that the preferred extremals of Kähler action depend on quantum numbers of the states of super-conformal representations as quantum classical correspondence

requires. The coupling constants appearing in the measurement interaction term are fixed by the condition that Kähler function transforms only by a real part of a holomorphic function of complex coordinates of WCW depending also on zero modes so that Kähler metric of WCW remains unchanged. This realizes also the effective 2-dimensionality of space-like 3-surfaces but only in finite regions where the slicing by light-like 3-surfaces makes sense.

### Hierarchy of Planck constants

The hierarchy of Planck constants realized as a replacement of  $CD$  and  $CP_2$  of  $CD \times CP_2$  with book like structures labeled by finite subgroups of  $SU(2)$  assignable to Jones inclusions is now relatively well understood as also its connection to dark matter, charge fractionization, and anyons [27, 57] .

1. This notion leads also to a unique identification of number theoretical braids as intersections of  $CD$  ( $CP_2$ ) projection of  $X^3$  and the back  $M^2$  (the backs  $S_I^2$  and  $S_{II}^2$ ) of  $M^4$  ( $CP_2$ ) book. The spheres  $S_I^2$  and  $S_{II}^2$  are geodesic spheres of  $CP_2$  orthogonal to each other).
2. The formulation of  $M$ -matrix should involve the local data from the points of number theoretic braids at partonic 2-surfaces. This data involves information about tangent space of  $X^4(X^3)$  so that the theory does not reduce to 2-D theory. The hierarchy of  $CD$ s within  $CD$ s means that the improvement of measurement resolution brings in new  $CD$ s with smaller size.
3. The points of number theoretical braids are by definition quantum critical with respect to the phase transitions changing Planck constant and meaning leakage between different pages of the books in question. This quantum criticality need not be equivalent with the quantum criticality in the sense of the degeneracy of the matrix like entity defined by the second variation of Kähler action. Note that the entire partonic 2-surface at the boundary of  $CD$  cannot be quantum critical unless it corresponds to vacuum state with only topological degrees of freedom excited (that is have as its  $CD$  ( $CP_2$ ) projection at the back of  $CD$  ( $CP_2$ ) book or both) since Planck constant would be ill-defined in this kind of situation.

### Super-conformal symmetries

There have been a considerable progress also in the understanding of super-conformal symmetries [15, 20] .

1. Super Kac-Moody and super-symplectic symmetries correspond to the dual slicings of  $X^4(X^3)$  to string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$ . The duality is realized for Super Virasoro algebras in terms of coset construction meaning that the differences of Super Virasoro generators annihilate physical states. The four-momenta assignable to the two representations correspond to gravitational and inertial four-momenta and Equivalence Principle in microscopic form follows.
2. Neither Super Kac-Moody nor super-symplectic Super-Virasoro generators annihilate the states separately and this gives justification for p-adic thermodynamics as thermodynamics of conformal weight with thermal expectation identified as mass squared.
3. A further step of progress relates to the understanding of the fusion rules of symplectic field theory [13] . These fusion rules makes sense only if one allows discretization that is number theoretic braids. An infinite hierarchy of symplectic fusion algebras can be identified with nice number theoretic properties (only roots of unity appear in structure constants). Hence there are good hopes that symplecto-conformal N-point functions defining the vertices of generalized Feynman diagrams can be constructed exactly.
4. The possible reduction of the fermionic Clifford algebra to a finite-dimensional one means that super-conformal algebras must have a cutoff in conformal weights. These algebras must reduce to finite dimensional ones and the replacement of integers with finite field is what comes first in mind.
5. The conserved fermionic currents implied by vanishing second variations of Kähler action for preferred extremal define a hierarchy of super-conformal algebras assignable to zero modes. These currents are appear in the expression of measurement interactions added to the modified

Dirac action in order to obtain stringy propagators and the coding of super-conformal quantum numbers to space-time geometry.

### 4.1.2 Various inputs to the construction of $M$ -matrix

It is perhaps wise to summarize briefly the vision about  $M$ -matrix.

#### Zero energy ontology and interpretation of light-like 3-surfaces as generalized Feynman diagrams

1. Zero energy ontology is the cornerstone of the construction. Zero energy states have vanishing net quantum numbers and consist of positive and negative energy parts, which can be thought of as being localized at the boundaries of light-like 3-surface  $X_l^3$  connecting the light-like boundaries of a causal diamond  $CD$  identified as intersection of future and past directed light-cones. There is entire hierarchy of  $CD$ s, whose scales are suggested to come as powers of 2. A more general proposal is that prime powers of fundamental size scale are possible and would conform with the most general form of p-adic length scale hypothesis. The hierarchy of size scales assignable to  $CD$ s corresponds to a hierarchy of length scales and code for a hierarchy of radiative corrections to generalized Feynman diagrams.
2. Light-like 3-surfaces are the basic dynamical objects of quantum TGD and have interpretation as generalized Feynman diagrams having light-like 3-surfaces as lines glued together along their ends defining vertices as 2-surfaces. By effective 2-dimensionality (holography) of light-like 3-surfaces the interiors of light-like 3-surfaces are analogous to gauge degrees of freedom and partially parameterized by Kac-Moody group respecting the light-likeness of 3-surfaces. This picture differs dramatically from that of string models since light-like 3-surfaces replacing stringy diagrams are singular as manifolds whereas 2-surfaces representing vertices are not.

#### Identification of TGD counterpart of $S$ -matrix as time-like entanglement coefficients

1. The TGD counterpart of  $S$ -matrix -call it  $M$ -matrix- defines time-like entanglement coefficients between positive and negative energy parts of zero energy state located at the light-like boundaries of  $CD$ . One can also assign to quantum jump between zero energy states a matrix- call it  $U$ -matrix - which is unitary and assumed to be expressible in terms of  $M$ -matrices.  $M$ -matrix need not be unitary unlike the  $U$ -matrix characterizing the unitary process forming part of quantum jump. There are several good arguments suggesting that that  $M$ -matrix cannot be unitary but can be regarded as thermal  $S$ -matrix so that thermodynamics would become an essential part of quantum theory. In fact,  $M$ -matrix can be decomposed to a product of positive diagonal matrix identifiable as square root of density matrix and unitary matrix so that quantum theory would be kind of square root of thermodynamics. Path integral formalism is given up although functional integral over the 3-surfaces is present.
2. In the general case only thermal  $M$ -matrix defines a normalizable zero energy state so that thermodynamics becomes part of quantum theory. One can assign to  $M$ -matrix a complex parameter whose real part has interpretation as interaction time and imaginary part as the inverse temperature.

#### Hyper-finite factors and $M$ -matrix

HFFs of type  $III_1$  provide a general vision about  $M$ -matrix.

1. The factors of type III allow unique modular automorphism  $\Delta^{it}$  (fixed apart from unitary inner automorphism). This raises the question whether the modular automorphism could be used to define the  $M$ -matrix of quantum TGD. This is not the case as is obvious already from the fact that unitary time evolution is not a sensible concept in zero energy ontology.
2. Concerning the identification of  $M$ -matrix the notion of state as it is used in theory of factors is a more appropriate starting point than the notion modular automorphism but as a generalization of thermodynamical state is certainly not enough for the purposes of quantum TGD and quantum

field theories (algebraic quantum field theorists might disagree!). Zero energy ontology requires that the notion of thermodynamical state should be replaced with its "complex square root" abstracting the idea about M-matrix as a product of positive square root of a diagonal density matrix and a unitary S-matrix. This generalization of thermodynamical state -if it exists- would provide a firm mathematical basis for the notion of M-matrix and for the fuzzy notion of path integral.

3. The existence of the modular automorphisms relies on Tomita-Takesaki theorem, which assumes that the Hilbert space in which HFF acts allows cyclic and separable vector serving as ground state for both HFF and its commutant. The translation to the language of physicists states that the vacuum is a tensor product of two vacua annihilated by annihilation oscillator type algebra elements of HFF and creation operator type algebra elements of its commutant isomorphic to it. Note however that these algebras commute so that the two algebras are not hermitian conjugates of each other. This kind of situation is exactly what emerges in zero energy ontology: the two vacua can be assigned with the positive and negative energy parts of the zero energy states entangled by M-matrix.
4. There exists infinite number of thermodynamical states related by modular automorphisms. This must be true also for their possibly existing "complex square roots". Physically they would correspond to different measurement interactions giving rise to Kähler functions of WCW differing only by a real part of holomorphic function of complex coordinates of WCW and arbitrary function of zero mode coordinates and giving rise to the same Kähler metric of WCW.

#### Connes tensor product as a realization of finite measurement resolution

The inclusions  $\mathcal{N} \subset \mathcal{M}$  of factors allow an attractive mathematical description of finite measurement resolution in terms of Connes tensor product but do not fix M-matrix as was the original optimistic belief.

1. In zero energy ontology  $\mathcal{N}$  would create states experimentally indistinguishable from the original one. Therefore  $\mathcal{N}$  takes the role of complex numbers in non-commutative quantum theory. The space  $\mathcal{M}/\mathcal{N}$  would correspond to the operators creating physical states modulo measurement resolution and has typically fractal dimension given as the index of the inclusion. The corresponding spinor spaces have an identification as quantum spaces with non-commutative  $\mathcal{N}$ -valued coordinates.
2. This leads to an elegant description of finite measurement resolution. Suppose that a universal M-matrix describing the situation for an ideal measurement resolution exists as the idea about square root of state encourages to think. Finite measurement resolution forces to replace the probabilities defined by the M-matrix with their  $\mathcal{N}$  "averaged" counterparts. The "averaging" would be in terms of the complex square root of  $\mathcal{N}$ -state and a direct analog of functionally or path integral over the degrees of freedom below measurement resolution defined by (say) length scale cutoff.
3. One can construct also directly M-matrices satisfying the measurement resolution constraint. The condition that  $\mathcal{N}$  acts like complex numbers on M-matrix elements as far as  $\mathcal{N}$ -"averaged" probabilities are considered is satisfied if M-matrix is a tensor product of M-matrix in  $\mathcal{M}(\mathcal{N})$  interpreted as finite-dimensional space with a projection operator to  $\mathcal{N}$ . The condition that  $\mathcal{N}$  averaging in terms of a complex square root of  $\mathcal{N}$  state produces this kind of M-matrix poses a very strong constraint on M-matrix if it is assumed to be universal (apart from variants corresponding to different measurement interactions).

#### Conformal symmetries and stringy diagrammatics

The modified Dirac equation has rich super-conformal symmetries helping to achieve concrete vision about the structure of M-matrix in terms of generalized Feynman diagrammatics

1. Both super-conformal symmetries, the slicing of space-time surface by string worlds sheets, and the reduction of space-time sheet to string world sheet as a consequence of finite measurement

resolution suggest that the generalized Feynman diagrams have as vertices  $N$ -point functions of a conformal field theory assignable to the partonic 2-surfaces at which the lines of Feynman diagram meet. Finite measurement resolution means that this conformal theory is defined in the discrete set defined by the number theoretic braid. The presence of symplectic invariants in turn suggest a symplectic variant of conformal field theory leading to a concrete construction of symplectic fusion rules relying in crucial manner to discretization.

2. The effective 3-dimensionality implied by the modified Dirac operator associated with Kähler action plays crucial role in the construction of both configuration space geometry (Kähler function is identified as Dirac determinant assignable to the modified Dirac operator) and of  $M$ -matrix. By effective 3-dimensionality the propagators reduce to the propagators assignable the light-like 3-surfaces. This does not give stringy propagators and massive stringy excitations would not appear at all in propagators. This does not conform with what p-adic mass calculations and conformal symmetries suggest.
3. The solution of the problem is provided by the already described addition of measurement interaction term to the modified Dirac action and assignable to wormhole throats or equivalently any light-like 3-surface parallel to them in the slicing of space-time sheet: this condition defines additional symmetry.

### TGD as almost topological QFT

The idea that TGD could be regarded as almost topological QFT has been very fruitful although the hypothesis that Chern-Simons term for induced Kähler gauge potential assignable to light-like 3-surfaces identified as regions of space-time where the Euclidian signature of induced metric assignable to the interior or generalized Feynman diagram changes to Minkowskian one turned out to be too strong. The reduction of configuration space and its Clifford algebra to finite dimensional structures due to finite measurement resolution however realizes this idea but in different manner.

1. There is functional integral over the small deformations of Feynman cobordisms corresponding to the maxima of Kähler function which is finite-dimensional if finite measurement resolution is taken into account. Almost topological QFT property of quantum suggests the identification of  $M$ -matrix as a functor from the category of generalized Feynman cobordisms (generalized Feynman diagrams) to the category of operators mapping the Hilbert space of positive energy states to that for negative energy states: these Hilbert spaces are assignable to partonic 2-surfaces.
2. The limit at which momenta vanish is well-defined for  $M$ -matrix since the modified Dirac action contains measurement interaction term and at this limit one indeed obtains topological QFT.
3. Almost TQFT property suggests that braiding  $S$ -matrices should have important role in the construction. It is indeed possible to assign the with the lines of the generalized Feynman diagram. The reduction of quantum TGD to topological QFT should occur at quantum criticality with respect to the change of Planck constant since in this situation the  $M$ -matrix should not depend at all on Planck constant. Factoring QFTs in 1+1 dimensions give examples of this kind of theories.

### Bosonic emergence

The construction of QFT limit of quantum TGD based on the notion of bosonic emergence led to the most concrete picture about  $M$ -matrix achieved hitherto.

1. An "almost stringy" fermion propagator arises as one adds to the modified Dirac action a term coupling the charges in a Cartan algebra of the isometry group of  $H = M^4 \times CP_2$  to conserved fermionic currents (there are several of them). Also more general observables allow this kind of coupling and the interpretation in terms of measurement interaction. This term also realizes quantum classical correspondence by feeding information about quantum numbers of partons to the geometry of space-time sheet so that quantum numbers entangle with the geometry of space-time sheet as holography requires. This measurement interaction was the last piece in the

puzzle "What are the basic equations of quantum TGD" and unified several visions about the physics predicted by quantum TGD. "Almost stringy" means that the on mass shell fermions obey stringy mass formulas dictated by super-conformal symmetry but that propagator itself -although it depends on four-momentum- is not the inverse of super-Virasoro generator  $G_0$  as it would be in string models.

2. The identification of bosons as wormhole contacts means that bosonic propagation reduces to a propagation of fermion and antifermion at opposite throats of the wormhole throat. In this framework bosonic  $n$ -vertex would correspond to the decay of bosons to fermion-antifermion pairs in the loop. Purely bosonic gauge boson couplings would be generated radiatively from triangle and box diagrams involving only fermion-boson couplings. In particular, bosonic propagator would be generated as a self-energy loop: bosons would propagate by decaying to fermion-antifermion pair and then fusing back to the boson. TGD counterpart for gauge theory dynamics would be emergent and bosonic couplings would have form factors with IR and UV behaviors allowing finiteness of the loops constructed from them since the constraint that virtual fermion pair corresponds to wormhole contact poses strong constraint on virtual momenta of fermion and antifermion.

This picture leads to generalized Feynman rules for  $M$ -matrix. The QFT limit based on this picture is able to reproduce the  $p$ -adic length scale evolution of various gauge coupling strengths with simple cutoffs on mass squared and hyperbolic angle characterizing the state of fermion in the rest system of virtual boson. The presence of these cutoffs is dictated by geometric picture about loops provided by zero energy ontology. The condition that the bosonic  $N > 3$ -vertices vanish when incoming states are on mass shell gives an infinite number of conditions which could fix the cutoffs uniquely.

### Heuristic picture about generalized Feynman rules

Concerning the understanding of the relationship between HFFs and  $M$ -matrix the basic implications are following.

1. General visions do not allow to provide explicit expressions for  $M$ -matrix elements. Therefore one must be humble and try to feed in all understanding about quantum TGD and from the quantum field theoretic picture. In particular, the dependence of  $M$ -matrix on Planck constant should be such that the addition of loop corrections as sub- $CD$ s corresponds to an expansion in powers of  $1/\hbar$  as in quantum field theory whereas for tree diagrams there is no dependence on  $\hbar$ .
2. The vacuum degeneracy of Kähler action and the identification of Kähler function as Dirac determinant strongly suggest that fermionic oscillator operators define what could be interpreted as a finite quantum-dimensional Clifford algebra identifiable as a factor space  $\mathcal{M}/\mathcal{N}$ ,  $\mathcal{N} \subset \mathcal{M}$ . One must be however very cautious since also an alternative option in which excitations of labeled by conformal weight are present cannot be excluded. Finite-dimensionality would mean an enormous simplification, and together with the unique identification of number theoretic braids as orbits of the end points of string world sheets this means that the dynamics is finite-quantum-dimensional conforming with the fact effective finite-dimensionality is the defining property of HFFs. Physical states would realize finite measurement resolution in their structure so that approximation would cease to be an approximation.
3. An interesting question is whether this means that  $M$ -matrix must be replaced with quantum  $M$ -matrix with operator valued matrix elements and whether the probabilities should be determined by taking traces of these operators having interpretation as averaging over  $\mathcal{N}$  defining the degrees of freedom below measurement resolution. This kind of picture would conform with the basic properties of HFFs.
4. To the strands of number theoretic braids one would attach fermionic propagators. Since bosons correspond to fermion pairs at the throats of wormhole contact, all propagators reduce to fermionic ones. As found, the addition of measurement interaction term fixes fermionic propagator completely and gives it a stringy character.

5. Similar correlation function in configuration space degrees of freedom would be given in lowest order -and perhaps exact - approximation in terms of the contravariant metric of the configuration space proportional to  $g_K^2$ . Besides this the exponent of Kähler action would be involved. For elementary particles it would be the exponent of Kähler action for  $CP_2$  type vacuum extremal. In this manner something combinatorially very similar to standard perturbation theory would result and there are excellent hopes that p-adic coupling constant evolution in powers of 2 is consistent with the standard coupling constant evolution.
6. Vertices correspond to n-point functions. The contribution depending on fermionic fields defines the quantum number dependent part of the vertices and comes from the fermion field and their conjugates attached to the ends of propagator lines identified as braid strands. Besides this there is a symplecto-conformal contribution to the vertex.

### The expansion of $M$ -matrix in powers of $\hbar$

One should understand how the proportionality of gauge couplings to  $g_K^2$  emerges and how loops give rise to powers of  $\alpha_K$ . In zero energy ontology one does not calculate  $M$ -matrix but tries to construct zero energy state in the hope that QFT wisdom yields cold help to construct Connes tensor product correctly.

1. The basic rule of quantum field theory is that each loop gives  $\alpha = g^2/4\pi$  and thus  $1/\hbar$  factor whereas in tree diagrams only  $g^2$  appears so that they correspond to the semiclassical approximation.
2. This rule is obtained if one assumes loops correspond to a hierarchy of sub- $CD$ s and that in loop one can distinguish one line as "base line" and other lines as radiative corrections. To each internal line one must assign the factor  $r^{-1/2} = (\hbar_0/\hbar)^{1/2}$  and factor  $g_K^2$  except to the portion of base line appearing in loop since otherwise double counting would result. This dictates the expansion of  $M$ -matrix in powers of  $r^{-1/2}$ . It would not be too surprising to have this kind of expansion.
3.  $g_K^2$  factor comes from the functional integral over the partonic 2-surface selected by stationary phase approximation using the exponent of Kähler action. The functional integral over the configuration space degrees of freedom is carried out using contravariant Kähler metric as a propagator and this gives  $g_K^2$  factor in the lowest non-trivial order since one must develop a perturbation theory with respect to the deformations at the partonic 2-surfaces at the ends of line. If the analogs of radiative corrections to this functional integral vanish -as suggested by quantum criticality and required by number theoretic universality - the resulting dependence on  $g_K^2$  is exact and completely analogous to the free field theory propagator. The numerical factors give the appropriate gauge coupling squared.
4. Besides this one must assign to the ends of the propagator line positive and negative energy parts of quantum state representing the particle in question. These give a contribution which is zeroth order in  $\hbar$ . For instance, gauge bosons correspond to fermionic bilinears. Essentially fermion currents formed from spinor fields at the two light-like wormhole throats of the wormhole contact at which the signature of the induced metric changes are in question. Correct dimension requires the presence of  $1/\hbar$  factor in boson state and  $1/\sqrt{\hbar}$  factor in fermion state. The correlators between fermionic fields at the end points of the line are proportional to  $\hbar$  so that normalization factors cancel the  $\hbar$  dependence. Besides this one would expect N-points function of symplecto-conformal QFT with  $N = N_{in} + N_{out}$  having no dependence on  $\hbar$ .

### 4.1.3 Topics of the chapter

The goal is to sketch an overall view about the ideas which have led to the recent view about the construction of  $M$ -matrix. First the basic philosophical ideas are discussed. These include the basic ideas behind TGD inspired theory of consciousness [73], the identification of p-adic physics as physics of cognition and intentionality forcing the central idea of number theoretic universality, quantum classical correspondence, and the crucial notion of zero energy ontology.

## 4.2 Basic philosophical ideas

The ontology of quantum TGD differs dramatically from that of standard quantum field theories and these differences play a key role in the proposed approach to the construction of  $M$ -matrix.

### 4.2.1 Zero energy ontology

Zero energy ontology has changed profoundly the views about the construction of  $S$ -matrix and forced to introduce the separate notions of  $M$ -matrix and  $U$ -matrix.  $M$ -matrix generalizes the notion of  $S$ -matrix as used in particle physics. The unitary  $U$ -matrix is something new having a natural place in TGD inspired theory of consciousness. Therefore it is best to begin the discussion with a brief summary of zero energy ontology.

#### Motivations for zero energy ontology

Zero energy ontology was first forced by the finding that the imbeddings of Robertson-Walker cosmologies to  $M^4 \times CP_2$  are vacuum extremals. The interpretation is that positive and negative energy parts of states compensate each other so that all quantum states have vanishing net quantum numbers. One can however assign to state quantum numbers as those of the positive energy part of the state. At space-time level zero energy state can be visualized as having positive energy part in geometric past and negative energy part in geometric future. In time scales shorter than the temporal distance between states positive energy ontology works. In longer time scales the state is analogous to a quantum fluctuation.

Zero energy ontology gives rise to a profound distinction between TGD and standard QFT. Physical states are identified as states with vanishing net quantum numbers, in particular energy. Everything is creatable from vacuum - and one could add- by intentional action so that zero energy ontology is profoundly Eastern. Positive *resp.* negative energy parts of states can be identified as states associated with 2-D partonic surfaces at the boundaries of future *resp.* past directed light-cones, whose tips correspond to the arguments of  $n$ -point functions. Each incoming/outgoing particle would define a mini-cosmology corresponding to not so big bang/crunch. If the time scale of perception is much shorter than time interval between positive and zero energy states, the ontology looks like the Western positive energy ontology. Bras and kets correspond naturally to the positive and negative energy states and phase conjugation for laser photons making them indeed something which seems to travel in opposite time direction is counterpart for bra-ket duality.

#### The notions of $U$ -matrix and $M$ -matrix

Zero energy ontology implies two kinds of matrices relevant for physics:  $U$ - and  $M$ .  $U$ -matrix characterizes the unitary process associated with the quantum jump and is universal.  $M$ -matrix has interpretation in terms of time-like entanglement coefficients between positive and negative energy parts of zero energy state and seems to characterize quantum states rather than the universal quantum dynamics. Unitarity conditions can be weakened so that thermodynamic becomes part of quantum theory in the sense that  $M$ -matrix is expressible as a product of positive square root of density matrix and unitary  $S$ -matrix analogous to thermal  $S$ -matrix assignable formally to a complex time parameter.  $U$ - and  $M$ -matrix differ in many respects.

1.  $M$ -matrix defines entanglement between positive and negative energy parts of zero energy state. This entanglement does not make sense between different number fields since the light-like 3-surface defining Feynmann cobordism connecting p-adic and real partonic 2-surfaces at boundaries of  $CD$  does not make sense. Hence  $M$ -matrix is diagonal with respect to number field.
2. If algebraic universality is accepted in its strongest form,  $U$ -matrix elements must be algebraic numbers so that in zero energy ontology  $U$ -matrix between zero energy states can have elements between different number fields. Note that the vanishing of conserved quantum numbers is absolutely essential for this. This suggests a description of intentional action as p-adic-to-real transitions in terms of  $U$ -matrix. Algebraic Universality in this sense might be too strong a condition since it becomes questionable whether one can speak at all about real and p-adic physics as distinct disciplines. A weaker form of number theoretic universality is that the real

and p-adic Universes relate to the algebraic Universes based on algebraic extensions of rationals in the same manner as reals and p-adic number fields and their extensions relate to rationals and algebraics. Also in this case transitions are possible but only between the states which live in rational or algebraic sub-Universes. One might say that real and p-adic universes are like pages of a book and algebraic universes are like the back of the book making it possible for zero energy states to leak between the pages.

3. Both options makes possible to assign  $U$ -matrix to quantum jumps transforming intention to action. The original hypothesis motivated by the stability of sensorily perceived world was that  $U$ -matrix is almost trivial but there is actually no need for this assumption. The stability of sensory perception can be understood if the ensembles formed by  $CD$ s in various scales are nearly thermal so that sensory experience which involves statistical averaging and becomes stable.
4. From the point of view of consciousness theory the natural statement is that  $M$ -matrix corresponds to the passive aspects of conscious experience, that is perception which reduces to quantum measurement and state function reduction at the fundamental level.  $U$ -matrix would in turn correspond to active aspects of conscious experience, including volitional acts and transformations of intentions to actions.

### 2. How $U$ - and $M$ -matrices relate to each other?

The obvious objection against zero energy ontology is that the universality of  $S$ -matrix in the sense of particle physics is lost since  $M$ -matrix characterizes the time-like entanglement of zero energy state and seems therefore to be highly state dependent. It would seem that one must give up the greatest dream of theoretician. The situation is not so bad.

1. The notion of measurement resolution realized in terms of Jones inclusions requires that the included sub-factor  $\mathcal{N} \subset \mathcal{M}$  representing the degrees of freedom below measurement resolution acts effectively like complex numbers on positive and negative energy parts of the zero energy state. This requires that time-like entanglement is given in terms of highly unique Connes tensor product.  $M$ -matrix decomposes to a product of the positive square root of density matrix and unitary  $S$ -matrix and one might hope that  $S$ -matrix is essentially unique for  $CD$  with a given scale.
2. There might be also a connection between  $M$ -matrix and universal  $U$ -matrix.  $U$ -matrix between zero energy states could reduce to a tensor product of possibly universal  $S$ -matrix and its Hermitian conjugate associated with  $M$ -matrices: the first one between positive energy parts and second one between negative energy parts of zero energy states in question. If this is the case, the same  $S$ -matrix would apply both  $U$ -process and state function reduction. One might argue that this connection is necessary since without it there would be no manner to deduce any information about  $U$ -matrix experimentally. Note that density matrix part of  $M$ -matrix can be unit matrix only for hyper-finite factors of type  $II_1$  are in question since only in this case the trace of  $S^\dagger S = Id$  equals to 1 as the normalization of zero energy states requires.
3.  $M$ -matrices associated with different size scales for  $CD$ s coming as powers of two would also have a natural fractal structure. The matrices associated with two  $CD$ s would differ only by the effects caused by p-adic coupling constant evolution. Two subsequent  $M$ -matrices in the hierarchy would differ only by the effects caused by a change in measurement resolution (the scales defining smallest sub- $CD$ s contributing to the calculation of  $M$  would be different). The infinite sequence of Jones inclusions for hyperfinite type  $II_1$  factors isomorphic as von Neumann algebras could express this fractal character algebraically.

### The relationship between $U$ -matrix and $M$ -matrix

The following represents the latest result concerning the relationship between the notions of  $U$ -matrix and  $M$ -matrix and probably provides answer to some of the questions posed in the chapter. What is highly satisfactory that  $U$ -matrix dictates  $M$ -matrix completely via unitarity conditions. A more detailed discussion can be [44] discussing Negentropy Maximization Principle, which is the basic

dynamical principle of TGD inspired theory of consciousness and states that the information content of conscious experience is maximal.

If the state function reduction associated with time-like entanglement leads always to a product of positive and negative energy states (so that there is no counterpart of bound state entanglement and negentropic entanglement possible for zero energy states: these notions are discussed below)  $U$ -matrix and can be regarded as a collection of  $M$ -matrices

$$U_{m_+n_-,r_+,s_-} = M(m_+,n_-)_{r_+,s_-} \quad (4.2.1)$$

labeled by the pairs  $(m_+,n_-)$  labelling zero energy states assumed to reduced to pairs of positive and negative energy states.  $M$ -matrix element is the counterpart of S-matrix element  $S_{r,s}$  in positive energy ontology. Unitarity conditions for  $U$ -matrix read as

$$\begin{aligned} (UU^\dagger)_{m_+n_-,r_+,s_-} &= \sum_{k_+,l_-} M(m_+,n_-)_{k_+,l_-} \overline{M}(r_+,s_-)_{k_+,l_-} = \delta_{m_+r_+,n_-s_-} \quad , \\ (U^\dagger U)_{m_+n_-,r_+,s_-} &= \sum_{k_+,l_-} \overline{M}(k_+,l_-)_{m_+,n_-} M(k_+,l_-)_{r_+,s_-} = \delta_{m_+r_+,n_-s_-} \quad . \end{aligned} \quad (4.2.2)$$

The conditions state that the zero energy states associated with different labels are orthogonal as zero energy states and also that the zero energy states defined by the dual  $M$ -matrix

$$M^\dagger(m_+,n_-)_{k_+,l_-} \equiv \overline{M}(k_+,l_-)_{m_+,n_-} \quad (4.2.3)$$

-perhaps identifiable as phase conjugate states- define an orthonormal basis of zero energy states.

When time-like binding and negentropic entanglement are allowed also zero energy states with a label not implying a decomposition to a product state are involved with the unitarity condition but this does not affect the situation dramatically. As a matter fact, the situation is mathematically the same as for ordinary S-matrix in the presence of bound states. Here time-like bound states are analogous to space-like bound states and by definition are unable to decay to product states (free states). Negentropic entanglement makes sense only for entanglement probabilities, which are rationals or belong to their algebraic extensions. This is possible in what might be called the intersection of real and p-adic worlds (partonic surfaces in question have representation making sense for both real and p-adic numbers). Number theoretic entropy is obtained by replacing in the Shannon entropy the logarithms of probabilities with the logarithms of their p-adic norms. They satisfy the same defining conditions as ordinary Shannon entropy but can be also negative. One can always find prime  $p$  for which the entropy is maximally negative. The interpretation of negentropic entanglement is in terms of formations of rule or association. Schrödinger cat knows that it is better to not open the bottle: open bottle-dead cat, closed bottle-living cat and negentropic entanglement measures this information.

### How the new ontology relates to the existing world view?

In the new rather Buddhistic ontology zero energy states are identified as experienced events and objective reality in the conventional sense becomes only an illusion. Before the new view can be taken seriously one must demonstrate how the illusion about positive energy reality is created and why it is so stable.

#### 1. How the arrow of geometric time emerges?

Before one can consider this question one must have an idea about how the arrow of geometric time emerges in TGD Universe.

1. Conscious entity- self- can be compared to a person sitting in a movie theater with an ability to put the film run in either direction. This person is curious and forces the film to run. Once she has chosen the direction she keeps it as it is since the interesting things are the things not yet known, and are contained by the part of film not yet seen. It might be also easier to run the film in another direction. Translating this to the language of quantum TGD one obtains the following description.

2. Self has as its imbedding space correlate causal diamond  $CD$ , the basic geometric structure of zero energy ontology. The light-like space-time surfaces inside  $CD \times CP_2$  define the basic unit for the "world of classical worlds" (WCW), and one can say that self corresponds to one particular sub-WCW. Geometric time is naturally assigned with  $CD$ .  $CD$  does not move anywhere in the 8-D imbedding space as the standard view about arrow of geometric time would suggest. Rather, self can be compared to the movie theater plus its conscious audience.
3. Self is curious to know what is in the geometric past and future. Since self can induce quantum jumps shifting the quantum superposition of the space-time surfaces to either direction of the geometric time, she does it. Since the contents of consciousness are about the region of space-time surface inside  $CD$  at particular moment of subjective time, correlation between the arrows of subjective time and geometric time results. The experience about the flow of geometric time can be regarded as an illusion analogous to train illusion in which a person sitting in a stationary train has an experience of motion induced by the motion of another train which has begun to move.
4. Once a preferred direction for the arrow is chosen, geometric past corresponds to what is already known and future to the unknown so that the direction of the arrow is stabilized. The  $CP$ -breaking predicted by TGD at fundamental level [15] might favor a preferred direction for the arrow. The generation of global arrow could involve a competition between selves, and a domino effect in the sense that the arrow for self induces that for sub-selves. Phase conjugate laser beams and self assembly in living matter seem to represent non-standard arrow of geometric time and might have interpretation in terms of local deviations from the standard arrow at some level of the scale hierarchy.
5. One must also understand why the contents of conscious experience seem to represent time=constant snapshot of the universe. Sub- $CD$ s are correlates for sub-selves identified as mental images. They tend to concentrate at near the light-like boundaries of  $CD$ , where the most interesting events are and generate mental images. This explains why the contents of conscious experience of self is about a narrow interval of geometric time rather than the entire 4-volume of  $CD$ .
6. The defender of the standard view might wonder whether the self is forced to sit for all her life in the same movie theater? Does self really correspond to single  $CD$  (sub-WCW) or should one speak about a wave function in the space of  $CD$ s?  $CD$  is partially characterized by the position of the lower tip of  $CD$  in  $H$ . Also the size of  $CD$  matters as well as the choice of quantization axes. In the case of color gauge group  $SU(3)$  the space for choices of quantization axes is flag-manifold, which pops up in a mysterious looking manner in the model of honeybee dance developed by topologist Barbara Shipman [116]. Could this wave function in the space of sub-WCWs correspond to a kind of wave packet moving in  $H$  so that the direction of geometric time could emerge also in more standard manner? Or could self expand its consciousness by growing -that is by performing quantum jumps in which the size of the  $CD$  characterizing self is scaled up but the lower tip of  $CD$  moves nowhere. Since the scales of  $CD$ s come in powers of 2, this means a testable predictions about the time scales of conscious experience [66].

## 2. How the stability of perceived reality can be understood?

Consider what the perceived stability of positive energy states, or equivalently that of zero energy states means.

1. What we perceive consciously are time-like state function reductions for events defined by zero energy states. Quantum jumps replace zero energy states with new ones all the subjective time (this corresponds to active aspect of conscious experience) and one can ask whether this makes impossible to experience any stable Universe.
2. Stability under quantum jumps is implied if there are statistical ensembles of  $CD$ s and corresponding zero energy states (fixed to a high degree by Connes tensor product property of time-like entanglement) in various time scales associated with  $CD$ s in  $H$ . Self experiences its sub-selves as mental images and the mental image defined by sub-self corresponds to an ensemble average over sub-selves of sub-self. Hence the stability of experienced world would reflect the

stability of thermal ensemble of events guaranteed by second law of thermodynamics for zero energy states. This allows also to re-interpret the standard trick made in deducing the rates for particle reactions from  $S$ -matrix elements. The problem is that  $|S_{m,n}|^2$  is proportional to a square of delta function expressing energy-momentum conservation. The trick is to interpret second delta function as space-time volume so that one ends up with the replacement of probability for a reaction with probability per four-volume interpreted as a reaction rate per volume. The density of events ( $CDs$ ) per four-volume is the natural interpretation in zero energy ontology.

3. An alternative explanation for the stability of positive energy states is due to that the  $U$ -matrix characterizing quantum jumps between zero energy states is almost trivial. This would mean that the effects of volitional action on zero energy state are very small. The event pairs would be extremely stable once they are generated (how they are generated is an unavoidable question to be addressed below). Infinite sequences of transition between states with same positive energies and same initial energies occur. What is nice that this makes it possible to test the predictions of the theory by experiencing the transition again and again.

### 3. Statistical physics for zero energy states

The statistical physics for zero energy states was already mentioned in the above argument. This need not be equivalent with statistical physics assignable to the zero energy states themselves and defined by the density matrix defined by  $M$ -matrix.

1. It is natural to speak about statistical physics for an ensemble consisting of zero energy states  $|m_+n_-\rangle$  including also their time reversals  $|n_+,m_-\rangle$ . In the usual kinetics one deduces equilibrium values for various particle densities as ratios for the rates for transitions  $m_+ \rightarrow n_+$  and their reversals  $n_+ \rightarrow m_+$  so that the densities are given by  $n(n_+)/n(m_+) = \sum_{n_+} \Gamma(m_+ \rightarrow n_+)/\sum_{n_+} \Gamma(n_+ \rightarrow m_+)$ . In the recent situation the same formula can be used to *define* the particle number densities in kinetic equilibrium using the proposed identification of the transition probabilities.
2. Because of the stability of the zero energy states, one can construct many particle systems consisting of zero energy states and can speak about the density of zero energy states per volume. Also the densities  $n_{+,i}$  ( $n_{-,i}$ ) of initial (final) states of given type can be defined and  $n_{+,i}$  can be identified as densities of positive energy states. Also the densities for particles contained by these states can be defined. It would seem that the new ontology can reproduce the standard ontology as something which is not necessary but to which we are accustomed and which does not produce too much harm.
3. The sequence of quantum jumps between zero energy states defines also a sequence between initial (final) states of quantum jump. Ordinary scattering experiment involves the measurement of the quantum numbers of particles in initial and final states. In the zero energy ontology one can perform separate quantum measurements for the observables associated with positive and negative energy components of zero energy states. This measurement would give rise to the scattering event.

### 5. How does the quantum measurement theory generalize?

There are also important questions related to the quantum measurement theory. The zero modes associated with the interior degrees of freedom of space-time surface represent classical observables entangled with partonic observables and this entanglement is reduced in quantum jump. Negentropy Maximization Principle [44] is the TGD based proposal for the variational principle governing the statistical dynamics of quantum jumps. NMP states that entanglement negentropy tends to be maximized in the reduction of entanglement. Number theoretic variants of Shannon entropy making sense for rationally or even algebraically entangled states can be positive so that NMP can also lead to generation of this kind of entanglement and gives rise to a highly stable bound state entanglement.

### 6. Is the direct creation of zero energy states from vacuum possible?

In principle generation of zero energy states from vacuum is possible. At the first glimpse this option does not seem to be consistent with the assumption that  $U$ -matrix between zero energy states

is induced by  $S$ -matrices between positive and negative energy parts of zero energy states. Should we accept that we are passive spectators who just observe the already existing zero energy states. It seems that this is not necessary.

1. Zero energy states are superpositions of state pairs with different values of conserved quantum numbers which sum up to vanishing net quantum numbers. In particular, zero energy states can contain also a part for which positive and negative energy parts have vanishing quantum numbers. Hence zero energy states can be created also from vacuum for both positive and negative energy parts of the state.
2. There is also a correlation between positive and negative energy parts of the state meaning that also quantum numbers are correlated and conservation laws do not apply locally anymore so that zero energy state is creatable from vacuum.
3. One can also ask whether the creation of zero energy state means a creation of entire  $CD$  or activation of  $CD$  from pure vacuum state. Or could it be that the wave function in the degrees of freedom characterizing position, size, and quantization axes characterizing of  $CD$  changes in quantum jump so that the final state wave function becomes non-vanishing in a new region of  $H$ ?

The creation of zero energy states from vacuum might take place also through intentional action.

1. The mechanism generating p-adic zero energy states as representations of intentions would be same as for the creation of genuine zero energy states. As far as quantum numbers are considered there seems to be no problems of principle involved. One can however wonder whether the notion of conserved classical quantities assignable to Kähler action makes sense p-adically since the notion of definite integral is not well-defined p-adically. A way out of the difficulty is that real and p-adic surfaces involved have same functional form in terms of algebraic functions so that real conserved quantities can be interpreted as p-adic ones when they reduce to algebraic numbers.
2. For zero energy states, p-adic-to-real transitions and vice versa are in principle possible and I have in fact proposed a general quantum model for how intentions might be transformed to actions in this manner [83]. In the second direction the process corresponds to a formation of cognitive representation of a zero energy physical state. The only thing that is required is that the zero energy states in question can be regarded as those possible for some algebraic extension of rationals so that they make sense both in real and p-adic context with appropriate algebraic extension of p-adic numbers.
3. In the degrees of freedom corresponding to configuration space spinors situation is very much like for reals. Rational, and more generally algebraic number based physics applies in both cases. p-Adic space-time sheets however differ dramatically from their real counterparts since they have only rational (algebraic) points in common with real space-time sheets and p-adic transcendentals are infinite as real numbers. The algebraic valued  $U$ -matrix elements for p-adic-to-real transitions can be formulated using  $n$ -point functions restricted to these rational points common to matter and mind stuff. If this picture is not terribly wrong, it would be possible to generate zero energy states from vacuum and the construction of quantum computer programs would be basically a long and tedious process involving very many intentional acts.
4. Real-to-p-adic transitions would represent transformation of reality to cognition and would be also possible. The characteristic and perhaps the defining feature of living matter could be its highly developed ability to reconstruct reality by performing p-adic-to-real transitions and their reversals.
5. Here an interesting aspect of the p-adic conservation laws might have some role. p-Adic integration constants are pseudo constants in the sense that a quantity having vanishing (say) time derivative can depend on a finite number of binary digits  $t_n$  of the time coordinate  $t = \sum_n t_n p^n$ . Could one think that quantum jumps can generate from vacuum exact vacuum states as vacuum tensor factors of the configuration space spinor, and that in subsequent quantum jumps p-adic

$U$ -matrix conserving quantum numbers only in p-adic sense transforms this state into a non-trivial zero energy state which then transforms to a real state in intentional action? Note that if conserved quantum numbers are integers they are automatically pseudo constants. p-Adic conservation laws could allow also the p-adic zero energy states to pop up directly from vacuum.

### 4.2.2 The anatomy of the quantum jump

In TGD framework quantum transitions correspond to a quantum jump between two different quantum histories rather than to a non-deterministic behavior of a single quantum history (understood as an evolution of Schrödinger equation). Therefore  $U$ -matrix relates to each other two quantum histories rather than the initial and final states of a single quantum history and this leads to a resolution of the basic paradox of quantum measurement theory.

To understand the philosophy behind the construction of  $U$ -matrix it is useful to notice that in TGD framework there is actually a 'holy trinity' of time developments instead of single time development encountered in ordinary quantum field theories.

1. The classical time development is coded by the preferred extremal of Kähler action inside each causal diamond  $CD$  defining a hierarchy of time scales coming as powers of 2.
2. The unitary "time development" defined by  $U$  associated with each quantum jump

$$\Psi_i \rightarrow U\Psi_i \rightarrow \Psi_f ,$$

and defining  $U$ -matrix. One cannot however assign to the  $U$ -matrix an interpretation as a unitary time-translation operator. There is a hierarchy of time scales associated with  $U$ -matrices.  $U$ -matrices are between zero energy states and do not correspond directly to the  $S$ -matrix of particle physics, which in zero energy ontology corresponds to the matrix  $M$  defining time-like entanglement coefficients between positive and negative energy parts of zero energy state.

3. The time development of subjective experiences by quantum jumps is identified as sequence of moments of consciousness. The value of geometric time associated with a given quantum jump is determined by the space-time locus for the contents of consciousness of the observer. The understanding of psychological time and its arrow and of the dynamics of subjective time development requires the construction of theory of consciousness [73, 4]. A crucial role is played by zero energy ontology and by the classical non-determinism of Kähler action implying that the non-determinism of quantum jump and hence also the contents of conscious experience can be concentrated into a finite volume of the imbedding space.

#### Unitary process

$U$  is informational "time development" operator, which is unitary like the  $S$ -matrix characterizing the unitary time evolution in standard quantum mechanics.  $U$ -process is however only formally analogous to Schrödinger time evolution of infinite duration since there is *no* real time evolution or translation involved.

Macro-temporal quantum coherence suggests strongly a fractal hierarchy of  $U$ -matrices defined for periods of macro-temporal quantum coherence consisting of sequences of quantum jumps defining selves. The hierarchy of these unitary  $S$ -matrices would not be only an approximation but provide exact descriptions consistent with the limitations of conscious experience. The duration of the macro-temporal quantum coherence would correspond to the time interval defining unitary time development. Also p-adic length scales would define similar hierarchy of  $U$ -matrices. The realization of zero energy ontology in terms of fractal hierarchy of causal diamonds ( $CD$ s) justifies of this expectation since one can assign to each  $CD$   $U$ -process.

#### State function reduction

The selection of quantization axes, the fact that the perceived world looks classical, and the correlation of outcome of measurement with classical observables should have first level explanation if quantum measurement theory is to be more more than ad hoc construct justifying the basic rules.

1. *Imbedding space correlate for the choice of the quantization axes*

The requirement that quantum jump corresponds to a measurement in the sense of quantum field theories implies that each quantum jump involves localization in zero modes which parameterize also the possible choices of the quantization axes. Thus the selection of the quantization axes performed by the Cartesian outsider becomes a part of quantum theory.

If one takes seriously the proposed hierarchy of Planck constants and the generalization of the imbedding space to a book like structure implied by it, the selection of quantization axes has also imbedding space correlate which means also breaking of fundamental symmetries at the level of given  $CD$  since quantization axes define physically preferred directions. Each  $CD$  would be replaced by a union of its copies with different selection of quantization axes to guarantee symmetries at fundamental level and quantum jump would involve localization to single choice unless one is willing to accept multi-verse picture for conscious experience.

2. *The outcome of the state function reduction must look classical*

Quantum classical correlation requires that quantum states have classical correlates. This means that the final states of quantum jump correspond to quantum superpositions of 3-surfaces which are macroscopically equivalent so that the world of conscious experience looks classical. "Macroscopically equivalent" translates "indistinguishable in the measurement resolution available" in the recent formulation of quantum TGD.

The finiteness of the measurement resolution is a precise quantitative prediction of quantum TGD proper in its recent form and essentially due to the vacuum degeneracy of Kähler actions responsible also for the classical non-determinism. The point is that the induced spinor fields allow only finite number of zero modes for given light-like 3-surface so that anti-commutation relations can be satisfied for a finite set of points only identified as intersection of partonic 2-surface and number theoretic braid. The resulting effective discretization is much more than one might have expected but emerges very naturally in terms of zero energy ontology. The inclusions of hyper-finite factors of type  $II_1$  (HFFs) allow a mathematical formulation of this picture in terms of quantum counterparts of configuration space Clifford algebras.

A way out of the problems caused by the lack of appropriate p-adic integration measure could be that p-adic configuration space spinor fields are localized to discrete subsets of the p-adic configuration space. Finite measurement resolution realized in terms of number theoretic braids implies that not only effective configuration space Clifford algebra has finite quantum dimension but also the effective configuration space itself. Vacuum functional identified as the exponent of Kähler function can be defined in terms of eigenvalues of the modified Dirac operator also in p-adic context and one can consider the possibility that these eigenvalues serve as coordinates for the p-adic configuration space and p-adic configuration space spinor fields are localized to discrete subsets of this space. Much depends also on the representation of 3-surfaces. For instance, the representation in terms of polynomials means that the coefficients of polynomials with some additional algebraic conditions characterize the point of the p-adic configuration space and one can forget the surface itself. Algebraization in terms of quantum coordinates for p-adic configuration space might also help.

### State preparation

TGD inspired theory of consciousness inspires the hypothesis that the standard quantum measurement is followed by a self measurement inside self, which reduces entanglement between some subsystem and its complement in quantum fluctuating degrees of freedom. Again a measurement of the density matrix is in question. Self measurements are repeated until a completely unentangled (within measurement resolution) product state of self results: the process is equivalent with the state preparation process, which is a purely phenomenological part of standard quantum measurement theory. In well defined sense state preparation corresponds to an analysis or decay process respecting only bound state entanglement.

The dynamics of self measurement is governed by Negentropy Maximization Principle (NMP, [44]), which specifies which subsystems are subject to quantum measurement in a given quantum jump. NMP can be regarded as a basic law for the dynamics of quantum jumps and states that the information content of conscious experience is maximized. In p-adic context NMP would dictate the dynamics of cognition. In real context, self measurement makes possible for the system to fight against thermalization by self-repair at quantum level, and might be a crucial additional element besides the

many-sheeted space-time concept needed to understand how bio-systems manage to be macroscopic quantum systems.

The hypothesis that bound state entanglement coefficients are in the hierarchy of extensions of rational numbers allows to use number theoretic definition of entanglement entropy. This allows to have also negative entropies and in this case NMP does not imply the reduction of entanglement in quantum jump so that there is no need to separately postulate the bound state entanglement is stable against NMP.

### Classical space-time correlates for the basic steps of quantum jump

The classical space-time correlates for the basic notions of quantum measurement theory should be of crucial help in the construction of the  $M$ -matrix. The natural first expectation is that these correlates are encountered only at the level of space-time surfaces. Zero energy ontology and the generalization of the imbedding space forced by the hierarchy of Planck constants led to the conclusion that this kind of correlates emerge also at the level of imbedding space.  $CD$ s serve as correlates for selves and the fractal hierarchy of  $CD$ s allows to characterize finite measurement resolution and treat also the implications of the non-determinism of Kähler action.

#### 1. Correlates at the level of space-time

Consider first space-time correlates for the basic steps of the quantum jump.

1. Space-time sheets correspond to coherence regions for various classical fields obtained by inducing various geometric structures of the imbedding space to the space-time surface. They correspond also to the coherence regions of the induced spinor fields. The classical non-determinism of Kähler action and of corresponding super-symmetrically related Dirac equation makes possible to have space-time correlates for the non-determinism of quantum jump sequence leading to de-coherence. One must be however cautious with what one really means with this notion.
  - (a) The first guess is that de-coherence at space-time level means simply the decomposition of a space-like 3-surface into pieces during its evolution: emission of on mass shell photon by charged elementary particle is the simplest possible example here. Non-determinism must be involved in an essential manner.
  - (b) At particle level  $M$ -matrices are associated with light-like 3-surfaces connecting the light-like boundaries of  $CD$  and representing generalized Feynman diagram with vertices identified as partonic 2-surfaces along with the lines represented by light-like 3-surfaces are glued together. At vertices 3-surfaces and also space-time surfaces are literally branched. State function reduction happens for the zero energy state assignable to this Feynman diagram like 3-surface. In this picture the coherence regions would correspond to connected parts of light-like 3-surfaces and the scale of the smallest  $CD$  in the hierarchy would characterize coherence length and time. De-coherence could be seen as the presence of sub- $CD$ s and corresponding non-deterministic details of space-time surface which serve as a correlate for non-determinism of quantum jumps. At the level of  $M$ -matrix sub- $CD$ s can be assigned to loop corrections in powers of  $\hbar$ .
2. As already explained, the classical non-determinism of the Kähler action allows to represent state function reduction at classical level via stationary phase approximation. Double slit experiment serves as a good example of what could happen.
  - (a) Before the decision to measure which slit the particle propagates through, the space-time surface representing the particle is branched (in the sense of string diagram rather than Feynman diagram) to two parts going through the slits and both branches contain classical spinor field.
  - (b) As the decision is made, p-adic space-time sheet representing the intention to make the measurement is transformed in quantum jump to real space-time sheets, most naturally negative energy topological light rays propagating to the geometric past and interacting with the spinor field and in such a manner that spinor field propagates only along the second branch of the space-time sheet.

- (c) This is achieved if the interaction of negative energy topological light ray transforms space-time sheet to vacuum extremal for which also spinorial energy momentum tensor and various currents vanish identically. Presumably the absorption of negative energy nullifies the energy otherwise propagating along the branch in question. Conservation of various currents implies that the total probability defined by the spinor field goes to the second space-time branch.
3. Also state preparation and NMP should have space-time correlate.
- (a) During state preparation process generation of de-coherence continues and involves maximal de-entanglement in quantum fluctuating degrees of freedom with the formation of bound states being exception. If join along boundaries bonds (realized in terms of magnetic flux tubes say) serve as correlates for the entanglement, the process should correspond at space-time level to the splitting of join along boundaries bonds connecting 3-sheets. 3-surface would quite literally decompose into pieces.
  - (b) Negentropy maximization should thus imply a non-deterministic splitting of 3-surface into pieces if standard expression for entanglement entropy is used. Generation of sub- $CD$ s would be equivalent correlate.
  - (c) If number theoretic variant of entanglement entropy is allow NMP could force formation of join along boundaries bonds. In [16] I have considered the possibility that Kähler action indeed has an information theoretic interpretation. The non-determinism of NMP would has as a space-time correlate the non-determinism of Kähler action.

### The three non-determinisms

Besides the non-determinism of quantum jump, TGD allows two other kinds of non-determinisms: the classical non-determinism basically due the vacuum degeneracy of the Kähler action and p-adic non-determinism of p-adic differential equations due to the fact that functions with vanishing p-adic derivative correspond to piecewise constant functions.

To achieve classical determinism in a generalized sense, one must generalize the definition of the 3-surfaces  $Y^3$  (belonging to light cone boundary) by allowing also "association sequences", that is 3-surfaces which have, besides the component belonging to the light cone boundary, also disjoint components which do not belong to the light cone boundary and have mutual *time like separations*. This means the introduction of additional, one might hope typically discrete, degrees of freedom (consider non-determinism based on bifurcations as an example). It is even possible to have quantum entanglement between the states corresponding to different values of time.

The explicit quantitative realization of this vision is provided by the fractal hierarchy of  $CD$ s within  $CD$ s. To specify the zero energy state one must characterize it for all  $CD$ s with scale above measurement resolution scale. Finite resolution scale is not an approximation to reality but a basic property of zero energy states forced by the quantization of the induced spinor fields.

Without the classical and p-adic non-determinisms general coordinate invariance would reduce the theory to the light cone boundary and this would mean essentially the loss of time which occurs also in the quantization of general relativity as a consequence of general coordinate invariance. Classical and p-adic non-determinisms imply that one can have quantum jumps with non-determinism (in conventional sense) located to a finite time interval. If quantum jumps correspond to moments of consciousness, and if the contents of consciousness are determined by the locus of the non-determinism, then these quantum jumps must give rise to a conscious experience with contents located in a finite time interval.

Also p-adic space-time sheets obey their own quantum physics and are identifiable as seats of cognitive representations. p-Adic non-determinism might be the basic prerequisite for imagination and simulation.

## 4.3 Zero energy ontology and conformal invariance

In the following some aspects of the role of zero energy ontology and conformal invariance in the construction of  $M$ -matrix are discussed. The emphasis is on the long standing difficulties related to

the realization of the analog of stringy picture about  $M$ -matrix. The general vision that emerged much after the writing the first version of this section is that vertices correspond to  $n$ -point functions of a symplecto-conformal field theory at partonic 2-surfaces. The basic deviation from string models are due to the presence of symplectic  $n$ -point functions (discussed in [13]) and due to the discretization caused by the notion of number theoretic braid. Propagators reduce to fermionic correlators assignable to the lines of the generalized Feynman diagram and the naive expectation supported by QFT like picture and effective 3-dimensionality of space-time is that the inverse of the longitudinal part of the modified Dirac operator  $D_K$ , rather than  $D_K$  itself, is in question. The problem is to understand how the analog of the stringy propagator as inverse of super Virasoro generator  $G$  is obtained. The solution of the problem is that different -one might say fundamental- representation of  $1/G$  determined as the propagator associated with the longitudinal part of  $D_K$  contains a sum over virtual states labeled by integer valued conformal weights rather than only on mass shell state with ground state conformal weight just as the QFT propagator contains sum over virtual momenta.

### 4.3.1 $M$ -matrix as characterizer of time-like entanglement between positive and negative energy components of zero energy state

The idea about giving up the notion of unitary  $S$ -matrix in the standard sense of the word might seem too radical and there is actually no fundamental reason forcing this in the conceptual framework provided by hyper-finite factors of type  $II_1$ . Just the opposite, the freedom to construct zero energy states rather freely could be restricted by the unitarity of the matrix determined by the entanglement coefficients. There are however both mathematical and physical reasons to believe that entanglement coefficients give rise to a thermal  $S$ -matrix which is counterpart of ordinary  $S$ -matrix but for complex time parameter.

Before continuing, it must be added that  $M$ -matrix identified as entanglement coefficients between positive and negative energy parts of zero energy states would characterize zero energy *states* and could be something totally different from the  $U$ -matrix describing unitary process associated with the *quantum jump*. If one however assumes that  $U$ -matrix reduces to a tensor product of  $S$ -matrix parts of  $M$ -matrix and its conjugate between positive energy parts and between negative energy parts of zero energy state, situation changes.

#### Unitarity in zero energy ontology

Quantum classical correspondence combined with the number theoretical view about conformal invariance could fix highly uniquely the dependence of  $M$ -matrix on cm degrees of freedom and on net momenta and color quantum numbers. The corner stone of the interpretation is zero energy ontology applied already earlier in classical TGD.

Unitary  $M$ -matrix is possible for zero energy ontology in case of HFFs of type  $II_1$ . The interpretation of the condition  $Tr(SS^\dagger) = Tr(Id) = 1$  as a normalization condition stimulates the hope that the entanglement between positive and negative energy states in zero energy states is coded by a unitary  $M$ -matrix in the conceptual framework provided by hyper-finite type  $II_1$  factors so that states would represent dynamics in their structure.

It must be however emphasized that unitarity is by no means obvious or necessary in zero energy ontology.

1. What can be measured are basically the ratios of scattering rates since one must always use a clock and clock corresponds to some standard scattering occurring with rate defining the time unit used.
2. If one gives up unitarity and allows the interpretation of  $M^\dagger M$  as density, thermodynamics becomes part of quantum theory. In particular,  $p$ -adic thermodynamics crucial for understanding of particle massivation could emerge in this manner.
3. It is not obvious whether unitarity is even possible in 4-dimensional context. For TQFTs with  $S$ -matrix identified as a functor from category of ordinary cobordisms, unitary  $S$ -matrix is assignable only to trivial cobordisms for  $D < 4$  [13], [47]. The situation might be same also for Feynman cobordisms. The whole point of holography is however that space-time is effectively 3-dimensional due to the constraint that virtual states appearing in the lines of Feynman diagram

are only virtual in 3-D sense and correspond to zero modes of the modified Dirac operator in 4-D sense.

4. There is a further strong argument in favor of identification of  $M$ -matrix as the analog of thermal  $S$ -matrix. It is quite possible that HFF of type  $II_1$  is replaced with  $II_\infty$  factor which is a tensor product factors of type  $II_1$  and type  $I$ . In the case of configuration degrees of freedom super-conformal symmetry might guarantee that HFF of type  $II_1$  is in question. Imbedding space degrees of freedom however seem to give rise to factor of type  $I$  via the representations of Poincare group and color partial waves and there seems to be no natural manner to avoid this. Only thermal  $M$ -matrix would define a normalizable state so that thermodynamical states would be genuine quantum states rather than only a useful fiction of theorist.
5. One can hope that  $M$ -matrix as analog of thermal matrix exists for general Feynman cobordisms meaning that thermodynamics and p-adic thermodynamics follow from fundamental principles somewhat like black hole temperature emerges as a property of black hole horizon. Note that for  $U$ -matrix the unitarity is necessary and  $U$ -matrix could be expressed in terms of the  $S$ -matrices associated with  $M$ -matrix.

### Finite measurement resolution and the procedure leading from $M$ -matrix to scattering rates

In standard QFT the procedure leading from from  $S$ -matrix to scattering rates breaks all rules of mathematical aesthetics. The ugliest step in this procedure involves the identification of the 4-dimensional momentum space delta function  $\delta^4(0)$  as a 4-D reaction volume. Encouragingly, zero energy ontology allows to get rid of this feature and also provides a clear physical interpretation for it.

1. In standard positive energy ontology the conservation of energy does not allow localization in time direction so that in time direction the reaction volume is necessarily infinite. In zero energy ontology causal diamonds  $CD$  define naturally finite reaction volumes. If their scales come as powers of 2 -as suggested by the geometry of  $CD$ - one can deduce p-adic length scale hypothesis from this picture in turn supported by the success of p-adic mass calculations. Additional scale hierarchy corresponds to scaled values of Planck constants so that all rational multiples of fundamental scale defined by  $CP_2$  size are in principle possible.
2. p-Adic length scale hierarchy assignable to the hierarchy of  $CD$ s within  $CD$ s is a good candidate for a hierarchy of Jones inclusions with increasing value of  $p$  defining an improved momentum resolution. This leads also to a vision about how p-adic coupling constant evolution for  $M$ -matrix is realized in terms of cutoff characterizing the size of the smallest sub- $CD$  possible.
3. In the framework of zero energy ontology one can say that there is an ensemble of  $CD$ s in  $M^4 \times CP_2$  representing scattering events and reaction rates are obtained by multiplying the density of  $CD$ s with the finite reaction probabilities determined by the  $M$ -matrix. Reaction probabilities are finite since the conservation of four-momentum is a property of states in zero energy ontology and momentum space delta functions can emerge only in the restriction of the four-momentum of positive energy states to a precise value. By the finite size of  $CD$  is is however not possible to make this kind of restriction in zero energy ontology. Only in the idealization that the four-momentum of the initial state is precisely determined the square of  $\delta^4(0)$  would appear and a similar limiting procedure as in the usual case would be needed but would have a clear physical interpretation.
4. Finite length scale resolution suggests at the level of super conformal algebras to a cutoff  $n_{cr}$  for the values of conformal weight and thus mass squared. The finite number of fermionic oscillator operators indeed leads to a cutoff of conformal weight of super-conformal algebras and the replacement of integers with finite field as values of conformal weights is suggestive. The finite truncations of super conformal algebras obtained by replacing the integers  $n$  labeling the states with integers in  $Z/kZ$  would be mathematically natural and define also physically natural Jones inclusions. Prime values of  $k$  would correspond to the replacement of  $Z$  with finite field  $G(k)$ . p-Adic mass calculations suggests that the value of conformal weight for which the mass of the state becomes equal to Hagedorn temperature fixes  $n_{cr}$  and predicts  $n_{cr} \sim \log_2(p)$  [51]

- . Combining this with p-adic length scale hypothesis ( $p \simeq 2^k$ ,  $k$  integer with primes favored) would encourage the hypothesis  $n_{cr} = k$ .

### 4.3.2 Feynman rules in configuration space degrees of freedom

The construction of the theory in fermionic degrees of freedom looks relatively straightforward. In configuration space degrees of freedom the situation seems extremely complicated and I have not been able to find elegant formulation although a reduction to finite-quantum-dimensional configuration space is suggestive, and should reflect the fact that all points of 2-surface except the points of braid are below measurement resolution. The elegant solution could be a formulation in terms of quantized  $M^2$  and  $CP_2$  coordinates allowing to calculate n-point functions and here conformal field theories with string reduced to a discrete set of points representing braid is the most plausible first guess.

#### Configuration space degrees of freedom

Configuration space degrees of freedom can be decomposed to center of mass degrees of freedom, zero modes, and quantum fluctuating degrees of freedom contributing to the configuration space metric including modular degrees of freedom.

1. Cm degrees of freedom correspond to the position of partonic 2-surface, the definition of which should be specified precisely, perhaps as a selection of preferred braid strand. It is not sensible to assign separate four momenta to the braid strands since they are constrained to move parallel.
2.  $M$ -matrix should reduce essentially to a Fourier transform of the N-point function assigned to the incoming and outgoing partonic two-surfaces. The decomposition  $M^4 = M^2(x) \times E^2(x)$  implied by number theoretic compactification and known extremals of field equations with Minkowskian signature of the induced metric suggests that four-momentum should be in the plane  $M^2(x)$  so that a correlation between space-time geometry and quantum numbers would result.
3. Quantum field theory analogy would suggest the association of four-momenta to the propagator lines. This can be done by the introduction of Fourier transform of various correlation functions. The restriction inside  $CD$  implies small breaking of momentum conservation also induced by the restriction to the points of braids.
4. There are also center of mass degrees of freedom associated with  $CP_2$  and here color partial waves are necessary. Color partial waves can be assigned with partonic 2-surfaces and propagators should give correlators conserving color quantum numbers.
5. For partonic 2-surface modular degrees of freedom characterizing the conformal equivalence class of 2-surface in the induced metric is expected to be of special importance and TGD based explanation of family replication phenomenon relies on the notion of elementary particle vacuum functional in these degrees of freedom. Therefore the reduction of the partonic 2-surface to a discrete set of points would mean the loss of crucially important information. At least the global data about topology and complex structure of  $X^2$  must be preserved. Elementary particle vacuum functionals in modular degrees of freedom labeling the complex structures of  $X^2$ , or perhaps punctured  $X^2$  would bring in the needed additional structure. Modular spaces have complex structure so that configuration space Kähler metric could be non-trivial in these degrees of freedom. Induced Kähler form is the most important zero mode and excellent candidate for information that should not be lost in discretization.

#### Configuration space functional integral

About configuration space functional integral one make only some general statements.

1. If only braid points are specified, there is a functional integral over a huge number of 2-surfaces meaning sum of perturbative contributions from very large number of partonic 2-surfaces selected as maxima of Kähler function or by stationary phase approximation. This kind of non-perturbative contribution makes it very difficult to understand what is involved so that it seems that some restrictions must be posed. Also all information about crucial vacuum degeneracy of Kähler action would be lost as a non-local information.

2. Induced Kähler form represents perhaps the most fundamental zero modes since it remains invariant under symplectic transformations acting as isometries of the configuration space. Therefore it seems natural organize configuration space integral in such a manner that each choice of the induced Kähler form represents its own quantized theory and functional integral is only over deformations leaving induced Kähler form invariant.
3. One can ask whether also the induced Kähler form of the light-cone boundary should be kept fixed so that the deformations of the partonic 2-surfaces would leave invariant both the induced areas and magnetic fluxes. The the symplectic orbits of the partonic 2-surfaces (and 3-surfaces) would therefore define a slicing of the configuration space with separate quantization for each slice. It is not clear whether this restriction is consistent with conformal field theory picture.
4. The functional integral would be over the symplectic group of  $CP_2$  and over  $M^4$  degrees of freedom -perhaps also in this case over the symplectic group of  $\delta M_+^4$  - a rather well-defined mathematical structure. Symplectic transformations of  $CP_2$  affect only the  $CP_2$  part of the induced metric so that a nice separation of degrees of freedom results and the functional integral can be assigned solely to the gravitational degrees of freedom in accordance with the idea that fundamental quantum fluctuating bosonic degrees of freedom are gravitational.
5. The configuration space integration around a partonic 2-surface for which the Kähler function is maximum (it could be also selected by a stationary phase approximation) should give only tree diagrams with propagator factors proportional to  $g_K^2$  if loop corrections to the configuration space integral vanish. One could hope that there exist preferred  $S^2$  and  $CP_2$  coordinates such that vertex factors involving finite polynomials of  $S^2$  and  $CP_2$  coordinates reduce to a finite number of diagrams just as in free field theory.

### Symplectic QFT

Also the symplectically invariant degrees of freedom must be treated and this leads to the notion of symplectic QFT. The explicit construction of symplectic fusion rules has been discussed in [13]. These rules make sense only as discretized version. Discreteness can be understood also as a manifestation of finite measurement resolution: at this time it is associated with the impossibility to know the induced Kähler form at each point of partonic 2-surface. What one can measure is the Kähler flux associated with a triangle and the density of triangulation determines the measurement accuracy. The discrete set of points associated with the symplectic algebra characterizes the measurement resolution and there is an infinite hierarchy of symplectic fusion algebras corresponding to gradually increasing measurement resolution in classical sense.

An interesting question is whether the symplectic triangulation could be used to represent a hierarchy of cutoffs of super conformal algebras by introducing additional fermionic oscillators at the points of the triangulation. The  $M^4$  coordinates at the points of symplectic triangulation of  $S_i^2$ ,  $i = I, II$  projection and  $CP_2$  coordinates at the points of symplectic triangulation of  $S^2$  could define discrete version of quantized conformal fields. The functional integral over symplectic group would mean integral over symplectic triangulations. Note that  $M^2$  number theoretic braid is trivial as symplectic triangulation.

Fusion algebra structure constants are equal to products of three roots of unity assignable to each point of braid strand. An open question is whether these phase factors should be identified as counterparts of plane waves factors. Momentum conservation would be replaced in this approach by a weaker condition that the product of these factors equals to unity at each vertex.

In the original variant of symplectic triangulation the exact form of triangulation was left free. It would be however nice if symplectic triangulation could be fixed purely physically by the properties of the induced Kähler form since also the number of fermionic oscillator modes and number theoretical braids is fixed by the dynamics of Kähler action.

1. A symplectically invariant manner to fix the nodes of the triangulation could be in terms of extrema of the symplectic invariant  $\epsilon^{\alpha\beta} J_{\alpha\beta}$ . The maxima of the magnitude of Kähler magnetic field are indeed natural observables.
2. It is not clear whether the precise specification of the edges of the triangulation is needed or has any physical meaning. One might consider the possibility of extremizing the fluxes but it

turns out impossible to formulate this in terms of a local variational principle. The situation is analogous to finding an extremum of function in a situation when the extremum happens to be at the end of the interval so that the vanishing of derivative cannot be taken as criterion. In the recent situation one can expect that the extrema correspond to "triangles" for which symplectic area vanishes or to regions inside which  $\epsilon^{\alpha\beta} J_{\alpha\beta}$  has a fixed sign.

### How string model type quantization could emerge from configuration space functional integral?

Conformal invariance suggests that n-point functions of conformal field theory result from the integration over configuration space degrees of freedom. This means quantization of  $M^4$  and  $CP_2$  coordinates. The quantum variant of configuration space is natural if also configuration space degrees of freedom form hyper-finite factor of type II<sub>1</sub> as super-conformal symmetry suggests, and could be realized through quantization of the imbedding space coordinates.

1. There are reasons to expect that the conformal field theory in question is rational. Also number theoretic universality favors this option. The vertex operators of rational conformal field theories are constructible in terms of the vertex operators :  $exp(i\alpha \cdot m)$  : plus factors for internal quantum numbers. The  $M^4$  coordinate  $m$  is quantized using rules of string theory.
2. In the recent case  $\alpha$  could correspond to four-momenta assignable to the internal lines emerging from the partonic 2-surface providing a close correspondence with quantum field theory. The dynamical Kac-Moody symmetry in transversal degrees of freedom indeed suggests that this kind of factors should be included. The transversal plane to which quantized  $m$  would be restricted could be identified as the plane  $E^2$  defined by the decomposition  $M^4 = M^2 \times E^2$  characterizing given  $CD$ . The well-known tachyonity of the ground state ( $\alpha \cdot \alpha = -2$ ) required by vertex operator construction would not be a catastrophe if  $\alpha$  corresponds to transversal four-momentum. The points of braid are arranged along a closed curve in  $X^2$  in string model but in the recent case it is not clear whether the ordering remains intact.
3. The  $M^4$  projections of the points of number theoretic  $M^2$  braid at  $X^2$  can vary along light-like ray. The problem is that the variations in transversal degrees of freedom for the arguments of n-point function of  $M^4$  coordinates vanish. The problem disappears if  $S^2_i \subset CP_2$  braids are also needed.  $M^2$  braids would allow the description of  $CP_2$  quantum fluctuations and  $CP_2$  braids the description of  $M^4$  quantum fluctuations.
4. Also  $CP_2$  coordinates must be quantized and the first guess is  $CP_2$  WZW model in the point set defined by  $M^2$  braid consisting of point at light-like ray and  $M^4$  string model in the point set defined by  $CP_2$  braid. These two models could allow to calculate the n-point functions for  $M^4$  and  $CP_2$  coordinates by performing functional integral over the symplectic group of  $\delta M^4_{\pm} \times CP_2$ .
5. There are also factors coming from  $CP_2$  color partial waves and  $S^2 \times CP_2$  Hamiltonians depending of center of mass coordinates. The quantized  $M^4$  coordinates would contain these degrees of freedom as center of mass term in the representations of rational conformal field as an ordered exponential. Same trick should work for  $CP_2 = SU(3)/U(2)$  coordinates for braid points.

### 4.3.3 Rational conformal field theories and stringy scattering amplitudes

Rational conformal field theories lead to stringy scattering amplitudes as N-point functions so that there are reasons to expect that they emerge from quantum TGD.

#### General assumptions

Let us list first the general assumptions leading to stringy scattering amplitudes.

1. Quantum criticality of TGD would suggest that, as far as conformal invariance is considered, all details about the microscopic dynamics can be forgotten and the amplitudes for the generation of zero energy states from vacuum can be expressed as vacuum expectation values of the products of primary fields of a rational conformal field theory at partonic 2-surfaces. The primary fields

in question do not directly correspond to the  $M^4$  local versions of fundamental super-conformal algebras creating states at the intersections of partonic causal determinants with  $\delta M_+^4 \times CP_2$ . Rather, they would describe the states created by these operators and possessing conformal weights consistent with rationality. Hence one can completely forget the detailed anatomy of these states and only the values of  $c$  and  $\alpha = \Delta_{mn}$  matters.

2. Since the conformal weights of primary fields are non-negative, mass squared identified as conformal weight using  $CP_2$  mass as unit is non-negative and no problems with tachyons are encountered. The deeper reason for the non-negativity of conformal weights would be that the super-symplectic and Kac-Moody contributions to conformal weight sum up to a non-negative net result. It is important to notice that the vertex operators  $V(z)$  representing Kac-Moody generators used to construct stringy scattering amplitudes have positive conformal weight  $\Delta = mm'$  for  $c \neq 0$  case and, as is clear on basis of Sugawara representation, they would correspond to a negative mass squared in stringy models. This would correspond to the convention  $m^2 = kL_0$ ,  $k < 0$  rather than  $k > 0$ , in TGD framework. It must be added that TGD mass formula is definitely not consistent with that of string models.
3. The first guess is that the expressions for the amplitudes for creating zero energy state generalize as such an could be expressed in terms of the vacuum expectation values of  $n$ -point functions for the primary fields of rational conformal field theories. Stringy form would be obtained by the integration of the arguments over a circle of the partonic 2-surface and by using standard arguments one could fix 3 of the arguments  $z_i$  to  $z = 0, 1, \infty$  in case of sphere. Apart from the normalization constant the resulting amplitude would have the general form

$$A(\alpha_1, \dots, \alpha_n) = \int \prod_{i=4}^n dz^i \langle \phi_{\alpha_1}(0), \phi_{\alpha_2}(1), \phi_{\alpha_3}(\infty) \phi_{\alpha_4}(z_4) \dots \phi_{\alpha_n}(z_n) \rangle ,$$

$$\sum_n \alpha_n = 0 . \quad (4.3.1)$$

Note that the conformal weights of negative energy particles are negative.

### Free field representation of rational conformal field theories gives stringy amplitudes

Rational conformal field theories allow a representation of the primary fields in terms of exponentials of massless free fields  $X(z)$  [55] with the energy momentum tensor

$$T(z) = -\frac{1}{4} : [\partial X(z)]^2 : \quad (4.3.2)$$

The correlation functions of  $X(z)$  and  $\partial X(z)$  are

$$\begin{aligned} \langle X(z)X(\zeta) \rangle &= -2\log(z - \zeta) , \\ \langle \partial X(z)\partial X(\zeta) \rangle &= -\frac{2}{(z - \zeta)^2} . \end{aligned} \quad (4.3.3)$$

$X(z)$  has the stringy expansion

$$\begin{aligned} X(z) &= \sqrt{2} \left( q - ip \times \log(z) + i \sum \frac{a_n}{n} z^n \right) , \\ [q, p] &= i , \quad [a_n, a_m] = n\delta_{n+m,0} . \end{aligned} \quad (4.3.4)$$

There is of course no need to assume that strings are the underlying dynamical objects and  $z$  corresponds to the complex coordinate of the partonic 2-surface in TGD context.

The normal order exponentials of the free field

$$\begin{aligned}
 V_\alpha(z) &= : \exp(i\alpha X(z)) : \\
 &= \exp(i\sqrt{2}\alpha q) \exp(i\sqrt{2}\alpha p) \exp\left(\sqrt{2}\alpha \sum_{n>0} \frac{a_{-n}}{n} z^n\right) \exp\left(-\sqrt{2}\alpha \sum_{n>0} \frac{a_n}{n} z^n\right) .
 \end{aligned}
 \tag{4.3.5}$$

are also primary fields of conformal weight  $\alpha^2$ . All primary fields of minimal models can be represented in this manner apart from possible factors relating to internal quantum numbers. For  $\alpha^2 = 1$  one obtains representation for the charged generators of ADE type Kac-Moody Lie-algebras in this manner.

The n-point function for these fields can be deduced by using Campbell-Hausdorff formula

$$: \exp(i\alpha X(z)) :: \exp(i\alpha X(\zeta)) := (z - \zeta)^{2\alpha\beta} : \exp(i\alpha X(z) + i\beta X(\zeta)) : ,
 \tag{4.3.6}$$

and is given by

$$\langle V_{\alpha_1}(z_1) V_{\alpha_2}(z_2) \dots \phi_\alpha(z_n) \rangle = \prod_{i<j} (z_i - z_j)^{2\alpha_i \alpha_j}
 \tag{4.3.7}$$

for  $\sum \alpha_i = 0$  and vanishes otherwise. Thus conformal invariance of zero energy states follows from mere internal consistency. Thus rational CFT:s and obviously also ( $c = h = 0$ ) case, would give the basic stringy expression for the amplitudes for creating zero energy states from vacuum.

Consider now whether and how four-momenta could appear in this formula.

1. The number theoretic  $M^4 = M^2 \times E^2$  decomposition and quantum classical correspondence are in accordance with the assignment of Kac-Moody generators with  $E^2$  degrees of freedom. The physical interpretation would be in terms of deformations of partonic 2-surface restricted to  $\delta M^4_\pm$  with one light-like coordinate so that only two degrees of freedom remain since light-like direction corresponds to Super Virasoro symmetries in the construction of configuration space geometry. The generator of Kac-Moody algebra with zero norm would naturally correspond to the light-like direction along  $M^4_+$  for super-symplectic algebra and along light-like partonic surface for Kac-Moody algebra.

One could wonder whether both of these zero norm generators could be included to the extended Dynkin diagram so that twisted affine Lie-algebra would result ( $A_2^{(2)}$ ,  $A_{2l}^{(2)}$  with  $l \geq 2$ ,  $A_{2l-1}^{(2)}$  with  $l \geq 3$ ,  $D_{l+1}^{(2)}$  with  $l \geq 2$ , and  $E_6^{(2)}$  are possible [55]).

2. Suppose therefore that the formula generalizes to 4-D case simply by assigning to each component  $p^k$  of four-momentum its own quantized  $M^4$  coordinate  $X^k$  such that oscillator operator contribution is absent in  $M^2$  degrees of freedom, and requiring  $p^k p_k = \alpha^k \alpha_k = \alpha^2$  in suitable units:  $\alpha^2$  is the conformal weight of the primary field. The identification of the mass squared value as conformal weight would follow automatically using this ansatz. The interpretation would differ from that adopted in string models since only the counterparts of tachyonic scattering amplitudes would be allowed as is indeed natural in zero energy ontology.
3. If  $CP_2$  mass is the unit of quantization the mass unit would be about  $10^{-4}$  Planck masses. This mass scale should apply to the fundamental representations associated with the symmetries of the imbedding spaces. Physical intuition would suggest that p-adic mass squared defines the natural unit of quantization and that hadronic mass squared could be quantized in this manner. This quantization might occur for the secondary Kac-Moody representations defined by ADE series in the case of  $q \neq 1$  Jones inclusions and extended ADE series in the case of  $q = 1$  Jones inclusions suggested in [27] to occur for large values of  $\hbar$ . The generation of multiplets of ADE quantum groups and ADE Kac Moody algebra could be made possible by the multiple coverings of  $M^4$  defined by the space-time sheets for which points covering given point of  $M^4$  are related by a discrete subgroup of  $G_a \times G_b \subset SL(2, C) \times SU(2)$  (where one has  $SU(2) \subset SU(3)$ ) defining the Jones inclusion. Thus one could say that TGD universal in the sense of being able to represent the quantum dynamics associated with any ADE type quantum group or Kac-Moody group.

### p-Adicization favors rational values for central extension parameter and vacuum conformal weights

p-Adicization strongly suggests that the vacuum conformal weights and central extension parameter are rational numbers. Also algebraic numbers could in principle be considered too: this would not give any conditions if square root allowing algebraic extension of p-adic numbers are used.

#### 1. $N = 0$ case

For ordinary conformal algebra the null states are characterized by the conditions

$$\begin{aligned}\Delta_{mm'} &= \Delta_0 + \frac{1}{4}(\alpha_+ m + \alpha_- m')^2, \quad m, m' \geq 1, \\ N &= mm', \\ \Delta_0 &= \frac{1}{24}(c-1), \\ \alpha_{\pm} &= \frac{\sqrt{1-c} \pm \sqrt{25-c}}{\sqrt{24}}.\end{aligned}\tag{4.3.8}$$

Thus arbitrarily high conformal weights  $N$  are possible in the construction. For  $c \in (1, 25)$  the conformal weights are complex.

For ordinary conformal algebra rationality implies that the ground state conformal weight satisfies

$$\Delta_{mm'} = \frac{(mp' - m'p)^2 - (p' - p)^2}{4pp'}, \quad 0 < m < p, \quad 0 < m' < p'.\tag{4.3.9}$$

A more elegant expression for the central charge and weights reads as

$$\begin{aligned}c &= 1 - \frac{6}{Q(Q+1)}, \\ \Delta_{mm'} &= \frac{1}{4Q(Q+1)} [(Q(m - m' + m))^2 - 1], \\ Q &= \frac{p}{p' - p}.\end{aligned}\tag{4.3.10}$$

These conditions also imply also that the fusion rules close for a finite number of primary fields in the corresponding conformal field theory.

For  $p' = p+1$  the minimal model is unitary. In this case one has  $Q = p$  integer  $n \geq 3$ . This range of integers characterizes also the allowed values of quantum phase characterizing Jones inclusions. Furthermore,  $Q$  is related to Kac-Moody central extension in  $SU(2)_k$  theories by  $Q = k + 2$ .

The ground state conformal weight corresponds to  $m = m' = 1$  and vanishes. The null norm state however possesses the conformal weight  $mm' \geq 1$  and is therefore massive. The tachyon of string theories with conformal weight 1 is transformed in TGD framework to the absence of massless states in full accordance with the breaking of conformal invariance.  $Q = p = n$  corresponds naturally to the integer labeling Jones inclusion defining both UV and IR cutoffs with respect to conformal weight. For  $c = 0$  representation without breaking of conformal invariance all states are null norm states and the spectrum contains also massless particles. These representations correspond to  $n = \infty$  case for Jones inclusions and to full Kac-Moody symmetry and ordinary string theory in accordance with the general picture.

Since minimal conformal field theories are in question, the number of primary fields is restricted by the conditions  $0 < m < p$  and  $0 < m' < p' = p + 1$ . By the symmetry  $\Delta_{mm'} = \Delta_{p-m, p'-m'}$ . If corresponding primary fields can be identified, one has  $0 < m < m' < p' (= p + 1)$  and  $0 < m < p$ .

#### 2. Rationality for $N = 1, 2$ super-conformal algebras

The previous considerations apply on Virasoro algebra. These considerations generalize to the case of Kac-Moody algebra and also to corresponding Super algebras. In case of Super Virasoro algebra rationality requirement gives rise to different conditions on the values of  $c$  and  $\Delta_{mn}$  depending in the

value of  $N$ .  $N = 1$  super-conformal algebra corresponds to one real super charge and one real super field and is non-physical in TGD framework.  $N = 2$  case corresponds to single complex super charge and one complex super-field. In this case the Super Virasoro algebra involves also  $U(1)$  Kac-Moody algebra as inherent algebra. If these algebras are important in TGD framework, it would be natural to assign these algebras to quark and lepton type gamma matrices.

The values of the central extension parameter and conformal weights for  $N = 0, 1, 2$  for unitary rational field theories at sphere are summarized by the following table [55].

$$\begin{array}{llll}
c_k & 1 - \frac{6}{(k+2)(k+3)} & \frac{3}{2}\left(1 - \frac{8}{(k+2)(k+4)}\right) & 3\left(1 - \frac{2}{k+2}\right) \\
\Delta_{mm'} & \frac{[(k+2)m - (k+1)m']^2 - 1}{4(k+2)(k+3)} & \frac{[(k+4)m - (k+2)m']^2 - 4}{8(k+2)(k+4)} & \frac{m(m+2) - m'^2}{4(k+2)} \\
& & & (q = \frac{mm'}{k+2}) \\
m, m' & 1 \leq m \leq k+1 & 1 \leq m \leq k+2 & 0 \leq m \leq k \\
& 1 \leq m' \leq k+2 & 1 \leq m' \leq k+4 & -m \leq m' \leq m
\end{array} \tag{4.3.11}$$

It must be stressed that the conformal weights assignable to zero energy states are given by  $\Delta_{m,m'} + mm'$  whereas in conformal field theories physical states have conformal weights  $\Delta_{m,m'}$ . For partonic 2-surfaces with handles modular invariance poses additional constraints since primary fields must form a closed set also under modular transformations [55]. In the table above  $q = m'/(k+2)$  corresponds to  $U(1)$  charge.

### 3. Rationality for $N = 4$ SCA

Large  $N = 4$  super-conformal symmetry with  $SU(2)_+ \times SU(2)_- \times U(1)$  inherent Kac-Moody symmetry defines the fundamental partonic super-conformal symmetry in TGD framework. In the case of SKM algebra the groups would act on induced spinors with  $SU(2)_+$  representing spin rotations and  $SU(2)_- \times U(1) = U(2)_{ew}$  electro-weak rotations. In super-symplectic sector the action would be geometric:  $SU(2)_+$  would act as rotations on light-cone boundary and  $U(2)$  as color rotations leaving invariant a preferred  $CP_2$  point.

A concise discussion of this symmetry with explicit expressions of commutation and anticommutation relations can be found in [105]. The representations of SCA are characterized by three central extension parameters for Kac-Moody algebras but only two of them are independent and given by

$$\begin{aligned}
k_{\pm} &\equiv k(SU(2)_{\pm}) , \\
k_1 &\equiv k(U(1)) = k_+ + k_- .
\end{aligned} \tag{4.3.12}$$

The central extension parameter  $c$  is given as

$$c = \frac{6k_+k_-}{k_+ + k_-} . \tag{4.3.13}$$

and is rational valued as required.

A much studied  $N = 4$  SCA corresponds to the special case

$$\begin{aligned}
k_- &= 1 , \quad k_+ = k + 1 , \quad k_1 = k + 2 , \\
c &= \frac{6(k+1)}{k+2} .
\end{aligned} \tag{4.3.14}$$

$c = 0$  would correspond to  $k_+ = 0, k_- = 1, k_1 = 1$ . Central extension would be trivial in rotational degrees of freedom but non-trivial in  $U(2)_{ew}$ . For  $k_+ > 0$  one has  $k_1 = k_+ + k_- \neq k_+$ . A possible interpretation is in terms of electro-weak symmetry breaking with  $k_+ > 0$  signalling for the massivation of electro-weak gauge bosons.

A conjecture consistent with the general vision about the quantization of Planck constants is that  $k_+$  and  $k_-$  relate directly to the integers  $n_a$  and  $n_b$  characterizing the values of  $M_{\pm}^4$  and  $CP_2$  Planck

constants via the formulas  $n_a = k_+ + 2$  and  $n_b = k_- + 2$ . This would require  $k_{\pm} \geq 1$  for  $G_i$  a finite subgroup of  $SU(2)$  ("anyonic" phases). In stringy phases with  $G_i = SU(2)$  for  $i = a$  or  $i = b$  or for both,  $k_i$  could also vanish so that also  $n_i = 2$  corresponding to  $A_2$  ADE diagram and  $SU(2)$  Kac-Moody algebra becomes possible. In the super-symplectic sector  $k_+ = 0$  would mean massless gluons and  $k_- = k_1$  that  $U(2) \subset SU(3)$  and possibly entire  $SU(3)$  represents an unbroken symmetry.

#### 4.3.4 Objection against zero energy ontology and quantum classical correspondence

The motivation for requiring geometry and topology of space-time as correlates for quantum states is the belief that quantum measurement theory requires the representability of the outcome of quantum measurement in terms of classical physics -and if one believes in geometrization- one ends up with generalization of Einstein's vision.

There is however a counter argument against this view and second one against zero energy ontology in which one assigns eigenstates of four-momentum with causal diamonds ( $CD$ s).

1. One can argue that momentum eigenstates for which particle regarded as a topological inhomogeneity of space-time surface, which is non-localized cannot allow a space-time correlate.
2. Even worse,  $CD$ s have finite size so that strict four-momentum eigenstates strictly are not possible.

On the other hand, the paradoxical fact is that we are able to perceive momentum eigenstates and they look localized to us. This cannot be understood in the framework of standard Poincare symmetry.

The resolution of the objections and of the apparent paradox could rely on conformal symmetry assignable to light-like 3-surfaces implying a generalization of Poincare symmetry and other symmetries with their Kac-Moody variants for which symmetry transformations become local.

1. Poincare group is replaced by its Kac-Moody variant so that all non-constant translations act as gauge symmetries. Translations which are constant in the interior of  $CD$  and trivial at the boundaries of  $CD$ s are physically equivalent with constant translations. Hence the latter objection can be circumvented.
2. The same argument allows also a localization of momentum eigenstates at the boundaries of  $CD$ . In the interior the state is non-local. Classically the momentum eigenstate assigned with the partonic 2-surface is characterized by its 4-D tangent space data coding for momentum classically. The modified Dirac equation and Kähler action indeed contain an additional term representing coupling to four-momenta of particles. Formally this corresponds only to a gauge transform linear in momentum but Kähler gauge potential has  $U(1)$  gauge symmetry only as a spin glass like degenerate, not as a gauge symmetry so that space-time surface depends on momenta.
3. Conscious observer corresponds in TGD inspired theory of consciousness to  $CD$  and the sensory data of the observer come from partonic 2-surfaces at the boundaries of  $CD$  and its sub- $CD$ s. This implies classicality of sensory experience and momentum eigenstates look classical for conscious perceiver.

The usual argument resolving the paradox is based on the notion of wave packet and also this notion could be involved. The notion of finite measurement resolution is key notion of TGD and it is quite possible that one can require the localization of momentum eigenstates at the boundaries of  $CD$ s only modulo finite measurement resolution for the position of the partonic 2-surfaces.

#### 4.3.5 Issues related to Lorentz symmetry

Lorentz invariance fixes the critical dimension of target space in super string models: 26 for bosonic string model and 10 for super-string model. This is strong argument for the claim that super string models have something to do with reality. Also in TGD framework one can ask whether Lorentz symmetric and even more- Poincare symmetric - theory is achieved.

### Evidence for the breaking of Lorentz and color symmetries in TGD framework

There are several reasons suggesting that spontaneous breaking of Poincare symmetries is unavoidable in TGD and has concrete physical meaning in TGD framework.

1. The realization of the hierarchy of Planck constants involves selection of preferred plane  $M^2 \subset M^4$  and geodesic sphere  $S_i^2 \subset CP_2$  implying breaking of Lorentz invariance. The interpretation is that the fixing of quantization axes forces breaking of Poincare and color symmetries at the level of imbedding space.
2. Number theoretical vision implies the hierarchy  $M^2 \subset M^4 \subset M^8$  interpreted as inclusion hierarchy hypercomplex numbers-hyperquaternions-hyper-octonions. Number theoretical compactification is responsible for most of the progress in the understanding of quantum TGD. This hierarchy has also local variant at space-time level and this hierarchy is absolutely essential for  $M^8 - H$  duality. The physical interpretation is in terms of the selection of local polarization plane and plane of four-momentum at space-level. The notion of number theoretic braid can be defined uniquely in terms of  $M^4$  and  $CP_2$  projections of partonic 2-surfaces.
3. One could interpret  $M^4 \rightarrow M^2 \times E^2$  symmetry breaking as a vanishing of the Kac-Moody central charge  $k$  in  $M^2$  factor so that un-broken gauge invariance results. This conforms with the fact that factorizing  $S$ -matrices in  $M^2$  correspond to finite-dimensional representations of loop group. Also the fact that only transversal degrees of freedom are quantum fluctuating degrees of freedom and contribute to configuration space metric correlates with this.
4. An interesting question is whether the breaking of Lorentz symmetry is already encountered in the hadronic scattering in quark model description, which involves the reduction of Lorentz group to  $SO(1, 1) \times SO(2)$  corresponding to longitudinal and transverse momenta. The selection of quantization axis in astrophysical length scales together with gigantic value of gravitational Planck constant is an especially fascinating possibility whose implications have been discussed in [64].

The breaking of fundamental symmetries would not take place at the level of the entire configuration space if the union of copies of  $CD$ s corresponding to different selections of the quantization axes is allowed and configuration space spinor fields are delocalized in the space labeling the choices of quantization axes before the decision to make the experiment. In quantum measurement a localization to fixed  $CD$  would occur unless one wants to believe to multiverse in the sense of conscious experience.

The fact that one can assign to each sector of generalized imbedding space a preferred quantization axis suggests that  $M$ -matrix identified as entanglement coefficients breaks Lorentz symmetry and color symmetry. This symmetry breaking would be interpreted as a space-time correlate for the selection of the Cartan sub-algebra of the isometry group in quantum measurement situation and would thus represent an inherent property of quantum theory, something much deeper than a trouble produced by a gauge choice as in string models. Since the interior degrees of freedom of the space-time sheets correspond to those assignable to the measurement apparatus, the breaking of Lorentz and color symmetries at space-time level would provide a space-time correlate for this symmetry breaking.

There are several instances where the spontaneous symmetry breaking makes itself manifest also at classical level.

1. The possibility to assign almost topological quantum numbers to  $M^4$  and  $CP_2$  degrees of freedom (see the appendix of the book or [38]) involves a selection of Cartan sub-algebra of the isometry group.
2. A very general solution ansatz for the field equations based on Hamilton-Jacobi coordinates discussed in [8] involves a local  $M^2 \times E^2$  decomposition of  $M^4$ .
3. The Abelian holonomy for the classical color fields could be interpreted in terms of the reduction of color symmetries to Cartan algebra.

Also momentum space discretization requires breaking of Lorentz invariance. Here however an interesting possibility arises. If only the phase factors defined by plane waves are observable, the explicit breaking of Lorentz and Poincare invariance is avoided. This argument generalizes also to

spin and color quantum numbers since also these correspond to phase factors. Number theoretic universality implies number theoretical variant of Uncertainty Principle in the sense that if plane wave factor is algebraic number then both momentum and position cannot be simultaneously algebraic numbers as required if only algebraic extensions of rationals and  $p$ -adic numbers are allowed. Number theoretic universality allows only roots of unity as possible values of the plane wave phase, which takes the role of observable instead of position or momentum in short scales where the effects of unavoidable discretization are largest. The structure constants of symplectic fusion algebras are products of three phase factors, which are roots of unity and are assigned to the vertices of symplectic triangulation defining arguments of symplectic fields. The interpretation as plane wave factors is suggestive. Note that the 3-dimensionality of 3-space would correlate with the fact that structure constants of symplectic fusion algebra involve three algebra elements.

### Is CPT breaking possible in zero energy ontology?

CPT breaking [2] requires the breaking of Lorentz invariance. Zero energy ontology could therefore allow a spontaneous breaking of CP and CPT. This might imply matter antimatter asymmetry at the level of given  $CD$ .

There is some evidence that the mixing matrices for neutrinos and antineutrinos are different in the experimental situations considered [4, 7]. This would require CPT breaking in the standard QFT framework. In TGD  $p$ -adic length scale hypothesis allowing neutrinos to reside in several  $p$ -adic mass scales. Hence one could have apparent CPT breaking if the measurement arrangements for neutrinos and antineutrinos select different  $p$ -adic length scales for them [45].

The measurement interaction term of Chern-Simons Dirac action contains a term proportional to four-momentum but this does not imply breaking of CP and CPT since the term involves a contraction of four-momentum with the gradient of  $M^4$  coordinates and is therefore PT even. In standard QFT framework Chern-Simons term breaks CP but in TGD framework one must distinguish between space-time coordinates and imbedding space coordinates. CP breaking occurs at the imbedding space level and instanton term and Chern-Simons term are odd under P and T only at the space-time level and thus distinguish between different orientations of space-time surface.

### Breaking of Lorentz invariance and $N = 4$ super-conformal symmetry

For  $c = 0$  representations of  $N = 4$  SCA critical dimension  $D = 4 + 4$  should guarantee Lorentz invariance: this is indeed expected since the situation corresponds to Jones inclusion with trivial group  $G$ . One cannot however exclude the breaking of the full Lorentz and color symmetries for  $c \neq 0$  representations of  $N = 4$  SCA, which at the level of Jones inclusion means a change of the geometry and topology of the imbedding space and space-time.

The loss of Lorentz invariance would not be a catastrophe since  $M$ -matrix is a property of state rather than that of Universe in TGD framework. As already explained, the interpretation would be in terms of quantum measurement theory selecting a preferred Cartan subgroup for observables. This kind of breaking of course happens in the realistic experimental situation and if state describes also the measurement situation, the breaking is expected. For the scattering of zero energy states Lorentz invariance is obtained in a statistical sense.

This relates interestingly to the claimed uniqueness of super-string model if one requires unitarity and Lorentz invariance. Super string theorists might be right: only 10-D super strings might give rise to a unitary and Lorentz invariant  $S$ -matrix in perturbative sense although the perturbation series does not converge. They might be wrong in their belief that  $S$ -matrix is property of the Universe.

Whether Lorentz invariance is achieved for the stringy  $S$ -matrix characterizing entanglement between positive and negative energy states, depends on the assumptions one is ready to make about states and about what happens in state function reduction. The light cone quantization of string models involves  $M^2 \times E^2$  decomposition interpreted now as a gauge choice and the scattering amplitudes are Lorentz invariant in the critical dimension. Due to the selection of preferred quantization axes the sectors of the configuration space are not Lorentz invariant. If zero energy states are identified as Lorentz invariant superposition of Lorentz transforms of a state in a given sector Lorentz invariance is achieved. Without this assumption it is not clear whether Lorentz invariance is achieved since zero energy ontology implies that the net Poincare quantum numbers assignable to the  $M$ -matrix elements

vanish but does not imply Lorentz invariance. Similar conclusions apply in case of color quantum numbers.

#### A light hearted conjecture about relationship to super-strings and M-theory

$N = 4$  topological QFT can be considered as a possible candidate for the theory describing purely topological aspects of quantum TGD quantum criticality with respect to phase transitions changing Planck constant. This is just a guess to be shown wrong. The experience has taught that this kind of conjectures usually wrong: the real progress has come from understanding of TGD itself.

The (4,4) signature characterizing  $N = 4$  SCA topological field theory need not be a problem since in TGD framework the target space becomes a fictive concept defined by the Cartan algebra. Both  $M^4 \times CP_2$  decomposition of the imbedding space and space-time dimension are crucial for the  $2+2+2+2$  structure of the Cartan algebra, which together with the notions of the configuration space and generalized coset representation formed from super Kac-Moody and super-symplectic algebras guarantees  $N = 4$  super-conformal invariance.

Including the 2 gauge degrees of freedom associated with  $M^2$  factor of  $M^4 = M^2 \times E^2$  the critical dimension becomes  $D = 10$  and including the radial degree of light-cone boundary the critical dimension becomes  $D = 11$  of M-theory. Hence the fictive target space associated with the vertex operator construction corresponds to a flat background of super-string theory and flat background of M-theory with one light-like direction. From TGD point view the difficulties of these approaches are due to the un-necessary assumption that the fictive target space defined by the Cartan algebra corresponds to the physical imbedding space. The flatness of the fictive target space forces to introduce the notion of spontaneous compactification and dynamical imbedding space and this in turn leads to the notion of landscape.

## 4.4 Are both symplectic and conformal field theories needed?

Symplectic (or canonical as I have called them) symmetries of  $\delta M_+^4 \times CP_2$  (light-cone boundary briefly) act as isometries of the "world of classical worlds". One can see these symmetries as analogs of Kac-Moody type symmetries with symplectic transformations of  $S^2 \times CP_2$ , where  $S^2$  is  $r_M = \text{constant}$  sphere of lightcone boundary, made local with respect to the light-like radial coordinate  $r_M$  taking the role of complex coordinate. Thus finite-dimensional Lie group  $G$  is replaced with infinite-dimensional group of symplectic transformations. This inspires the question whether a symplectic analog of conformal field theory at  $\delta M_+^4 \times CP_2$  could be relevant for the construction of n-point functions in quantum TGD and what general properties these n-point functions would have. This section appears already in the previous chapter about symmetries of quantum TGD [20] but because the results of the section provide the first concrete construction recipe of  $M$ -matrix in zero energy ontology, it is included also in this chapter.

### 4.4.1 Symplectic QFT at sphere

Actually the notion of symplectic QFT emerged as I tried to understand the properties of cosmic microwave background which comes from the sphere of last scattering which corresponds roughly to the age of  $5 \times 10^5$  years [55]. In this situation vacuum extremals of Kähler action around almost unique critical Robertson-Walker cosmology imbeddable in  $M^4 \times S^2$ , where there is homologically trivial geodesic sphere of  $CP_2$ . Vacuum extremal property is satisfied for any space-time surface which is surface in  $M^4 \times Y^2$ ,  $Y^2$  a Lagrangian sub-manifold of  $CP_2$  with vanishing induced Kähler form. Symplectic transformations of  $CP_2$  and general coordinate transformations of  $M^4$  are dynamical symmetries of the vacuum extremals so that the idea of symplectic QFT emerges natural. Therefore I shall consider first symplectic QFT at the sphere  $S^2$  of last scattering with temperature fluctuation  $\Delta T/T$  proportional to the fluctuation of the metric component  $g_{aa}$  in Robertson-Walker coordinates.

1. In quantum TGD the symplectic transformation of the light-cone boundary would induce action in the "world of classical worlds" (light-like 3-surfaces). In the recent situation it is convenient to regard perturbations of  $CP_2$  coordinates as fields at the sphere of last scattering (call it  $S^2$ ) so that symplectic transformations of  $CP_2$  would act in the field space whereas those of  $S^2$  would act in the coordinate space just like conformal transformations. The deformation of the metric

would be a symplectic field in  $S^2$ . The symplectic dimension would be induced by the tensor properties of R-W metric in R-W coordinates: every  $S^2$  coordinate index would correspond to one unit of symplectic dimension. The symplectic invariance in  $CP_2$  degrees of freedom is guaranteed if the integration measure over the vacuum deformations is symplectic invariant. This symmetry does not play any role in the sequel.

2. For a symplectic scalar field  $n \geq 3$ -point functions with a vanishing anomalous dimension would be functions of the symplectic invariants defined by the areas of geodesic polygons defined by subsets of the arguments as points of  $S^2$ . Since  $n$ -polygon can be constructed from 3-polygons these invariants can be expressed as sums of the areas of 3-polygons expressible in terms of symplectic form.  $n$ -point functions would be constant if arguments are along geodesic circle since the areas of all sub-polygons would vanish in this case. The decomposition of  $n$ -polygon to 3-polygons brings in mind the decomposition of the  $n$ -point function of conformal field theory to products of 2-point functions by using the fusion algebra of conformal fields (very symbolically  $\Phi_k \Phi_l = c_{kl}^m \Phi_m$ ). This intuition seems to be correct.
3. Fusion rules stating the associativity of the products of fields at different points should generalize. In the recent case it is natural to assume a non-local form of fusion rules given in the case of symplectic scalars by the equation

$$\Phi_k(s_1)\Phi_l(s_2) = \int c_{kl}^m f(A(s_1, s_2, s_3))\Phi_m(s)d\mu_s . \quad (4.4.1)$$

Here the coefficients  $c_{kl}^m$  are constants and  $A(s_1, s_2, s_3)$  is the area of the geodesic triangle of  $S^2$  defined by the symplectic measure and integration is over  $S^2$  with symplectically invariant measure  $d\mu_s$  defined by symplectic form of  $S^2$ . Fusion rules pose powerful conditions on  $n$ -point functions and one can hope that the coefficients are fixed completely.

4. The application of fusion rules gives at the last step an expectation value of 1-point function of the product of the fields involves unit operator term  $\int c_{kl} f(A(s_1, s_2, s))Idd\mu_s$  so that one has

$$\langle \Phi_k(s_1)\Phi_l(s_2) \rangle = \int c_{kl} f(A(s_1, s_2, s))d\mu_s . \quad (4.4.2)$$

Hence 2-point function is average of a 3-point function over the third argument. The absence of non-trivial symplectic invariants for 1-point function means that  $n = 1$ - an are constant, most naturally vanishing, unless some kind of spontaneous symmetry breaking occurs. Since the function  $f(A(s_1, s_2, s_3))$  is arbitrary, 2-point correlation function can have both signs. 2-point correlation function is invariant under rotations and reflections.

#### 4.4.2 Symplectic QFT with spontaneous breaking of rotational and reflection symmetries

CMB data suggest breaking of rotational and reflection symmetries of  $S^2$ . A possible mechanism of spontaneous symmetry breaking is based on the observation that in TGD framework the hierarchy of Planck constants assigns to each sector of the generalized imbedding space a preferred quantization axes. The selection of the quantization axis is coded also to the geometry of "world of classical worlds", and to the quantum fluctuations of the metric in particular. Clearly, symplectic QFT with spontaneous symmetry breaking would provide the sought-for really deep reason for the quantization of Planck constant in the proposed manner.

1. The coding of angular momentum quantization axis to the generalized imbedding space geometry allows to select South and North poles as preferred points of  $S^2$ . To the three arguments  $s_1, s_2, s_3$  of the 3-point function one can assign two squares with the added point being either North or South pole. The difference

$$\Delta A(s_1, s_2, s_3) \equiv A(s_1, s_2, s_3, N) - A(s_1, s_2, s_3, S) \quad (4.4.3)$$

of the corresponding areas defines a simple symplectic invariant breaking the reflection symmetry with respect to the equatorial plane. Note that  $\Delta A$  vanishes if arguments lie along a geodesic line or if any two arguments co-incide. Quite generally, symplectic QFT differs from conformal QFT in that correlation functions do not possess singularities.

2. The reduction to 2-point correlation function gives a consistency conditions on the 3-point functions

$$\begin{aligned} \langle (\Phi_k(s_1)\Phi_l(s_2))\Phi_m(s_3) \rangle &= c_{kl}^r \int f(\Delta A(s_1, s_2, s)) \langle \Phi_r(s)\Phi_m(s_3) \rangle d\mu_s \\ &= \end{aligned} \quad (4.4.4)$$

$$c_{kl}^r c_{rm} \int f(\Delta A(s_1, s_2, s)) f(\Delta A(s, s_3, t)) d\mu_s d\mu_t . \quad (4.4.5)$$

Associativity requires that this expression equals to  $\langle \Phi_k(s_1)(\Phi_l(s_2)\Phi_m(s_3)) \rangle$  and this gives additional conditions. Associativity conditions apply to  $f(\Delta A)$  and could fix it highly uniquely.

3. 2-point correlation function would be given by

$$\langle \Phi_k(s_1)\Phi_l(s_2) \rangle = c_{kl} \int f(\Delta A(s_1, s_2, s)) d\mu_s \quad (4.4.6)$$

4. There is a clear difference between  $n > 3$  and  $n = 3$  cases: for  $n > 3$  also non-convex polygons are possible: this means that the interior angle associated with some vertices of the polygon is larger than  $\pi$ .  $n = 4$  theory is certainly well-defined, but one can argue that so are also  $n > 4$  theories and skeptic would argue that this leads to an inflation of theories. TGD however allows only finite number of preferred points and fusion rules could eliminate the hierarchy of theories.
5. To sum up, the general predictions are following. Quite generally, for  $f(0) = 0$  n-point correlation functions vanish if any two arguments co-incide which conforms with the spectrum of temperature fluctuations. It also implies that symplectic QFT is free of the usual singularities. For symmetry breaking scenario 3-point functions and thus also 2-point functions vanish also if  $s_1$  and  $s_2$  are at equator. All these are testable predictions using ensemble of CMB spectra.

### 4.4.3 Generalization to quantum TGD

Since number theoretic braids are the basic objects of quantum TGD, one can hope that the n-point functions assignable to them could code the properties of ground states and that one could separate from n-point functions the parts which correspond to the symplectic degrees of freedom acting as symmetries of vacuum extremals and isometries of the 'world of classical worlds'.

1. This approach indeed seems to generalize also to quantum TGD proper and the n-point functions associated with partonic 2-surfaces can be decomposed in such a manner that one obtains coefficients which are symplectic invariants associated with both  $S^2$  and  $CP_2$  Kähler form.
2. Fusion rules imply that the gauge fluxes of respective Kähler forms over geodesic triangles associated with the  $S^2$  and  $CP_2$  projections of the arguments of 3-point function serve basic building blocks of the correlation functions. The North and South poles of  $S^2$  and three poles of  $CP_2$  can be used to construct symmetry breaking n-point functions as symplectic invariants. Non-trivial 1-point functions vanish also now.

3. The important implication is that  $n$ -point functions vanish when some of the arguments coincide. This might play a crucial role in taming of the singularities: the basic general prediction of TGD is that standard infinities of local field theories should be absent and this mechanism might realize this expectation.

Next some more technical but elementary first guesses about what might be involved.

1. It is natural to introduce the moduli space for  $n$ -tuples of points of the symplectic manifold as the space of symplectic equivalence classes of  $n$ -tuples. In the case of sphere  $S^2$  convex  $n$ -polygon allows  $n + 1$  3-sub-polygons and the areas of these provide symplectically invariant coordinates for the moduli space of symplectic equivalence classes of  $n$ -polygons ( $2^n$ -D space of polygons is reduced to  $n + 1$ -D space). For non-convex polygons the number of 3-sub-polygons is reduced so that they seem to correspond to lower-dimensional sub-space. In the case of  $CP_2$   $n$ -polygon allows besides the areas of 3-polygons also 4-volumes of 5-polygons as fundamental symplectic invariants. The number of independent 5-polygons for  $n$ -polygon can be obtained by using induction: once the numbers  $N(k, n)$  of independent  $k \leq n$ -simplices are known for  $n$ -simplex, the numbers of  $k \leq n+1$ -simplices for  $n+1$ -polygon are obtained by adding one vertex so that by little visual gymnastics the numbers  $N(k, n+1)$  are given by  $N(k, n+1) = N(k-1, n) + N(k, n)$ . In the case of  $CP_2$  the allowance of 3 analogs  $\{N, S, T\}$  of North and South poles of  $S^2$  means that besides the areas of polygons  $(s_1, s_2, s_3)$ ,  $(s_1, s_2, s_3, X)$ ,  $(s_1, s_2, s_3, X, Y)$ , and  $(s_1, s_2, s_3, N, S, T)$  also the 4-volumes of 5-polygons  $(s_1, s_2, s_3, X, Y)$ , and of 6-polygon  $(s_1, s_2, s_3, N, S, T)$ ,  $X, Y \in \{N, S, T\}$  can appear as additional arguments in the definition of 3-point function.
2. What one really means with symplectic tensor is not clear since the naive first guess for the  $n$ -point function of tensor fields is not manifestly general coordinate invariant. For instance, in the model of CMB, the components of the metric deformation involving  $S^2$  indices would be symplectic tensors. Tensorial  $n$ -point functions could be reduced to those for scalars obtained as inner products of tensors with Killing vector fields of  $SO(3)$  at  $S^2$ . Again a preferred choice of quantization axis would be introduced and special points would correspond to the singularities of the Killing vector fields.

The decomposition of Hamiltonians of the "world of classical worlds" expressible in terms of Hamiltonians of  $S^2 \times CP_2$  to irreps of  $SO(3)$  and  $SU(3)$  could define the notion of symplectic tensor as the analog of spherical harmonic at the level of configuration space. Spin and gluon color would have natural interpretation as symplectic spin and color. The infinitesimal action of various Hamiltonians on  $n$ -point functions defined by Hamiltonians and their super counterparts is well-defined and group theoretical arguments allow to deduce general form of  $n$ -point functions in terms of symplectic invariants.

3. The need to unify  $p$ -adic and real physics by requiring them to be completions of rational physics, and the notion of finite measurement resolution suggest that discretization of also fusion algebra is necessary. The set of points appearing as arguments of  $n$ -point functions could be finite in a given resolution so that the  $p$ -adically troublesome integrals in the formulas for the fusion rules would be replaced with sums. Perhaps rational/algebraic variants of  $S^2 \times CP_2 = SO(3)/SO(2) \times SU(3)/U(2)$  obtained by replacing these groups with their rational/algebraic variants are involved. Tetrahedra, octahedra, and dodecahedra suggest themselves as simplest candidates for these discretized spaces. Also the symplectic moduli space would be discretized to contain only  $n$ -tuples for which the symplectic invariants are numbers in the allowed algebraic extension of rationals. This would provide an abstract looking but actually very concrete operational approach to the discretization involving only areas of  $n$ -tuples as internal coordinates of symplectic equivalence classes of  $n$ -tuples. The best that one could achieve would be a formulation involving nothing below measurement resolution.
4. This picture based on elementary geometry might make sense also in the case of conformal symmetries. The angles associated with the vertices of the  $S^2$  projection of  $n$ -polygon could define conformal invariants appearing in  $n$ -point functions and the algebraization of the corresponding phases would be an operational manner to introduce the space-time correlates for the roots of unity introduced at quantum level. In  $CP_2$  degrees of freedom the projections of  $n$ -tuples to the homologically trivial geodesic sphere  $S^2$  associated with the particular sector of  $CH$  would allow

to define similar conformal invariants. This framework gives dimensionless areas (unit sphere is considered). p-Adic length scale hypothesis and hierarchy of Planck constants would bring in the fundamental units of length and time in terms of  $CP_2$  length.

The recent view about  $M$ -matrix described is something almost unique determined by Connes tensor product providing a formal realization for the statement that complex rays of state space are replaced with  $\mathcal{N}$  rays where  $\mathcal{N}$  defines the hyper-finite sub-factor of type  $II_1$  defining the measurement resolution.  $M$ -matrix defines time-like entanglement coefficients between positive and negative energy parts of the zero energy state and need not be unitary. It is identified as square root of density matrix with real expressible as product of real and positive square root and unitary  $S$ -matrix. This  $S$ -matrix is what is measured in laboratory. There is also a general vision about how vertices are realized: they correspond to light-like partonic 3-surfaces obtained by gluing incoming and outgoing partonic 3-surfaces along their ends together just like lines of Feynman diagrams. Note that in string models string world sheets are non-singular as 2-manifolds whereas 1-dimensional vertices are singular as 1-manifolds. These ingredients we should be able to fuse together. So we try once again!

1. *Iteration* starting from vertices and propagators is the basic approach in the construction of  $n$ -point function in standard QFT. This approach does not work in quantum TGD. Symplectic and conformal field theories suggest that *recursion* replaces iteration in the construction. One starts from an  $n$ -point function and reduces it step by step to a vacuum expectation value of a 2-point function using fusion rules. Associativity becomes the fundamental dynamical principle in this process. Associativity in the sense of classical number fields has already shown its power and led to a hyper-octonionic formulation of quantum TGD promising a unification of various visions about quantum TGD [72] .
2. Let us start from the representation of a zero energy state in terms of a causal diamond defined by future and past directed light-cones. Zero energy state corresponds to a quantum superposition of light-like partonic 3-surfaces each of them representing possible particle reaction. These 3-surfaces are very much like generalized Feynman diagrams with lines replaced by light-like 3-surfaces coming from the upper and lower light-cone boundaries and glued together along their ends at smooth 2-dimensional surfaces defining the generalized vertices.
3. It must be emphasized that the generalization of ordinary Feynman diagrammatics arises and conformal and symplectic QFTs appear only in the calculation of single generalized Feynman diagram. Therefore one could still worry about loop corrections. The fact that no integration over loop momenta is involved and there is always finite cutoff due to discretization together with recursive instead of iterative approach gives however good hopes that everything works. Note that this picture is in conflict with one of the earlier approaches based on positive energy ontology in which the hope was that only single generalized Feynman diagram could define the  $U$ -matrix thought to correspond to physical  $S$ -matrix at that time.
4. One can actually simplify things by identifying generalized Feynman diagrams as maxima of Kähler function with functional integration carried over perturbations around it. Thus one would have conformal field theory in both fermionic and configuration space degrees of freedom. The light-like time coordinate along light-like 3-surface is analogous to the complex coordinate of conformal field theories restricted to some curve. If it is possible continue the light-like time coordinate to a hyper-complex coordinate in the interior of 4-D space-time sheet, the correspondence with conformal field theories becomes rather concrete. Same applies to the light-like radial coordinates associated with the light-cone boundaries. At light-cone boundaries one can apply fusion rules of a symplectic QFT to the remaining coordinates. Conformal fusion rules are applied only to point pairs which are at different ends of the partonic surface and there are no conformal singularities since arguments of  $n$ -point functions do not co-incide. By applying the conformal and symplectic fusion rules one can eventually reduce the  $n$ -point function defined by the various fermionic and bosonic operators appearing at the ends of the generalized Feynman diagram to something calculable.
5. Finite measurement resolution defining the Connes tensor product is realized by the discretization applied to the choice of the arguments of  $n$ -point functions so that discretion is not only a

space-time correlate of finite resolution but actually defines it. No explicit realization of the measurement resolution algebra  $\mathcal{N}$  seems to be needed. Everything should boil down to the fusion rules and integration measure over different 3-surfaces defined by exponent of Kähler function and by imaginary exponent of Chern-Simons action. The continuation of the configuration space Clifford algebra for 3-surfaces with cm degrees of freedom fixed to a hyper-octonionic variant of gamma matrix field of super-string models defined in  $M^8$  (hyper-octonionic space) and  $M^8 \leftrightarrow M^4 \times CP_2$  duality leads to a unique choice of the points, which can contribute to n-point functions as intersection of  $M^4$  subspace of  $M^8$  with the counterparts of partonic 2-surfaces at the boundaries of light-cones of  $M^8$ . Therefore there are hopes that the resulting theory is highly unique. Symplectic fusion algebra reduces to a finite algebra for each space-time surface if this picture is correct.

6. Consider next some of the details of how the light-like 3-surface codes for the fusion rules associated with it. The intermediate partonic 2-surfaces must be involved since otherwise the construction would carry no information about the properties of the light-like 3-surface, and one would not obtain perturbation series in terms of the relevant coupling constants. The natural assumption is that partonic 2-surfaces belong to future/past directed light-cone boundary depending on whether they are on lower/upper half of the causal diamond. Hyper-octonionic conformal field approach fixes the  $n_{int}$  points at intermediate partonic two-sphere for a given light-like 3-surface representing generalized Feynman diagram, and this means that the contribution is just  $N$ -point function with  $N = n_{out} + n_{int} + n_{in}$  calculable by the basic fusion rules. Coupling constant strengths would emerge through the fusion coefficients, and at least in the case of gauge interactions they must be proportional to Kähler coupling strength since n-point functions are obtained by averaging over small deformations with vacuum functional given by the exponent of Kähler function. The first guess is that one can identify the spheres  $S^2 \subset \delta M_{\pm}^4$  associated with initial, final and, and intermediate states so that symplectic n-points functions could be calculated using single sphere.

These findings raise the hope that quantum TGD is indeed a solvable theory. Even if one is not willing to swallow any bit of TGD, the classification of the symplectic QFTs remains a fascinating mathematical challenge in itself. A further challenge is the fusion of conformal QFT and symplectic QFT in the construction of n-point functions. One might hope that conformal and symplectic fusion rules can be treated separately. This separation indeed happens since conformal degrees of freedom correspond to quantum fluctuations contributing to the configuration space metric and affecting the induced metric whereas symplectic invariants correspond to non-quantum fluctuating zero modes defining the part of quantum state not affected by quantum fluctuations parameterized by the symplectic group of  $\delta M_{\pm}^4 \times CP_2$ . Also the dream about symplectic fusion rules have been realized. An explicit construction of symplectic fusion algebras is represented in [13].

## 4.5 Weak form of electric-magnetic duality and fermionic propagator

The ideas about what generalized Feynman diagrams could be have developed rather slowly and basically through trial and mostly error. Bosonic emergence implies that fermionic propagator is the fundamental object and its identification has become one of the basic challenges of TGD. For long time the belief was that a straightforward generalization of stringy propagators could make sense but it turned out that TGD requires something more original. The weak form of electric-magnetic duality meant a decisive step of progress also in the understanding of fermionic propagator. In the following the implications of weak form of electric-magnetic duality for TGD are explained by starting from classical theory and ending up with fermionic propagator.

### 4.5.1 Could Quantum TGD reduce to almost topological QFT?

There seems to be a profound connection with the earlier unrealistic proposal that TGD reduces to almost topological quantum theory in the sense that the counterpart of Chern-Simons action assigned with the wormhole throats somehow dictates the dynamics. This proposal can be formulated also

for the modified Dirac action. I gave up this proposal but the following argument shows that Kähler action with weak form of electric-magnetic duality effectively reduces to Chern-Simons action plus Coulomb term.

1. Kähler action density can be written as a 4-dimensional integral of the Coulomb term  $j_K^\alpha A_\alpha$  plus and integral of the boundary term  $J^{n\beta} A_\beta \sqrt{g_4}$  over the wormhole throats and of the quantity  $J^{0\beta} A_\beta \sqrt{g_4}$  over the ends of the 3-surface.
2. If the self-duality conditions generalize to  $J^{n\beta} = 4\pi\alpha_K \epsilon^{n\beta\gamma\delta} J_{\gamma\delta}$  at throats and to  $J^{0\beta} = 4\pi\alpha_K \epsilon^{0\beta\gamma\delta} J_{\gamma\delta}$  at the ends, the Kähler function reduces to the counterpart of Chern-Simons action evaluated at the ends and throats. It would have same value for each branch and the replacement  $\hbar_0 \rightarrow r\hbar_0$  would effectively describe this. Boundary conditions would however give  $1/r$  factor so that  $\hbar$  would disappear from the Kähler function! The original attempt to realize quantum TGD as an almost topological QFT was in terms of Chern-Simons action but was given up. It is somewhat surprising that Kähler action gives Chern-Simons action in the vacuum sector defined as sector for which Kähler current is light-like or vanishes.

Holography encourages to ask whether also the Coulomb interaction terms could vanish. This kind of dimensional reduction would mean an enormous simplification since TGD would reduce to an almost topological QFT. The attribute "almost" would come from the fact that one has non-vanishing classical Noether charges defined by Kähler action and non-trivial quantum dynamics in  $M^4$  degrees of freedom. One could also assign to space-time surfaces conserved four-momenta which is not possible in topological QFTs. For this reason the conditions guaranteeing the vanishing of Coulomb interaction term deserve a detailed analysis.

1. For the known extremals  $j_K^\alpha$  either vanishes or is light-like ("massless extremals" for which weak self-duality condition does not make sense [8]) so that the Coulombic term vanishes identically in the gauge used. The addition of a gradient to  $A$  induces terms located at the ends and wormhole throats of the space-time surface but this term must be cancelled by the other boundary terms by gauge invariance of Kähler action. This implies that the  $M^4$  part of WCW metric vanishes in this case. Therefore massless extremals as such are not physically realistic: wormhole throats representing particles are needed.
2. The original naive conclusion was that since Chern-Simons action depends on  $CP_2$  coordinates only, its variation with respect to Minkowski coordinates must vanish so that the WCW metric would be trivial in  $M^4$  degrees of freedom. This conclusion is in conflict with quantum classical correspondence and was indeed too hasty. The point is that the allowed variations of Kähler function must respect the weak electro-magnetic duality which relates Kähler electric field depending on the induced 4-metric at 3-surface to the Kähler magnetic field. Therefore the dependence on  $M^4$  coordinates creeps via a Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x . \quad (4.5.1)$$

The (1,1) part of second variation contributing to  $M^4$  metric comes from this term.

3. This erratic conclusion about the vanishing of  $M^4$  part WCW metric raised the question about how to achieve a non-trivial metric in  $M^4$  degrees of freedom. The proposal was a modification of the weak form of electric-magnetic duality. Besides  $CP_2$  Kähler form there would be the Kähler form assignable to the light-cone boundary reducing to that for  $r_M = \text{constant}$  sphere - call it  $J^1$ . The generalization of the weak form of self-duality would be  $J^{n\beta} = \epsilon^{n\beta\gamma\delta} K (J_{\gamma\delta} + \epsilon J_{\gamma\delta}^1)$ . This form implies that the boundary term gives a non-trivial contribution to the  $M^4$  part of the WCW metric even without the constraint from electric-magnetic duality. Kähler charge is not affected unless the partonic 2-surface contains the tip of  $CD$  in its interior. In this case the value of Kähler charge is shifted by a topological contribution. Whether this term can survive depends on whether the resulting vacuum extremals are consistent with the basic facts about classical gravitation.

4. The Coulombic interaction term is not invariant under gauge transformations. The good news is that this might allow to find a gauge in which the Coulomb term vanishes. The vanishing condition fixing the gauge transformation  $\phi$  is

$$j_K^\alpha \partial_\alpha \phi = -j^\alpha A_\alpha \quad . \quad (4.5.2)$$

This differential equation can be reduced to an ordinary differential equation along the flow lines  $j_K$  by using  $dx^\alpha/dt = j_K^\alpha$ . Global solution is obtained only if one can combine the flow parameter  $t$  with three other coordinates- say those at the either end of  $CD$  to form space-time coordinates. The condition is that the parameter defining the coordinate differential is proportional to the covariant form of Kähler current:  $dt = \phi j_K$ . This condition in turn implies  $d^2t = d(\phi j_K) = d\phi \wedge j_K + \phi dj_K = 0$  implying  $j_K \wedge dj_K = 0$  or more concretely,

$$\epsilon^{\alpha\beta\gamma\delta} j_\beta^K \partial_\gamma j_\delta^K = 0 \quad . \quad (4.5.3)$$

$j_K$  is a four-dimensional counterpart of Beltrami field [48] and could be called generalized Beltrami field.

The integrability conditions follow also from the construction of the extremals of Kähler action [8] . The conjecture was that for the extremals the 4-dimensional Lorentz force vanishes (no dissipation): this requires  $j_K \wedge J = 0$ . One manner to guarantee this is the topologization of the Kähler current meaning that it is proportional to the instanton current:  $j_K = \phi j_I$ , where  $j_I = *(J \wedge A)$  is the instanton current, which is not conserved for 4-D  $CP_2$  projection. The conservation of  $j_K$  implies the condition  $j_I^\alpha \partial_\alpha \phi = \partial_\alpha j^\alpha \phi$  and from this  $\phi$  can be integrated if the integrability condition  $j_I \wedge dj_I = 0$  holds true implying the same condition for  $j_K$ . By introducing at least 3 or  $CP_2$  coordinates as space-time coordinates, one finds that the contravariant form of  $j_I$  is purely topological so that the integrability condition fixes the dependence on  $M^4$  coordinates and this selection is coded into the scalar function  $\phi$ . These functions define families of conserved currents  $j_K^\alpha \phi$  and  $j_I^\alpha \phi$  and could be also interpreted as conserved currents associated with the critical deformations of the space-time surface.

5. There are gauge transformations respecting the vanishing of the Coulomb term. The vanishing condition for the Coulomb term is gauge invariant only under the gauge transformations  $A \rightarrow A + \nabla\phi$  for which the scalar function the integral  $\int j_K^\alpha \partial_\alpha \phi$  reduces to a total divergence a giving an integral over various 3-surfaces at the ends of  $CD$  and at throats vanishes. This is satisfied if the allowed gauge transformations define conserved currents

$$D_\alpha(j^\alpha \phi) = 0 \quad . \quad (4.5.4)$$

As a consequence Coulomb term reduces to a difference of the conserved charges  $Q_\phi^e = \int j^0 \phi \sqrt{g_4} d^3x$  at the ends of the CD vanishing identically. The change of the imons type term is trivial if the total weighted Kähler magnetic flux  $Q_\phi^m = \sum \int J \phi dA$  over wormhole throats is conserved. The existence of an infinite number of conserved weighted magnetic fluxes is in accordance with the electric-magnetic duality. How these fluxes relate to the flux Hamiltonians central for WCW geometry is not quite clear.

6. The gauge transformations respecting the reduction to almost topological QFT should have some special physical meaning. The measurement interaction term in the modified Dirac interaction corresponds to a critical deformation of the space-time sheet and is realized as an addition of a gauge part to the Kähler gauge potential of  $CP_2$ . It would be natural to identify this gauge transformation giving rise to a conserved charge so that the conserved charges would provide a representation for the charges associated with the infinitesimal critical deformations not affecting Kähler action. The gauge transformed Kähler potential couples to the modified

Dirac equation and its effect could be visible in the value of Kähler function and therefore also in the properties of the preferred extremal. The effect on WCW metric would however vanish since  $K$  would transform only by an addition of a real part of a holomorphic function. Kähler function is identified as a Dirac determinant for Chern-Simons Dirac action and the spectrum of this operator should not be invariant under these gauge transformations if this picture is correct. This is achieved if the gauge transformation is carried only in the Dirac action corresponding to the Chern-Simons term: this assumption is motivated by the breaking of time reversal invariance induced by quantum measurements. The modification of Kähler action can be guessed to correspond just to the Chern-Simons contribution from the instanton term.

7. A reasonable looking guess for the explicit realization of the quantum classical correspondence between quantum numbers and space-time geometry is that the deformation of the preferred extremal due to the addition of the measurement interaction term is induced by a  $U(1)$  gauge transformation induced by a transformation of  $\delta CD \times CP_2$  generating the gauge transformation represented by  $\phi$ . This interpretation makes sense if the fluxes defined by  $Q_\phi^m$  and corresponding Hamiltonians affect only zero modes rather than quantum fluctuating degrees of freedom.

To sum up, one could understand the basic properties of WCW metric in this framework. Effective 2-dimensionality would result from the existence of an infinite number of conserved charges in two different time directions (genuine conservation laws plus gauge fixing). The infinite-dimensional symmetric space for given values of zero modes corresponds to the Cartesian product of the WCWs associated with the partonic 2-surfaces at both ends of  $CD$  and the generalized Chern-Simons term decomposes into a sum of terms from the ends giving single particle Kähler functions and to the terms from light-like wormhole throats giving interaction term between positive and negative energy parts of the state. Hence Kähler function could be calculated without any knowledge about the interior of the space-time sheets and TGD would reduce to almost topological QFT as speculated earlier. Needless to say this would have immense boost to the program of constructing WCW Kähler geometry.

### 4.5.2 A general solution ansatz based on almost topological QFT property

The basic vision behind the ansatz is the reduction of quantum TGD to almost topological field theory. This requires that the flow parameters associated with the flow lines of isometry currents and Kähler current extend to global coordinates. This leads to integrability conditions implying generalized Beltrami flow and Kähler action for the preferred extremals reduces to Chern-Simons action when weak electro-weak duality is applied as boundary conditions. The strongest form of the hydrodynamical interpretation requires that all conserved currents are parallel to Kähler current. In the more general case one would have several hydrodynamic flows. Also the braidings (several of them for the most general ansatz) assigned with the light-like 3-surfaces are naturally defined by the flow lines of conserved currents. The independent behavior of particles at different flow lines can be seen as a realization of the complete integrability of the theory. In free quantum field theories on mass shell Fourier components are in a similar role but the geometric interpretation in terms of flow is of course lacking. This picture should generalize also to the solution of the modified Dirac equation.

#### Basic field equations

Consider first the equations at general level.

1. The breaking of the Poincare symmetry due to the presence of monopole field occurs and leads to the isometry group  $T \times SO(3) \times SU(3)$  corresponding to time translations, rotations, and color group. The Cartan algebra is four-dimensional and field equations reduce to the conservation laws of energy  $E$ , angular momentum  $J$ , color isospin  $I_3$ , and color hypercharge  $Y$ .
2. Quite generally, one can write the field equations as conservation laws for  $I, J, I_3$ , and  $Y$ .

$$D_\alpha [D_\beta (J^{\alpha\beta} H_A) - j_K^\alpha H^A + T^{\alpha\beta} j_A^l h_{kl} \partial_\beta h^l] = 0 . \quad (4.5.5)$$

The first term gives a contraction of the symmetric Ricci tensor with antisymmetric Kähler form and vanishes so that one has

$$D_\alpha [j_K^\alpha H^A - T^{\alpha\beta} j_A^k h_{kl} \partial_\beta h^l] = 0 . \quad (4.5.6)$$

For energy one has  $H_A = 1$  and energy current associated with the flow lines is proportional to the Kähler current. Its divergence vanishes identically.

3. One can express the divergence of the term involving energy momentum tensor as a sum of terms involving  $j_K^\alpha J_{\alpha\beta}$  and contraction of second fundamental form with energy momentum tensor so that one obtains

$$j_K^\alpha D_\alpha H^A = j_K^\alpha J_{\alpha\beta} j_\beta^A + T^{\alpha\beta} H_{\alpha\beta}^k j_k^A . \quad (4.5.7)$$

### Hydrodynamical solution ansatz

The characteristic feature of the solution ansatz would be the reduction of the dynamics to hydrodynamics analogous to that for a continuous distribution of particles initially at the end of  $X^3$  of the light-like 3-surface moving along flow lines defined by currents  $j_A$  satisfying the integrability condition  $j_A \wedge dj_A = 0$ . Field theory would reduce effectively to particle mechanics along flow lines with conserved charges defined by various isometry currents. The strongest condition is that all isometry currents  $j_A$  and also Kähler current  $j_K$  are proportional to the same current  $j$ . The more general option corresponds to multi-hydrodynamics.

Conserved currents are analogous to hydrodynamical currents in the sense that the flow parameter along flow lines extends to a global space-time coordinate. The conserved current is proportional to the gradient  $\nabla\Phi$  of the coordinate varying along the flow lines:  $J = \Psi\nabla\Phi$  and by a proper choice of  $\Psi$  one can allow to have conservation. The initial values of  $\Psi$  and  $\Phi$  can be selected freely along the flow lines beginning from either the end of the space-time surface or from wormhole throats.

If one requires hydrodynamics also for Chern-Simons action (effective 2-dimensionality is required for preferred extremals), the initial values of scalar functions can be chosen freely only at the partonic 2-surfaces. The freedom to choose the initial values of the charges conserved along flow lines at the partonic 2-surfaces means the existence of an infinite number of conserved charges so that the theory would be integrable and even in two different coordinate directions. The basic difference as compared to ordinary conservation laws is that the conserved currents are parallel and their flow parameter extends to a global coordinate.

1. The most general assumption is that the conserved isometry currents

$$J_A^\alpha = j_K^\alpha H^A - T^{\alpha\beta} j_A^k h_{kl} \partial_\beta h^l \quad (4.5.8)$$

and Kähler current are integrable in the sense that  $J_A \wedge J_A = 0$  and  $j_K \wedge j_K = 0$  hold true. One could imagine the possibility that the currents are not parallel.

2. The integrability condition  $dJ_A \wedge J_A = 0$  is satisfied if one has

$$J_A = \Psi_A d\Phi_A . \quad (4.5.9)$$

The conservation of  $J_A$  gives

$$d * (\Psi_A d\Phi_A) = 0 . \quad (4.5.10)$$

This would mean separate hydrodynamics for each of the currents involved. In principle there is no need to assume any further conditions and one can imagine infinite basis of scalar function pairs  $(\Psi_A, \Phi_A)$  since criticality implies infinite number deformations implying conserved Noether currents.

3. The conservation condition reduces to d'Alembert equation in the induced metric if one assumes that  $\nabla\Psi_A$  is orthogonal with every  $d\Phi_A$ .

$$d * d\Phi_A = 0 \ , \ d\Psi_A \cdot d\Phi_A = 0 \ . \quad (4.5.11)$$

Taking  $x = \Phi_A$  as a coordinate the orthogonality condition states  $g^{xj}\partial_j\Psi_A = 0$  and in the general case one cannot solve the condition by simply assuming that  $\Psi_A$  depends on the coordinates transversal to  $\Phi_A$  only. These conditions bring in mind  $p \cdot p = 0$  and  $p \cdot e$  condition for massless modes of Maxwell field having fixed momentum and polarization.  $d\Phi_A$  would correspond to  $p$  and  $d\Psi_A$  to polarization. The condition that each isometry current corresponds its own pair  $(\Psi_A, \Phi_A)$  would mean that each isometry current corresponds to independent light-like momentum and polarization. Ordinary free quantum field theory would support this view whereas hydrodynamics and QFT limit of TGD would support single flow.

These are the most general hydrodynamical conditions that one can assume. One can consider also more restricted scenarios.

1. The strongest ansatz is inspired by the hydrodynamical picture in which all conserved isometry charges flow along same flow lines so that one would have

$$J_A = \Psi_A d\Phi \ . \quad (4.5.12)$$

In this case same  $\Phi$  would satisfy simultaneously the d'Alembert type equations.

$$d * d\Phi = 0 \ , \ d\Psi_A \cdot d\Phi = 0. \quad (4.5.13)$$

This would mean that the massless modes associated with isometry currents move in parallel manner but can have different polarizations. The spinor modes associated with light-like like 3-surfaces carry parallel four-momenta, which suggest that this option is correct. This allows a very general family of solutions and one can have a complete 3-dimensional basis of functions  $\Psi_A$  with gradient orthogonal to  $d\Phi$ .

2. Isometry invariance under  $T \times SO(3) \times SU(3)$  allows to consider the possibility that one has

$$J_A = k_A \Psi_A d\Phi_{G(A)} \ , \ d * (d\Phi_{G(A)}) = 0 \ , \ d\Psi_A \cdot d\Phi_{G(A)} = 0 \ . \quad (4.5.14)$$

where  $G(A)$  is  $T$  for energy current,  $SO(3)$  for angular momentum currents and  $SU(3)$  for color currents. Energy would thus flow along its own flux lines, angular momentum along its own flow lines, and color quantum numbers along their own flow lines. For instance, color currents would differ from each other only by a numerical constant. The replacement of  $\Psi_A$  with  $\Psi_{G(A)}$  would be too strong a condition since Killing vector fields are not related by a constant factor.

To sum up, the most general option is that each conserved current  $J_A$  defines its own integrable flow lines defined by the scalar function pair  $(\Psi_A, \Phi_A)$ . A complete basis of scalar functions satisfying the d'Alembert type equation guaranteeing current conservation could be imagined with restrictions coming from the effective 2-dimensionality reducing the scalar function basis effectively to the partonic 2-surface. The diametrically opposite option corresponds to the basis obtained by assuming that only single  $\Phi$  is involved.

The proposed solution ansatz can be compared to the earlier ansatz [35] stating that Kähler current is topologized in the sense that for  $D(CP_2) = 3$  it is proportional to the identically conserved

instanton current (so that 4-D Lorentz force vanishes) and vanishes for  $D(CP_2) = 4$  (Maxwell phase). This hypothesis requires that instanton current is Beltrami field for  $D(CP_2) = 3$ . In the recent case the assumption that also instanton current satisfies the Beltrami hypothesis in strong sense (single function  $\Phi$ ) generalizes the topologization hypothesis for  $D(CP_2) = 3$ . As a matter fact, the topologization hypothesis applies to isometry currents also for  $D(CP_2) = 4$  although instanton current is not conserved anymore.

### Can one require the extremal property in the case of Chern-Simons action?

Effective 2-dimensionality is achieved if the ends and wormhole throats are extremals of Chern-Simons action. The strongest condition would be that space-time surfaces allow orthogonal slicings by 3-surfaces which are extremals of Chern-Simons action.

Also in this case one can require that the flow parameter associated with the flow lines of the isometry currents extends to a global coordinate. Kähler magnetic field  $B = *J$  defines a conserved current so that all conserved currents would flow along the field lines of  $B$  and one would have 3-D Beltrami flow. Note that in magnetohydrodynamics the standard assumption is that currents flow along the field lines of the magnetic field.

For wormhole throats light-likeness causes some complications since the induced metric is degenerate and the contravariant metric must be restricted to the complement of the light-like direction. This means that d'Alembert equation reduces to 2-dimensional Laplace equation. For space-like 3-surfaces one obtains the counterpart of Laplace equation with partonic 2-surfaces serving as sources. The interpretation in terms of analogs of Coulomb potentials created by 2-D charge distributions would be natural.

### 4.5.3 Hydrodynamic picture in fermionic sector

Super-symmetry inspires the conjecture that the hydrodynamical picture applies also to the solutions of the modified Dirac equation.

#### 4-dimensional modified Dirac equation and hydrodynamical picture

Consider first the solutions of the induced spinor field in the interior of space-time surface.

1. The local inner products of the modes of the induced spinor fields define conserved currents

$$\begin{aligned} D_\alpha J_{mn}^\alpha &= 0 \ , \\ J_{mn}^\alpha &= \bar{u}_m \hat{\Gamma}^\alpha u_n \ , \\ \hat{\Gamma}^\alpha &= \frac{\partial L_K}{\partial(\partial_\alpha h^k)} \Gamma_k \ . \end{aligned} \tag{4.5.15}$$

The conjecture is that the flow parameters of also these currents extend to a global coordinate so that one would have in the completely general case the condition

$$\begin{aligned} J_{mn}^\alpha &= \Phi_{mn} d\Psi_{mn} \ , \\ d * (d\Phi_{mn}) &= 0 \ , \quad \nabla \Psi_{mn} \cdot \Phi_{mn} = 0 \ . \end{aligned} \tag{4.5.16}$$

The condition  $\Phi_{mn} = \Phi$  would mean that the massless modes propagate in parallel manner and along the flow lines of Kähler current. The conservation condition along the flow line implies that the current component  $J_{mn}$  is constant along it. Everything would reduce to initial values at the ends of the space-time sheet boundaries of  $CD$  and 3-D modified Dirac equation would reduce everything to initial values at partonic 2-surfaces.

2. One might hope that the conservation of these super currents for all modes is equivalent with the modified Dirac equation. The modes  $u_n$  appearing in  $\Psi$  in quantized theory would be kind of "square roots" of the basis  $\Phi_{mn}$  and the challenge would be to deduce the modes from the conservation laws.
3. The quantization of the induced spinor field in 4-D sense would be fixed by those at 3-D space-like ends by the fact that the oscillator operators are carried along the flow lines as such so that the anti-commutator of the induced spinor field at the opposite ends of the flow lines at the light-like boundaries of  $CD$  is in principle fixed by the anti-commutations at the either end. The anti-commutations at 3-D surfaces cannot be fixed freely since one has 3-D Chern-Simons flow reducing the anti-commutations to those at partonic 2-surfaces.

The following argument suggests that induced spinor fields are in a suitable gauge simply constant along the flow lines of the Kähler current just as massless spinor modes are constant along the geodesic in the direction of momentum.

1. The modified gamma matrices are of form  $T_k^\alpha \Gamma^k$ ,  $T_k^\alpha = \partial L_K / \partial (\partial_\alpha h^k)$ . The H-vectors  $T_k^\alpha$  can be expressed as linear combinations of a subset of Killing vector fields  $j_A^k$  spanning the tangent space of  $H$ . For  $CP_2$  the natural choice are the 4 Lie-algebra generators in the complement of  $U(2)$  sub-algebra. For  $CD$  one can use generator time translation and three generators of rotation group  $SO(3)$ . The completeness of the basis defined by the subset of Killing vector fields gives completeness relation  $h_l^k = j^{Ak} j_{Ak}$ . This implies  $T^{\alpha k} = T^{\alpha k} j_A^k j_A^k = T^{\alpha A} j_A^k$ . One can define gamma matrices  $\Gamma_A$  as  $\Gamma_k j_A^k$  to get  $T_k^\alpha \Gamma^k = T^{\alpha A} \Gamma_A$ .
2. This together with the condition that all isometry currents are proportional to the Kähler current (or if this vanishes to same conserved current- say energy current) satisfying Beltrami flow property implies that one can reduce the modified Dirac equation to an ordinary differential equation along flow lines. The quantities  $T^{tA}$  are constant along the flow lines and one obtains

$$T^{tA} j_A D_t \Psi = 0 . \tag{4.5.17}$$

By choosing the gauge suitably the spinors are just constant along flow lines so that the spinor basis reduces by effective 2-dimensionality to a complete spinor basis at partonic 2-surfaces.

**Generalized eigen modes for the modified Chern-Simons Dirac equation and hydrodynamical picture**

Hydrodynamical picture helps to understand also the construction of generalized eigen modes of 3-D Chern-Simons Dirac equation.

*1. The general form of generalized eigenvalue equation for Chern-Simons Dirac action*

Consider first the the general form and interpretation of the generalized eigenvalue equation assigned with the modified Dirac equation for Chern-Simons action [15] . This is of course only an approximation since an additional contribution to the modified gamma matrices from the Lagrangian multiplier term guaranteeing the weak form of electric-magnetic duality must be included.

1. The modified Dirac equation for  $\Psi$  is consistent with that for its conjugate if the coefficient of the instanton term is real and one uses the Dirac action  $\bar{\Psi}(D^\rightarrow - D^\leftarrow)\Psi$  giving modified Dirac equation as

$$D_{C-S} \Psi + \frac{1}{2} (D_\alpha \hat{\Gamma}_{C-S}^\alpha) \Psi = 0 . \tag{4.5.18}$$

As noticed, the divergence  $D_\alpha \hat{\Gamma}_{C-S}^\alpha$  does not contain second derivatives in the case of Chern-Simons action. In the case of Kähler action they occur unless field equations equivalent with the

vanishing of the divergence term are satisfied. The extremals of Chern-Simons action provide a natural manner to define effective 2-dimensionality.

Also the fermionic current is conserved in this case, which conforms with the idea that fermions flow along the light-like 3-surfaces. If one uses the action  $\bar{\Psi}D^{\rightarrow}\Psi$ ,  $\bar{\Psi}$  does not satisfy the Dirac equation following from the variational principle and fermion current is not conserved.

2. The generalized eigen modes of  $D_{C-S}$  should be such that one obtains the counterpart of Dirac propagator which is purely algebraic and does not therefore depend on the coordinates of the throat. This is satisfied if the generalized eigenvalues are expressible in terms of covariantly constant combinations of gamma matrices and here only  $M^4$  gamma matrices are possible. Therefore the eigenvalue equation would read as

$$D\Psi = \lambda^k \gamma_k \Psi, \quad D = D_{C-S} + \frac{1}{2} D_{\alpha} \hat{\Gamma}_{C-S}^{\alpha}, \quad D_{C-S} = \hat{\Gamma}_{C-S}^{\alpha} D_{\alpha}. \quad (4.5.19)$$

Here the covariant derivatives  $D_{\alpha}$  contain the measurement interaction term as an apparent gauge term. For extremals one has

$$D = D_{C-S}. \quad (4.5.20)$$

Covariant constancy allows to take the square of this equation and one has

$$(D^2 + [D, \lambda^k \gamma_k])\Psi = \lambda^k \lambda_k \Psi. \quad (4.5.21)$$

The commutator term is analogous to magnetic moment interaction.

3. The generalized eigenvalues correspond to  $\lambda = \sqrt{\lambda^k \lambda_k}$  and Dirac determinant is defined as a product of the eigenvalues and conjecture to give the exponent of Kähler action reducing to Chern-Simons term.  $\lambda$  is completely analogous to mass.  $\lambda_k$  cannot be however interpreted as ordinary four-momentum: for instance, number theoretic arguments suggest that  $\lambda_k$  must be restricted to the preferred plane  $M^2 \subset M^4$  interpreted as a commuting hyper-complex plane of complexified quaternions. For incoming lines this mass would vanish so that all incoming particles irrespective their actual quantum numbers would be massless in this sense and the propagator is indeed that for a massless particle. Note that the eigen-modes define the boundary values for the solutions of  $D_K \Psi = 0$  so that the values of  $\lambda$  indeed define the counterpart of the momentum space.

This transmutation of massive particles to effectively massless ones might make possible the application of the twistor formalism as such in TGD framework [82].  $N = 4$  SUSY is one of the very few gauge theory which might be UV finite but it is definitely unphysical due to the masslessness of the basic quanta. Could the resolution of the interpretational problems be that the four-momenta appearing in this theory do not directly correspond to the observed four-momenta?

## 2. Inclusion of the constraint term

As already noticed one must include also the constraint term due to the weak form of electric-magnetic duality and this changes somewhat the above simple picture.

1. At the 3-dimensional ends of the space-time sheet and at wormhole throats the 3-dimensionality allows to introduce a coordinate varying along the flow lines of Kähler magnetic field  $B = *J$ . In this case the integrability conditions state that the flow is Beltrami flow. Note that the value of  $B^\alpha$  along the flow line defining magnetic flux appearing in anti-commutation relations is constant. This suggests that the generalized eigenvalue equation for the Chern-Simons action reduces to a collection of ordinary apparently independent differential equations associated with the flow lines beginning from the partonic 2-surface. This indeed happens when the  $CP_2$  projection is 2-dimensional. In this case it however seems that the basis  $u_n$  is not of much help.
2. The conclusion is wrong: the variations of Chern-Simons action are subject to the constraint that electric-magnetic duality holds true expressible in terms of Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x . \quad (4.5.22)$$

This gives a constraint force to the field equations and also a dependence on the induced 4-metric so that one has only almost topological QFT. This term also guarantees the  $M^4$  part of WCW Kähler metric is non-trivial. The condition that the ends of space-time sheet and wormhole throats are extrema of Chern-Simons action subject to the electric-magnetic duality constraint is strongly suggested by the effective 2-dimensionality. Without the constraint term Chern-Simons action would vanish for its extremals so that Kähler function would be identically zero.

This term implies also an additional contribution to the modified gamma matrices besides the contribution coming from Chern-Simons action so that the first guess for the modified Dirac operator would not be quite correct. This contribution is of exactly of the same general form as the contribution for any general coordinate invariant action. The dependence of the induced metric on  $M^4$  degrees of freedom guarantees that also  $M^4$  gamma matrices are present. In the following this term will not be considered.

3. When the contribution of the constraint term to the modified gamma matrices is neglected, the explicit expression of the modified Dirac operator  $D_{C-S}$  associated with the Chern-Simons term is given by

$$\begin{aligned} D &= \hat{\Gamma}^\mu D_\mu + \frac{1}{2} D_\mu \hat{\Gamma}^\mu , \\ \hat{\Gamma}^\mu &= \frac{\partial L_{C-S}}{\partial_\mu \hbar^k} \Gamma_k = \epsilon^{\mu\alpha\beta} [2J_{kl} \partial_\alpha h^l A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_\mu , \\ D_\mu \hat{\Gamma}^\mu &= B_K^\alpha (J_{k\alpha} + \partial_\alpha A_k) , \\ B_K^\alpha &= \epsilon^{\alpha\beta\gamma} J_{\beta\gamma} , \quad J_{k\alpha} = J_{kl} \partial_\alpha s^l , \quad \hat{\epsilon}^{\alpha\beta\gamma} = \epsilon^{\alpha\beta\gamma} \sqrt{g_3} . \end{aligned} \quad (4.5.23)$$

For the extremals of Chern-Simons action one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ . Analogous condition holds true when the constraining contribution to the modified gamma matrices is added.

### 3. Generalized eigenvalue equation for Chern-Simons Dirac action

Consider now the Chern-Simons Dirac equation in more detail assuming that the inclusion of the constraint contribution to the modified gamma matrices does not induce any complications. Assume also extremal property for Chern-Simons action with constraint term and Beltrami flow property.

1. For the extremals the Chern-Simons Dirac operator (constraint term not included) reduces to a one-dimensional Dirac operator

$$D_{C-S} = \hat{\epsilon}^{r\alpha\beta} [2J_{k\alpha} A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_r . \quad (4.5.24)$$

Constraint term implies only a modification of the modified gamma matrices but the form of the operator remains otherwise same when extrema are in question so that one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ .

2. For the extremals of Chern-Simons action the general solution of the modified Chern-Simons Dirac equation ( $\lambda^k = 0$ ) is covariantly constant with respect to the coordinate  $r$ :

$$D_r \Psi = 0 . \quad (4.5.25)$$

The solution to this condition can be written immediately in terms of a non-integrable phase factor  $P \exp(i \int A_r dr)$ , where integration is along curve with constant transversal coordinates. If  $\hat{\Gamma}^v$  is light-like vector field also  $\hat{\Gamma}^v \Psi_0$  defines a solution of  $D_{C-S}$ . This solution corresponds to a zero mode for  $D_{C-S}$  and does not contribute to the Dirac determinant (suggested to give rise to the exponent of Kähler function identified as Kähler action). Note that the dependence of these solutions on transversal coordinates of  $X_l^3$  is arbitrary which conforms with the hydrodynamic picture. The solutions of Chern-Simons-Dirac are obtained by similar integration procedure also when extremals are not in question.

The formal solution associated with a general eigenvalue  $\lambda$  can be constructed by integrating the eigenvalue equation separately along all coordinate curves. This makes sense if  $r$  indeed assigned to possibly light-like flow lines of  $B^\alpha$  or more general Beltrami field possible induced by the constraint term. There are very strong consistency conditions coming from the conditions that  $\Psi$  in the interior is constant along the flow lines of Kähler current and continuous at the ends and throats (call them collectively boundaries), where  $\Psi$  has a non-trivial variation along the flow lines of  $B^\alpha$ .

1. This makes sense only if the flow lines of the Kähler current are transversal to the boundaries so that the spinor modes at boundaries dictate the modes of the spinor field in the interior. Effective 2-dimensionality means that the spinor modes in the interior can be calculated either by starting from the throats or from the ends so that the data at either upper or lower partonic 2-surfaces dictates everything in accordance with zero energy ontology.
2. This gives an infinite number of commuting diagrams stating that the flow-line time evolution along flow lines along wormhole throats from lower partonic 2-surface to the upper one is equivalent with the flow-line time evolution along the lower end of space-time surface to interior, then along interior to the upper end of the space-time surface and then back to the upper partonic 2-surface. If the space-time surface allows a slicing by partonic 2-surfaces these conditions can be assumed for any pair of partonic 2-surfaces connected by Chern-Simons flow evolution.
3. Since the time evolution along interior keeps the spinor field as constant in the proper gauge and since the flow evolutions at the lower and upper ends are in a reverse direction, there is a strong attemptation to assume that the spinor field at the ends of the of the flow lines of Kähler magnetic field are identical apart from a gauge transformation. This leads to a particle-in-box quantization of the values of the pseudo-mass (periodic boundary conditions). These conditions will be assumed in the sequel.

These assumptions lead to the following picture about the generalized eigen modes.

1. By choosing the gauge so that covariant derivative reduces to ordinary derivative and using the constancy of  $\hat{\Gamma}^r$ , the solution of the generalized eigenvalue equation can be written as

$$\begin{aligned} \Psi &= \exp(iL(r)\hat{\Gamma}^r \lambda^k \Gamma_k) \Psi_0 , \\ L(r) &= \int_0^r \frac{1}{\sqrt{\hat{g}^{rr}}} dr . \end{aligned} \quad (4.5.26)$$

$L(r)$  can be regarded as the along flux line as defined by the effective metric defined by modified gamma matrices. If  $\lambda_k$  is linear combination of  $\Gamma^0$  and  $\Gamma^{rM}$  it anti-commutes with  $\Gamma^r$  which contains only  $CP_2$  gamma matrices so that the pseudo-momentum is a priori arbitrary.

2. When the constraint term taking care of the electric-magnetic duality is included, also  $M^4$  gamma matrices are present. If they are in the orthogonal complement of a preferred plane  $M^2 \subset M^4$ , anti-commutativity is achieved. This assumption cannot be fully justified yet but conforms with the general physical vision. There is an obvious analogy with the condition that polarizations are in a plane orthogonal to  $M^2$ . The condition indeed states that only transversal deformations define quantum fluctuating WCW degrees of freedom contributing to the WCW Kähler metric. In  $M^8-H$  duality the preferred plane  $M^2$  is interpreted as a hyper-complex plane belonging to the tangent space of the space-time surface and defines the plane of non-physical polarizations. Also a generalization of this plane to an integrable distribution of planes  $M^2(x)$  has been proposed and one must consider also now the possibility of a varying plane  $M^2(x)$  for the pseudo-momenta. The scalar function  $\Phi$  appearing in the general solution ansatz for the field equations satisfies massless d'Alembert equation and its gradient defines a local light-like direction at space-time-level and hence a 2-D plane of the tangent space. Maybe the projection of this plane to  $M^4$  could define the preferred  $M^2$ . The minimum condition is that these planes are defined only at the ends of space-time surface and at wormhole throats.
3. If one accepts this hypothesis, one can write

$$\begin{aligned}\Psi &= \left[ \cos(L(r)\lambda) + i \sin(\lambda(r)) \hat{\Gamma}^r \lambda^k \Gamma_k \right] \Psi_0, \\ \lambda &= \sqrt{\lambda_k \lambda^k}.\end{aligned}\tag{4.5.27}$$

4. Boundary conditions should fix the spectrum of masses. If the the flow lines of Kähler current coincide with the flow lines of Kähler magnetic field or more general Beltrami current at wormhole throats one ends up with difficulties since the induced spinor fields must be constant along flow lines and only trivial eigenvalues are possible. Hence it seems that the two Beltrami fields must be transversal. This requires that at the partonic 2-surfaces the value of the induced spinor mode in the interior coincides with its value at the throat. Since the induced spinor fields in interior are constant along flow lines, one must have

$$\exp(i\lambda L_{(max)}) = 1.\tag{4.5.28}$$

This implies that one has essentially particle in a box with size defined by the effective metric

$$\lambda_n = \frac{n2\pi}{L(r_{max})}.\tag{4.5.29}$$

5. This condition cannot however hold true simultaneously for all points of the partonic 2-surfaces since  $L(r_{max})$  depends on the point of the surface. In the most general case one can consider only a subset consisting of the points for which the values of  $L(r_{max})$  are rational multiples of the value of  $L(r_{max})$  at one of the points -call it  $L_0$ . This implies the notion of number theoretical braid. Induced spinor fields are localized to the points of the braid defined by the flow lines of the Kähler magnetic field (or equivalently, any conserved current- this resolves the longstanding issue about the identification of number theoretical braids). The number of the included points depends on measurement resolution characterized somehow by the number rationals which are allowed. Only finite number of harmonics and sub-harmonics of  $L_0$  are possible so that for integer multiples the number of points is finite. If  $n_{max}L_0$  and  $L_0/n_{min}$  are the largest and smallest lengths involved, one can argue that the rationals  $n_{max}/n$ ,  $n = 1, \dots, n_{max}$  and  $n/n_{min}$ ,  $n = 1, \dots, n_{min}$  are the natural ones.

6. One can consider also algebraic extensions for which  $L_0$  is scaled from its reference value by an algebraic number so that the mass scale  $m$  must be scaled up in similar manner. The spectrum comes also now in integer multiples. p-Adic mass calculations predicts mass scales to the inverses of square roots of prime and this raises the expectation that  $\sqrt{n}$  harmonics and sub-harmonics of  $L_0$  might be necessary. Notice however that pseudo-momentum spectrum is in question so that this argument is on shaky grounds.

There is also the question about the allowed values of  $(\lambda_0, \lambda_3)$  for a given value of  $\lambda$ . This issue will be discussed in the next section devoted to the attempt to calculate the Dirac determinant assignable to this spectrum: suffice it to say that integer valued spectrum is the first guess implying that the pseudo-momenta satisfy  $n_0^2 - n_3^2 = n^2$  and therefore correspond to Pythagorean triangles. What is remarkable that the notion of number theoretic braid pops up automatically from the Beltrami flow hypothesis.

#### 4.5.4 Hyper-octonionic primes

Before detailed discussion of the hyper-octonionic option it is good to consider the basic properties of hyper-octonionic primes.

1. Hyper-octonionic primes are of form

$$\Pi_p = (n_0, n_3, n_1, n_2, \dots, n_7) , \quad \Pi_p^2 = n_0^2 - \sum_i n_i^2 = p \text{ or } p^2 . \quad (4.5.30)$$

2. Hyper-octonionic primes have a standard representation as hyper-complex primes. The Minkowski norm squared factorizes into a product as

$$n_0^2 - n_3^2 = (n_0 + n_3)(n_0 - n_3) . \quad (4.5.31)$$

If one has  $n_3 \neq 0$ , the prime property implies  $n_0 - n_3 = 1$  so that one obtains  $n_0 = n_3 + 1$  and  $2n_3 + 1 = p$  giving

$$(n_0, n_3) = ((p+1)/2, (p-1)/2) . \quad (4.5.32)$$

Note that one has  $(p+1)/2$  odd for  $p \bmod 4 = 1$  and  $(p+1)/2$  even for  $p \bmod 4 = 3$ . The difference  $n_0 - n_3 = 1$  characterizes prime property.

If  $n_3$  vanishes the prime property implies equivalence with ordinary prime and one has  $n_0^2 = p^2$ . These hyper-octonionic primes represent particles at rest.

3. The action of a discrete subgroup  $G(p)$  of the octonionic automorphism group  $G_2$  generates form hyper-complex primes with  $n_3 \neq 0$  further hyper-octonionic primes  $\Pi(p, k)$  corresponding to the same value of  $n_0$  and  $p$  and for these the integer valued projection to  $M^2$  satisfies  $n_0^2 - n_3^2 = n > p$ . It is also possible to have a state representing the system at rest with  $(n_0, n_3) = ((p+1)/2, 0)$  so that the pseudo-mass varies in the range  $[\sqrt{p}, (p+1)/2]$ . The subgroup  $G(n_0, n_3) \subset SU(3)$  leaving invariant the projection  $(n_0, n_3)$  generates the hyper-octonionic primes corresponding to the same value of mass for hyper-octonionic primes with same Minkowskian length  $p$  and pseudo-mass  $\lambda = n \geq \sqrt{p}$ .
4. One obtains two kinds of primes corresponding to the lengths of pseudo-momenta equal to  $p$  or  $\sqrt{p}$ . The first kind of particles are always at rest whereas the second kind of particles can be brought at rest only if one interprets the pseudo-momentum as  $M^2$  projection. This brings in mind the secondary p-adic length scales assigned to causal diamonds (CDs) and the primary p-adic lengths scales assigned to particles.

If the  $M^2$  projections of hyper-octonionic primes with length  $\sqrt{p}$  characterize the allowed basic momenta,  $\zeta_D$  is sum of zeta functions associated with various projections which must be in the limits dictated by the geometry of the orbit of the partonic surface giving upper and lower bounds  $L_{max}$  and  $L_{min}$  on the length  $L$ .  $L_{min}$  is scaled up to  $\sqrt{n_0^2 - n_3^2}L_{min}$  for a given projection  $(n_0, n_3)$ . In general a given  $M^2$  projection  $(n_0, n_3)$  corresponds to several hyper-octonionic primes since  $SU(3)$  rotations give a new hyper-octonionic prime with the same  $M^2$  projection. This leads to an inconsistency unless one has a good explanation for why some basic momentum can appear several times. One might argue that the spinor mode is degenerate due to the possibility to perform discrete color rotations of the state. For hyper complex representatives there is no such problem and it seems favored. In any case, one can look how the degeneracy factors for given projection can be calculated.

1. To calculate the degeneracy factor  $D(n)$  associated with given pseudo-mass value  $\lambda = n$  one must find all hyper-octonionic primes  $\Pi$ , which can have projection in  $M^2$  with length  $n$  and sum up the degeneracy factors  $D(n, p)$  associated with them:

$$\begin{aligned}
 D(n) &= \sum_p D(n, p) , \\
 D(n, p) &= \sum_{n_0^2 - n_3^2 = p} D(p, n_0, n_3) , \\
 n_0^2 - n_3^2 &= n , \quad \Pi_p^2(n_0, n_3) = n_0^2 - n_3^2 - \sum_i n_i^2 = n - \sum_i n_i^2 = p .
 \end{aligned}
 \tag{4.5.33}$$

2. The condition  $n_0^2 - n_3^2 = n$  allows only Pythagorean triangles and one must find the discrete subgroup  $G(n_0, n_3) \subset SU(3)$  producing hyper-octonions with integer valued components with length  $p$  and components  $(n_0, n_3)$ . The points at the orbit satisfy the condition

$$\sum n_i^2 = p - n .
 \tag{4.5.34}$$

The degeneracy factor  $D(p, n_0, n_3)$  associated with given mass value  $n$  is the number of elements of in the coset space  $G(n_0, n_3, p)/H(n_0, n_3, p)$ , where  $H(n_0, n_3, p)$  is the isotropy group of given hyper-octonionic prime obtained in this manner. For  $n_0^2 - n_3^2 = p^2$   $D(n_0, n_3, p)$  obviously equals to unity.

### 4.5.5 Three basic options for the pseudo-momentum spectrum

The calculation of the scaling factor of the Kähler function requires the knowledge of the degeneracies of the mass squared eigen values. There are three options to consider.

#### First option: all pseudo-momenta are allowed

If the degeneracy for pseudo-momenta in  $M^2$  is same for all mass values- and formally characterizable by a number  $N$  telling how many 2-D pseudo-momenta reside on mass shell  $n_0^2 - n_3^2 = m^2$ . In this case zeta function would be proportional to a sum of Riemann Zetas with scaled arguments corresponding to scalings of the basic mass  $m$  to  $m/q$ .

$$\zeta_D(s) = N \sum_q \zeta(\log(qx)s) , \quad x = \frac{L_{min}}{R} .
 \tag{4.5.35}$$

This option provides no idea about the possible values of  $1 \leq q \leq L_{max}/L_{min}$ . The number  $N$  is given by the integral of relativistic density of states  $\int dk/2\sqrt{k^2 + m^2}$  over the hyperbola and is logarithmically divergent so that the normalization factor  $N$  of the Kähler function would be infinite.

### Second option: All integer valued pseudomomenta are allowed

Second option is inspired by number theoretic vision and assumes integer valued components for the momenta using  $m_{max} = 2\pi/L_{min}$  as mass unit. p-Adicization motivates also the assumption that momentum components using  $m_{max}$  as mass scale are integers. This would restrict the choice of the number theoretical braids.

Integer valuedness together with masses coming as integer multiples of  $m_{max}$  implies  $(\lambda_0, \lambda_3) = (n_0, n_3)$  with on mass shell condition  $n_0^2 - n_3^2 = n^2$ . Note that the condition is invariant under scaling. These integers correspond to Pythagorean triangles plus the degenerate situation with  $n_3 = 0$ . There exists a finite number of pairs  $(n_0, n_3)$  satisfying this condition as one finds by expressing  $n_0 = n_3 + k$  giving  $2n_3k + k^2 = p^2$  giving  $n_3 < n^2/2, n_0 < n^2/2 + 1$ . This would be enough to have a finite degeneracy  $D(n) \geq 1$  for a given value of mass squared and  $\zeta_D$  would be well defined.  $\zeta_D$  would be a modification of Riemann zeta given by

$$\begin{aligned} \zeta_D &= \sum_q \zeta_1(\log(qx)s) , \quad x = \frac{L_{min}}{R} , \\ \zeta_1(s) &= \sum g_n n^{-s} , \quad g_n \geq 1 . \end{aligned} \quad (4.5.36)$$

For generalized Feynman diagrams this option allows conservation of pseudo-momentum and for loops no divergences are possible since the integral over two-dimensional virtual momenta is replaced with a sum over discrete mass shells containing only a finite number of points. This option looks thus attractive but requires a regularization. On the other hand, the appearance of a zeta function having a strong resemblance with Riemann zeta could explain the finding that Riemann zeta is closely related to the description of critical systems. This point will be discussed later.

### Third option: Infinite primes code for the allowed mass scales

According to the proposal of [70] , [8] the hyper-complex parts of hyper-octonionic primes appearing in their infinite counterparts correspond to the  $M^2$  projections of real four-momenta. This hypothesis suggests a very detailed map between infinite primes and standard model quantum numbers and predicts a universal mass spectrum [70] . Since pseudo-momenta are automatically restricted to the plane  $M^2$ , one cannot avoid the question whether they could actually correspond to the hyper-octonionic primes defining the infinite prime. These interpretations need not of course exclude each other. This option allows several variants and at this stage it is not possible to exclude any of these options.

1. One must choose between two alternatives for which pseudo-momentum corresponds to hyper-complex prime serving as a canonical representative of a hyper-octonionic prime or a projection of hyper-octonionic prime to  $M^2$ .
2. One must decide whether one allows a) only the momenta corresponding to hyper-complex primes, b) also their powers (p-adic fractality), or c) all their integer multiples ("Riemann option").

One must also decide what hyper-octonionic primes are allowed.

1. The first guess is that all hyper-complex/hyper-octonionic primes defining length scale  $\sqrt{p}L_{min} \leq L_{max}$  or  $pL_{min} \leq L_{max}$  are allowed. p-Adic fractality suggests that also the higher p-adic length scales  $p^{n/2}L_{min} < L_{max}$  and  $p^n L_{min} < L_{max}$ ,  $n \geq 1$ , are possible.

It can however happen that no primes are allowed by this criterion. This would mean vanishing Kähler function which is of course also possible since Kähler action can vanish (for instance, for massless extremals). It seems therefore safer to allow also the scale corresponding to the trivial prime  $(n_0, n_3) = (1, 0)$  (1 is formally prime because it is not divisible by any prime different from 1) so that at least  $L_{min}$  is possible. This option also allows only rather small primes unless the partonic 2-surface contains vacuum regions in which case  $L_{max}$  is infinite: in this case all primes would be allowed and the exponent of Kähler function would vanish.

2. The hypothesis that only the hyper-complex or hyper-octonionic primes appearing in the infinite hyper-octonionic prime are possible looks more reasonable since large values of  $p$  would be possible and could be identified in terms of the  $p$ -adic length scale hypothesis. All hyper-octonionic primes appearing in infinite prime would be possible and the geometry of the orbit of the partonic 2-surface would define an infinite prime. This would also give a concrete physical interpretation for the earlier hypothesis that hyper-octonionic primes appearing in the infinite prime characterize partonic 2-surfaces geometrically. One can also identify the fermionic and purely bosonic primes appearing in the infinite prime as braid strands carrying fermion number and purely bosonic quantum numbers. This option will be assumed in the following.

## 4.6 How to define generalized Feynman diagrams?

S-matrix codes to a high degree the predictions of quantum theories. The longstanding challenge of TGD has been to construct or at least demonstrate the mathematical existence of S-matrix- or actually M-matrix which generalizes this notion in zero energy ontology (ZEO) [61]. This work has led to the notion of generalized Feynman diagram and the challenge is to give a precise mathematical meaning for this object. The attempt to understand the counterpart of twistors in TGD framework [82] has inspired several key ideas in this respect but it turned out that twistors themselves need not be absolutely necessary in TGD framework.

1. The notion of generalized Feynman diagram defined by replacing lines of ordinary Feynman diagram with light-like 3-surfaces (elementary particle sized wormhole contacts with throats carrying quantum numbers) and vertices identified as their 2-D ends - I call them partonic 2-surfaces is central. Speaking somewhat loosely, generalized Feynman diagrams (plus background space-time sheets) define the "world of classical worlds" (WCW). These diagrams involve the analogs of stringy diagrams but the interpretation is different: the analogs of stringy loop diagrams have interpretation in terms of particle propagating via two different routes simultaneously (as in the classical double slit experiment) rather than as a decay of particle to two particles. For stringy diagrams the counterparts of vertices are singular as manifolds whereas the entire diagrams are smooth. For generalized Feynman diagrams vertices are smooth but entire diagrams represent singular manifolds just like ordinary Feynman diagrams do. String like objects however emerge in TGD and even ordinary elementary particles are predicted to be magnetic flux tubes of length of order weak gauge boson Compton length with monopoles at their ends as shown in accompanying article. This stringy character should become visible at LHC energies.
2. Zero energy ontology (ZEO) and causal diamonds (intersections of future and past directed lightcones) is second key ingredient. The crucial observation is that in ZEO it is possible to identify off mass shell particles as pairs of on mass shell particles at throats of wormhole contact since both positive and negative signs of energy are possible. The propagator defined by modified Dirac action does not diverge (except for incoming lines) although the fermions at throats are on mass shell. In other words, the generalized eigenvalue of the modified Dirac operator containing a term linear in momentum is non-vanishing and propagator reduces to  $G = i/\lambda\gamma$ , where  $\gamma$  is so called modified gamma matrix in the direction of stringy coordinate [15]. This means opening of the black box of the off mass shell particle-something which for some reason has not occurred to anyone fighting with the divergences of quantum field theories.
3. A powerful constraint is number theoretic universality requiring the existence of Feynman amplitudes in all number fields when one allows suitable algebraic extensions: roots of unity are certainly required in order to realize  $p$ -adic counter parts of plane waves. Also imbedding space, partonic 2-surfaces and WCW must exist in all number fields and their extensions. These constraints are enormously powerful and the attempts to realize this vision have dominated quantum TGD for last two decades.
4. Representation of 8-D gamma matrices in terms of octonionic units and 2-D sigma matrices is a further important element as far as twistors are considered [82]. Modified gamma matrices at space-time surfaces are quaternionic/associative and allow a genuine matrix representation. As a matter fact, TGD and WCW can be formulated as study of associative local sub-algebras of the local Clifford algebra of 8-D imbedding space parameterized by quaternionic space-time

surfaces. Central conjecture is that quaternionic 4-surfaces correspond to preferred extremals of Kähler action [15] identified as critical ones (second variation of Kähler action vanishes for infinite number of deformations defining super-conformal algebra) and allow a slicing to string worldsheets parametrized by points of partonic 2-surfaces.

5. As far as twistors are considered, the first key element is the reduction of the octonionic twistor structure to quaternionic one at space-time surfaces and giving effectively 4-D spinor and twistor structure for quaternionic surfaces.

Quite recently quite a dramatic progress took place in this approach [28, 82] .

1. The progress was stimulated by the simple observation that on mass shell property puts enormously strong kinematic restrictions on the loop integrations. With mild restrictions on the number of parallel fermion lines appearing in vertices (there can be several since fermionic oscillator operator algebra defining SUSY algebra generates the parton states)- all loops are manifestly finite and if particles has always mass -say small p-adic thermal mass also in case of massless particles and due to IR cutoff due to the presence largest CD- the number of diagrams is finite. Unitarity reduces to Cutkosky rules [30] automatically satisfied as in the case of ordinary Feynman diagrams.
2. Ironically, twistors which stimulated all these development do not seem to be absolutely necessary in this approach although they are of course possible. Situation changes if one does not assume small p-adically thermal mass due to the presence of massless particles and one must sum infinite number of diagrams. Here a potential problem is whether the infinite sum respects the algebraic extension in question.

This is about fermionic and momentum space aspects of Feynman diagrams but not yet about the functional (not path-) integral over small deformations of the partonic 2-surfaces. The basic challenges are following.

1. One should perform the functional integral over WCW degrees of freedom for fixed values of on mass shell momenta appearing in the internal lines. After this one must perform integral or summation over loop momenta. Note that the order is important since the space-time surface assigned to the line carries information about the quantum numbers associated with the line by quantum classical correspondence realized in terms of modified Dirac operator.
2. One must define the functional integral also in the p-adic context. p-Adic Fourier analysis relying on algebraic continuation raises hopes in this respect. p-Adicity suggests strongly that the loop momenta are discretized and ZEO predicts this kind of discretization naturally.

It indeed seems that the functional integrals over WCW could be carried out at general level both in real and p-adic context. This is due to the symmetric space property (maximal number of isometries) of WCW required by the mere mathematical existence of Kähler geometry [35] in infinite-dimensional context already in the case of much simpler loop spaces [78] .

1. The p-adic generalization of Fourier analysis allows to algebraize integration- the horrible looking technical challenge of p-adic physics- for symmetric spaces for functions allowing the analog of discrete Fourier decomposition. Symmetric space property is indeed essential also for the existence of Kähler geometry for infinite-D spaces as was learned already from the case of loop spaces. Plane waves and exponential functions expressible as roots of unity and powers of p multiplied by the direct analogs of corresponding exponent functions are the basic building bricks and key functions in harmonic analysis in symmetric spaces. The physically unavoidable finite measurement resolution corresponds to algebraically unavoidable finite algebraic dimension of algebraic extension of p-adics (at least some roots of unity are needed). The cutoff in roots of unity is very reminiscent to that occurring for the representations of quantum groups and is certainly very closely related to these as also to the inclusions of hyper-finite factors of type II<sub>sub*l*</sub> defining the finite measurement resolution.

2. WCW geometrization reduces to that for a single line of the generalized Feynman diagram defining the basic building brick for WCW. Kähler function decomposes to a sum of "kinetic" terms associated with its ends and interaction term associated with the line itself. p-Adicization boils down to the condition that Kähler function, matrix elements of Kähler form, WCW Hamiltonians and their super counterparts, are rational functions of complex WCW coordinates just as they are for those symmetric spaces that I know of. This allows straightforward continuation to p-adic context.
3. As far as diagrams are considered, everything is manifestly finite as the general arguments (non-locality of Kähler function as functional of 3-surface) developed two decades ago indeed allow to expect. General conditions on the holomorphy properties of the generalized eigenvalues  $\lambda$  of the modified Dirac operator can be deduced from the conditions that propagator decomposes to a sum of products of harmonics associated with the ends of the line and that similar decomposition takes place for exponent of Kähler action identified as Dirac determinant. This guarantees that the convolutions of propagators and vertices give rise to products of harmonic functions which can be Glebsch-Gordanized to harmonics and only the singlet contributes to the WCW integral in given vertex. The still unproven central conjecture is that Dirac determinant equals the exponent of Kähler function.

In the following this vision about generalized Feynman diagrams is discussed in more detail.

#### 4.6.1 Questions

The goal is a proposal for how to perform the integral over WCW for generalized Feynman digrams and the best manner to proceed to to this goal is by making questions.

##### What does finite measurement resolution mean?

The first question is what finite measurement resolution means.

1. One expects that the algebraic continuation makes sense only for a finite measurement resolution in which case one obtains only finite sums of what one might hope to be algebraic functions. The finiteness of the algebraic extension would be in fact equivalent with the finite measurement resolution.
2. Finite measurement resolution means a discretization in terms of number theoretic braids. p-Adicization condition suggests that that one must allow only the number theoretic braids. For these the ends of braid at boundary of  $CD$  are algebraic points of the imbedding space. This would be true at least in the intersection of real and p-adic worlds.
3. The question is whether one can localize the points of the braid. The necessity to use momentum eigenstates to achieve quantum classical correspondence in the modified Dirac action [15] suggests however a delocalization of braid points, that is wave function in space of braid points. In real context one could allow all possible choices for braid points but in p-adic context only algebraic points are possible if one wants to replace integrals with sums. This implies finite measurement resolution analogous to that in lattice. This is also the only possibility in the intersection of real and p-adic worlds.

A non-trivial prediction giving a strong correlation between the geometry of the partonic 2-surface and quantum numbers is that the total number  $n_F + n_{\bar{F}}$  of fermions and antifermions is bounded above by the number  $n_{alg}$  of algebraic points for a given partonic 2-surface:  $n_F + n_{\bar{F}} \leq n_{alg}$ . Outside the intersection of real and p-adic worlds the problematic aspect of this definition is that small deformations of the partonic 2-surface can radically change the number of algebraic points unless one assumes that the finite measurement resolution means restriction of WCW to a sub-space of algebraic partonic surfaces.

4. One has also a discretization of loop momenta if one assumes that virtual particle momentum corresponds to ZEO defining rest frame for it and from the discretization of the relative position of the second tip of  $CD$  at the hyperboloid isometric with mass shell. Only the number of braid points and their momenta would matter, not their positions. The measurement interaction term

in the modified Dirac action gives coupling to the space-time geometry and Kähler function through generalized eigenvalues of the modified Dirac operator with measurement interaction term linear in momentum and in the color quantum numbers assignable to fermions [15].

### How to define integration in WCW degrees of freedom?

The basic question is how to define the integration over WCW degrees of freedom.

1. What comes mind first is Gaussian perturbation theory around the maxima of Kähler function. Gaussian and metric determinants cancel each other and only algebraic expressions remain. Finiteness is not a problem since the Kähler function is non-local functional of 3-surface so that no local interaction vertices are present. One should however assume the vanishing of loops required also by algebraic universality and this assumption look unrealistic when one considers more general functional integrals than that of vacuum functional since free field theory is not in question. The construction of the inverse of the WCW metric defining the propagator is also a very difficult challenge. Duistermaat-Hecke theorem states that something like this known as localization might be possible and one can also argue that something analogous to localization results from a generalization of mean value theorem.
2. Symmetric space property is more promising since it might reduce the integrations to group theory using the generalization of Fourier analysis for group representations so that there would be no need for perturbation theory in the proposed sense. In finite measurement resolution the symmetric spaces involved would be finite-dimensional. Symmetric space structure of WCW could also allow to define p-adic integration in terms of p-adic Fourier analysis for symmetric spaces. Essentially algebraic continuation of the integration from the real case would be in question with additional constraints coming from the fact that only phase factors corresponding to finite algebraic extensions of rationals are used. Cutoff would emerge automatically from the cutoff for the dimension of the algebraic extension.

### How to define generalized Feynman diagrams?

Integration in symmetric spaces could serve as a model at the level of WCW and allow both the understanding of WCW integration and p-adicization as algebraic continuation. In order to get a more realistic view about the problem one must define more precisely what the calculation of the generalized Feynman diagrams means.

1. WCW integration must be carried out separately for all values of the momenta associated with the internal lines. The reason is that the spectrum of eigenvalues  $\lambda_i$  of the modified Dirac operator  $D$  depends on the momentum of line and momentum conservation in vertices translates to a correlation of the spectra of  $D$  at internal lines.
2. For tree diagrams algebraic continuation to the p-adic context if the expression involves only the replacement of the generalized eigenvalues of  $D$  as functions of momenta with their p-adic counterparts besides vertices. If these functions are algebraically universal and expressible in terms of harmonics of symmetric space, there should be no problems.
3. If loops are involved, one must integrate/sum over loop momenta. In p-adic context difficulties are encountered if the spectrum of the momenta is continuous. The integration over on mass shell loop momenta is analogous to the integration over sub-CDs, which suggests that internal line corresponds to a *sub-CD* in which it is at rest. There are excellent reasons to believe that the moduli space for the positions of the upper tip is a discrete subset of hyperboloid of future light-cone. If this is the case, the loop integration indeed reduces to a sum over discrete positions of the tip. p-Adicization would thus give a further good reason why for zero energy ontology.
4. Propagator is expressible in terms of the inverse of generalized eigenvalue and there is a sum over these for each propagator line. At vertices one has products of WCW harmonics assignable to the incoming lines. The product must have vanishing quantum numbers associated with the phase angle variables of WCW. Non-trivial quantum numbers of the WCW harmonic correspond

to WCW quantum numbers assignable to excitations of ordinary elementary particles. WCW harmonics are products of functions depending on the "radial" coordinates and phase factors and the integral over the angles leaves the product of the first ones analogous to Legendre polynomials  $P_{l,m}$ . These functions are expected to be rational functions or at least algebraic functions involving only square roots.

5. In ordinary QFT incoming and outgoing lines correspond to propagator poles. In the recent case this would mean that the generalized eigenvalues  $\lambda = 0$  characterize them. Internal lines coming as pairs of throats of wormhole contacts would be on mass shell with respect to momentum but off shell with respect to  $\lambda$ .

#### 4.6.2 Generalized Feynman diagrams at fermionic and momentum space level

Negative energy ontology has already led to the idea of interpreting the virtual particles as pairs of positive and negative energy wormhole throats. Hitherto I have taken it as granted that ordinary Feynman diagrammatics generalizes more or less as such. It is however far from clear what really happens in the vertices of the generalized Feynmann diagrams. The safest approach relies on the requirement that unitarity realized in terms of Cutkosky rules in ordinary Feynman diagrammatics allows a generalization. This requires loop diagrams. In particular, photon-photon scattering can take place only via a fermionic square loop so that it seems that loops must be present at least in the topological sense.

One must be however ready for the possibility that something unexpectedly simple might emerge. For instance, the vision about algebraic physics allows naturally only finite sums for diagrams and does not favor infinite perturbative expansions. Hence the true believer on algebraic physics might dream about finite number of diagrams for a given reaction type. For simplicity generalized Feynman diagrams without the complications brought by the magnetic confinement since by the previous arguments the generalization need not bring in anything essentially new.

The basic idea of duality in early hadronic models was that the lines of the dual diagram representing particles are only re-arranged in the vertices. This however does not allow to get rid of off mass shell momenta. Zero energy ontology encourages to consider a stronger form of this principle in the sense that the virtual momenta of particles could correspond to pairs of on mass shell momenta of particles. If also interacting fermions are pairs of positive and negative energy throats in the interaction region the idea about reducing the construction of Feynman diagrams to some kind of lego rules might work.

#### Virtual particles as pairs of on mass shell particles in ZEO

The first thing is to try to define more precisely what generalized Feynman diagrams are. The direct generalization of Feynman diagrams implies that both wormhole throats and wormhole contacts join at vertices.

1. A simple intuitive picture about what happens is provided by diagrams obtained by replacing the points of Feynman diagrams (wormhole contacts) with short lines and imagining that the throats correspond to the ends of the line. At vertices where the lines meet the incoming on mass shell quantum numbers would sum up to zero. This approach leads to a straightforward generalization of Feynman diagrams with virtual particles replaced with pairs of on mass shell throat states of type  $++$ ,  $--$ , and  $+-$ . Incoming lines correspond to  $++$  type lines and outgoing ones to  $--$  type lines. The first two line pairs allow only time like net momenta whereas  $+-$  line pairs allow also space-like virtual momenta. The sign assigned to a given throat is dictated by the the sign of the on mass shell momentum on the line. The condition that Cutkosky rules generalize as such requires  $++$  and  $--$  type virtual lines since the cut of the diagram in Cutkosky rules corresponds to on mass shell outgoing or incoming states and must therefore correspond to  $++$  or  $--$  type lines.
2. The basic difference as compared to the ordinary Feynman diagrammatics is that loop integrals are integrals over mass shell momenta and that all throats carry on mass shell momenta. In each vertex of the loop mass incoming on mass shell momenta must sum up to on mass shell

momentum. These constraints improve the behavior of loop integrals dramatically and give excellent hopes about finiteness. It does not however seem that only a finite number of diagrams contribute to the scattering amplitude besides tree diagrams. The point is that if a the reactions  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ , where  $N_i$  denote particle numbers, are possible in a common kinematical region for  $N_2$ -particle states then also the diagrams  $N_1 \rightarrow N_2 \rightarrow N_2 \rightarrow N_3$  are possible. The virtual states  $N_2$  include all all states in the intersection of kinematically allow regions for  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ . Hence the dream about finite number possible diagrams is not fulfilled if one allows massless particles. If all particles are massive then the particle number  $N_2$  for given  $N_1$  is limited from above and the dream is realized.

3. For instance, loops are not possible in the massless case or are highly singular (bringing in mind twistor diagrams) since the conservation laws at vertices imply that the momenta are parallel. In the massive case and allowing mass spectrum the situation is not so simple. As a first example one can consider a loop with three vertices and thus three internal lines. Three on mass shell conditions are present so that the four-momentum can vary in 1-D subspace only. For a loop involving four vertices there are four internal lines and four mass shell conditions so that loop integrals would reduce to discrete sums. Loops involving more than four vertices are expected to be impossible.
4. The proposed replacement of the elementary fermions with bound states of elementary fermions and monopoles  $X_{\pm}$  brings in the analog of stringy diagrammatics. The 2-particle wave functions in the momentum degrees of freedom of fermions and  $X_{\pm}$  might allow more flexibility and allow more loops. Note however that there are excellent hopes about the finiteness of the theory also in this case.

### Loop integrals are manifestly finite

One can make also more detailed observations about loops.

1. The simplest situation is obtained if only 3-vertices are allowed. In this case conservation of momentum however allows only collinear momenta although the signs of energy need not be the same. Particle creation and annihilation is possible and momentum exchange is possible but is always light-like in the massless case. The scattering matrices of supersymmetric YM theories would suggest something less trivial and this raises the question whether something is missing. Magnetic monopoles are an essential element of also these theories as also massivation and symmetry breaking and this encourages to think that the formation of massive states as fermion  $X_{\pm}$  pairs is needed. Of course, in TGD framework one has also high mass excitations of the massless states making the scattering matrix non-trivial.
2. In YM theories on mass shell lines would be singular. In TGD framework this is not the case since the propagator is defined as the inverse of the 3-D dimensional reduction of the modified Dirac operator  $D$  containing also coupling to four-momentum (this is required by quantum classical correspondence and guarantees stringy propagators),

$$\begin{aligned} D &= i\hat{\Gamma}^{\alpha} p_{\alpha} + \hat{\Gamma}^{\alpha} D_{\alpha} \ , \\ p_{\alpha} &= p_k \partial_{\alpha} h^k \ . \end{aligned} \tag{4.6.1}$$

The propagator does not diverge for on mass shell massless momenta and the propagator lines are well-defined. This is of course of essential importance also in general case. Only for the incoming lines one can consider the possibility that 3-D Dirac operator annihilates the induced spinor fields. All lines correspond to generalized eigenstates of the propagator in the sense that one has  $D_3 \Psi = \lambda \gamma \Psi$ , where  $\gamma$  is modified gamma matrix in the direction of the stringy coordinate emanating from light-like surface and  $D_3$  is the 3-dimensional dimensional reduction of the 4-D modified Dirac operator. The eigenvalue  $\lambda$  is analogous to energy. Note that the eigenvalue spectrum depends on 4-momentum as a parameter.

3. Massless incoming momenta can decay to massless momenta with both signs of energy. The integration measure  $d^2k/2E$  reduces to  $dx/x$  where  $x \geq 0$  is the scaling factor of massless momentum. Only light-like momentum exchanges are however possible and scattering matrix is essentially trivial. The loop integrals are finite apart from the possible delicacies related to poles since the loop integrands for given massless wormhole contact are proportional to  $dx/x^3$  for large values of  $x$ .
4. Irrespective of whether the particles are massless or not, the divergences are obtained only if one allows too high vertices as self energy loops for which the number of momentum degrees of freedom is  $3N - 4$  for  $N$ -vertex. The construction of SUSY limit of TGD in [29] led to the conclusion that the parallelly propagating  $N$  fermions for given wormhole throat correspond to a product of  $N$  fermion propagators with same four-momentum so that for fermions and ordinary bosons one has the standard behavior but for  $N > 2$  non-standard so that these excitations are not seen as ordinary particles. Higher vertices are finite only if the total number  $N_F$  of fermions propagating in the loop satisfies  $N_F > 3N - 4$ . For instance, a 4-vertex from which  $N = 2$  states emanate is finite.

### Taking into account magnetic confinement

What has been said above is not quite enough. The weak form of electric-magnetic duality [10] leads to the picture about elementary particles as pairs of magnetic monopoles inspiring the notions of weak confinement based on magnetic monopole force. Also color confinement would have magnetic counterpart. This means that elementary particles would behave like string like objects in weak boson length scale. Therefore one must also consider the stringy case with wormhole throats replaced with fermion- $X_{\pm}$  pairs ( $X_{\pm}$  is electromagnetically neutral and  $\pm$  refers to the sign of the weak isospin opposite to that of fermion) and their super partners.

1. The simplest assumption in the stringy case is that fermion- $X_{\pm}$  pairs behave as coherent objects, that is scatter elastically. In more general case only their higher excitations identifiable in terms of stringy degrees of freedom would be created in vertices. The massivation of these states makes possible non-collinear vertices. An open question is how the massivation fermion- $X_{\pm}$  pairs relates to the existing TGD based description of massivation in terms of Higgs mechanism and modified Dirac operator.
2. Mass renormalization could come from self energy loops with negative energy lines as also vertex normalization. By very general arguments supersymmetry implies the cancellation of the self energy loops but would allow non-trivial vertex renormalization [29] .
3. If only 3-vertices are allowed, the loops containing only positive energy lines are possible if on mass shell fermion- $X_{\pm}$  pair (or its superpartner) can decay to a pair of positive energy pair particles of same kind. Whether this is possible depends on the masses involved. For ordinary particles these decays are not kinematically possible below intermediate boson mass scale (the decays  $F_1 \rightarrow F_2 + \gamma$  are forbidden kinematically or by the absence of flavor changing neutral currents whereas intermediate gauge bosons can decay to on mass shell fermion-antifermion pair).
4. The introduction of IR cutoff for 3-momentum in the rest system associated with the largest  $CD$  (causal diamond) looks natural as scale parameter of coupling constant evolution and p-adic length scale hypothesis favors the inverse of the size scale of  $CD$  coming in powers of two. This parameter would define the momentum resolution as a discrete parameter of the p-adic coupling constant evolution. This scale does not have any counterpart in standard physics. For electron,  $d$  quark, and  $u$  quark the proper time distance between the tips of  $CD$  corresponds to frequency of 10 Hz, 1280 Hz, and 160 Hz: all these frequencies define fundamental bio-rhythms [24] .

These considerations have left completely untouched one important aspect of generalized Feynman diagrams: the necessity to perform a functional integral over the deformations of the partonic 2-surfaces at the ends of the lines- that is integration over WCW. Number theoretical universality requires that WCW and these integrals make sense also p-adically and in the following these aspects of generalized Feynman diagrams are discussed.

### 4.6.3 Harmonic analysis in WCW as a manner to calculate WCW functional integrals

Previous examples suggest that symmetric space property, Kähler and symplectic structure and the use of symplectic coordinates consisting of canonically conjugate pairs of phase angles and corresponding "radial" coordinates are essential for WCW integration and p-adicization. Kähler function, the components of the metric, and therefore also metric determinant and Kähler function depend on the "radial" coordinates only and the possible generalization involves the identification the counterparts of the "radial" coordinates in the case of WCW.

#### Conditions guaranteing the reduction to harmonic analysis

The basic idea is that harmonic analysis in symmetric space allows to calculate the functional integral over WCW.

1. Each propagator line corresponds to a symmetric space defined as a coset space  $G/H$  of the symplectic group and Kac-Moody group and one might hope that the proposed p-adicization works for it- at least when one considers the hierarchy of measurement resolutions forced by the finiteness of algebraic extensions. This coset space is as a manifold Cartesian product  $(G/H) \times (G/H)$  of symmetric spaces  $G/H$  associated with ends of the line. Kähler metric contains also an interaction term between the factors of the Cartesian product so that Kähler function can be said to reduce to a sum of "kinetic" terms and interaction term.
2. Effective 2-dimensionality and ZEO allow to treat the ends of the propagator line independently. This means an enormous simplification. Each line contributes besides propagator a piece to the exponent of Kähler action identifiable as interaction term in action and depending on the propagator momentum. This contribution should be expressible in terms of generalized spherical harmonics. Essentially a sum over the products of pairs of harmonics associated with the ends of the line multiplied by coefficients analogous to  $1/(p^2 - m^2)$  in the case of the ordinary propagator would be in question. The optimal situation is that the pairs are harmonics and their conjugates appear so that one has invariance under  $G$  analogous to momentum conservation for the lines of ordinary Feynman diagrams.
3. Momentum conservation correlates the eigenvalue spectra of the modified Dirac operator  $D$  at propagator lines [15].  $G$ -invariance at vertex dictates the vertex as the singlet part of the product of WCW harmonics associated with the vertex and one sums over the harmonics for each internal line. p-Adicization means only the algebraic continuation to real formulas to p-adic context.
4. The exponent of Kähler function depends on both ends of the line and this means that the geometries at the ends are correlated in the sense that that Kähler form contains interaction terms between the line ends. It is however not quite clear whether it contains separate "kinetic" or self interaction terms assignable to the line ends. For Kähler function the kinetic and interaction terms should have the following general expressions as functions of complex WCW coordinates:

$$\begin{aligned}
 K_{kin,i} &= \sum_n f_{i,n}(Z_i) \overline{f_{i,n}(Z_i)} + c.c. , \\
 K_{int} &= \sum_n g_{1,n}(Z_1) \overline{g_{2,n}(Z_2)} + c.c. , i = 1, 2 .
 \end{aligned}
 \tag{4.6.2}$$

Here  $K_{kin,i}$  define "kinetic" terms and  $K_{int}$  defines interaction term. One would have what might be called holomorphic factorization suggesting a connection with conformal field theories. Symmetric space property -that is isometry invariance- suggests that one has

$$f_{i,n} = f_{2,n} \equiv f_n , \quad g_{1,n} = g_{2,n} \equiv g_n
 \tag{4.6.3}$$

such that the products are invariant under the group  $H$  appearing in  $G/H$  and therefore have opposite  $H$  quantum numbers. The exponent of Kähler function does not factorize although the terms in its Taylor expansion factorize to products whose factors are products of holomorphic and antiholomorphic functions.

5. If one assumes that the exponent of Kähler function reduces to a product of eigenvalues of the modified Dirac operator eigenvalues must have the decomposition

$$\lambda_k = \prod_{i=1,2} \exp \left[ \sum_n c_{k,n} g_n(Z_i) \overline{g_n(Z_i)} + c.c \right] \times \exp \left[ \sum_n d_{k,n} g_n(Z_1) \overline{g_n(Z_2)} + c.c \right] \quad (4.6.4)$$

Hence also the eigenvalues coming from the Dirac propagators have also expansion in terms of  $G/H$  harmonics so that in principle WCW integration would reduce to Fourier analysis in symmetric space.

### Generalization of WCW Hamiltonians

This picture requires a generalization of the view about configuration space Hamiltonians since also the interaction term between the ends of the line is present not taken into account in the previous approach.

1. The proposed representation of WCW Hamiltonians as flux Hamiltonians [17, 15]

$$\begin{aligned} Q(H_A) &= \int H_A (1 + K) J d^2x , \\ J &= \epsilon^{\alpha\beta} J_{\alpha\beta} , \quad J^{03} \sqrt{g_4} = K J_{12} . \end{aligned} \quad (4.6.5)$$

works for the kinetic terms only since  $J$  cannot be the same at the ends of the line. The formula defining  $K$  assumes weak form of self-duality (<sup>03</sup> refers to the coordinates in the complement of  $X^2$  tangent plane in the 4-D tangent plane).  $K$  is assumed to be symplectic invariant and constant for given  $X^2$ . The condition that the flux of  $F^{03} = (\hbar/g_K) J^{03}$  defining the counterpart of Kähler electric field equals to the Kähler charge  $g_K$  gives the condition  $K = g_K^2/\hbar$ , where  $g_K$  is Kähler coupling constant. Within experimental uncertainties one has  $\alpha_K = g_K^2/4\pi\hbar_0 = \alpha_{em} \simeq 1/137$ , where  $\alpha_{em}$  is finite structure constant in electron length scale and  $\hbar_0$  is the standard value of Planck constant.

The assumption that Poisson bracket of WCW Hamiltonians reduces to the level of imbedding space - in other words  $\{Q(H_A), Q(H_B)\} = Q(\{H_A, H_B\})$  - can be justified. One starts from the representation in terms of say flux Hamiltonians  $Q(H_A)$  and defines  $J_{A,B}$  as  $J_{A,B} \equiv Q(\{H_A, H_B\})$ . One has  $\partial H_A / \partial t_B = \{H_B, H_A\}$ , where  $t_B$  is the parameter associated with the exponentiation of  $H_B$ . The inverse  $J^{AB}$  of  $J_{A,B} = \partial H_B / \partial t_A$  is expressible as  $J^{A,B} = \partial t_A / \partial H_B$ . From these formulas one can deduce by using chain rule that the bracket  $\{Q(H_A), Q(H_B)\} = \partial t_C Q(H_A) J^{CD} \partial t_D Q(H_B)$  of flux Hamiltonians equals to the flux Hamiltonian  $Q(\{H_A, H_B\})$ .

2. One should be able to assign to WCW Hamiltonians also a part corresponding to the interaction term. The symplectic conjugation associated with the interaction term permutes the WCW coordinates assignable to the ends of the line. One should reduce this apparently non-local symplectic conjugation (if one thinks the ends of line as separate objects) to a non-local symplectic conjugation for  $\delta CD \times CP_2$  by identifying the points of lower and upper end of  $CD$  related by time reflection and assuming that conjugation corresponds to time reflection. Formally this gives a well defined generalization of the local Poisson brackets between time reflected points at the boundaries of  $CD$ . The connection of Hermitian conjugation and time reflection in quantum field theories is in accordance with this picture.

3. The only manner to proceed is to assign to the flux Hamiltonian also a part obtained by the replacement of the flux integral over  $X^2$  with an integral over the projection of  $X^2$  to a sphere  $S^2$  assignable to the light-cone boundary or to a geodesic sphere of  $CP_2$ , which come as two varieties corresponding to homologically trivial and non-trivial spheres. The projection is defined as by the geodesic line orthogonal to  $S^2$  and going through the point of  $X^2$ . The hierarchy of Planck constants assigns to  $CD$  a preferred geodesic sphere of  $CP_2$  as well as a unique sphere  $S^2$  as a sphere for which the radial coordinate  $r_M$  or the light-cone boundary defined uniquely is constant: this radial coordinate corresponds to spherical coordinate in the rest system defined by the time-like vector connecting the tips of  $CD$ . Either spheres or possibly both of them could be relevant.

Recall that also the construction of number theoretic braids and symplectic QFT [19] led to the proposal that braid diagrams and symplectic triangulations could be defined in terms of projections of braid strands to one of these spheres. One could also consider a weakening for the condition that the points of the number theoretic braid are algebraic by requiring only that the  $S^2$  coordinates of the projection are algebraic and that these coordinates correspond to the discretization of  $S^2$  in terms of the phase angles associated with  $\theta$  and  $\phi$ .

This gives for the corresponding contribution of the WCW Hamiltonian the expression

$$Q(H_A)_{int} = \int_{S^2_{\pm}} H_A X \delta^2(s_+, s_-) d^2 s_{\pm} = \int_{P(X^2_+) \cap P(X^2_-)} \frac{\partial(s^1, s^2)}{\partial(x^1_{\pm}, x^2_{\pm})} d^2 x_{\pm} . \tag{4.6.6}$$

Here the Poisson brackets between ends of the line using the rules involve delta function  $\delta^2(s_+, s_-)$  at  $S^2$  and the resulting Hamiltonians can be expressed as a similar integral of  $H_{[A,B]}$  over the upper or lower end since the integral is over the intersection of  $S^2$  projections.

The expression must vanish when the induced Kähler form vanishes for either end. This is achieved by identifying the scalar  $X$  in the following manner:

$$\begin{aligned} X &= J^k_l J^-_{kl} , \\ J^k_{\pm} &= (1 + K_{\pm}) \partial_{\alpha} s^k \partial_{\beta} s^l J^{\alpha\beta}_{\pm} . \end{aligned} \tag{4.6.7}$$

The tensors are lifts of the induced Kähler form of  $X^2_{\pm}$  to  $S^2$  (not  $CP_2$ ).

4. One could of course ask why these Hamiltonians could not contribute also to the kinetic terms and why the brackets with flux Hamiltonians should vanish. This relate to how one *defines* the Kähler form. It was shown above that in case of flux Hamiltonians the definition of Kähler form as brackets gives the basic formula  $\{Q(H_A), Q(H_B)\} = Q(\{H_A, H_B\})$  and same should hold true now. In the recent case  $J_{A,B}$  would contain an interaction term defined in terms of flux Hamiltonians and the previous argument should go through also now by identifying Hamiltonians as sums of two contributions and by introducing the doubling of the coordinates  $t_A$ .
5. The quantization of the modified Dirac operator must be reconsidered. It would seem that one must add to the super-Hamiltonian completely analogous term obtained by replacing  $(1 + K)J$  with  $X \partial(s^1, s^2) / \partial(x^1_{\pm}, x^2_{\pm})$ . Besides the anticommutation relations defining correct anticommutators to flux Hamiltonians, one should pose anticommutation relations consistent with the anticommutation relations of super Hamiltonians. In these anticommutation relations  $(1 + K)J \delta^2(x, y)$  would be replaced with  $X \delta^2(s^+, s^-)$ . This would guarantee that the oscillator operators at the ends of the line are not independent and that the resulting Hamiltonian reduces to integral over either end for  $H_{[A,B]}$ .
6. In the case of  $CP_2$  the Hamiltonians generating isometries are rational functions. This should hold true also now so that p-adic variants of Hamiltonians as functions in WCW would make sense. This in turn would imply that the components of the WCW Kähler form are rational functions. Also the exponentiation of Hamiltonians make sense p-adically if one allows the exponents of group parameters to be functions  $Exp_p(t)$ .

### Does the expansion in terms of partial harmonics converge?

The individual terms in the partial wave expansion seem to be finite but it is not at all clear whether the expansion in powers of  $K$  actually converges.

1. In the proposed scenario one performs the expansion of the vacuum functional  $\exp(K)$  in powers of  $K$  and therefore in negative powers of  $\alpha_K$ . In principle an infinite number of terms can be present. This is analogous to the perturbative expansion based on using magnetic monopoles as basic objects whereas the expansion using the contravariant Kähler metric as a propagator would be in positive powers of  $\alpha_K$  and analogous to the expansion in terms of magnetically bound states of wormhole throats with vanishing net value of magnetic charge. At this moment one can only suggest various approaches to how one could understand the situation.
2. Weak form of self-duality and magnetic confinement could change the situation. Performing the perturbation around magnetic flux tubes together with the assumed slicing of the space-time sheet by stringy world sheets and partonic 2-surfaces could mean that the perturbation corresponds to the action assignable to the electric part of Kähler form proportional to  $\alpha_K$  by the weak self-duality. Hence by  $K = 4\pi\alpha_K$  relating Kähler electric field to Kähler magnetic field the expansion would come in powers of a term containing sum of terms proportional to  $\alpha_K^0$  and  $\alpha_K$ . This would leave to the scattering amplitudes the exponents of Kähler function at the maximum of Kähler function so that the non-analytic dependence on  $\alpha_K$  would not disappear.

A further reason to be worried about is that the expansion containing infinite number of terms proportional to  $\alpha_K^0$  could fail to converge.

1. This could be also seen as a reason for why magnetic singlets are unavoidable except perhaps for  $\hbar < \hbar_0$ . By the holomorphic factorization the powers of the interaction part of Kähler action in powers of  $1/\alpha_K$  would naturally correspond to increasing and opposite net values of the quantum numbers assignable to the WCW phase coordinates at the ends of the propagator line. The magnetic bound states could have similar expansion in powers of  $\alpha_K$  as pairs of states with arbitrarily high but opposite values of quantum numbers. In the functional integral these quantum numbers would compensate each other. The functional integral would leave only an expansion containing powers of  $\alpha_K$  starting from some finite possibly negative (unless one assumes the weak form of self-duality) power. Various gauge coupling strengths are expected to be proportional to  $\alpha_K$  and these expansions should reduce to those in powers of  $\alpha_K$ .
2. Since the number of terms in the fermionic propagator expansion is finite, one might hope on basis of super-symmetry that the same is true in the case of the functional integral expansion. By the holomorphic factorization the expansion in powers of  $K$  means the appearance of terms with increasingly higher quantum numbers. Quantum number conservation at vertices would leave only a finite number of terms to tree diagrams. In the case of loop diagrams pairs of particles with opposite and arbitrarily high values of quantum numbers could be generated at the vertex and magnetic confinement might be necessary to guarantee the convergence. Also super-symmetry could imply cancellations in loops.

### Could one do without flux Hamiltonians?

The fact that the Kähler functions associated with the propagator lines can be regarded as interaction terms inspires the question whether the Kähler function could contain only the interaction terms so that Kähler form and Kähler metric would have components only between the ends of the lines.

1. The basic objection is that flux Hamiltonians too beautiful objects to be left without any role in the theory. One could also argue that the WCW metric would not be positive definite if only the non-diagonal interaction term is present. The simplest example is Hermitian  $2 \times 2$ -matrix with vanishing diagonal for which eigenvalues are real but of opposite sign.
2. One could of course argue that the expansions of  $\exp(K)$  and  $\lambda_k$  give in the general powers  $(f_n \overline{f_n})^m$  analogous to diverging tadpole diagrams of quantum field theories due to local interaction vertices. These terms do not produce divergences now but the possibility that the

exponential series of this kind of terms could diverge cannot be excluded. The absence of the kinetic terms would allow to get rid of these terms and might be argued to be the symmetric space counterpart for the vanishing of loops in WCW integral.

3. In zero energy ontology this idea does not look completely non-sensical since physical states are pairs of positive and negative energy states. Note also that in quantum theory only creation operators are used to create positive energy states. The manifest non-locality of the interaction terms and absence of the counterparts of kinetic terms would provide a trivial manner to get rid of infinities due to the presence of local interactions. The safest option is however to keep both terms.

### Summary

The discussion suggests that one must treat the entire Feynman graph as single geometric object with Kähler geometry in which the symmetric space is defined as product of what could be regarded as analogs of symmetric spaces with interaction terms of the metric coming from the propagator lines. The exponent of Kähler function would be the product of exponents associated with all lines and contributions to lines depend on quantum numbers (momentum and color quantum numbers) propagating in line via the coupling to the modified Dirac operator. The conformal factorization would allow the reduction of integrations to Fourier analysis in symmetric space. What is of decisive importance is that the entire Feynman diagrammatics at WCW level would reduce to the construction of WCW geometry for a single propagator line as a function of quantum numbers propagating on the line.

## Chapter 5

# Category Theory and Quantum TGD

### 5.1 Introduction

TGD predicts several hierarchical structures involving a lot of new physics. These structures look frustratingly complex and category theoretical thinking might help to build a bird's eye view about the situation. I have already earlier considered the question how category theory might be applied in TGD [19, 14]. Besides the far from complete understanding of the basic mathematical structure of TGD also my own limited understanding of category theoretical ideas have been a serious limitation. During last years considerable progress in the understanding of quantum TGD proper has taken place and the recent formulation of TGD is in terms of light-like 3-surfaces, zero energy ontology and number theoretic braids [80, 78]. There exist also rather detailed formulations for the fusion of p-adic and real physics and for the dark matter hierarchy. This motivates a fresh look to how category theory might help to understand quantum TGD.

The fusion rules for the symplectic variant of conformal field theory, whose existence is strongly suggested by quantum TGD, allow rather precise description using the basic notions of category theory and one can identify a series of finite-dimensional nilpotent algebras as discretized versions of field algebras defined by the fusion rules. These primitive fusion algebras can be used to construct more complex algebras by replacing any algebra element by a primitive fusion algebra. Trees with arbitrary numbers of branches in any node characterize the resulting collection of fusion algebras forming an operad. One can say that an exact solution of symplectic scalar field theory is obtained.

Conformal fields and symplectic scalar field can be combined to form symplecto-formal fields. The combination of symplectic operad and Feynman graph operad leads to a construction of Feynman diagrams in terms of n-point functions of conformal field theory. M-matrix elements with a finite measurement resolution are expressed in terms of a hierarchy of symplecto-conformal n-point functions such that the improvement of measurement resolution corresponds to an algebra homomorphism mapping conformal fields in given resolution to composite conformal fields in improved resolution. This expresses the idea that composites behave as independent conformal fields. Also other applications are briefly discussed.

### 5.2 S-matrix as a functor

John Baez's [48] discusses in a physicist friendly manner the possible application of category theory to physics. The lessons obtained from the construction of topological quantum field theories (TQFTs) suggest that category theoretical thinking might be very useful in attempts to construct theories of quantum gravitation.

The point is that the Hilbert spaces associated with the initial and final state n-1-manifold of n-cobordism indeed form in a natural manner category. Morphisms of Hilb in turn are unitary or possibly more general maps between Hilbert spaces. TQFT itself is a functor assigning to a cobordism the counterpart of S-matrix between the Hilbert spaces associated with the initial and final n-1-manifold.

The surprising result is that for  $n \leq 4$  the S-matrix can be unitary S-matrix only if the cobordism is trivial. This should lead even string theorist to raise some worried questions.

In the hope of feeding some category theoretic thinking into my spine, I briefly summarize some of the category theoretical ideas discussed in the article and relate it to the TGD vision, and after that discuss the worried questions from TGD perspective. That space-time makes sense only relative to imbedding space would conform with category theoretic thinking.

### 5.2.1 The \*-category of Hilbert spaces

Baez considers first the category of Hilbert spaces. Intuitively the definition of this category looks obvious: take linear spaces as objects in category Set, introduce inner product as additional structure and identify morphisms as maps preserving this inner product. In finite-D case the category with inner product is however identical to the linear category so that the inner product does not seem to be absolutely essential. Baez argues that in infinite-D case the morphisms need not be restricted to unitary transformations: one can consider also bounded linear operators as morphisms since they play key role in quantum theory (consider only observables as Hermitian operators). For hyper-finite factors of type  $II_1$  inclusions define very important morphisms which are not unitary transformations but very similar to them. This challenges the belief about the fundamental role of unitarity and raises the question about how to weaken the unitarity condition without losing everything.

The existence of the inner product is essential only for the metric topology of the Hilbert space. Can one do without inner product as an inherent property of state space and reduce it to a morphism? One can indeed express inner product in terms of morphisms from complex numbers to Hilbert space and their conjugates. For any state  $\Psi$  of Hilbert space there is a unique morphisms  $T_\Psi$  from  $\mathbb{C}$  to Hilbert space satisfying  $T_\Psi(1) = \Psi$ . If one assumes that these morphisms have conjugates  $T_\Psi^*$  mapping Hilbert space to  $\mathbb{C}$ , inner products can be defined as morphisms  $T_\Psi^* T_\Psi$ . The Hermitian conjugates of operators can be defined with respect to this inner product so that one obtains \*-category. Reader has probably realized that  $T_\Psi$  and its conjugate correspond to ket and bra in Dirac's formalism.

Note that in TGD framework based on hyper-finite factors of type  $II_1$  (HFFs) the inclusions of complex rays might be replaced with inclusions of HFFs with included factor representing the finite measurement resolution. Note also the analogy of inner product with the representation of space-times as 4-surfaces of the imbedding space in TGD.

### 5.2.2 The monoidal \*-category of Hilbert spaces and its counterpart at the level of nCob

One can give the category of Hilbert spaces a structure of monoid by introducing explicitly the tensor products of Hilbert spaces. The interpretation is obvious for physicist. Baez describes the details of this identification, which are far from trivial and in the theory of quantum groups very interesting things happen. A non-commutative quantum version of the tensor product implying braiding is possible and associativity condition leads to the celebrated Yang-Baxter equations: inclusions of HFFs lead to quantum groups too.

At the level of nCob the counterpart of the tensor product is disjoint union of n-1-manifolds. This unavoidably creates the feeling of cosmic loneliness. Am I really a disjoint 3-surface in emptiness which is not vacuum even in the geometric sense? Cannot be true!

This horrifying sensation disappears if n-1-manifolds are n-1-surfaces in some higher-dimensional imbedding space so that there would be at least something between them. I can emit a little baby manifold moving somewhere perhaps being received by some-one somewhere and I can receive radiation from some-one at some distance and in some direction as small baby manifolds making gentle tosses on my face!

This consoling feeling could be seen as one of the deep justifications for identifying fundamental objects as light-like partonic 3-surfaces in TGD framework. Their ends correspond to 2-D partonic surfaces at the boundaries of future or past directed light-cones (states of positive and negative energy respectively) and are indeed disjoint but not in the desperately existential sense as 3-geometries of General Relativity.

This disjointness has also positive aspect in TGD framework. One can identify the color degrees of freedom of partons as those associated with  $CP_2$  degrees of freedom. For instance,  $SU(3)$  analogs for rotational states of rigid body become possible. 4-D space-time surfaces as preferred extremals

of Kähler action connect the partonic 3-surfaces and bring in classical representation of correlations and thus of interactions. The representation as sub-manifolds makes it also possible to speak about positions of these sub-Universes and about distances between them. The inhabitants of TGD Universe are maximally free but not completely alone.

### 5.2.3 TQFT as a functor

The category theoretic formulation of TQFT relies on a very elegant and general idea. Quantum transition has as a space-time correlate an  $n$ -dimensional surface having initial final states as its  $n-1$ -dimensional ends. One assigns Hilbert spaces of states to the ends and S-matrix would be a unitary morphism between the ends. This is expressed in terms of the category theoretic language by introducing the category  $n\text{Cob}$  with objects identified as  $n-1$ -manifolds and morphisms as cobordisms and  $*$ -category  $\text{Hilb}$  consisting of Hilbert spaces with inner product and morphisms which are bounded linear operators which do not however preserve the unitarity. Note that the morphisms of  $n\text{Cob}$  cannot anymore be identified as maps between  $n-1$ -manifolds interpreted as sets with additional structure so that in this case category theory is more powerful than set theory.

TQFT is identified as a functor  $n\text{Cob} \rightarrow \text{Hilb}$  assigning to  $n-1$ -manifolds Hilbert spaces, and to cobordisms unitary S-matrices in the category  $\text{Hilb}$ . This looks nice but the surprise is that for  $n \leq 4$  unitary S-matrix exists only if the cobordism is trivial so that topology changing transitions are not possible unless one gives up unitarity.

This raises several worried questions.

1. Does this result mean that in TQFT sense unitary S-matrix for topology changing transitions from a state containing  $n_i$  closed strings to a state containing  $n_f \neq n_i$  strings does not exist? Could the situation be same also for more general non-topological stringy S-matrices? Could the non-converging perturbation series for S-matrix with finite individual terms matrix fail to have non-perturbative counterpart? Could it be that M-theory is doomed to remain a dream with no hope of being fulfilled?
2. Should one give up the unitarity condition and require that the theory predicts only the relative probabilities of transitions rather than absolute rates? What the proper generalization of the S-matrix could be?
3. What is the relevance of this result for quantum TGD?

### 5.2.4 The situation is in TGD framework

The result about the non-existence of unitary S-matrix for topology changing cobordisms allows new insights about the meaning of the departures of TGD from string models.

#### Cobordism cannot give interesting selection rules

When I started to work with TGD for more than 28 years ago, one of the first ideas was that one could identify the selection rules of quantum transitions as topological selection rules for cobordisms. Within week or two came the great disappointment: there were practically no selection rules. Could one revive this naive idea? Could the existence of unitary S-matrix force the topological selection rules after all? I am skeptic. If I have understood correctly the discussion of what happens in 4-D case [109] only the exotic diffeo-structures modify the situation in 4-D case.

#### Light-like 3-surfaces allow cobordism

In the physically interesting GRT like situation one would expect the cobordism to be mediated by a space-time surface possessing Lorentz signature. This brings in metric and temporal distance. This means complications since one must leave the pure TQFT context. Also the classical dynamics of quantum gravitation brings in strong selection rules related to the dynamics in metric degrees of freedom so that TQFT approach is not expected to be useful from the point of view of quantum gravity and certainly not the limit of a realistic theory of quantum gravitation.

In TGD framework situation is different. 4-D space-time sheets can have Euclidian signature of the induced metric so that Lorentz signature does not pose conditions. The counterparts of cobordisms

correspond at fundamental level to light-like 3-surfaces, which are arbitrarily except for the light-likeness condition (the effective 2-dimensionality implies generalized conformal invariance and analogy with 3-D black-holes since 3-D vacuum Einstein equations are satisfied). Field equations defined by the Chern-Simons action imply that  $CP_2$  projection is at most 2-D but this condition holds true only for the extremals and one has functional integral over all light-like 3-surfaces. The temporal distance between points along light-like 3-surface vanishes. The constraints from light-likeness bring in metric degrees of freedom but in a very gentle manner and just to make the theory physically interesting.

### Feynmann cobordism as opposed to ordinary cobordism

In string model context the discouraging results from TQFT hold true in the category of  $n\text{Cob}$ , which corresponds to trouser diagrams for closed strings or for their open string counterparts. In TGD framework these diagrams are replaced with a direct generalization of Feynman diagrams for which 3-D light-like partonic 3-surfaces meet along their 2-D ends at the vertices. In honor of Feynman one could perhaps speak of Feynman cobordisms. These surfaces are singular as 3-manifolds but vertices are nice 2-manifolds. In contrast to this, in string models diagrams are nice 2-manifolds but vertices are singular as 1-manifolds (say eye-glass type configurations for closed strings).

This picture gains a strong support for the interpretation of fermions as light-like throats associated with connected sums of  $CP_2$  type extremals with space-time sheets with Minkowski signature and of bosons as pairs of light-like wormhole throats associated with  $CP_2$  type extremal connecting two space-time sheets with Minkowski signature of induced metric. The space-time sheets have opposite time orientations so that also zero energy ontology emerges unavoidably. There is also consistency TGD based explanation of the family replication phenomenon in terms of genus of light-like partonic 2-surfaces.

One can wonder what the 4-D space-time sheets associated with the generalized Feynman diagrams could look like? One can try to gain some idea about this by trying to assign 2-D surfaces to ordinary Feynman diagrams having a subset of lines as boundaries. In the case of  $2 \rightarrow 2$  reaction open string is pinched to a point at vertex.  $1 \rightarrow 2$  vertex, and quite generally, vertices with odd number of lines, are impossible. The reason is that 1-D manifolds of finite size can have either 0 or 2 ends whereas in higher-D the number of boundary components is arbitrary. What one expects to happen in TGD context is that wormhole throats which are at distance characterized by  $CP_2$  fuse together in the vertex so that some kind of pinches appear also now.

### Zero energy ontology

Zero energy ontology gives rise to a second profound distinction between TGD and standard QFT. Physical states are identified as states with vanishing net quantum numbers, in particular energy. Everything is creatable from vacuum - and one could add- by intentional action so that zero energy ontology is profoundly Eastern. Positive *resp.* negative energy parts of states can be identified as states associated with 2-D partonic surfaces at the boundaries of future *resp.* past directed light-cones, whose tips correspond to the arguments of  $n$ -point functions. Each incoming/outgoing particle would define a mini-cosmology corresponding to not so big bang/crunch. If the time scale of perception is much shorter than time interval between positive and zero energy states, the ontology looks like the Western positive energy ontology. Bras and kets correspond naturally to the positive and negative energy states and phase conjugation for laser photons making them indeed something which seems to travel in opposite time direction is counterpart for bra-ket duality.

The new element would be quantum measurements performed separately for observables assignable to positive and negative energy states. These measurements would be characterized in terms of Jones inclusions. The state function reduction for the negative energy states could be interpreted as a detection of a particle reaction.

### Finite temperature S-matrix defines genuine quantum state in zero energy ontology

In TGD framework one encounters two S-matrix like operators.

1. There is U-matrix between zero energy states. This is expected to be rather trivial but very important from the point of view of description of intentional actions as transitions transforming p-adic partonic 3-surfaces to their real counterparts.

2. The S-matrix like operator describing what happens in laboratory corresponds to the time-like entanglement coefficients between positive and negative energy parts of the state. Measurement of reaction rates would be a measurement of observables reducing time like entanglement and very much analogous to an ordinary quantum measurement reducing space-like entanglement. There is a finite measurement resolution described by inclusion of HFFs and this means that situation reduces effectively to a finite-dimensional one.

p-Adic thermodynamics strengthened with p-adic length scale hypothesis predicts particle masses with an amazing success. At first the thermodynamical approach seems to be in contradiction with the idea that elementary particles are quantal objects. Unitarity is however *not* necessary if one accepts that only relative probabilities for reductions to pairs of initial and final states interpreted as particle reactions can be measured.

The beneficial implications of unitarity are not lost if one replaces QFT with thermal QFT. Category theoretically this would mean that the time-like entanglement matrix associated with the product of cobordisms is a product of these matrices for the factors. The time parameter in S-matrix would be replaced with a complex time parameter with the imaginary part identified as inverse temperature. Hence the interpretation in terms of time evolution is not lost.

In the theory of hyper-finite factors of type  $III_1$  the partition function for thermal equilibrium states and S-matrix can be neatly fused to a thermal S-matrix for zero energy states and one could introduce p-adic thermodynamics at the level of quantum states. It seems that this picture applies to HFFs by restriction. Therefore the loss of unitarity S-matrix might after all turn to a victory by more or less forcing both zero energy ontology and p-adic thermodynamics. Note that also the presence of factor of type I coming from imbedding space degrees of freedom forces thermal S-matrix.

### Time-like entanglement coefficients as a square root of density matrix?

All quantum states do not correspond to thermal states and one can wonder what might be the most general identification of the quantum state in zero energy ontology. Density matrix formalism defines a very general formulation of quantum theory. Since the quantum states in zero energy ontology are analogous to operators, the idea that time-like entanglement coefficients in some sense define a square root of density matrix is rather natural. This would give the defining conditions

$$\begin{aligned} \rho^+ &= SS^\dagger, \rho^- = S^\dagger S, \\ \text{Tr}(\rho^\pm) &= 1. \end{aligned} \tag{5.2.1}$$

$\rho^\pm$  would define density matrix for positive/negative energy states. In the case HFFs of type  $II_1$  one obtains unitary S-matrix and also the analogs of pure quantum states are possible for factors of type I. The numbers  $p_{m,n}^+ = |S_{m,n}^2|/\rho_{m,m}^+$  and  $p_{m,n}^- = |S_{n,m}^2|/\rho_{m,m}^-$  give the counterparts of the usual scattering probabilities.

A physically well-motivated hypothesis would be that  $S$  has expression  $S = \sqrt{\rho}S_0$  such that  $S_0$  is a universal unitary S-matrix, and  $\sqrt{\rho}$  is square root of a state dependent density matrix. Note that in general  $S$  is not diagonalizable in the algebraic extension involved so that it is not possible to reduce the scattering to a mere phase change by a suitable choice of state basis.

What makes this kind of hypothesis aesthetically attractive is the unification of two fundamental matrices of quantum theory to single one. This unification is completely analogous to the combination of modulus squared and phase of complex number to a single complex number: complex valued Schrödinger amplitude is replaced with operator valued one.

### S-matrix as a functor and the groupoid structure formed by S-matrices

In zero energy ontology S-matrix can be seen as a functor from the category of Feynman cobordisms to the category of operators. S-matrix can be identified as a "square root" of the positive energy density matrix  $S = \rho_+^{1/2}S_0$ , where  $S_0$  is a unitary matrix and  $\rho_+$  is the density matrix for positive energy part of the zero energy state. Obviously one has  $SS^\dagger = \rho_+$ .  $S^\dagger S = \rho_-$  gives the density matrix for negative energy part of zero energy state. Clearly, S-matrix can be seen as matrix valued generalization of Schrödinger amplitude. Note that the "indices" of the S-matrices correspond to configuration space spinors (fermions and their bound states giving rise to gauge bosons and gravitons)

and to configuration space degrees of freedom (world of classical worlds). For hyper-finite factor of  $II_1$  it is not strictly speaking possible to speak about indices since the matrix elements are traces of the S-matrix multiplied by projection operators to infinite-dimensional subspaces from right and left.

The functor property of S-matrices implies that they form a multiplicative structure analogous but not identical to groupoid [14]. Recall that groupoid has associative product and there exist always right and left inverses and identity in the sense that  $ff^{-1}$  and  $f^{-1}f$  are always defined but not identical and one has  $fgg^{-1} = f$  and  $f^{-1}fg = g$ .

The reason for the groupoid like property is that S-matrix is a map between state spaces associated with initial and final sets of partonic surfaces and these state spaces are different so that inverse must be replaced with right and left inverse. The defining conditions for groupoid are replaced with more general ones. Also now associativity holds but the role of inverse is taken by hermitian conjugate. Thus one has the conditions  $fgg^\dagger = f\rho_{g,+}$  and  $f^\dagger fg = \rho_{f,-}g$ , and the conditions  $ff^\dagger = \rho_+$  and  $f^\dagger f = \rho_-$  are satisfied. Here  $\rho_\pm$  is density matrix associated with positive/negative energy parts of zero energy state. If the inverses of the density matrices exist, groupoid axioms hold true since  $f_L^{-1} = f^\dagger \rho_{f,+}^{-1}$  satisfies  $ff_L^{-1} = Id_+$  and  $f_R^{-1} = \rho_{f,-}^{-1} f^\dagger$  satisfies  $f_R^{-1}f = Id_-$ .

There are good reasons to believe that also tensor product of its appropriate generalization to the analog of co-product makes sense with non-triviality characterizing the interaction between the systems of the tensor product. If so, the S-matrices would form very beautiful mathematical structure bringing in mind the corresponding structures for 2-tangles and N-tangles. Knowing how incredibly powerful the group like structures have been in physics one has good reasons to hope that groupoid like structure might help to deduce a lot of information about the quantum dynamics of TGD.

A word about nomenclature is in order.  $S$  has strong associations to unitarity and it might be appropriate to replace  $S$  with some other letter. The interpretation of S-matrix as a generalized Schrödinger amplitude would suggest  $\Psi$ -matrix. Since the interaction with Kea's M-theory blog at <http://kea-monad.blogspot.com/> ( $M$  denotes Monad or Motif in this context) was led to the realization of the connection with density matrix, also  $M$ -matrix might be considered. S-matrix as a functor from the category of Feynman cobordisms in turn suggests C or F. Or could just Matrix denoted by  $M$  in formulas be enough? Certainly it would inspire feeling of awe!

## 5.3 Further ideas

The work of John Baez and students has inspired also the following ideas about the role of category theory in TGD.

### 5.3.1 Operads, number theoretical braids, and inclusions of HFFs

The description of braids leads naturally to category theory and quantum groups when the braiding operation, which can be regarded as a functor, is not a mere permutation. Discreteness is a natural notion in the category theoretical context. To me the most natural manner to interpret discreteness is - not something emerging in Planck scale- but as a correlate for a finite measurement resolution and quantum measurement theory with finite measurement resolution leads naturally to number theoretical braids as fundamental discrete structures so that category theoretic approach becomes well-motivated. Discreteness is also implied by the number theoretic approach to quantum TGD from number theoretic associativity condition [6] central also for category theoretical thinking as well as from the realization of number theoretical universality by the fusion of real and p-adic physics to single coherent whole.

Operads are formally single object multi-categories [23, 115]. This object consist of an infinite sequence of sets of n-ary operations. These operations can be composed and the compositions are associative (operations themselves need not be associative) in the sense that the is natural isomorphism (symmetries) mapping differently bracketed compositions to each other. The coherence laws for operads formulate the effect of permutations and bracketing (association) as functors acting as natural isomorphisms. A simple manner to visualize the composition is as an addition of  $n_1, \dots, n_k$  leaves to the leaves  $1, \dots, k$  of k-leaved tree.

An interesting example of operad is the braid operad formulating the combinatorics for a hierarchy of braids formed from braids by grouping subsets of braids having  $n_1, \dots, n_k$  strands and defining the strands of a  $k$ -braid. In TGD framework this grouping can be identified in terms of the formation

bound states of particles topologically condensed at larger space-time sheet and coherence laws allow to deduce information about scattering amplitudes. In conformal theories braided categories indeed allow to understand duality of stringy amplitudes in terms of associativity condition.

Planar operads [68] define an especially interesting class of operads. The reason is that the inclusions of HFFs give rise to a special kind of planar operad [26]. The object of this multi-category [21] consists of planar  $k$ -tangles. Planar operads are accompanied by planar algebras. It will be found that planar operads allow a generalization which could provide a description for the combinatorics of the generalized Feynman diagrams and also rigorous formulation for how the arrow of time emerges in TGD framework and related heuristic ideas challenging the standard views.

### 5.3.2 Generalized Feynman diagram as category?

John Baez has proposed a category theoretical formulation of quantum field theory as a functor from the category of  $n$ -cobordisms to the category of Hilbert spaces [48, 47]. The attempt to generalize this formulation looks well motivated in TGD framework because TGD can be regarded as almost topological quantum field theory in a well defined sense and braids appear as fundamental structures. It however seems that formulation as a functor from  $n\text{Cob}$  to  $\text{Hilb}$  is not general enough.

In zero energy ontology events of ordinary ontology become quantum states with positive and negative energy parts of quantum states localizable to the upper and lower light-like boundaries of causal diamond (CD).

1. Generalized Feynman diagrams associated with a given  $CD$  involve quantum superposition of light-like 3-surfaces corresponding to given generalized Feynman diagram. These superpositions could be seen as categories with 3-D light-like surfaces containing braids as arrows and 2-D vertices as objects. Zero energy states would represent quantum superposition of categories (different topologies of generalized Feynman diagram) and M-matrix defined as Connes tensor product would define a functor from this category to the Hilbert space of zero energy states for given  $CD$  (tensor product defines quite generally a functor).
2. What is new from the point of view of physics that the sequences of generalized lines would define compositions of arrows and morphisms having identification in terms of braids which replicate in vertices. The possible interpretation of the replication is in terms of copying of information in classical sense so that even elementary particles would be information carrying and processing structures. This structure would be more general than the proposal of John Baez that S-matrix corresponds to a function from the category of  $n$ -dimensional cobordisms to the category  $\text{Hilb}$ .
3. p-Adic length scale hypothesis follows if the temporal distance between the tips of  $CD$  measured as light-cone proper time comes as an octave of  $CP_2$  time scale:  $T = 2^n T_0$ . This assumption implies that the p-adic length scale resolution interpreted in terms of a hierarchy of increasing measurement resolutions comes as octaves of time scale. A weaker condition would be  $T_p = pT_0$ ,  $p$  prime, and would assign all p-adic time scales to the size scale hierarchy of  $CD$ s.

This preliminary picture is of course not far complete since it applies only to single  $CD$ . There are several questions. Can one allow  $CD$ s within  $CD$ s and is every vertex of generalized Feynman diagram surrounded by this kind of  $CD$ . Can one form unions of  $CD$ s freely?

1. Since light-like 3-surfaces in 8-D imbedding space have no intersections in the generic position, one could argue that the overlap must be allowed and makes possible the interaction of between zero energy states belonging to different  $CD$ s. This interaction would be something new and present also for sub- $CD$ s of a given  $CD$ .
2. The simplest guess is that the unrestricted union of  $CD$ s defines the counterpart of tensor product at geometric level and that extended M-matrix is a functor from this category to the tensor product of zero energy state spaces. For non-overlapping  $CD$ s ordinary tensor product could be in question and for overlapping  $CD$ s tensor product would be non-trivial. One could interpret this M-matrix as an arrow between M-matrices of zero energy states at different  $CD$ s: the analog of natural transformation mapping two functors to each other. This hierarchy could be continued ad infinitum and would correspond to the hierarchy of  $n$ -categories.

This rough heuristics represents of course only one possibility among many since the notion of category is extremely general and the only limits are posed by the imagination of the mathematician. Also the view about zero energy states is still rather primitive.

## 5.4 Planar operads, the notion of finite measurement resolution, and arrow of geometric time

In the sequel the idea that planar operads or their appropriate generalization might allow to formulate generalized Feynman diagrammatics in zero energy ontology will be considered. Also a description of measurement resolution and arrow of geometric time in terms of operads is discussed.

### 5.4.1 Zeroth order heuristics about zero energy states

Consider now the existing heuristic picture about the zero energy states and coupling constant evolution provided by  $CD$ s.

1. The tentative description for the increase of the measurement resolution in terms  $CD$ s is that one inserts to the upper and/or lower light-like boundary of  $CD$  smaller  $CD$ s by gluing them along light-like radial ray from the tip of  $CD$ . It is also possible that the vertices of generalized Feynman diagrams belong inside smaller  $CD$ s and it turns out that these  $CD$ s must be allowed.
2. The considerations related to the arrow of geometric time suggest that there is asymmetry between upper and lower boundaries of  $CD$ . The minimum requirement is that the measurement resolution is better at upper light-like boundary.
3. In zero energy ontology communications to the direction of geometric past are possible and phase conjugate laser photons represent one example of this.
4. Second law of thermodynamics must be generalized in such a manner that it holds with respect to subjective time identified as sequence of quantum jumps. The arrow of geometric time can however vary so that apparent breaking of second law is possible in shorter time scales at least. One must however understand why second law holds true in so good an approximation.
5. One must understand also why the contents of sensory experience is concentrated around a narrow time interval whereas the time scale of memories and anticipation are much longer. The proposed mechanism is that the resolution of conscious experience is higher at the upper boundary of  $CD$ . Since zero energy states correspond to light-like 3-surfaces, this could be a result of self-organization rather than a fundamental physical law.
  - (a)  $CD$ s define the perceptive field for self. Selves are curious about the space-time sheets outside their perceptive field in the geometric future of the imbedding space and perform quantum jumps tending to shift the superposition of the space-time sheets to the direction of geometric past (past defined as the direction of shift!). This creates the illusion that there is a time=snapshot front of consciousness moving to geometric future in fixed background space-time as an analog of train illusion.
  - (b) The fact that news come from the upper boundary of  $CD$  implies that self concentrates its attention to this region and improves the resolutions of sensory experience and quantum measurement here. The sub- $CD$ s generated in this manner correspond to mental images with contents about this region. As a consequence, the contents of conscious experience, in particular sensory experience, tend to be about the region near the upper boundary.
  - (c) This mechanism in principle allows the arrow of the geometric time to vary and depend on p-adic length scale and the level of dark matter hierarchy. The occurrence of phase transitions forcing the arrow of geometric time to be same everywhere are however plausible for the reason that the lower and upper boundaries of given  $CD$  must possess the same arrow of geometric time.
  - (d) If this is the mechanism behind the arrow of time, planar operads can provide a description of the arrow of time but not its explanation.

This picture is certainly not general enough, can be wrong at the level of details, and at best relates to the the whole like single particle wave mechanics to quantum field theory.

### 5.4.2 Planar operads

The geometric definition of planar operads [28, 23, 26, 68] without using the category theoretical jargon goes as follows.

1. There is an external disk and some internal disks and a collection of disjoint lines connecting disk boundaries.
2. To each disk one attaches a non-negative integer  $k$ , called the color of disk. The disk with color  $k$  has  $k$  points at each boundary with the labeling  $1, 2, \dots, k$  running clockwise and starting from a distinguished marked point, decorated by  $*$ . A more restrictive definition is that disk colors are correspond to even numbers so that there are  $k = 2n$  points lines leaving the disk boundary boundary. The planar tangles with  $k = 2n$  correspond to inclusions of HFFs.
3. Each curve is either closed (no common points with disk boundaries) or joins a marked point to another marked point. Each marked point is the end point of exactly one curve.
4. The picture is planar meaning that the curves cannot intersect and disks cannot overlap.
5. Disks differing by isotopies preserving  $*$ 's are equivalent.

Given a planar  $k$ -tangle-one of whose internal disks has color  $k_i$ - and a  $k_i$ -tangle  $S$ , one can define the tangle  $T \circ_i S$  by isotoping  $S$  so that its boundary, together with the marked points and the  $*$ 's co-indices with that of  $D_i$  and after that erase the boundary of  $D_i$ . The collection of planar tangle together with the the composition defined in this manner- is called the colored operad of planar tangles.

One can consider also generalizations of planar operads.

1. The composition law is not affected if the lines of operads branch outside the disks. Branching could be allowed even at the boundaries of the disks although this does not correspond to a generic situation. One might call these operads branched operads.
2. The composition law could be generalized to allow additional lines connecting the points at the boundary of the added disk so that each composition would bring in something genuinely new. Zero energy insertion could correspond to this kind of insertions.
3. TGD picture suggests also the replacement of lines with braids. In category theoretical terms this means that besides association one allows also permutations of the points at the boundaries of the disks.

The question is whether planar operads or their appropriate generalizations could allow a characterization of the generalized Feynman diagrams representing the combinatorics of zero energy states in zero energy ontology and whether also the emergence of arrow of time could be described (but probably not explained) in this framework.

### 5.4.3 Planar operads and zero energy states

Are planar operads sufficiently powerful to code the vision about the geometric correlates for the increase of the measurement resolution and coupling constant evolution formulated in terms of  $CDs$ ? Or perhaps more realistically, could one improve this formulation by assuming that zero energy states correspond to wave functions in the space of planar tangles or of appropriate modifications of them? It seems that the answer to the first question is almost affirmative.

1. Disks are analogous to the white regions of a map whose details are not visible in the measurement resolution used. Disks correspond to causal diamonds ( $CDs$ ) in zero energy ontology. Physically the white regions relate to the vertices of the generalized Feynman diagrams and possibly also to the initial and final states (strictly speaking, the initial and final states correspond to the legs of generalized Feynman diagrams rather than their ends).

2. The composition of tangles means addition of previously unknown details to a given white region of the map and thus to an increase of the measurement resolution. This conforms with the interpretation of inclusions of HFFs as a characterization of finite measurement resolution and raises the hope that planar operads or their appropriate generalization could provide the proper language to describe coupling constant evolution and their perhaps even generalized Feynman diagrams.
3. For planar operad there is an asymmetry between the outer disk and inner disks. One might hope that this asymmetry could explain or at least allow to describe the arrow of time. This is not the case. If the disks correspond to causal diamonds ( $CD$ s) carrying positive *resp.* negative energy part of zero energy state at upper *resp.* lower light-cone boundary, the TGD counterpart of the planar tangle is  $CD$  containing smaller  $CD$ s inside it. The smaller  $CD$ s contain negative energy particles at their upper boundary and positive energy particles at their lower boundary. In the ideal resolution vertices represented 2-dimensional partonic at which light-like 3-surfaces meet become visible. There is no inherent asymmetry between positive and negative energies and no inherent arrow of geometric time at the fundamental level. It is however possible to model the arrow of time by the distribution of sub- $CD$ s. By previous arguments self-organization of selves can lead to zero energy states for which the measurement resolution is better near the upper boundary of the  $CD$ .
4. If the lines carry fermion or anti-fermion number, the number of lines entering to a given  $CD$  must be even as in the case of planar operads as the following argument shows.
  - (a) In TGD framework elementary fermions correspond to single wormhole throat associated with topologically condensed  $CP_2$  type extremal and the signature of the induced metric changes at the throat.
  - (b) Elementary bosons correspond to pairs of wormhole throats associated with wormhole contacts connecting two space-time sheets of opposite time orientation and modellable as a piece of  $CP_2$  type extremal. Each boson therefore corresponds to 2 lines within  $CP_2$  radius.
  - (c) As a consequence the total number of lines associated with given  $CD$  is even and the generalized Feynman diagrams can correspond to a planar algebra associated with an inclusion of HFFs.
5. This picture does not yet describe zero energy insertions.
  - (a) The addition of zero energy insertions corresponds intuitively to the allowance of new lines inside the smaller  $CD$ s not coming from the exterior. The addition of lines connecting points at the boundary of disk is possible without losing the basic geometric composition of operads. In particular one does not lose the possibility to color the added tangle using two colors (colors correspond to two groups  $G$  and  $H$  which characterize an inclusion of HFFs [68]).
  - (b) There is however a problem. One cannot remove the boundaries of sub- $CD$  after the composition of  $CD$ s since this would give lines beginning from and ending to the interior of disk and they are invisible only in the original resolution. Physically this is of course what one wants but the inclusion of planar tangles is expected to fail in its original form, and one must generalize the composition of tangles to that of  $CD$ s so that the boundaries of sub- $CD$ s are not thrown away in the process.
  - (c) It is easy to see that zero energy insertions are inconsistent with the composition of planar tangles. In the inclusion defining the composition of tangles both sub-tangle and tangle induce a color to a given segment of the inner disk. If these colors are identical, one can forget the presence of the boundary of the added tangle. When zero energy insertions are allowed, situation changes as is easy to see by adding a line connecting points in a segment of given color at the boundary of the included tangle. There exists no consistent coloring of the resulting structure by using only two colors. Coloring is however possible using four colors, which by four-color theorem is the minimum number of colors needed for a coloring of planar map: this however requires that the color can change as one moves through the boundary of the included disk - this is in accordance with the physical picture.

- (d) Physical intuition suggests that zero energy insertion as an improvement of measurement resolution maps to an improved color resolution and that the composition of tangles generalizes by requiring that the included disk is colored by using new nuances of the original colors. The role of groups in the definition of inclusions of HFFs is consistent with idea that  $G$  and  $H$  describe color resolution in the sense that the colors obtained by their action cannot be resolved. If so, the improved resolution means that  $G$  and  $H$  are replaced by their subgroups  $G_1 \subset G$  and  $H_1 \subset H$ . Since the elements of a subgroup have interpretation as elements of group, there are good hopes that by representing the inclusion of tangles as inclusion of groups, one can generalize the composition of tangles.
6. Also  $CD$ :s glued along light-like ray to the upper and lower boundaries of  $CD$  are possible in principle and -according the original proposal- correspond to zero energy insertions according. These  $CD$ :s might be associated with the phase transitions changing the value of  $\hbar$  leading to different pages of the book like structure defined by the generalized imbedding space.
  7. p-Adic length scale hypothesis is realized if the hierarchy of  $CD$ s corresponds to a hierarchy of temporal distances between tips of  $CD$ s given as  $a = T_n = 2^{-n}T_0$  using light-cone proper time.
  8. How this description relates to braiding? Each line corresponds to an orbit of a partonic boundary component and in principle one must allow internal states containing arbitrarily high fermion and antifermion numbers. Thus the lines decompose into braids and one must allow also braids of braids hierarchy so that each line corresponds to a braid operad in improved resolution.

#### 5.4.4 Relationship to ordinary Feynman diagrammatics

The proposed description is not equivalent with the description based on ordinary Feynman diagrams.

1. In standard physics framework the resolution scale at the level of vertices of Feynman diagrams is something which one is forced to pose in practical calculations but cannot pose at will as opposed to the measurement resolution. Light-like 3-surfaces can be however regarded only locally orbits of partonic 2-surfaces since generalized conformal invariance is true only in 3-D patches of the light-like 3-surface. This means that light-like 3-surfaces are in principle the fundamental objects so that zero energy states can be regarded only locally as a time evolutions. Therefore measurement resolution can be applied also to the distances between vertices of generalized Feynman diagrams and calculational resolution corresponds to physical resolution. Also the resolution can be better towards upper boundary of  $CD$  so that the arrow of geometric time can be understood. This is a definite prediction which can in principle kill the proposed scenario.
2. A further counter argument is that generalized Feynman diagrams are identified as light-like 3-surfaces for which Kähler function defined by a preferred extremal of Kähler action is maximum. Therefore one cannot pose any ad hoc rules on the positions of the vertices. One can of course insist that maximum of Kähler function with the constraint posed by  $T_n = 2^n T_0$  (or  $T_p = p T_0$ ) hierarchy is in question.

It would be too optimistic to believe that the details of the proposal are correct. However, if the proposal is on correct track, zero energy states could be seen as wave functions in the operad of generalized tangles (zero energy insertions and braiding) as far as combinatorics is involved and the coherence rules for these operads would give strong constraints on the zero energy state and fix the general structure of coupling constant evolution.

## 5.5 Category theory and symplectic QFT

Besides the counterpart of the ordinary Kac-Moody invariance quantum TGD possesses so called super-symplectic conformal invariance. This symmetry leads to the proposal that a symplectic variant of conformal field theory should exist. The  $n$ -point functions of this theory defined in  $S^2$  should be expressible in terms of symplectic areas of triangles assignable to a set of  $n$ -points and satisfy the duality rules of conformal field theories guaranteeing associativity. The crucial prediction is that symplectic  $n$ -point functions vanish whenever two arguments co-incide. This provides a mechanism

guaranteeing the finiteness of quantum TGD implied by very general arguments relying on non-locality of the theory at the level of 3-D surfaces.

The classical picture suggests that the generators of the fusion algebra formed by fields at different point of  $S^2$  have this point as a continuous index. Finite quantum measurement resolution and category theoretic thinking in turn suggest that only the points of  $S^2$  corresponding the strands of number theoretic braids are involved. It turns out that the category theoretic option works and leads to an explicit hierarchy of fusion algebras forming a good candidate for so called little disk operad whereas the first option has difficulties.

### 5.5.1 Fusion rules

Symplectic fusion rules are non-local and express the product of fields at two points  $s_k$  and  $s_l$  of  $S^2$  as an integral over fields at point  $s_r$ , where integral can be taken over entire  $S^2$  or possibly also over a 1-D curve which is symplectic invariant in some sense. Also discretized version of fusion rules makes sense and is expected to serve as a correlate for finite measurement resolution.

By using the fusion rules one can reduce  $n$ -point functions to convolutions of 3-point functions involving a sequence of triangles such that two subsequent triangles have one vertex in common. For instance, 4-point function reduces to an expression in which one integrates over the positions of the common vertex of two triangles whose other vertices have fixed. For  $n$ -point functions one has  $n-3$  freely varying intermediate points in the representation in terms of 3-point functions.

The application of fusion rules assigns to a line segment connecting the two points  $s_k$  and  $s_l$  a triangle spanned by  $s_k$ ,  $s_l$  and  $s_r$ . This triangle should be symplectic invariant in some sense and its symplectic area  $A_{klm}$  would define the basic variable in terms of which the fusion rule could be expressed as  $C_{klm} = f(A_{klm})$ , where  $f$  is fixed by some constraints. Note that  $A_{klm}$  has also interpretations as solid angle and magnetic flux.

### 5.5.2 What conditions could fix the symplectic triangles?

The basic question is how to identify the symplectic triangles. The basic criterion is certainly the symplectic invariance: if one has found  $N$ -D symplectic algebra, symplectic transformations of  $S^2$  must provide a new one. This is guaranteed if the areas of the symplectic triangles remain invariant under symplectic transformations. The questions are how to realize this condition and whether it might be replaced with a weaker one. There are two approaches to the problem.

#### Physics inspired approach

In the first approach inspired by classical physics symplectic invariance for the edges is interpreted in the sense that they correspond to the orbits of a charged particle in a magnetic field defined by the Kähler form. Symplectic transformation induces only a  $U(1)$  gauge transformation and leaves the orbit of the charged particle invariant if the vertices are not affected since symplectic transformations are not allowed to act on the orbit directly in this approach. The general functional form of the structure constants  $C_{klm}$  as a function  $f(A_{klm})$  of the symplectic area should guarantee fusion rules.

If the action of the symplectic transformations does not affect the areas of the symplectic triangles, the construction is invariant under general symplectic transformations. In the case of uncharged particle this is not the case since the edges are pieces of geodesics: in this case however fusion algebra however trivializes so that one cannot conclude anything. In the case of charged particle one might hope that the area remains invariant under general symplectic transformations whose action is induced from the action on vertices. The equations of motion for a charged particle involve a Kähler metric determined by the symplectic structure and one might hope that this is enough to achieve this miracle. If this is not the case - as it might well be - one might hope that although the areas of the triangles are not preserved, the triangles are mapped to each other in such a manner that the fusion algebra rules remain intact with a proper choice of the function  $f(A_{klm})$ . One could also consider the possibility that the function  $f(A_{klm})$  is dictated from the condition that it remains invariant under symplectic transformations. It however turns that this approach does not work as such.

### Category theoretical approach

The second realization is guided by the basic idea of category theoretic thinking: the properties of an object are determined its relationships to other objects. Rather than postulating that the symplectic triangle is something which depends solely on the three points involved via some geometric notion like that of geodesic line of orbit of charged particle in magnetic field, one assumes that the symplectic triangle reflects the properties of the fusion algebra, that is the relations of the symplectic triangle to other symplectic triangles. Thus one must assign to each triplet  $(s_1, s_2, s_3)$  of points of  $S^2$  a triangle just from the requirement that braided associativity holds true for the fusion algebra.

All symplectic transformations leaving the  $N$  points fixed and thus generated by Hamiltonians vanishing at these points would give new gauge equivalent realizations of the fusion algebra and deform the edges of the symplectic triangles without affecting their area. One could even say that symplectic triangulation defines a new kind geometric structure in  $S^2$ . The quantum fluctuating degrees of freedom are parameterized by the symplectic group of  $S^2 \times CP_2$  in TGD so that symplectic the geometric representation of the triangulation changes but its inherent properties remain invariant.

The elegant feature of category theoretical approach is that one can in principle construct the fusion algebra without any reference to its geometric realization just from the braided associativity and nilpotency conditions and after that search for the geometric realizations. Fusion algebra has also a hierarchy of discrete variants in which the integral over intermediate points in fusion is replaced by a sum over a fixed discrete set of points and this variant is what finite measurement resolution implies. In this case it is relatively easy to see if the geometric realization of a given abstract fusion algebra is possible.

### The notion of number theoretical braid

Braids -not necessary number theoretical- provide a realization discretization as a space-time correlate for the finite measurement resolution. The notion of braid was inspired by the idea about quantum TGD as almost topological quantum field theory. Although the original form of this idea has been buried, the notion of braid has survived: in the decomposition of space-time sheets to string world sheets, the ends of strings define representatives for braid strands at light-like 3-surfaces.

The notion of number theoretic universality inspired the much more restrictive notion of number theoretic braid requiring that the points in the intersection of the braid with the partonic 2-surface correspond to rational or at most algebraic points of  $H$  in preferred coordinates fixed by symmetry considerations. The challenge has been to find a unique identification of the number theoretic braid or at least of the end points of the braid. The following consideration suggest that the number theoretic braids are not a useful notion in the generic case but make sense and are needed in the intersection of real and p-adic worlds which is in crucial role in TGD based vision about living matter [44] .

It is only the braiding that matters in topological quantum field theories used to classify braids. Hence braid should require only the fixing of the end points of the braids at the intersection of the braid at the light-like boundaries of  $CDs$  and the braiding equivalence class of the braid itself. Therefore it is enough is to specify the topology of the braid and the end points of the braid in accordance with the attribute "number theoretic". Of course, the condition that all points of the strand of the number theoretic braid are algebraic is impossible to satisfy.

The situation in which the equations defining  $X^2$  make sense both in real sense and p-adic sense using appropriate algebraic extension of p-adic number field is central in the TGD based vision about living matter [44] . The reason is that in this case the notion of number entanglement theoretic entropy having negative values makes sense and entanglement becomes information carrying. This motivates the identification of life as something in the intersection of real and p-adic worlds. In this situation the identification of the ends of the number theoretic braid as points belonging to the intersection of real and p-adic worlds is natural. These points -call them briefly algebraic points- belong to the algebraic extension of rationals needed to define the algebraic extension of p-adic numbers. This definition however makes sense also when the equations defining the partonic 2-surfaces fail to make sense in both real and p-adic sense. In the generic case the set of points satisfying the conditions is discrete. For instance, according to Fermat's theorem the set of rational points satisfying  $X^n + Y^n = Z^n$  reduces to the point  $(0, 0, 0)$  for  $n = 3, 4, \dots$ . Hence the constraint might be quite enough in the intersection of real and p-adic worlds where the choice of the algebraic extension is unique.

One can however criticize this proposal.

1. One must fix the the number of points of the braid and outside the intersection and the non-uniqueness of the algebraic extension makes the situation problematic. Physical intuition suggests that the points of braid define carriers of quantum numbers assignable to second quantized induced spinor fields so that the total number of fermions antifermions would define the number of braids. In the intersection the highly non-trivial implication is that this number cannot exceed the number of algebraic points.
2. In the generic case one expects that even the smallest deformation of the partonic 2-surface can change the number of algebraic points and also the character of the algebraic extension of rational numbers needed. The restriction to rational points is not expected to help in the generic case. If the notion of number theoretical braid is meant to be practical, must be able to decompose WCW to open sets inside which the numbers of algebraic points of braid at its ends are constant. For real topology this is expected to be impossible and it does not make sense to use p-adic topology for WCW whose points do not allow interpretation as p-adic partonic surfaces.
3. In the intersection of real and p-adic worlds which corresponds to a discrete subset of WCW, the situation is different. Since the coefficients of polynomials involved with the definition of the partonic 2-surface must be rational or at most algebraic, continuous deformations are not possible so that one avoids the problem.
4. This forces to ask the reason why for the number theoretic braids. In the generic case they seem to produce only troubles. In the intersection of real and p-adic worlds they could however allow the construction of the elements of  $M$ -matrix describing quantum transitions changing p-adic to real surfaces and vice versa as realizations of intentions and generation of cognitions. In this the case it is natural that only the data from the intersection of the two worlds are used. In [44] I have sketched the idea about number theoretic quantum field theory as a description of intentional action and cognition.

There is also the the problem of fixing the interior points of the braid modulo deformations not affecting the topology of the braid.

1. Infinite number of non-equivalent braidings are possible. Should one allow all possible braidings for a fixed light-like 3-surface and say that their existence is what makes the dynamics essentially three-dimensional even in the topological sense? In this case there would be no problems with the condition that the points at both ends of braid are algebraic.
2. Or should one try to characterize the braiding uniquely for a given partonic 2-surfaces and corresponding 4-D tangent space distributions? The slicing of the space-time sheet by partonic 2-surfaces and string world sheets suggests that the ends of string world sheets could define the braid strands in the generic context when there is no algebraicity condition involved. This could be taken as a very natural manner to fix the topology of braid but leave the freedom to choose the representative for the braid. In the intersection of real and p-adic worlds there is no good reason for the end points of strands in this case to be algebraic at both ends of the string world sheet. One can however start from the braid defined by the end points of string world sheets, restrict the end points to be algebraic at the end with a smaller number of algebraic points and then perform a topologically non-trivial deformation of the braid so that also the points at the other end are algebraic? Non-trivial deformations need not be possible for all possible choices of algebraic braid points at the other end of braid and different choices of the set of algebraic points would give rise to different braidings. A further constraint is that only the algebraic points at which one has assign fermion or antifermion are used so that the number of braid points is not always maximal.
3. One can also ask whether one should perform the gauge fixing for the strands of the number theoretic braid using algebraic functions making sense both in real and p-adic context. This question does not seem terribly relevant since since it is only the topology of the braid that matters.

### Symplectic triangulations and braids

The identification of the edges of the symplectic triangulation as the end points of the braid is favored by conceptual economy. The nodes of the symplectic triangulation would naturally correspond to the points in the intersection of the braid with the light-like boundaries of  $CD$  carrying fermion or antifermion number. The number of these points could be arbitrarily large in the generic case but in the intersection of real and p-adic worlds these points correspond to subset of algebraic points belonging to the algebraic extension of rationals associated with the definition of partonic 2-surfaces so that the sum of fermion and antifermion numbers would be bounded above. The presence of fermions in the nodes would be the physical prerequisite for measuring the phase factors defined by the magnetic fluxes. This could be understood in terms of gauge invariance forcing to assign to a pair of points of triangulation the non-integrable phase factor defined by the Kähler gauge potential.

The remaining problem is how uniquely the edges of the triangulation can be determined.

1. The allowance of all possible choices for edges would bring in an infinite number of degrees of freedom. These curves would be analogous to freely vibrating strings. This option is not attractive. One should be able to pose conditions on edges and whatever the manner to specify the edges might be, it must make sense also in the intersection of real and p-adic worlds. In this case the total phase factor must be a root of unity in the algebraic extension of rationals involved and this poses quantization rules analogous to those for magnetic flux. The strongest condition is that the edges are such that the non-integrable phase factor is a root of unity for each edge. It will be found that similar quantization is implied also by the associativity conditions and this justifies the interpretation of phase factors defining the fusion algebra in terms of the Kähler magnetic fluxes. This would pose strong constraints on the choice of edges but would not fix completely the phase factors, and it seems that one must allow all possible triangulations consistent with this condition and the associativity conditions so that physical state is a quantum superposition over all possible symplectic triangulations characterized by the fusion algebras.
2. In the real context one would have an infinite hierarchy of symplectic triangulations and fusion algebras satisfying the associativity conditions with the number of edges equal to the total number  $N$  of fermions and antifermions. Encouragingly, this hierarchy corresponds also to a hierarchy of  $\mathcal{N} = N$  SUSY algebras [29] (large values of  $\mathcal{N}$  are not a catastrophe in TGD framework since the physical content of SUSY symmetry is not the same as that in the standard approach). In the intersection of real and p-adic worlds the value of  $\mathcal{N}$  would be bounded by the total number of algebraic points. Hence the notion of finite measurement resolution, cutoff in  $\mathcal{N}$  and bound on the total fermion number would make physics very simple in the intersection of real and p-adic worlds.

Two kinds of symplectic triangulations are possible since one can use the symplectic forms associated with  $CP_2$  and  $r_M = \text{constant}$  sphere  $S^2$  of light-cone boundary. For a given collection of nodes the choices of edges could be different for these two kinds of triangulations. Physical state would be proportional to the product of the phase factors assigned to these triangulations.

#### 5.5.3 Associativity conditions and braiding

The generalized fusion rules follow from the associativity condition for n-point functions modulo phase factor if one requires that the factor assignable to n-point function has interpretation as n-point function. Without this condition associativity would be trivially satisfied by using a product of various bracketing structures for the  $n$  fields appearing in the n-point function. In conformal field theories the phase factor defining the associator is expressible in terms of the phase factor associated with permutations represented as braidings and the same is expected to be true also now.

1. Already in the case of 4-point function there are three different choices corresponding to the 4 possibilities to connect the fixed points  $s_k$  and the varying point  $s_r$  by lines. The options are (1-2, 3-4), (1-3,2-4), and (1-4,2-3) and graphically they correspond to s-, t-, and u-channels in string diagrams satisfying also this kind of fusion rules. The basic condition would be that same amplitude results irrespective of the choice made. The duality conditions guarantee associativity

in the formation of the n-point amplitudes without any further assumptions. The reason is that the writing explicitly the expression for a particular bracketing of n-point function always leads to some bracketing of one particular 4-point function and if duality conditions hold true, the associativity holds true in general. To be precise, in quantum theory associativity must hold true only in projective sense, that is only modulo a phase factor.

2. This framework encourages category theoretic approach. Besides different bracketing there are different permutations of the vertices of the triangle. These permutations can induce a phase factor to the amplitude so that braid group representations are enough. If one has representation for the basic braiding operation as a quantum phase  $q = \exp(i2\pi/N)$ , the phase factors relating different bracketings reduce to a product of these phase factors since  $(AB)C$  is obtained from  $A(BC)$  by a cyclic permutation involving to permutations represented as a braiding. Yang-Baxter equations express the reduction of associator to braidings. In the general category theoretical setting associators and braidings correspond to natural isomorphisms leaving category theoretical structure invariant.
3. By combining the duality rules with the condition that 4-point amplitude vanishes, when any two points co-incide, one obtains from  $s_k = s_l$  and  $s_m = s_n$  the condition stating that the sum (or integral in possibly existing continuum version) of  $U^2(A_{klm})|f|^2(x_{kmr})$  over the third point  $s_r$  vanishes. This requires that the phase factor  $U$  is non-trivial so that  $Q$  must be non-vanishing if one accepts the identification of the phase factor as Bohm-Aharonov phase.
4. Braiding operation gives naturally rise to a quantum phase. A good guess is that braiding operation maps triangle to its complement since only in this manner orientation is preserved so that area is  $A_{klm}$  is mapped to  $A_{klm} - 4\pi$ . If the  $f$  is proportional to the exponent  $\exp(-A_{klm}Q)$ , braiding operation induces a complex phase factor  $q = \exp(-i4\pi Q)$ .
5. For half-integer values of  $Q$  the algebra is commutative. For  $Q = M/N$ , where  $M$  and  $N$  have no common factors, only braided commutativity holds true for  $N \geq 3$  just as for quantum groups characterizing also Jones inclusions of HFFs. For  $N = 4$  anti-commutativity and associativity hold true. Charge fractionization would correspond to non-trivial braiding and presumably to non-standard values of Planck constant and coverings of  $M^4$  or  $CP_2$  depending on whether  $S^2$  corresponds to a sphere of light-cone boundary or homologically trivial geodesic sphere of  $CP_2$ .

### 5.5.4 Finite-dimensional version of the fusion algebra

Algebraic discretization due to a finite measurement resolution is an essential part of quantum TGD. In this kind of situation the symplectic fields would be defined in a discrete set of  $N$  points of  $S^2$ : natural candidates are subsets of points of p-adic variants of  $S^2$ . Rational variant of  $S^2$  has as its points points for which trigonometric functions of  $\theta$  and  $\phi$  have rational values and there exists an entire hierarchy of algebraic extensions. The interpretation for the resulting breaking of the rotational symmetry would be a geometric correlate for the choice of quantization axes in quantum measurement and the book like structure of the imbedding space would be direct correlate for this symmetry breaking. This approach gives strong support for the category theory inspired philosophy in which the symplectic triangles are dictated by fusion rules.

#### General observations about the finite-dimensional fusion algebra

1. In this kind of situation one has an algebraic structure with a finite number of field values with integration over intermediate points in fusion rules replaced with a sum. The most natural option is that the sum is over all points involved. Associativity conditions reduce in this case to conditions for a finite set of structure constants vanishing when two indices are identical. The number  $M(N)$  of non-vanishing structure constants is obtained from the recursion formula  $M(N) = (N - 1)M(N - 1) + (N - 2)M(N - 2) + \dots + 3M(3) = NM(N - 1)$ ,  $M(3) = 1$  given  $M(4) = 4$ ,  $M(5) = 20$ ,  $M(6) = 120, \dots$  With a proper choice of the set of points associativity might be achieved. The structure constants are necessarily complex so that also the complex conjugate of the algebra makes sense.

2. These algebras resemble nilpotent algebras ( $x^n = 0$  for some  $n$ ) and Grassmann algebras ( $x^2 = 0$  always) in the sense that also the products of the generating elements satisfy  $x^2 = 0$  as one can find by using duality conditions on the square of a product  $x = yz$  of two generating elements. Also the products of more than  $N$  generating elements necessary vanish by braided commutativity so that nilpotency holds true. The interpretation in terms of measurement resolution is that partonic states and vertices can involve at most  $N$  fermions in this measurement resolution. Elements anti-commute for  $q = -1$  and commute for  $q = 1$  and the possibility to express the product of two generating elements as a sum of generating elements distinguishes these algebras from Grassman algebras. For  $q = -1$  these algebras resemble Lie-algebras with the difference that associativity holds true in this particular case.
3. I have not been able to find whether this kind of hierarchy of algebras corresponds to some well-known algebraic structure with commutativity and associativity possibly replaced with their braided counterparts. Certainly these algebras would be category theoretical generalization of ordinary algebras for which commutativity and associativity hold true in strict sense.
4. One could forget the representation of structure constants in terms of triangles and think these algebras as abstract algebras. The defining equations are  $x_i^2 = 0$  for generators plus braided commutativity and associativity. Probably there exists solutions to these conditions. One can also hope that one can construct braided algebras from commutative and associative algebras allowing matrix representations. Note that the solution the conditions allow scalings of form  $C_{klm} \rightarrow \lambda_k \lambda_l \lambda_m C_{klm}$  as symmetries.

#### Formulation and explicit solution of duality conditions in terms of inner product

Duality conditions can be formulated in terms of an inner product in the function space associated with  $N$  points and this allows to find explicit solutions to the conditions.

1. The idea is to interpret the structure constants  $C_{klm}$  as wave functions  $C_{kl}$  in a discrete space consisting of  $N$  points with the standard inner product

$$\langle C_{kl}, C_{mn} \rangle = \sum_r C_{klr} \bar{C}_{mnr} \quad . \quad (5.5.1)$$

2. The associativity conditions for a trivial braiding can be written in terms of the inner product as

$$\langle C_{kl}, \bar{C}_{mn} \rangle = \langle C_{km}, \bar{C}_{ln} \rangle = \langle C_{kn}, \bar{C}_{ml} \rangle \quad . \quad (5.5.2)$$

3. Irrespective of whether the braiding is trivial or not, one obtains for  $k = m$  the orthogonality conditions

$$\langle C_{kl}, \bar{C}_{kn} \rangle = 0 \quad . \quad (5.5.3)$$

For each  $k$  one has basis of  $N - 1$  wave functions labeled by  $l \neq k$ , and the conditions state that the elements of basis and conjugate basis are orthogonal so that conjugate basis is the dual of the basis. The condition that complex conjugation maps basis to a dual basis is very special and is expected to determine the structure constants highly uniquely.

4. One can also find explicit solutions to the conditions. The most obvious trial is based on orthogonality of function basis of circle providing representation for  $Z_{N-2}$  and is following:

$$C_{klm} = E_{klm} \times \exp(i\phi_k + \phi_l + \phi_m) \quad , \quad \phi_m = \frac{n(m)2\pi}{N-2} \quad . \quad (5.5.4)$$

Here  $E_{klm}$  is non-vanishing only if the indices have different values. The ansatz reduces the conditions to the form

$$\sum_r E_{klr} E_{mnr} \exp(i2\phi_r) = \sum_r E_{kmr} E_{lnr} \exp(i2\phi_r) = \sum_r E_{knr} E_{mlr} \exp(i2\phi_r) . \quad (5.5.5)$$

In the case of braiding one can allow overall phase factors. Orthogonality conditions reduce to

$$\sum_r E_{klr} E_{knr} \exp(i2\phi_r) = 0 . \quad (5.5.6)$$

If the integers  $n(m)$ ,  $m \neq k, l$  span the range  $(0, N - 3)$  orthogonality conditions are satisfied if one has  $E_{klr} = 1$  when the indices are different. This guarantees also duality conditions since the inner products involving  $k, l, m, n$  reduce to the same expression

$$\sum_{r \neq k, l, m, n} \exp(i2\phi_r) . \quad (5.5.7)$$

5. For a more general choice of phases the coefficients  $E_{klm}$  must have values differing from unity and it is not clear whether the duality conditions can be satisfied in this case.

### Do fusion algebras form little disk operad?

The improvement of measurement resolution means that one adds further points to an existing set of points defining a discrete fusion algebra so that a small disk surrounding a point is replaced with a little disk containing several points. Hence the hierarchy of fusion algebras might be regarded as a realization of a little disk operad [19] and there would be a hierarchy of homomorphisms of fusion algebras induced by the fusion. The inclusion homomorphism should map the algebra elements of the added points to the algebra element at the center of the little disk.

A more precise prescription goes as follows.

1. The replacement of a point with a collection of points in the little disk around it replaces the original algebra element  $\phi_{k_0}$  by a number of new algebra elements  $\phi_K$  besides already existing elements  $\phi_k$  and brings in new structure constants  $C_{KLM}$ ,  $C_{KLk}$  for  $k \neq k_0$ , and  $C_{Klm}$ .
2. The notion of improved measurement resolution allows to conclude

$$C_{KLk} = 0 , \quad k \neq k_0 , \quad C_{Klm} = C_{k_0lm} . \quad (5.5.8)$$

3. In the homomorphism of new algebra to the original one the new algebra elements and their products should be mapped as follows:

$$\begin{aligned} \phi_K &\rightarrow \phi_{k_0} , \\ \phi_K \phi_L &\rightarrow \phi_{k_0}^2 = 0 , \quad \phi_K \phi_l \rightarrow \phi_{k_0} \phi_l . \end{aligned} \quad (5.5.9)$$

Expressing the products in terms of structure constants gives the conditions

$$\sum_M C_{KLM} = 0 , \quad \sum_r C_{Klr} = \sum_r C_{k_0lr} = 0 . \quad (5.5.10)$$

The general ansatz for the structure constants based on roots of unity guarantees that the conditions hold true.

- Note that the resulting algebra is more general than that given by the basic ansatz since the improvement of the measurement resolution at a given point can correspond to different value of  $N$  as that for the original algebra given by the basic ansatz. Therefore the original ansatz gives only the basic building bricks of more general fusion algebras. By repeated local improvements of the measurement resolution one obtains an infinite hierarchy of algebras labeled by trees in which each improvement of measurement resolution means the splitting of the branch with arbitrary number  $N$  of branches. The number of improvements of the measurement resolution defining the height of the tree is one invariant of these algebras. The fusion algebra operad has a fractal structure since each point can be replaced by any fusion algebra.

### How to construct geometric representation of the discrete fusion algebra?

Assuming that solutions to the fusion conditions are found, one could try to find whether they allow geometric representations. Here the category theoretical philosophy shows its power.

- Geometric representations for  $C_{klm}$  would result as functions  $f(A_{klm})$  of the symplectic area for the symplectic triangles assignable to a set of  $N$  points of  $S^2$ .
- If the symplectic triangles can be chosen freely apart from the area constraint as the category theoretic philosophy implies, it should be relatively easy to check whether the fusion conditions can be satisfied. The phases of  $C_{klm}$  dictate the areas  $A_{klm}$  rather uniquely if one uses Bohm-Aharonov ansatz for a fixed the value of  $Q$ . The selection of the points  $s_k$  would be rather free for phases near unity since the area of the symplectic triangle associated with a given triplet of points can be made arbitrarily small. Only for the phases far from unity the points  $s_k$  cannot be too close to each other unless  $Q$  is very large. The freedom to chose the points rather freely conforms with the general view about the finite measurement resolution as the origin of discretization.
- The remaining conditions are on the moduli  $|f(A_{klm})|$ . In the discrete situation it is rather easy to satisfy the conditions just by fixing the values of  $f$  for the particular triangles involved:  $|f(A_{klm})| = |C_{klm}|$ . For the exact solution to the fusion conditions  $|f(A_{klm})| = 1$  holds true.
- Constraints on the functional form of  $|f(A_{klm})|$  for a fixed value of  $Q$  can be deduced from the correlation between the modulus and phase of  $C_{klm}$  without any reference to geometric representations. For the exact solution of fusion conditions there is no correlation.
- If the phase of  $C_{klm}$  has  $A_{klm}$  as its argument, the decomposition of the phase factor to a sum of phase factors means that the  $A_{klm}$  is sum of contributions labeled by the vertices. Also the symplectic area defined as a magnetic flux over the triangle is expressible as sum of the quantities  $\int A_\mu dx^\mu$  associated with the edges of the triangle. These fluxes should correspond to the fluxes assigned to the vertices deduced from the phase factors of  $\Psi(s_k)$ . The fact that vertices are ordered suggest that the phase of  $\Psi(s_j)$  fixes the value of  $\int A_\mu dx^\mu$  for an edge of the triangle starting from  $s_k$  and ending to the next vertex in the ordering. One must find edges giving a closed triangle and this should be possible. The option for which edges correspond to geodesics or to solutions of equations of motion for a charged particle in magnetic field is not flexible enough to achieve this purpose.
- The quantization of the phase angles as multiples of  $2\pi/(N-2)$  in the case of  $N$ -dimensional fusion algebra has a beautiful geometric correlate as a quantization of symplecto-magnetic fluxes identifiable as symplectic areas of triangles defining solid angles as multiples of  $2\pi/(N-2)$ . The generalization of the fusion algebra to p-adic case exists if one allows algebraic extensions containing the phase factors involved. This requires the allowance of phase factors  $\exp(i2\pi/p)$ ,  $p$  a prime dividing  $N-2$ . Only the exponents  $\exp(i \int A_\mu dx^\mu) = \exp(in2\pi/(N-2))$  exist p-adically. The p-adic counterpart of the curve defining the edge of triangle exists if the curve can be defined purely algebraically (say as a solution of polynomial equations with rational coefficients) so that p-adic variant of the curve satisfies same equations.

### Does a generalization to the continuous case exist?

The idea that a continuous fusion algebra could result as a limit of its discrete version does not seem plausible. The reason is that the spatial variation of the phase of the structure constants increases as the spatial resolution increases so that the phases  $\exp(i\phi(s))$  cannot be continuous at continuum limit. Also the condition  $E_{klm} = 1$  for  $k \neq l \neq m$  satisfied by the explicit solutions to fusion rules fails to have direct generalization to continuum case.

To see whether the continuous variant of fusion algebra can exist, one can consider an approximate generalization of the explicit construction for the discrete version of the fusion algebra by the effective replacement of points  $s_k$  with small disks which are not allowed to intersect. This would mean that the counterpart  $E(s_k, s_l, s_m)$  vanishes whenever the distance between two arguments is below a cutoff a small radius  $d$ . Puncturing corresponds physically to the cutoff implied by the finite measurement resolution.

1. The ansatz for  $C_{klm}$  is obtained by a direct generalization of the finite-dimensional ansatz:

$$C_{klm} = \kappa_{s_k, s_l, s_m} \Psi(s_k) \Psi(s_l) \Psi(s_m) . \quad (5.5.11)$$

where  $\kappa_{s_k, s_l, s_m}$  vanishes whenever the distance of any two arguments is below the cutoff distance and is otherwise equal to 1.

2. Orthogonality conditions read as

$$\Psi(s_k) \Psi(s_l) \int \kappa_{s_k, s_l, s_r} \kappa_{s_k, s_l, s_r} \Psi^2(s_m) d\mu(s_r) = \Psi(s_k) \Psi(s_l) \int_{S^2(s_k, s_l, s_n)} \Psi^2(s_r) d\mu(s_r) = (5.5.12)$$

The resulting condition reads as

$$\int_{S^2(s_k, s_l, s_n)} \Psi^2(s_r) d\mu(s_r) = 0 \quad (5.5.13)$$

This condition holds true for any pair  $s_k, s_l$  and this might lead to difficulties.

3. The general duality conditions are formally satisfied since the expression for all fusion products reduces to

$$\begin{aligned} X &= \Psi(s_k) \Psi(s_l) \Psi(s_m) \Psi(s_n) X , \\ X &= \int_{S^2} \kappa_{s_k, s_l, s_m, s_n} \Psi(s_r) d\mu(s_r) \\ &= \int_{S^2(s_k, s_l, s_m, s_n)} \Psi(s_m) d\mu(s_r) \\ &= - \int_{D^2(s_i)} \Psi^2(s_r) d\mu(s_r) , \quad i = k, l, s, m . \end{aligned} \quad (5.5.14)$$

These conditions state that the integral of  $\Psi^2$  any disk of fixed radius  $d$  is same: this result follows also from the orthogonality condition. This condition might be difficult to satisfy exactly and the notion of finite measurement resolution might be needed. For instance, it might be necessary to restrict the consideration to a discrete lattice of points which would lead back to a discretized version of algebra. Thus it seems that the continuum generalization of the proposed solution to fusion rules does not work.

## 5.6 Could operads allow the formulation of the generalized Feynman rules?

The previous discussion of symplectic fusion rules leaves open many questions.

1. How to combine symplectic and conformal fields to what might be called symplecto-conformal fields?
2. The previous discussion applies only in super-symplectic degrees of freedom and the question is how to generalize the discussion to super Kac-Moody degrees of freedom.
3. How four-momentum and its conservation in the limits of measurement resolution enters this picture?
4. At least two operads related to measurement resolution seem to be present: the operads formed by the symplecto-conformal fields and by generalized Feynman diagrams. For generalized Feynman diagrams causal diamond ( $CD$ ) is the basic object whereas disks of  $S^2$  are the basic objects in the case of symplecto-conformal QFT with a finite measurement resolution. These two different views about finite measurement resolution should be more or less equivalent and one should understand this equivalence at the level of details.
5. Is it possible to formulate generalized Feynman diagrammatics and improved measurement resolution algebraically?

### 5.6.1 How to combine conformal fields with symplectic fields?

The conformal fields of conformal field theory should be somehow combined with symplectic scalar field to form what might be called symplecto-conformal fields.

1. The simplest thing to do is to multiply ordinary conformal fields by a symplectic scalar field so that the fields would be restricted to a discrete set of points for a given realization of  $N$ -dimensional fusion algebra. The products of these symplecto-conformal fields at different points would define a finite-dimensional algebra and the products of these fields at same point could be assumed to vanish.
2. There is a continuum of geometric realizations of the symplectic fusion algebra since the edges of symplectic triangles can be selected rather freely. The integrations over the coordinates  $z_k$  (most naturally the complex coordinate of  $S^2$  transforming linearly under rotations around quantization axes of angular momentum) restricted to the circle appearing in the definition of simplest stringy amplitudes would thus correspond to the integration over various geometric realizations of a given  $N$ -dimensional symplectic algebra.

Fusion algebra realizes the notion of finite measurement resolution. One implication is that all  $n$ -point functions vanish for  $n > N$ . Second implication could be that the points appearing in the geometric realizations of  $N$ -dimensional symplectic fusion algebra have some minimal distance. This would imply a cutoff to the multiple integrals over complex coordinates  $z_k$  varying along circle giving the analogs of stringy amplitudes. This cutoff is not absolutely necessary since the integrals defining stringy amplitudes are well-defined despite the singular behavior of  $n$ -point functions. One can also ask whether it is wise to introduce a cutoff that is not necessary and whether fusion algebra provides only a justification for the  $1 + i\epsilon$  prescription to avoid poles used to obtain finite integrals.

The fixed values for the quantities  $\int A_\mu dx^\mu$  along the edges of the symplectic triangles could indeed pose a lower limit on the distance between the vertices of symplectic triangles. Whether this occurs depends on what one precisely means with symplectic triangle.

1. The conformally invariant condition that the angles between the edges at vertices are smaller than  $\pi$  for triangle and larger than  $\pi$  for its conjugate is not enough to exclude loopy edges and one would obtain ordinary stringy amplitudes multiplied by the symplectic phase factors. The outcome would be an integral over arguments  $z_1, z_2, \dots, z_n$  for standard stringy  $n$ -point amplitude multiplied by a symplectic phase factor which is piecewise constant in the integration domain.

2. The condition that the points at different edges of the symplectic triangle can be connected by a geodesic segment belonging to the interior of the triangle is much stronger and would induce a length scale cutoff since loops cannot be used to create large enough value of  $\int A_\mu dx^\mu$  for a given side of triangle. Symplectic invariance would be obtained for small enough symplectic transformations. How to realize this cutoff at the level of calculations is not clear. One could argue that this problem need not have any nice solution and since finite measurement resolution requires only finite calculational resolution, the approximation allowing loopy edges is acceptable.
3. The restriction of the edges of the symplectic triangle within a tubular neighborhood of a geodesic - more more generally an orbit of charged particle - with thickness determined by the length scale resolution in  $S^2$  would also introduce the length scale cutoff with symplectic invariance within measurement resolution.

Symplecto-conformal should form an operad. This means that the improvement of measurement resolution should correspond also to an algebra homomorphism in which super-symplectic symplecto-conformal fields in the original resolution are mapped by algebra homomorphism into fields which contain sum over products of conformal fields at different points: for the symplectic parts of field the products reduces always to a sum over the values of field. For instance, if the field at point  $s$  is mapped to an average of fields at points  $s_k$ , nilpotency condition  $x^2 = 0$  is satisfied.

### 5.6.2 Symplecto-conformal fields in Super-Kac-Moody sector

The picture described above is an over-simplification since it applies only in super-symplectic degrees of freedom. The vertices of generalized Feynman diagrams are absent from the description and  $CP_2$  Kähler form induced to space-time surface which is absolutely essential part of quantum TGD is nowhere visible in the treatment.

How should one bring in Super Kac-Moody (SKM) algebra representing the stringy degrees of freedom in the conventional sense of the world? The condition that the basic building bricks are same for the treatment of these degrees of freedom is a valuable guideline.

1. In the transition from super-symplectic to SKM degrees of freedom the light-cone boundary is replaced with the light-like 3-surface  $X^3$  representing the light-like random orbit of parton and serving as the basic dynamical object of quantum TGD. The sphere  $S^2$  of light-cone boundary is in turn replaced with a partonic 2-surface  $X^2$ . This suggests how to proceed.
2. In the case of SKM algebra the symplectic fusion algebra is represented geometrically as points of partonic 2-surface  $X^2$  by replacing the symplectic form of  $S^2$  with the induced  $CP_2$  symplectic form at the partonic 2-surface and defining  $U(1)$  gauge field. This gives similar hierarchy of symplecto-conformal fields as in the super-symplectic case. This also realizes the crucial aspects of the classical dynamics defined by Kähler action. In particular, for vacuum 2-surfaces symplectic fusion algebra trivializes since Kähler magnetic fluxes vanish identically and 2-surfaces near vacua require a large value of  $N$  for the dimension of the fusion algebra since the available Kähler magnetic fluxes are small.
3. In super-symplectic case the projection along light-like ray allows to map the points at the light-cone boundaries of  $CD$  to points of same sphere  $S^2$ . In the case of light-like 3-surfaces light-like geodesics representing braid strands allow to map the points of the partonic two-surfaces at the future and past light-cone boundaries to the partonic 2-surface representing the vertex. The earlier proposal was that the ends of strands meet at the partonic 2-surface so that braids would replicate at vertices. The properties of symplectic fields would however force identical vanishing of the vertices if this were the case. There is actually no reason to assume this condition and with this assumption vertices involving total number  $N$  of incoming and outgoing strands correspond to symplecto-conformal  $N$ -point function as is indeed natural. Also now Kähler magnetic flux induces cutoff distance.
4. SKM braids reside at light-like 3-surfaces representing lines of generalized Feynman diagrams. If super-symplectic braids are needed at all, they must be assigned to the two light-like boundaries of  $CD$  meeting each other at the sphere  $S^2$  at which future and past directed light-cones meet.

### 5.6.3 The treatment of four-momentum and other quantum numbers

Four-momentum enjoys a special role in super-symplectic and SKM representations in that it does not correspond to a quantum number assignable to the generators of these algebras. It would be nice if the somewhat mysterious phase factors associated with the representation of the symplectic algebra could code for the four-momentum - or rather the analogs of plane waves representing eigenstates of four-momentum at the points associated with the geometric representation of the symplectic fusion algebra. The situation is more complex as the following considerations show.

#### The representation of longitudinal momentum in terms of phase factors

1. The generalized coset representation for super-symplectic and SKM algebras implies Equivalence Principle in the generalized sense that the differences of the generators of two super Virasoro algebras annihilate the physical states. In particular, the four-momenta associated with super-symplectic *resp.* SKM degrees of freedom are identified as inertial *resp.* gravitational four-momenta and are equal by Equivalence Principle. The question is whether four-momentum could be coded in both algebras in terms of non-integrable phase factors appearing in the representations of the symplectic fusion algebras.
2. Four different phase factors are needed if all components of four-momentum are to be coded. Both number theoretical vision about quantum TGD and the realization of the hierarchy of Planck constants assign to each point of space-time surface the same plane  $M^2 \subset M^4$  having as the plane of non-physical polarizations. This condition allows to assign to a given light-like partonic 3-surface unique extremal of Kähler action defining the Kähler function as the value of Kähler action. Also p-adic mass calculations support the view that the physical states correspond to eigen states for the components of longitudinal momentum only (also the parton model for hadrons assumes this). This encourages to think that only  $M^2$  part of four-momentum is coded by the phase factors. Transversal momentum squared would be a well defined quantum number and determined from mass shell conditions for the representations of super-symplectic (or equivalently SKM) conformal algebra much like in string model.
3. The phase factors associated with the symplectic fusion algebra mean a deviation from conformal n-point functions, and the innocent question is whether these phase factors could be identified as plane-wave phase factors associated with the transversal part of the four-momentum so that the n-point functions would be strictly analogous with stringy amplitudes. In fact, the identification of the phase factors  $\exp(i \int A_\mu dx^\mu / \hbar)$  along a path as a phase factors  $\exp(ip_{L,k} \Delta m^k)$  defined by the ends of the path and associated with the longitudinal part of four-momentum would correspond to an integral form of covariant constancy condition  $\frac{dx^\mu}{ds} (\partial_\mu - iA_\mu) \Psi = 0$  along the edge of the symplectic triangle of more general path. Second phase factor would come from the integral along the (most naturally) light-like curve defining braid strand associated with the point in question. A geometric representation for the two projections of the gravitational four-momentum would thus result in SKM degrees of freedom and apart from the non-uniqueness related to the multiples of  $2\pi$  the components of  $M^2$  momentum could be deduced from the phase factors. If one is satisfied with the projection of momentum in  $M^2$ , this is enough.
4. The phase factors assignable to  $CP_2$  Kähler gauge potential are Lorentz invariant unlike the phase factors assignable to four-momentum. One can try to resolve the problem by noticing an important delicacy involved with the formulation of quantum TGD as almost topological QFT. In order to have a non-vanishing four-momentum it is necessary to assume that  $CP_2$  Kähler form has Kähler gauge potential having  $M^4$  projection, which is Lorentz invariant constant vector in the direction of the vector field defined by light-cone proper time. One cannot eliminate this part of Kähler gauge potential by a gauge transformation since the symplectic transformations of  $CP_2$  do not induce genuine gauge transformations but only symmetries of vacuum extremals of Kähler action. The presence of the  $M^4$  projection is necessary for having a non-vanishing gravitational mass in the fundamental theory relying on Chern-Simons action for light-like 3-surface and the magnitude of this vector brings gravitational constant into TGD as a fundamental constant and its value is dictated by quantum criticality.

5. Since the phase of the time-like phase factor is proportional to the increment of the proper time coordinate of light-cone, it is also Lorentz invariant! Since the selection of  $S^2$  fixes a rest frame, one can however argue that the representation in terms of phases is only for the rest energy in the case of massive particle. Also number theoretic approach selects a preferred rest frame by assigning time direction to the hyper-quaternionic real unit. In the case of massless particle this interpretation does not work since the vanishing of the rest mass implies that light-like 3-surface is piece of light-cone boundary and thus vacuum extremal. p-Adic thermodynamics predicting small mass even for massless particles can save the situation. Second possibility is that the phase factor defined by Kähler gauge potential is proportional to the Kähler charge of the particle and vanishes for massless particles.
6. This picture would mean that the phase factors assignable to the symplectic triangles have nothing to do with momentum. Because the space-like phase factor  $\exp(iS_z \Delta\phi/\hbar)$  associated with the edge of the symplectic triangle is completely analogous to that for momentum, one can argue that the symplectic triangulation should define a kind of spin network utilized in discretized approaches to quantum gravity. The interpretation raises the question about the interpretation of the quantum numbers assignable to the Lorentz invariant phase factors defined by the  $CP_2$  part of  $CP_2$  Kähler gauge potential.
7. By generalized Equivalence Principle one should have two phase factors also in super-symplectic degrees of freedom in order to characterize inertial four-momentum and spin. The inclusion of the phase factor defined by the radial integral along light-like radial direction of the light-cone boundary gives an additional phase factor if the gauge potential of the symplectic form of the light-cone boundary contains a gradient of the radial coordinate  $r_M$  varying along light-rays. Gravitational constant would characterize the scale of the "gauge parts" of Kähler gauge potentials both in  $M^4$  and  $CP_2$  degrees of freedom. The identity of inertial and gravitational four-momenta means that super-symplectic and SKM algebras represent one and same symplectic field in  $S^2$  and  $X^2$ .
8. Equivalence Principle in the generalized form requires that also the super-symplectic representation allows two additional Lorentz invariant phase factors. These phase factors are obtained if the Kähler gauge potential of the light-cone boundary has a gauge part also in  $CP_2$ . The invariance under  $U(2) \subset SU(3)$  fixes the choice the gauge part to be proportional to the gradient of the  $U(2)$  invariant radial distance from the origin of  $CP_2$  characterizing the radii of 3-spheres around the origin. Thus  $M^4 \times CP_2$  would deviate from a pure Cartesian product in a very delicate manner making possible to talk about almost topological QFT instead of only topological QFT.

### The quantum numbers associated with phase factors for $CP_2$ parts of Kähler gauge potentials

Suppose that it is possible to assign two independent and different phase factors to the same geometric representation, in other words have two independent symplectic fields with the same geometric representation. The product of two symplectic fields indeed makes sense and satisfies the defining conditions. One can define prime symplectic algebras and decompose symplectic algebras to prime factors. Since one can allow permutations of elements in the products it becomes possible to detect the presence of product structure experimentally by detecting different combinations for products of phases caused by permutations realized as different combinations of quantum numbers assigned with the factors. The geometric representation for the product of  $n$  symplectic fields would correspond to the assignment of  $n$  edges to any pair of points. The question concerns the interpretation of the phase factors assignable to the  $CP_2$  parts of Kähler gauge potentials of  $S^2$  and  $CP_2$  Kähler form.

1. The only reasonable interpretation for the two additional phase factors would be in terms of two quantum numbers having both gravitational and inertial variants and identical by Equivalence Principle. These quantum numbers should be Lorentz invariant since they are associated with the  $CP_2$  projection of the Kähler gauge potential of  $CP_2$  Kähler form.
2. Color hyper charge and isospin are mathematically completely analogous to the components of four-momentum so that a possible identification of the phase factors is as a representation of

these quantum numbers. The representation of plane waves as phase factors  $\exp(ip_k \Delta m^k / \hbar)$  generalizes to the representation  $\exp(iQ_A \Delta \Phi^A / \hbar)$ , where  $\Phi_A$  are the angle variables conjugate to the Hamiltonians representing color hyper charge and isospin. This representation depends on end points only so that the crucial symplectic invariance with respect to the symplectic transformations respecting the end points of the edge is not lost ( $U(1)$  gauge transformation is induced by the scalar  $j^k A_k$ , where  $j^k$  is the symplectic vector field in question).

3. One must be cautious with the interpretation of the phase factors as a representation for color hyper charge and isospin since a breaking of color gauge symmetry would result since the phase factors associated with different values of color isospin and hypercharge would be different and could not correspond to same edge of symplectic triangle. This is questionable since color group itself represents symplectic transformations. The construction of  $CP_2$  as a coset space  $SU(3)/U(2)$  identifies  $U(2)$  as the holonomy group of spinor connection having interpretation as electro-weak group. Therefore also the interpretation of the phase factors in terms of em charge and weak charge can be considered. In TGD framework electro-weak gauge potential indeed suffer a non-trivial gauge transformation under color rotations so that the correlation between electro-weak quantum numbers and non-integrable phase factors in Cartan algebra of the color group could make sense. Electro-weak symmetry breaking would have a geometric correlate in the sense that different values of weak isospin cannot correspond to paths with same values of phase angles  $\Delta \Phi^A$  between end points.
4. If the phase factors associated with the  $M^4$  and  $CP_2$  are assumed to be identical, the existence of geometric representation is guaranteed. This however gives constraints between rest mass, spin, and color (or electro-weak) quantum numbers.

### Some general comments

Some further comments about phase factors are in order.

1. By number theoretical universality the plane wave factors associated with four-momentum must have values coming as roots of unity (just as for a particle in box consisting of discrete lattice of points). At light-like boundary the quantization conditions reduce to the condition that the value of light-like coordinate is rational of form  $m/N$ , if  $N$ :th roots of unity are allowed.
2. In accordance with the finite measurement resolution of four-momentum, four-momentum conservation is replaced by a weaker condition stating that the products of phase factors representing incoming and outgoing four-momenta are identical. This means that positive and negative energy states at opposite boundaries of  $CD$  would correspond to complex conjugate representations of the fusion algebra. In particular, the product of phase factors in the decomposition of the conformal field to a product of conformal fields should correspond to the original field value. This would give constraints on the trees physically possible in the operad formed by the fusion algebras. Quite generally, the phases expressible as products of phases  $\exp(in\pi/p)$ , where  $p \leq N$  is prime must be allowed in a given resolution and this suggests that the hierarchy of p-adic primes is involved. At the limit of very large  $N$  exact momentum conservation should emerge.
3. Super-conformal invariance gives rise to mass shell conditions relating longitudinal and transversal momentum squared. The massivation of massless particles by Higgs mechanism and p-adic thermodynamics pose additional constraints to these phase factors.

#### 5.6.4 What does the improvement of measurement resolution really mean?

To proceed one must give a more precise meaning for the notion of measurement resolution. Two different views about the improvement of measurement resolution emerge. The first one relies on the replacement of braid strands with braids applies in SKM degrees of freedom and the homomorphism maps symplectic fields into their products. The homomorphism based on the averaging of symplectic fields over added points consistent with the extension of fusion algebra described in previous section is very natural in super-symplectic degrees of freedom. The directions of these two algebra homomorphisms are different. The question is whether both can be involved with both super-symplectic and SKM case. Since the end points of SKM braid strands correspond to both super-symplectic and SKM degrees of freedom, it seems that division of labor is the only reasonable option.

1. Quantum classical correspondence requires that measurement resolution has a purely geometric meaning. A purely geometric manner to interpret the increase of the measurement resolution is as a replacement of a braid strand with a braid in the improved resolution. If one assigns the phase factor assigned with the fusion algebra element with four-momentum, the conservation of the phase factor in the associated homomorphism is a natural constraint. The mapping of a fusion algebra element (strand) to a product of fusion algebra elements (braid) allows to realize this condition. Similar mapping of field value to a product of field values should hold true for conformal parts of the fields. There exists a large number equivalent geometric representations for a given symplectic field value so that one obtains automatically an averaging in conformal degrees of freedom. This interpretation for the improvement of measurement resolution looks especially natural for SKM degrees of freedom for which braids emerge naturally.
2. One can also consider the replacement of symplecto-conformal field with an average over the points becoming visible in the improved resolution. In super-symplectic degrees of freedom this looks especially natural since the assignment of a braid with light-cone boundary is not so natural as with light-like 3-surface. This map does not conserve the phase factor but this could be interpreted as reflecting the fact that the values of the light-like radial coordinate are different for points involved. The proposed extension of the symplectic algebra proposed in the previous section conforms with this interpretation.
3. In the super-symplectic case the improvement of measurement resolution means improvement of angular resolution at sphere  $S^2$ . In SKM sector it means improved resolution for the position at partonic 2-surface. For SKM algebra the increase of the measurement resolution related to the braiding takes place inside light-like 3-surface. This operation corresponds naturally to an addition of sub- $CD$  inside which braid strands are replaced with braids. This is like looking with a microscope a particular part of line of generalized Feynman graph inside  $CD$  and corresponds to a genuine physical process inside parton. In super-symplectic case the replacement of a braid strand with braid (at light-cone boundary) is induced by the replacement of the projection of a point of a partonic 2-surface to  $S^2$  with a collection of points coming from several partonic 2-surfaces. This replaces the point  $s$  of  $S^2$  associated with  $CD$  with a set of points  $s_k$  of  $S^2$  associated with sub- $CD$ . Note that the solid angle spanned by these points can be rather larger so that zoom-up is in question.
4. The improved measurement resolution means that a point of  $S^2$  ( $X^2$ ) at boundary of  $CD$  is replaced with a point set of  $S^2$  ( $X^2$ ) assignable to sub- $CD$ . The task is to map the point set to a small disk around the point. Light-like geodesics along light-like  $X^3$  defines this map naturally in both cases. In super-symplectic case this map means scaling down of the solid angle spanned by the points of  $S^2$  associated with sub- $CD$ .

### 5.6.5 How do the operads formed by generalized Feynman diagrams and symplecto-conformal fields relate?

The discussion above leads to following overall view about the situation. The basic operation for both symplectic and Feynman graph operads corresponds to an improvement of measurement resolution. In the case of planar disk operad this means to a replacement of a white region of a map with smaller white regions. In the case of Feynman graph operad this means better space-time resolution leading to a replacement of generalized Feynman graph with a new one containing new sub- $CD$  bringing new vertices into daylight. For braid operad the basic operation means looking a braid strand with a microscope so that it can resolve into a braid: braid becomes a braid of braids. The latter two views are equivalent if sub- $CD$  contains the braid of braids.

The disks  $D^2$  of the planar disk operad has natural counterparts in both super-symplectic and SKM sector.

1. For the geometric representations of the symplectic algebra the image points vary in continuous regions of  $S^2$  ( $X^2$ ) since the symplectic area of the symplectic triangle is a highly flexible constraint. Posing the condition that any point at the edges of symplectic triangle can be connected to any another edge excludes symplectic triangles with loopy sides so that constraint becomes non-trivial. In fact, since two different elements of the symplectic algebra cannot

correspond to the same point for a given geometric representation, each element must correspond to a connected region of  $S^2$  ( $X^2$ ). This allows a huge number of representations related by the symplectic transformations  $S^2$  in super-symplectic case and by the symplectic transformations of  $CP_2$  in SKM case. In the case of planar disk operad different representations are related by isotopies of plane.

This decomposition to disjoint regions naturally correspond to the decomposition of the disk to disjoint regions in the case of planar disk operad and Feynman graph operad (allowing zero energy insertions). Perhaps one might say that  $N$ -dimensional elementary symplectic algebra defines an  $N$ -coloring of  $S^2$  ( $S^2$ ) which is however not the same thing as the 2-coloring possible for the planar operad. TGD based view about Higgs mechanism leads to a decomposition of partonic 2-surface  $X^2$  (its light-like orbit  $X^3$ ) into conformal patches. Since also these decompositions correspond to effective discretizations of  $X^2$  ( $X^3$ ), these two decompositions would naturally correspond to each other.

2. In SKM sector disk  $D^2$  of the planar disk operad is replaced with the partonic 2-surface  $X^2$  and since measurement resolution is a local notion, the topology of  $X^2$  does not matter. The improvement of measurement resolution corresponds to the replacement of braid strand with braid and homomorphism is to the direction of improved spatial resolution.
3. In super-symplectic case  $D^2$  is replaced with the sphere  $S^2$  of light-cone boundary. The improvement of measurement resolution corresponds to introducing points near the original point and the homomorphism maps field to its average. For the operad of generalized Feynman diagrams  $CD$  defined by future and past directed light-cones is the basic object. Given  $CD$  can be indeed mapped to sphere  $S^2$  in a natural manner. The light-like boundaries of  $CD$ s are metrically spheres  $S^2$ . The points of light-cone boundaries can be projected to any sphere at light-cone boundary. Since the symplectic area of the sphere corresponds to solid angle, the choice of the representative for  $S^2$  does not matter. The sphere defined by the intersection of future and past light-cones of  $CD$  however provides a natural identification of points associated with positive and negative energy parts of the state as points of the same sphere. The points of  $S^2$  appearing in  $n$ -point function are replaced by point sets in a small disks around the  $n$  points.
4. In both super-symplectic and SKM sectors light-like geodesic along  $X^3$  mediate the analog of the map gluing smaller disk to a hole of a disk in the case of planar disk operad defining the decomposition of planar tangles. In super-symplectic sector the set of points at the sphere corresponding to a sub- $CD$  is mapped by SKM braid to the larger  $CD$  and for a typical braid corresponds to a larger angular span at sub- $CD$ . This corresponds to the gluing of  $D^2$  along its boundaries to a hole in  $D^2$  in disk operad. A scaling transformation allowed by the conformal invariance is in question. This scaling can have a non-trivial effect if the conformal fields have anomalous scaling dimensions.
5. Homomorphisms between the algebraic structures assignable to the basic structures of the operad (say tangles in the case of planar tangle operad) are an essential part of the power of the operad. These homomorphisms associated with super-symplectic and SKM sector code for two views about improvement of measurement resolution and might lead to a highly unique construction of M-matrix elements.

The operad picture gives good hopes of understanding how M-matrices corresponding to a hierarchy of measurement resolutions can be constructed using only discrete data.

1. In this process the  $n$ -point function defining M-matrix element is replaced with a superposition of  $n$ -point functions for which the number of points is larger:  $n \rightarrow \sum_{k=1, \dots, m} n_k$ . The numbers  $n_k$  vary in the superposition. The points are also obtained by downwards scaling from those of smaller  $S^2$ . Similar scaling accompanies the composition of tangles in the case of planar disk operad. Algebra homomorphism property gives constraints on the compositeness and should govern to a high degree how the improved measurement resolution affects the amplitude. In the lowest order approximation the M-matrix element is just an  $n$ -point function for conformal fields of positive and negative energy parts of the state at this sphere and one would obtain ordinary stringy amplitude in this approximation.

2. Zero energy ontology means also that each addition in principle brings in a new zero energy insertion as the resolution is improved. Zero energy insertions describe actual physical processes in shorter scales in principle affecting the outcome of the experiment in longer time scales. Since zero energy states can interact with positive (negative) energy particles, zero energy insertions are not completely analogous to vacuum bubbles and cannot be neglected. In an idealized experiment these zero energy states can be assumed to be absent. The homomorphism property must hold true also in the presence of the zero energy insertions. Note that the Feynman graph operad reduces to planar disk operad in absence of zero energy insertions.

## 5.7 Possible other applications of category theory

It is not difficult to imagine also other applications of category theory in TGD framework.

### 5.7.1 Categorification and finite measurement resolution

I read a very stimulating article by John Baez with title Categorification [46] about the basic ideas behind a process called categorification. The process starts from sets consisting of elements. In the following I describe the basic ideas and propose how categorification could be applied to realize the notion of finite measurement resolution in TGD framework.

#### What categorification is?

In categorification sets are replaced with categories and elements of sets are replaced with objects. Equations between elements are replaced with isomorphisms between objects: the right and left hand sides of equations are not the same thing but only related by an isomorphism so that they are not tautologies anymore. Functions between sets are replaced with functors between categories taking objects to objects and morphisms to morphisms and respecting the composition of morphisms. Equations between functions are replaced with natural isomorphisms between functors, which must satisfy certain coherence laws representable in terms of commuting diagrams expressing conditions such as commutativity and associativity.

The isomorphism between objects represents equation between elements of set replaces identity. What about isomorphisms themselves? Should also these be defined only up to an isomorphism of isomorphism? And what about functors? Should one continue this replacement ad infinitum to obtain a hierarchy of what might be called n-categories, for which the process stops after n:th level. This rather fuzzy business is what mathematicians like John Baez are actually doing.

#### Why categorification?

There are good motivations for the categorification. Consider the fact that natural numbers. Mathematically oriented person would think number '3' in terms of an abstract set theoretic axiomatization of natural numbers. One could also identify numbers as a series of digits. In the real life the representations of three-ness are more concrete involving many kinds of associations. For a child '3' could correspond to three fingers. For a mystic it could correspond to holy trinity. For a Christian "faith, hope, love". All these representations are isomorphic representation of threeness but as real life objects three sheep and three cows are not identical.

We have however performed what might be called decategorification: that is forgotten that the isomorphic objects are not equal. Decategorification was of course a stroke of mathematical genius with enormous practical implications: our information society represents all kinds of things in terms of numbers and simulates successfully the real world using only bit sequences. The dark side is that treating people as mere numbers can lead to a rather cold society.

Equally brilliant stroke of mathematical genius is the realization that isomorphic objects are not equal. Decategorization means a loss of information. Categorification brings back this information by bringing in consistency conditions known as coherence laws and finding these laws is the hard part of categorization meaning discovery of new mathematics. For instance, for braid groups commutativity modulo isomorphisms defines a highly non-trivial coherence law leading to an extremely powerful notion of quantum group having among other things applications in topological quantum computation.

The so called associahedrons [58] emerging in  $n$ -category theory could replace space-time and space as fundamental objects. Associahedrons are polygons used to represent geometrically associativity or its weaker form modulo isomorphism for the products of  $n$  objects bracketed in all possible manners. The polygon defines a hierarchy containing sub-polygons as its edges containing.... Associativity states the isomorphy of these polygons. Associahedrons and related geometric representations of category theoretical arrow complexes in terms of simplexes allow a beautiful geometric realization of the coherence laws. One could perhaps say that categories as discrete structures are not enough: only by introducing the continuum allowing geometric representations of the coherence laws things become simple.

No-one would have proposed categorification unless it were demanded by practical needs of mathematics. In many mathematical applications it is obvious that isomorphism does not mean identity. For instance, in homotopy theory all paths deformable to each other in continuous manner are homotopy equivalent but not identical. Isomorphism is now homotopy. These paths can be connected and form a groupoid. The outcome of the groupoid operation is determined up to homotopy. The deformations of closed path starting from a given point modulo homotopies form homotopy group and one can interpret the elements of homotopy group as copies of the point which are isomorphic. The replacement of the space with its universal covering makes this distinction explicit. One can form homotopies of homotopies and continue this process ad infinitum and obtain in this manner homotopy groups as characterizes of the topology of the space.

### Categorification as a manner to describe finite measurement resolution?

In quantum physics gauge equivalence represents a standard example about equivalence modulo isomorphisms which are now gauge transformations. There is a practical strategy to treat the situation: perform a gauge choice by picking up one representative amongst infinitely many isomorphic objects. At the level of natural numbers a very convenient gauge fixing would correspond the representation of natural number as a sequence of decimal digits rather than image of three cows.

In TGD framework a excellent motivation for categorification is the need to find an elegant mathematical realization for the notion of finite measurement resolution. Finite measurement resolutions (or cognitive resolutions) at various levels of information transfer hierarchy imply accumulation of uncertainties. Consider as a concrete example uncertainty in the determination of basic parameters of a mathematical model. This uncertainty is reflected to final outcome as via a long sequence of mathematical maps and additional uncertainties are produced by the approximations at each step of this process.

How could one describe the finite measurement resolution elegantly in TGD Universe? Categorification suggests a natural method. The points equivalent with measurement resolution are isomorphic with each other. A natural guess inspired by gauge theories is that one should perform a gauge choice as an analog of decategorification. This allows also to avoid continuum of objects connected by arrows not in spirit with the discreteness of category theoretical approach.

1. At space-time level gauge choice means discretization of partonic 2-surfaces replacing them with a discrete set points serving as representatives of equivalence classes of points equivalent under finite measurement resolution. An especially interesting choice of points is as rational points or algebraic numbers and emerges naturally in  $p$ -adicization process. One can also introduce what I have called symplectic triangulation of partonic 2-surfaces with the nodes of the triangulation representing the discretization and carrying quantum numbers of various kinds.
2. At the level of "world classical worlds" (WCW) this means the replacement of the sub-group if the symplectic group of  $\delta M^4 \times CP_2$  -call it  $G$  - permuting the points of the symplectic triangulation with its discrete subgroup obtained as a factor group  $G/H$ , where  $H$  is the normal subgroup of  $G$  leaving the points of the symplectic triangulation fixed. One can also consider subgroups of the permutation group for the points of the triangulation. One can also consider flows with these properties to get braided variant of  $G/H$ . It would seem that one cannot regard the points of triangulation as isomorphic in the category theoretical sense. This because, one can have quantum superpositions of states located at these points and the factor group acts as the analog of isometry group. One can also have many-particle states with quantum numbers at several points. The possibility to assign quantum numbers to a given point becomes the physical counterpart for the axiom of choice.

The finite measurement resolution leads to a replacement of the infinite-dimensional world of classical points with a discrete structure. Therefore operation like integration over entire "world of classical worlds" is replaced with a discrete sum.

3. What suggests itself strongly is a hierarchy of  $n$ -categories as a proper description for the finite measurement resolution. The increase of measurement resolution means increase for the number of braid points. One has also braids of braids structure implied by the possibility to map infinite primes, integers, and rationals to rational functions of several variables and the conjecture possibility to represent the hierarchy of Galois groups involved as symplectic flows. If so the hierarchy of  $n$ -categories would correspond to the hierarchy of infinite primes having also interpretation in terms of repeated second quantization of an arithmetic SUSY such that many particle states of previous level become single particle states of the next level.

The finite measurement resolution has also a representation in terms of inclusions of hyperfinite factors of type  $II_1$  defined by the Clifford algebra generated by the gamma matrices of WCW [83]

1. The included algebra represents finite measurement resolution in the sense that its action generates states which are cannot be distinguished from each other within measurement resolution used. The natural conjecture is that this indistinguishability corresponds to a gauge invariance for some gauge group and that TGD Universe is analogous to Turing machine in that almost any gauge group can be represented in terms of finite measurement resolution.
2. Second natural conjecture inspired by the fact that symplectic groups have enormous representability power is that these gauge symmetries allow representation as subgroups of the symplectic group of  $\delta M^4 \times CP_2$ . A nice article about universality of symplectic groups is the article The symplectification of science by Mark. J. Gotay [36].
3. An interesting question is whether there exists a finite-dimensional space, whose symplectomorphisms would allow a representation of any gauge group (or of all possible Galois groups as factor groups) and whether  $\delta M^4 \times CP_2$  could be a space of this kind with the smallest possible dimension.

### 5.7.2 Inclusions of HFFs and planar tangles

Finite index inclusions of HFFs are characterized by non-branched planar algebras for which only an even number of lines can emanate from a given disk. This makes possible a consistent coloring of the  $k$ -tangle by black and white by painting the regions separated by a curve using opposite colors. For more general algebras, also for possibly existing branched tangle algebras, the minimum number of colors is four by four-color theorem. For the description of zero energy states the 2-color assumption is not needed so that the necessity to have general branched planar algebras is internally consistent. The idea about the inclusion of positive energy state space into the space of negative energy states might be consistent with branched planar algebras and the requirement of four colors since this inclusion involves also conjugation and is thus not direct.

In [28] it was proposed that planar operads are associated with conformal field theories at sphere possessing defect lines separating regions with different color. In TGD framework and for branched planar algebras these defect lines would correspond to light-like 3-surfaces. For fermions one has single wormhole throat associated with topologically condensed  $CP_2$  type extremal and the signature of the induced metric changes at the throat. Bosons correspond to pairs of wormhole throats associated with wormhole contacts connecting two space-time sheets modellable as a piece of  $CP_2$  type extremal. Each boson thus corresponds to 2 lines within  $CP_2$  radius so that in purely bosonic case the planar algebra can correspond to that associated with an inclusion of HFFs.

### 5.7.3 2-plectic structures and TGD

Chris Rogers and Alex Hoffnung have demonstrated [108] that the notion of symplectic structure generalizes to  $n$ -plectic structure and in  $n = 2$  case leads to a categorification of Lie algebra to 2-Lie-algebra. In this case the generalization replaces the closed symplectic 2-form with a closed 3-form  $\omega$  and assigns to a subset of one-forms defining generalized Hamiltonians vector fields leaving the 3-form invariant.

There are two equivalent definitions of the Poisson bracket in the sense that these Poisson brackets differ only by a gradient, which does not affect the vector field assignable to the Hamiltonian one-form. The first bracket is simply the Lie-derivate of Hamiltonian one form  $G$  with respect to vector field assigned to  $F$ . Second bracket is contraction of Hamiltonian one-forms with the three-form  $\omega$ . For the first variant Jacobi identities hold true but Poisson bracket is antisymmetric only modulo gradient. For the second variant Jacobi identities hold true only modulo gradient but Poisson bracket is antisymmetric. This modulo property is in accordance with category theoretic thinking in which commutativity, associativity, antisymmetry,... hold true only up to isomorphism.

For 3-dimensional manifolds  $n=2$ -plectic structure has the very nice property that *all* one-forms give rise to Hamiltonian vector field. In this case any 3-form is automatically closed so that a large variety of 2-plectic structures exists. In TGD framework the natural choice for the 3-form  $\omega$  is as Chern-Simons 3-form defined by the projection of the Kähler gauge potential to the light-like 3-surface. Despite the fact the induced metric is degenerate, one can deduce the Hamiltonian vector field associated with the one-form using the general defining conditions

$$i_{v_F}\omega = dF \quad (5.7.1)$$

since the vanishing of the metric determinant appearing in the formal definition cancels out in the expression of the Hamiltonian vector field.

The explicit formula is obtained by writing  $\omega$  as

$$\begin{aligned} \omega &= K\epsilon_{\alpha\beta\gamma} \times \epsilon^{\mu\nu\delta} A_\mu J_{\nu\delta} \sqrt{g} = \epsilon_{\alpha\beta\gamma} \times C - S, \\ C - S &= KE^{\alpha\beta\gamma} A_\alpha J_{\beta\gamma}. \end{aligned} \quad (5.7.2)$$

Here  $E^{\alpha\beta\gamma} = \epsilon_{\alpha\beta\gamma}$  holds true numerically and metric determinant, which vanishes for light-like 3-surfaces, has disappeared.

The Hamiltonian vector field is the curl of  $F$  divided by the Chern-Simons action density  $C - S$ :

$$v_F^\alpha = \frac{1}{2} \times \frac{\epsilon^{\alpha\beta\gamma} (\partial_\beta F_\gamma - \partial_\gamma F_\beta) \sqrt{g}}{C - S \sqrt{g}} = \frac{1}{2} \times \frac{E^{\alpha\beta\gamma} (\partial_\beta F_\gamma - \partial_\gamma F_\beta)}{C - S}. \quad (5.7.3)$$

The Hamiltonian vector field multiplied by the dual of 3-form multiplied by the metric determinant has a vanishing divergence and is analogous to a vector field generating volume preserving flow. and the value of Chern Simons 3-form defines the analog of the metric determinant for light-like 3-surfaces. The generalized Poisson bracket for Hamiltonian 1-forms defined in terms of the action of Hamiltonian vector field on Hamiltonian as  $J_1^\beta D_\beta F_2 \alpha - J_2^\beta D_\beta H_2 \alpha$  is Hamiltonian 1-form. Here  $J_i$  denotes the Hamiltonian vector field associated with  $F_i$ . The bracketed unique apart from gradient. The corresponding vector field is the commutator of the Hamiltonian vector fields.

The objection is that gauge invariance is broken since the expression for the vector field assigned to the Hamiltonian one-form depends on gauge. In TGD framework there is no need to worry since Kähler gauge potential has unique natural expression and the  $U(1)$  gauge transformations of Kähler gauge potential induced by symplectic transformations of  $CP_2$  are not genuine gauge transformations but dynamical symmetries since the induced metric changes and space-time surface is deformed. Another important point is that Kähler gauge potential for a given CD has  $M^4$  part which is "pure gauge" constant Lorentz invariant vector and proportional to the inverse of gravitational constant  $G$ . Its ratio to  $CP_2$  radius squared is determined from electron mass by p-adic mass calculations and mathematically by quantum criticality fixing also the value of Kähler coupling strength.

#### 5.7.4 TGD variant for the category nCob

John Baez has suggested that quantum field theories could be formulated as functors from the category of  $n$ -cobordisms to the category of Hilbert spaces [48, 47]. In TGD framework light-like 3-surfaces containing the number theoretical braids define the analogs of 3-cobordisms and surface property brings in new structure. The motion of topological condensed 3-surfaces along 4-D space-time sheets brings in non-trivial topology analogous to braiding and not present in category nCob.

Intuitively it seems possible to speak about one-dimensional orbits of wormhole throats and -contacts (fermions and bosons) in background space-time (homological dimension). In this case linking or knotting are not possible since knotting is co-dimension 2 phenomenon and only objects whose homological dimensions sum up to  $D - 1$  can get linked in dimension  $D$ . String like objects could topologically condense along wormhole contact which is string like object. The orbits of closed string like objects are homologically co-dimension 2 objects and could get knotted if one does not allow space-time sheets describing un-knotting. The simplest examples are ordinary knots which are not allowed to evolve by forming self intersections. The orbits of point like wormhole contact and closed string like wormhole contact can get linked: a point particle moving through a closed string is basic dynamical example. There is no good reason preventing unknotting and unlinking in absolute sense.

### 5.7.5 Number theoretical universality and category theory

Category theory might be also a useful tool to formulate rigorously the idea of number theoretical universality and ideas about cognition. What comes into mind first are functors real to p-adic physics and vice versa. They would be obtained by composition of functors from real to rational physics and back to p-adic physics or vice versa. The functors from real to p-adic physics would provide cognitive representations and the reverse functors would correspond to the realization of intentional action. The functor mapping real 3-surface to p-adic 3-surfaces would be simple: interpret the equations of 3-surface in terms of rational functions with coefficients in some algebraic extension of rationals as equations in arbitrary number field. Whether this description applies or is needed for 4-D space-time surface is not clear.

At the Hilbert space level the realization of these functors would be quantum jump in which quantum state localized to p-adic sector tunnels to real sector or vice versa. In zero energy ontology this process is allowed by conservation laws even in the case that one cannot assign classical conserved quantities to p-adic states (their definition as integrals of conserved currents does not make sense since definite integral is not a well-defined concept in p-adic physics). The interpretation would be in terms of generalized M-matrix applying to cognition and intentionality. This M-matrix would have values in the field of rationals or some algebraic extension of rationals. Again a generalization of Connes tensor product is suggestive.

### 5.7.6 Category theory and fermionic parts of zero energy states as logical deductions

Category theory has natural applications to quantum and classical logic and theory of computation [47]. In TGD framework these applications are very closely related to quantum TGD itself since it is possible to identify the positive and negative energy pieces of fermionic part of the zero energy state as a pair of Boolean statements connected by a logical deduction, or rather- quantum superposition of them. An alternative interpretation is as rules for the behavior of the Universe coded by the quantum state of Universe itself. A further interpretation is as structures analogous to quantum computation programs with internal lines of Feynman diagram would represent communication and vertices computational steps and replication of classical information coded by number theoretical braids.

### 5.7.7 Category theory and hierarchy of Planck constants

Category theory might help to characterize more precisely the proposed geometric realization of the hierarchy of Planck constants explaining dark matter as phases with non-standard value of Planck constant. The situation is topologically very similar to that encountered for generalized Feynman diagrams. Singular coverings and factor spaces of  $M^4$  and  $CP_2$  are glued together along 2-D manifolds playing the role of object and space-time sheets at different vertices could be interpreted as arrows going through this object.

SUPERSYMMETRY**

## Chapter 6

# Twistors, $N = 4$ Super-Conformal Symmetry, and Quantum TGD

### 6.1 Introduction

Twistors - a notion discovered by Penrose [61] - have provided a fresh approach to the construction of perturbative scattering amplitudes in Yang-Mills theories and in  $N = 4$  supersymmetric Yang-Mills theory. This approach was pioneered by Witten [70]. The latest step in the progress was the proposal by Nima Arkani-Hamed and collaborators [58] that super Yang Mills and super gravity amplitudes might be formulated in 8-D twistor space possessing real metric signature  $(4, 4)$ . The questions considered below are following.

1. Could twistor space provide a natural realization of  $N = 4$  super-conformal theory requiring critical dimension  $D = 8$  and signature metric  $(4, 4)$ ? Could string like objects in TGD sense be understood as strings in twistor space? More concretely, could one in some sense lift quantum TGD from  $M^4 \times CP_2$  to 8-D twistor space  $T$  so that one would have three equivalent descriptions of quantum TGD.
2. Could one construct the preferred extremals of Kähler action in terms of twistors -may be by mimicking the construction of hyper-quaternionic *resp.* co-hyper-quaternionic surfaces in  $M^8$  as surfaces having hyper-quaternionic tangent space *resp.* normal space at each point with the additional property that one can assign to each point  $x$  a plane  $M^2(x) \subset M^4$  as sub-space or as sub-space defined by light-like tangent vector in  $M^4$ . Could one mimic this construction by assigning to each point of  $X^4$  regarded as a 4-surface in  $T$  a 4-D plane of twistor space satisfying some conditions making possible the interpretation as a tangent plane and guaranteeing the existence of a map of  $X^4$  to a surface in  $M^4 \times CP_2$ . Could twistor formalism help to resolve the integrability conditions involved?
3. Could one define 8-D counterpart of twistors in order to avoid the problems posed by the description of massive states by regarding them as massless states in 8-D context. Could the octonionic realization of 8-D gamma matrices allow to define twistors in 8-D framework? Could associativity constraint reducing twistors to quaternionic twistors locally imply effective reduction to four-dimensional twistors.
4. Are 8-D counterparts of twistors needed at all? Could the reduction of the dynamics to that for 4-D surfaces and effective 2-dimensionality have twistorial counterparts in the sense that 4-D twistors or their suitable generalization or even 2-D twistors could make sense at the fundamental level? Number theoretical vision based on the requirement of not only associativity but also of commutativity would suggest a reduction to  $M^2$ -valued momenta having description in terms of 2-D twistors. The preferred  $M^2 \subset M^4$  identified as hyper-complex plane plays also a key role in the realization of the zero energy ontology and hierarchy of Planck constants.

The arguments of this chapter suggest that some these questions might have affirmative answers. It must be of course emphasized that all considerations are highly speculative first thoughts of an

innocent novice. The proposals to be discussed do not form a single coherent picture but are just alternatives between which one might choose in the lack of anything better. In the next chapter [84] a proposal for the realization of twistor program inspired by the Yangian symmetry [41] to the twistor Grassmannian program [33] and looks much more realistic. I have however decided to keep this chapter as a document about the development of ideas.

### 6.1.1 Twistors and classical TGD

Consider first the twistorialization at the classical space-time level.

1. One can assign twistors to only 4-D Minkowski space (also to other than Lorentzian signature). One of the challenges of the twistor program is how to define twistors in the case of a general curved space-time. In TGD framework the structure of the imbedding space allows to circumvent this problem.
2. The lifting of classical TGD to twistor space level is a natural idea. Consider space-time surfaces representable as graphs of maps  $M^4 \rightarrow CP_2$ . At classical level the Hamilton-Jacobi structure [8] required by the number theoretic compactification means dual slicings of the  $M^4$  projection of the space-time surface  $X^4$  by stringy world sheets and partonic two-surfaces. Stringy slicing allows to assign to each point of the projection of  $X^4$  two light-like tangent vectors  $U$  and  $V$  parallel to light-like Hamilton-Jacobi coordinate curves. These vectors define components  $\tilde{\mu}$  and  $\lambda$  of a projective twistor, and twistor equation assigns to this pair a point  $m$  of  $M^4$ . The conjecture is that for preferred extremals of Kähler action this point corresponds to the  $M^4$  projection of the point in the natural  $M^4$  coordinates associated with the upper or lower tip of causal diamond  $CD$ . If this conjecture is correct one can lift the  $M^4$  projection of the space-time surface in  $CD \times CP_2 \subset M^4 \times CP_2$  to a surface in  $PT \times CP_2$ , where  $CP_3$  is projective twistor space  $PT = CP_3$ . Also induced spinor fields and induced gauge fields can be lifted to twistor space.
3. If one can fix the scales of the tangent vectors  $U$  and  $V$  and fix the phase of spinor  $\lambda$  one can consider also the lifting to 8-D twistor space  $T$  rather than 6-D projective twistor space  $PT$ . Kind of symmetry breaking would be in question. The proposal for how to achieve this relies on the notion of finite measurement resolution. The scale of  $V$  at partonic 2-surface  $X^2 \subset \delta CD \times X_l^3$  would naturally correlate with the energy of the massless particle assignable to the light-like curve beginning from that point and thus fix the scale of  $V$  coordinate. Symplectic triangulation discussed in [13] in turn allows to assign a phase factor to each strand of the number theoretic braid as the Kähler magnetic flux associated with the triangle having the point at its center. This allows to lift the stringy world sheets associated with number theoretic braids to their twistor variants but not the entire space-time surface. String model in twistor space is obtained in accordance with the fact that  $N = 4$  super-conformal invariance is realized as a string model in a target space with  $(4, 4)$  signature of metric. Note however that  $CP_2$  defines additional degrees of freedom for the target space so that 12-D space is actually in question.
4. One can consider also a more general problem of identifying the counterparts for the preferred extremals of Kähler action with arbitrary dimensions of  $M^4$  and  $CP_2$  projections in 10-D space  $PT \times CP_2$ . The key idea is the reduction of field equations to holomorphy as in Penrose's twistor representation of solutions of positive and negative frequency parts of free fields in  $M^4$ . A very helpful observation is that  $CP_2$  as a sub-manifold of  $PT$  corresponds to the 2-D space of null rays of the complexified Minkowski space  $M_c^4$ . For the 5-D space  $N \subset PT$  of null twistors this 2-D space contains 1-dimensional light ray in  $M^4$  so that  $N$  parameterizes the light-rays of  $M^4$ . The idea is to consider holomorphic surfaces in  $PT_{\pm} \times CP_2$  ( $\pm$  correlates with positive and negative energy parts of zero energy state) having dimensions  $D = 6, 8, 10$ ; restrict them to  $N \times CP_2$ , select a sub-manifold of light-rays from  $N$ , and select from each light-ray subset of points which can be discrete or portion of the light-ray in order to get a 4-D space-time surface. If integrability conditions for the resulting distribution of light-like vectors  $U$  and  $V$  can be satisfied (in other words they are gradients), a good candidate for a preferred extremal of Kähler action is obtained. Note that this construction raises light-rays to a role of fundamental geometric object.

### 6.1.2 Twistors and Feynman diagrams

The recent successes of twistor concept in the understanding of 4-D gauge theories and  $N = 4$  SYM motivate the question of how twistorialization could help to understand construction of  $M$ -matrix in terms of Feynman diagrammatics or its generalization.

1. One of the basic problems of twistor program is how to treat massive particles. Massive four-momentum can be described in terms of two twistors but their choice is uniquely only modulo  $SO(3)$  rotation. This is ugly and one can consider several cures to the situation.
  - (a) Number theoretic compactification and hierarchy of Planck constants leading to a generalization of the notion of imbedding space assign to each sector of configuration space defined by a particular  $CD$  a unique plane  $M^2 \subset M^4$  defining quantization axes. The line connecting the tips of the  $CD$  selects also unique rest frame (time axis). The representation of a light-like four-momentum as a sum of four-momentum in this plane and second light-like momentum is unique and same is true for the spinors  $\lambda$  apart from the phase factors (the spinor associated with  $M^2$  corresponds to spin up or spin down eigen state).
  - (b) The tangent vectors of braid strands define light-like vectors in  $H$  and their  $M^4$  projection is time-like vector allowing a representation as a combination of  $U$  and  $V$ . Could also massive momenta be represented as unique combinations of  $U$  and  $V$ ?
  - (c) One can consider also the possibility to represent massive particles as bound states of massless particles.

It will be found that one can lift ordinary Feynman diagrams to spinor diagrams and integrations over loop momenta correspond to integrations over the spinors characterizing the momentum.

2. One assign to ordinary momentum eigen states spinor  $\lambda$  but it is not clear how to identify the spinor  $\tilde{\mu}$  needed for a twistor.
  - (a) Could one assign  $\tilde{\mu}$  to spin polarization or perhaps to the spinor defined by the light-like  $M^2$  part of the massive momentum? Or could  $\lambda$  and  $\tilde{\mu}$  correspond to the vectors proportional to  $V$  and  $U$  needed to represent massive momentum?
  - (b) Or is something more profound needed? The notion of light-ray is central for the proposed construction of preferred extremals. Should momentum eigen states be replaced with light ray momentum eigen states with a complete localization in degrees of freedom transversal to light-like momentum? This concept is favored both by the notion of number theoretic braid and by the massless extremals (MEs) representing "topological light rays" as analogs of laser beams and serving as space-time correlates for photons represented as wormhole contacts connecting two parallel MEs. The transversal position of the light ray would bring in  $\tilde{\mu}$ . This would require a modification of the perturbation theory and the introduction of the ray analog of Feynman propagator. This generalization would be  $M^4$  counterpart for the highly successful twistor diagrammatics relying on twistor Fourier transform but making sense only for the (2,2) signature of Minkowski space.

### 6.1.3 Massive particles and the generalization of twistors to 8-D case

The basic problem of the twistor approach is that one cannot represent massive momenta in terms of twistors in elegant manner. This problem might be circumvented.

1. In quantum TGD massive states in  $M^4$  can be regarded as massless states in  $M^8$  and  $CP_2$  (recall  $M^8 - H$  duality), and one can map any massive  $M^4$  momentum to a light-like  $M^8$  momentum and hope that this association could be made in a unique manner.
2. One should assign to a massless 8-momentum an 8-dimensional spinor of fixed chirality. The spinor assigned with the light-like four-momentum is not unique without additional conditions. The existence of covariantly constant right-handed neutrino in  $CP_2$  degrees generating the super-conformal symmetries could allow to eliminate the non-uniqueness. 8-dimensional twistor in  $M^8$  would be a pair of this kind of spinors fixing the momentum of massless particle and the point

through which the corresponding light-geodesic goes through: the set of these points forms 8-D light-cone and one can assign to each point a spinor. In  $M^4 \times CP_2$  definitions makes also in the case of  $M^4 \times CP_2$  and twistor space would also now be a lifting of the space of light-like geodesics.

3. The possibility to interpret  $M^8$  as hyperoctonionic space suggests also the possibility to define the 8-D counterparts of sigma matrices to hyperoctonions to obtain a representation of sigma matrix algebra which is not a matrix representation. The mapping of gamma matrices to this representation allows to define a notion of hyper-quaternionicity in terms of the modified gamma matrices both in  $M^8$  and  $H$ . In this case however hyper-quaternionic 4-plane associated with a given point of  $X^4$  is not tangent plane in the general case. This approach allows to deduce an ansatz to the modified Dirac equation working also in the general case.

### 6.1.4 Twistors and electric-magnetic duality

The vision involves the notions of bosonic emergence, the identification of virtual states as pairs of on mass shell states assignable to wormhole throats inspired by zero energy ontology and the associated realization of Cutkosky rules in terms of manifestly finite Feynman diagrammatics, and as the latest and most important piece the weak form of electric-magnetic duality and the notion of  $M^2$ -valued pseudo-momentum associated with the generalized eigen states of the Chern-Simons Dirac operator. There must be a correlation between pseudo-momenta and real momenta and the identification of the difference of pseudo-momenta of wormhole throats representing virtual particle as the difference of corresponding on-mass-shell momenta is what gives a connection between ordinary virtual momenta and pseudo-momenta. One would obtain not only 4-D twistors but much simpler 2-D twistors with a discrete pseudo-momentum spectrum containing possibly only a finite number of momenta.

To sum up, the ideas about twistors are just ideas and it takes years to transform them to a genuine theory. At this moment the simplest and most promising approach is the one inspired by zero energy ontology combined with the implications of electric-magnetic duality and the combination of this approach with the twistor Grassmannian program discussed in the next chapter looks much more realistic than the considerations of this chapter.

## 6.2 Could the target space be identified in terms of twistors?

The problem of quantum theory in  $(2, 2)$  signature and corresponding real twistors is that a spacetime with this metric signature does not conform with the standard view about causality. The challenge is to find a physical interpretation consistent with the metric signature of Minkowski space: somehow  $M^4$  or at least light-cone boundary should be lifted to twistor space. The  $(2,2)$  *resp.*  $(4,4)$  signature of the metric of the target space is a problem of also  $N = 2$  *resp.*  $N = 4$  super-conformal string theories, and  $N = 4$  super-conformal string theory could be relevant for quantum TGD since TGD has  $N = 4$  superconformal symmetries as broken symmetries. The identification of the target space of  $N = 4$  theory as twistor space  $T$  looks natural.

Number theoretical compactification implies dual slicings of the space-time surface to string world sheets and partonic 2-surfaces. Finite measurement resolution reduces light-like 3-surfaces to braids defining boundaries of string world sheets. String model in  $T$  is obtained if one can lift the string world sheets from  $CD \times CP_2$  to  $T$ . It turns out that this is possible and one can also find an interpretation for the phases associated with the spinors defining the twistor.

A physically attractive realization of the braids - and more generally- of slicings of space-time surface by 3-surfaces and string world sheets, is discussed in [36] by starting from the observation that TGD defines an almost topological QFT of braids, braid cobordisms, and 2-knots. The boundaries of the string world sheets at the space-like 3-surfaces at boundaries of  $CD$ s and wormhole throats would define space-like and time-like braids uniquely.

The idea relies on a rather direct translation of the notions of singular surfaces and surface operators used in gauge theory approach to knots [129] to TGD framework. It leads to the identification of slicing by three-surfaces as that induced by the inverse images of  $r = \text{constant}$  surfaces of  $CP_2$ , where  $r$  is  $U(2)$  invariant radial coordinate of  $CP_2$  playing the role of Higgs field vacuum expectation value in gauge theories.  $r = \infty$  surfaces correspond to geodesic spheres and define analogs of fractionally magnetically charged Dirac strings identifiable as preferred string world sheets. The union of these

sheets labelled by subgroups  $U(2) \subset SU(3)$  would define the slicing of space-time surface by string world sheets. The choice of  $U(2)$  relates directly to the choice of quantization axes for color quantum numbers characterizing  $CD$  and would have the choice of braids and string world sheets as a space-time correlate.

### 6.2.1 General remarks

Some remarks are in order before considering a detailed proposal for how to achieve the above described goal.

1. Penrose ends up with the notion of twistor by expressing Pauli-Lubanski vector and four-momentum vector of massless particle in terms of two spinors and their conjugates. Twistor  $Z^A$  consists of a pair  $(\tilde{\mu}^{\dot{a}}, \lambda_a)$  of spinors in representations  $(1/2, 0)$  and  $(0, 1/2)$  of Lorentz group. The antisymmetric tensor  $\epsilon^{ab}$  defines Kähler form in the space of 2-spinors and  $i\epsilon^{ab}$  defines Kähler metric which reduces to the  $(1, 1, -1, -1)$  diagonal form in real representation. The hermitian matrix defined by the tensor product of  $\lambda_{\dot{a}}$  and its conjugate characterizes the four-momentum of massless particle in the representation  $p^a \sigma_a$  using Pauli's sigma matrices. In Penrose's original approach  $\tilde{\mu}^{\dot{a}}$  characterizes the angular momentum of the particle: spin is given by  $s = Z^\alpha \bar{Z}_\alpha$ . The representation is not unique since  $\lambda_a$  is fixed only apart from a phase factor, which might be called "twist". The phases of two spinors are completely correlated.
2. This interpretation is not equivalent with that discussed mostly in [70] and [58]. Scattering amplitudes are not functions of momenta and polarizations but of a spinor, its conjugate defining light-like momentum, and helicity having values  $\pm 1$ . In Minkowski space with Lorentz signature the momentum as kinematic variable is replaced with spinor and its conjugate and spinor is defined apart from a phase factor. In the latter article the signature of Minkowski space is taken to be  $(2,2)$  so that the situation changes dramatically. Light rays assignable to twistors are 2-D light-like light-like surfaces and the spinor associated with light-like point decomposes to two independent real spinors replacing light-like momentum as a kinematic variable. The phase factor as an additional kinematic variable is replaced by a real scaling factors  $t$  and  $1/t$  for the two spinors. Fourier transform with respect to the real spinor or its conjugate is possible and gives scattering amplitude as a function of a twistor variable. In Lorentz signature the twistor Fourier transform in this sense is not possible so one cannot replace spinor and its conjugate by a twistor.
3. The space of 2-spinors has a Hermitian metric with real signature  $(2,2)$  since the Lorentz invariant Hermitian metric  $i\epsilon^{ab}$  has diagonal form  $(1, -1)$  in complex coordinates. Twistors consist of two spinors and the 8-D twistor space -call it  $T$ - has Kähler metric with complex metric signature  $(2,2)$  and real metric signature  $(4,4)$ , and could correspond to the target space of  $N = 4$  super-conformally symmetric theory and might define the target space of  $N = 4$  super-conformally symmetric string theory with strings identified as  $T$  lifts of the string world sheets having braid strands at their ends. The minimum requirement is that one can assign to each point of string world sheet a twistor.

### 6.2.2 What twistor Fourier transform could mean in TGD framework?

For the existence of twistor Fourier transform the reality and independence of the spinors  $\lambda$  and  $\tilde{\mu}$  is essential and are satisfied for  $(2,2)$  signature. In Lorentzian signature these conditions fail. The question is whether TGD framework could allow to construct twistor amplitudes.

1. From Witten's paper [70] one learns that twistor-space scattering amplitudes obtained as Fourier-transforms with respect to the real conjugate spinor in Minkowski space with  $(2,2)$  signature correspond to incoming and outgoing states for which the wave functions are not plane waves but are located to 2-D sub-spaces of Minkowski space defined by the equation

$$\tilde{\mu}_{\dot{a}} + x_{\dot{a}a} \lambda^a = 0 . \tag{6.2.1}$$

In a more familiar notation one has  $x^\mu \sigma_\mu \lambda = \tilde{\mu}$ . This condition follows directly from twistor Fourier transform.

2. In Lorentz signature similar equation is obtained from Penrose transform relating the solutions of free wave equations for various spins to the elements of sheaf cohomology assignable to projective twistor space (see the appendix of [70]). In this case the solution is unique apart from the shift  $x^\mu \rightarrow x^\mu + k p^\mu$ , where  $p^\mu$  is the light-like momentum associated with  $\lambda$  identified as a solution of massless Dirac equation. Hence twistor corresponds to a wave function localized at light ray.
3. If the equivalent of twistor Fourier transform exists in some sense in Lorentz signature, the geometric interpretation would be as a decomposition of massless plane wave to a superposition of wave functions localized to light-like rays in the direction of momentum. Uncertainty Principle does not deny the existence of this kind of wave functions. These highly singular wave functions would be labeled by momentum and one point at the light ray or equivalently (apart from the phase factor) by  $\lambda_a$  and  $\tilde{\mu}^{\dot{a}}$  defining the twistor. The wave functions would be constant at the rays and thus wave functions in a 3-dimensional sub-manifold of  $M^4$  labeling the light rays. This sub-manifold could be taken light-cone boundary as is easy to see so that the overlap of wave function with different direction of 3-momentum would take place only at the tip of the light-cone. Fields in twistor space would be fields in the space of light-rays characterized by a wave vector.
4. Light-likeness fixes  $x$  and  $\mu$  for given  $\lambda$  uniquely if one assumes that  $\mu$  is in the plane  $M^2$  defined by  $\lambda$  and thus light-like dual of the momentum vector satisfying  $x \cdot p = -1$ . Clearly, momentum conservation gives to conservation of  $x$  and one can interpret  $x$  as a geometric representation of momentum analogous to the representation momentum increment in X-ray scattering at "heavenly sphere". Quantum classical correspondence encourages to consider at least half seriously this kind of coding of momentum to a position of braid point at light-cone boundary. Since twistor Fourier transform does not work, one must invent some other manner to introduce these wave functions. Here the lifting of space-time surface to twistor space suggests itself.
5. The basic challenge is to assign to space-time surface or to each point of space-time surface a momentum like quantity. If this is achieved one can assign to the point also  $\lambda$  and  $\tilde{\mu}$ .
  - (a) One can assign to space-time sheet a conserved four-momentum identifiable by quantum classical correspondence as its quantal variant. This option would fix  $\lambda$  to be same at each point of the space-time surface about from a possible phase factor depending on space-time point. The resulting surfaces in twistor space would be rather boring.
  - (b) Hamilton-Jacobi coordinates [8] suggest the possibility of defining  $\lambda$  as a quantity depending on space-time point. The two light-like  $M^4$  coordinates  $u, v$  define preferred coordinates for the string world sheets  $Y^2$  appearing in the slicing of  $X^4(X_i^3)$ , and the light-like tangent vectors  $U$  and  $V$  of these curves define a pair  $(\lambda, \tilde{\mu})$  of spinors defining twistor  $Z$ . The vector  $V$  defining the tangent vector of the braid strand is analogous to four-momentum. Twistor equation defines a point  $m$  of  $M^4$  apart from a shift along the light ray defined by  $V$  and the consistency implying that the construction is not mere triviality is that  $m$  corresponds to the projection of space-time point to  $M^4$  in coordinates having origin at the tip of  $CD$ . One could distinguish between negative and positive energy extremals according to whether the tip is upper or lower one. One can assign to  $\lambda$  and  $\tilde{\mu}$  also two polarization vectors by a standard procedure [70] to be discussed later having identification as tangent vectors of coordinate curves of transversal Hamilton-Jacobi coordinates. This would give additional consistency conditions.
6. In this manner space-time surface representable as a graph of a map from  $M^4$  to  $CP_2$  would be mapped to a 4-surface in twistor space apart from the non-uniqueness related to the phase factor of  $\lambda$ . Also various field quantities, in particular induced spinor fields at space-time surface, could be lifted to fields restricted to a 4-dimensional surface of the twistor space so that the classical dynamics in twistor space would be induced from that in imbedding space.

7. This mapping would induce also a mapping of the string world sheets  $Y^2 \subset P_{M^4}(X^4(X_l^3))$  to twistor space.  $V$  would determine  $\lambda$  and  $U$  -taking the role of light-cone point  $m$  - would determine  $\tilde{\mu}$  in terms of the twistor equation. 2-surfaces in twistor space would be defined as images of the 2-D string world sheets if the integrability of the distribution for  $(U, V)$  pairs implies the integrability of  $(\lambda, \tilde{\mu})$  pairs.
8. Twistor scattering amplitude would describe the scattering of a set of incoming light-rays to a set of outgoing light-rays so that the non-locality of interactions is obvious. Discretization of partonic 2-surfaces to discrete point sets would indeed suggest wave functions localized at light-like rays going through the braid points at the ends of  $X_l^3$  as a proper basis so that problems with Uncertainty Principle would be overcome. The incoming and outgoing twistor braid points would be determined by  $M^4$  projections of the braid points at the ends of  $X_l^3$ . By quantum classical correspondence the conservation law of classical four-momentum would apply to the total classical four-momentum although for individual braid strands classical four-momenta would not be conserved. The interpretation would be in terms of interactions. The orbits of stringy curves connecting braid points would give string like objects in  $T$  required by  $N = 4$  super-conformal field theory.

### 6.2.3 Could one define the phase factor of the twistor uniquely?

The proposed construction says nothing about the phase of the spinors assigned to the tangent vectors  $V$  and  $U$ . One can consider two possible interpretations.

1. Since the tangent vectors  $U$  and  $V$  are determined only apart from overall scaling the phase indeterminacy could be interpreted by saying that projective twistors are in question.
2. If one can fix the absolute magnitude of  $U$  and  $V$  -say by fixing the scale of Hamilton Jacobi coordinates by some physical argument- then the map is to twistors and one should be able to fix the phase.

It turns out that the twistor formulation of field equations taking into account also  $CP_2$  degrees of freedom to be discussed later favors the first option. The reason why the following argument deserves a consideration is that it would force braid picture and thus replacement of space-time sheets by string world sheets in twistor formulation.

1. The phase of the spinor  $\lambda_a$  associated with the light-like four-momentum and light-like point of  $\delta M_{\pm}^4$  should represent genuine physical information giving the twistor its "twist". Algebraically twist corresponds to a  $U(1)$  rotation along closed orbit with a physical significance, possibly a gauge rotation. Since the induced  $CP_2$  Kähler form plays a central role in the construction of quantum TGD, the "twist" could correspond to the non-integrable phase factor defined as the exponent of Kähler magnetic flux (to achieve symplectic invariance and thus zero mode property) through an area bounded by some closed curve assignable with the point of braid strand at  $X^2$ . Both  $CP_2$  and  $\delta M_{\pm}^4$  Kähler forms define fluxes of this kind so that two kinds of phase factors are available but  $CP_2$  Kähler flux looks more natural.
2. The symplectic triangulation defined by  $CP_2$  Kähler form allows to identify the closed curve as the triangle defined by the nearest three vertices to which the braid point is connected by edges. Since each point of  $X^4(X_l^3)$  belongs to a unique partonic 2-surface  $X^2$ , this identification can be made for the braid strands contained by any light-like 3-surface  $Y_l^3$  parallel to  $X_l^3$  so that phase factors can be assigned to all points of string world sheets having braid strands as their ends. One cannot assign phases to all points of  $X^4(X_l^3)$ . The exponent of this phase factor is proportional to the coupling of Kähler gauge potential to fermion and distinguishes between quarks and leptons.
3. The phase factor associated with the light-like four-momentum defined by  $V$  could be identified as the non-integrable phase factor defined by -say-  $CP_2$  Kähler form. The basic condition would fix the phase of  $\tilde{\mu}$ . The phases could be permuted but the assignment of  $\delta M_{\pm}^4$  Kähler form with  $m$  is natural. Note that the phases of the twistors are symplectic invariants and not subject to quantum fluctuations in the sense that they would contribute to the line element of the metric of the world of classical worlds. This conforms with the interpretation as kinematical variables.

4. Rather remarkably, this construction can assign the non-integrable phase factor only to the points of the number theoretic braid for each  $Y_l^3$  parallel to  $X_l^3$  so that one obtains only a union of string world sheets in  $T$  rather than lifting of the entire  $X^4(X_l^3)$  to  $T^2$ . The phases of the twistors would code for non-local information about space-time surface coded by the tangent space of  $X^4(X_l^3)$  at the points of stringy curves.

### 6.3 Could one regard space-time surfaces as surfaces in twistor space?

Twistors are used to construct solutions of free wave equations with given spin and self-dual solutions of both YM theories and Einstein's equations [61]. Twistor analyticity plays a key role in the construction of construction of solutions of free field equations. In General Relativity the problem of the twistor approach is that twistor space does not make sense for a general space-time metric [61]. In TGD framework this problem disappears and one can ask how twistors could possibly help to construct preferred extremals. In particular, one can ask whether it might be possible to interpret space-time surfaces as surfaces - not necessarily four-dimensional - in twistor space.

#### 6.3.1 How $M^4 \times CP_2$ emerges in twistor context?

The finding that  $CP_2$  emerges naturally in twistor space considerations is rather encouraging.

1. Twistor space allows two kinds of 2-planes in complexified  $M^4$  known as  $\alpha$ - and  $\beta$ -planes and assigned to twistor and its dual [61]. This reflects the fundamental duality of the twistor geometry stating that the points  $Z$  of  $PT$  label also complex planes ( $CP_2$ ) of  $PT$  via the condition

$$Z_a W^a = 0. \quad (6.3.1)$$

To the twistor  $Z$  one can assign via twistor equation complex  $\alpha$ -plane, which contains only null vectors and correspond to the plane defined by the twistors intersecting at  $Z$ .

For null twistors (5-D sub-space  $N$  of  $PT$ ) satisfying  $Z^a \tilde{Z}_a = 0$  and identifiable as the space of light-like geodesics of  $M^4$   $\alpha$ -plane contains single real light-ray.  $\beta$ -planes in turn correspond to dual twistors which define 2-D null plane  $CP_2$  in twistor space via the equation  $Z_a W^a = 0$  and containing the point  $W = \tilde{Z}$ . Since all lines  $CP_1$  of  $CP_2$  intersect, also they parameterize a 2-D null plane of complexified  $M^4$ . The  $\beta$ -planes defined by the duals of null twistors  $Z$  contain single real light-like geodesic and intersection of two  $CP_2$ :s defined by two points of line of  $N$  define  $CP_1$  coding for a point of  $M^4$ .

2. The natural appearance of  $CP_2$  in twistor context suggests a concrete conjecture concerning the solutions of field equations. Light rays of  $M^4$  are in 1-1 correspondence with the 5-D space  $N \subset P$  of null twistors. Compactified  $M^4$  corresponds to the real projective space  $PN$ . The dual of the null twistor  $Z$  defines 2-plane  $CP_2$  of  $PT$ .
3. This suggests the interpretation of the counterpart of  $M^4 \times CP_2$  as a bundle like structure with total space consisting of complex 2-planes  $CP_2$  determined by the points of  $N$ . Fiber would be  $CP_2$  and base space 5-D space of light-rays of  $M^4$ . The fact that  $N$  does not allow holomorphic structure suggests that one should extend the construction to  $PT$  and restrict it to  $N$ . The twistor counterparts of space-time surfaces in  $T$  would be holomorphic surfaces of  $PT \times CP_2$  or possibly of  $PT_{\pm}$  (twistor analogs of lower and upper complex plane and assignable to positive and negative frequency parts of classical and quantum fields) restricted to  $N \times CP_2$ .

### 6.3.2 How to identify twistorial surfaces in $PT \times CP_2$ and how to map them to $M^4 \times CP_2$ ?

The question is whether and how one could construct the correspondence between the points of  $M^4$  and  $CP_2$  defining space-time surface from a holomorphic correspondence between points of  $PT$  and  $CP_2$  restricted to  $N$ .

1. The basic constraints are that space-time surfaces with varying values for dimensions of  $M^4$  and  $CP_2$  projections are possible and that these surfaces should result by a restriction from  $PT \times CP_2$  to  $N \times CP_2$  followed by a map from  $N$  to  $M^4$  either by selecting some points from the light ray or by identifying entire light rays or their portions as sub-manifolds of  $X^4$ .
2. Quantum classical correspondence would suggest that surfaces holomorphic only in  $PT_+$  or  $PT_-$  should be used so that one could say that positive and negative energy states have space-time correlates. This would mean an analogy with the construction of positive and negative energy solutions of free massless fields. The corresponding space-time surfaces would emerge from the lower and upper light-like boundaries of the causal diamond  $CD$ .
3. A rather general approach is based on an assignment of a sub-manifold of  $CP_2$  to each light ray in  $PT_{\pm}$  in holomorphic manner that is by  $n$  equations of form

$$F_i(\xi^1, \xi^2, Z) = 0, \quad i = 1, \dots, n \leq 2. \quad (6.3.2)$$

The dimension of this kind of surface in  $PT \times CP_2$  is  $D = 10 - 2n$  and equals to 6, 8 or 10 so that a connection or at least analogy with M-theory and branes is suggestive. For  $n = 0$  entire  $CP_2$  is assigned with the point  $Z$  ( $CP_2$  type vacuum extremals with constant  $M^4$  coordinates): this is obviously a trivial case. For  $n = 1$  8-D manifold is obtained. In the case that  $Z$  is expressible as a function of  $CP_2$  coordinates, one could obtain  $CP_2$  type vacuum extremals or their deformations. Cosmic strings could be obtained in the case that there is no  $Z$  dependence. For  $n = 4$  discrete set of points of  $CP_2$  are assigned with  $Z$  and this would correspond to field theory limit, in particular massless extremals. If the dimension of  $CP_2$  projection for fixed  $Z$  is  $n$ , one must construct  $4 - n$ -dimensional subset of  $M^4$  for given point of  $CP_2$ .

4. If one selects a discrete subset of points from each light ray, one must consider a  $4 - n$ -dimensional subset of light rays. The selection of points of  $M^4$  must be carried out in a smooth manner in this set. The light rays of  $M^4$  with given direction can be parameterized by the points of light-cone boundary having a possible interpretation as a surface from which the light rays emerge (boundary of  $CD$ ).
5. One could also select entire light rays or portions of them. In this case a  $4 - n - 1$ -dimensional subset of light rays must be selected. This option could be relevant for the simplest massless extremals representing propagation along light-like geodesics (in a more general case the first option must be considered). The selection of the subset of light rays could correspond to a choice of  $4 - n - 1$ -dimensional sub-manifold of light-cone boundary identifiable as part of the boundary of  $CD$  in this case. In this case one could worry about the intersections of selected light rays. Generically the intersections occur in a discrete set of points of  $H$  so that this problem does not seem to be acute. The lines of generalized Feynman diagrams interpreted as space-time surfaces meet at 3-D vertex surfaces and in this case one must pose the condition that  $CP_2$  projections at the 3-D vertices are identical.
6. The use of light rays as the basic building bricks in the construction of space-time surfaces would be the space-time counterpart for the idea that light ray momentum eigen states are more fundamental than momentum eigen states.

$M^8 - H$  duality is Kähler isometry in the sense that both induced metric and induced Kähler form are identical in  $M^8$  and  $M^4 \times CP_2$  representations of the space-time surface. In the recent case this would mean that the metric induced to the space-time surface by the selection of the subset of light-rays in  $N$  and subsets of points at them has the same property. This might be true trivially in the recent case.

### 6.3.3 How to code the basic parameters of preferred extremals in terms of twistors?

One can proceed by trying to code what is known about preferred extremals to the twistor language.

1. A very large class of preferred extremals assigns to a given point of  $X^4$  two light-like vectors  $U$  and  $V$  of  $M^4$  and two polarization vectors defining the tangent vectors of the coordinate lines of Hamilton-Jacobi coordinates of  $M^4$  [8]. As already noticed, given null-twistor defines via  $\lambda$  and  $\tilde{\mu}$  two light-like directions  $V$  and  $U$  and twistor equation defines  $M^4$  coordinate  $m$  apart from a shift in the direction of  $V$ . The polarization vectors  $\epsilon_i$  in turn can be defined in terms of  $U$  and  $V$ .  $\lambda = \mu$  corresponds to a degenerate case in which  $U$  and  $V$  are conjugate light-like vectors in plane  $M^2$  and polarization vector is also light-like. This could correspond to the situation for  $CP_2$  type vacuum extremals. For the simplest massless extremals light-like vector  $U$  is constant and the solution depends on  $U$  and transverse polarization  $\epsilon$  vector only. More generally, massless extremals depend only on two  $M^4$  coordinates defined by  $U$  coordinate and the coordinate varying in the direction of local polarization vector  $\epsilon$ .
2. Integrable distribution of these light-like vectors and polarization vectors required. This means that these vectors are gradients of corresponding Hamilton-Jacobi coordinate variables. This poses conditions on the selection of the subset of light rays and the selection of  $M^4$  points at them. Hyper-quaternionic and co-hyper-quaternionic surfaces of  $M^8$  are also defined by fixing an integrable distribution of 4-D tangent planes, which are parameterized by points of  $CP_2$  provided one can assign to the tangent plane  $M^2(x)$  either as a sub-space or via the assignment of light-like tangent vector of  $x$ .
3. Positive (negative) helicity polarization vector [70] can be constructed by taking besides  $\lambda$  arbitrary spinor  $\mu_a$  and defining

$$\epsilon_{a\dot{a}} = \frac{\lambda_a \tilde{\mu}^{\dot{a}}}{\left[ \begin{smallmatrix} \tilde{\lambda} \\ \tilde{\mu} \end{smallmatrix} \right]}, \quad \left[ \begin{smallmatrix} \tilde{\lambda} \\ \tilde{\mu} \end{smallmatrix} \right] \equiv \epsilon_{\dot{a}b} \lambda^{\dot{a}} \mu^b \quad (6.3.3)$$

for negative helicity and

$$\epsilon_{a\dot{a}} = \frac{\mu_a \tilde{\lambda}^{\dot{a}}}{\langle \lambda, \mu \rangle}, \quad \langle \lambda, \mu \rangle \equiv \epsilon_{ab} \mu^a \lambda^b \quad (6.3.4)$$

for positive helicity. Real polarization vectors correspond to sums and differences of these vectors. In the recent case a natural identification of  $\mu$  would be as the second light-like vector defining point of  $m$ . One should select one light-like vector and one real polarization vector at each point and find the corresponding Hamilton-Jacobi coordinates. These vectors could also code for directions of tangents of coordinate curves in transversal degrees of freedom.

The proposed construction seems to be consistent with the proposed lifting of preferred extremals representable as a graph of some map  $M^4 \rightarrow CP_2$  to surfaces in twistor space. What was done in one variant of the construction was to assign to the light-like tangent vectors  $U$  and  $V$  spinors  $\tilde{\mu}$  and  $\lambda$  assuming that twistor equation gives the  $M^4$  projection  $m$  of the point of  $X^4(X_l^3)$ . This is the inverse of the process carried out in the recent construction and would give  $CP_2$  coordinates as functions of the twistor variable in a 4-D subset of  $N$  determined by the lifting of the space-time surface. The facts that tangent vectors  $U$  and  $V$  are determined only apart from overall scaling factor and the fact that twistor is determined up to a phase, imply that projective twistor space  $PT$  is in question. This excludes the interpretation of the phase of the twistor as a local Kähler magnetic flux. The next steps would be extension to entire  $N$  and a further continuation to holomorphic field in  $PT$  or  $PT_{\pm}$ .

To summarize, although these arguments are far from final or convincing and are bound to reflect my own rather meager understanding of twistors, they encourage to think that twistors are indeed

natural approach in TGD framework. If the recent picture is correct, they code only for a distribution of tangent vectors of  $M^4$  projection and one must select both a subset of light rays and a set of  $M^4$  points from each light-ray in order to construct the space-time surface. What remains open is how to solve the integrability conditions and show that solutions of field equations are in question. The possibility to characterize preferred extremal property in terms of holomorphy and integrability conditions would mean analogy with both free field equations in  $M^4$  and minimal surfaces. For known extremals holomorphy in fact guarantees the extremal property.

### 6.3.4 Hyper-quaternionic and co-hyper-quaternionic surfaces and twistor duality

In TGD framework space-time surface decomposes into two kinds of regions corresponding to hyper-quaternionic and co-hyper-quaternionic regions of the space-time surface in  $M^8$  (hyper-quaternionic regions were considered in preceding arguments). The regions of space-time with  $M^4$  (Euclidian) signature of metric are identified tentatively as the counterparts of hyper-quaternionic (co-hyper-quaternionic) space-time regions. Pieces  $CP_2$  type vacuum extremals representing generalized Feynman diagrams and having light-like random curve as  $M^4$  projection represent the basic example here. Also these space-time regions should have any twistorial counterpart and one can indeed assign to  $M^4$  projection of  $CP_2$  type vacuum extremal a spinor  $\lambda$  as its tangent vector and spinor  $\mu$  via twistor equation once  $M^4$  projection is known.

The first guess would the correspondence hyper-quaternionic  $\leftrightarrow \alpha$  and co-hyper-quaternionic  $\leftrightarrow \beta$ . Previous arguments in turn suggest that hyper-quaternionic space-time surfaces are mapped to surfaces for which two null twistors are assigned with given point of  $M^4$  whereas co-hyper-quaternionic space-time surfaces are mapped to the surfaces for which only single twistor corresponds to a given  $M^4$  point.

## 6.4 Could one lift Feynman diagrams to twistor space?

In [58] the possibility of twistor diagrammatics is considered and it is interesting to look this from TGD perspective where standard beliefs about what quantum theory is must be given up.

1. The arguments start from ordinary momentum space perturbation theory. The amplitudes for the scattering of massless particles are expressed in terms of twistors after which one performs twistor Fourier transform obtaining amazingly simple expressions for the amplitudes. For instance, the 4-point one loop amplitude in N=4 SYM is extremely simple in twistor space having only values '1' and '0' in twistor space and vanishes for generic momenta.
2. Also IR divergences are absent in twistor transform of the scattering amplitude but are generated by the transform to the momentum space. Since plane waves are replaced with light rays, it is not surprising that the IR divergences coming from transversal degrees of freedom are absent. Interestingly, TGD description of massless particles as wormhole throats connecting two massless extremals extends ideal light-ray to massless extremal having finite transversal thickness so that IR cutoff emerges purely dynamically.
3. This approach fails at the level of loops unless one just uses the already calculated loops. The challenge would be a generalization of the ordinary perturbation theory so that loops could be calculated in twistor space formulation.

The vision about lifting TGD from 8-D  $M^4 \times CP_2$  to 8-D twistor space suggests that it should be possible to lift also ordinary  $M^4$  propagators to propagators to twistor space. The first problem is that the momenta of massive virtual particles do not allow any obvious unique representation in terms of twistors. Second problem relates to massive incoming momenta necessarily encountered in stringy picture even if one forgets massivation of light states by p-adic thermodynamics.

### 6.4.1 The treatment of massive case in terms of twistors

Massive incoming momenta and loop momenta are problematic from the point of view of twistor description. TGD suggests two alternative approaches to the problem.

1. One can express arbitrary four-momentum as a sum of two light-like momenta. What makes this representation inelegant is its non-uniqueness. For time-like momentum the two light-like momenta in opposite directions can have any direction so that sphere  $SO(3)/SO(2) = S^2$  labels the degeneracy and for space-like case the degeneracy corresponds to the hyperboloid  $SL(2, R)/SO(2)$  of  $M^3$ . This degeneracy has no obvious physical meaning unless virtual momentum corresponds physically to a pair of light-like momenta which can have also opposite signs of energy. This would however mean effectively introduction of two light-like loop momenta instead of one and therefore doubling of the loop. A possible interpretation would be as an introduction of an additional braid strand.
2. Also massive particles should be treated in practical approach. The existence of preferred  $M^2 \subset M^4$  forced both by the number theoretic compactification and by the hierarchy of Planck constants would allow to express massive four-momenta uniquely as sums of two light-like momenta, with second momentum in the plane  $M^2$ . This would bring in two twistors with second twistor corresponding to a spin  $\pm 1/2$  spinor depending on the direction of the momentum. Whether it is possible to interpret the momentum in terms of a genuine composition to a state of two massless particles with second particle moving in the preferred plane  $M^2$  remains an open question. This would allow also to treat massive particles by assuming that loop momenta are on shell momenta. For both stringy excitations and particles receiving their mass by p-adic thermodynamics this might be an appropriate approach.
3. From the twistor point of view a more satisfactory description would be the identification of the massive states as bound states of massless fermions associated with braid strands. If braid strands carry light-like momenta which are not parallel, one can obtain massive off mass shell momenta. For conformal excitations it would be natural to assign the action of the Kac-Moody generators and corresponding Virasoro generators creating the state to separate braid strands. In QCD description of hadrons in terms of massless partons this kind of description is of course already applied.
4. A further possibility making sense in massless theories is the restriction of the momenta rotating in loops to be light-like. This idea turned out to be short lived but led to a first quantitatively precise proposal for how QFT like Feynman diagrammatics could emerge from TGD framework.

### 6.4.2 Purely twistorial formulation of Feynman graphs

In the following twistorial formulation of Feynman diagrammatics in TGD framework is considered. If only light-like loop momenta are allowed one can lift the 3-dimensional integral  $d^3k/2E$  appearing in the propagators to an integral over twistor variables, which means that complete twistorialization of Feynman diagrams is possible if the loop integrals involve only light-like momenta. This formulation generalizes to the case when loop momenta are massive but requires the introduction of an auxiliary twistor corresponding to momenta restricted to the preferred plane  $M^2 \subset M^4$  predicted by the number theoretical compactification and hierarchy of Planck constants.

1. It is convenient to introduce double cylindrical coordinates  $\lambda_i = \rho_i \exp(i(\phi \pm \psi))$  in twistor space. The integration over overall phase  $\phi$  gives only a  $2\pi$  factor since ordinary Feynman amplitude has no dependence on this variable so that the non-redundant variables are  $\rho_1, \rho_2, \psi$ .
2. The condition is that the integral measure  $d^4uX$  of the spinor space with a suitable weight function  $X$  is equivalent with the measure  $d^3k/2E$  in cylindrical coordinates. This gives

$$d^4uX = d\phi \frac{d^3k}{2E} \tag{6.4.1}$$

when the integrand does not depend on  $\phi$ .

3. In cylindrical coordinates this gives

$$2\rho_1\rho_2d\rho_1d\rho_2d\psi X\delta(U - k_z)\delta(V - k_x)\delta(W - k_y) = 1 , \quad (6.4.2)$$

$$U = \frac{\rho_1^2 - \rho_2^2}{2} , \quad V = \frac{\rho_1\rho_2\cos(\psi)}{2} , \quad W = \frac{\rho_1\rho_2\sin(\psi)}{2} .$$

Here the functions  $U$ ,  $V$ , and  $W$  are obtained from the representations of  $k_z, k_x, k_y$  in terms of spinor and its conjugate.

4. Taking  $U, V, W$  as integration variables one has

$$2\rho_1\rho_2 \frac{\partial(\rho_1, \rho_2, \psi)}{\partial(U, V, W)} X = 1 . \quad (6.4.3)$$

5. The calculation of the Jacobian gives  $X = (\rho_1^2 + \rho_2^2)/4 = E/2$  so that one has the equivalence

$$\frac{1}{4\pi} d^4u \leftrightarrow \frac{d^3k}{2E} . \quad (6.4.4)$$

6. Similar lifting can be carried out for the integration measure defined at light-cone boundary in  $M^4$ . If the integrations in generalized Feynman diagrams are over amplitudes depending on light-like momenta and coordinates of the light-like boundaries of CDs in given length scales coming as  $T_n = 2^n T_0$  or  $T_p = p T_0$  the integrals of momentum space and light-one can be transformed to integrals over twistor space in given length scale. Twistorialization requirement obviously gives a justification for the basic assumption of zero ontology that all transition amplitudes can be formulated in terms of data at the intersections of light-like 3-surfaces with the boundaries of CDs.

7. It should be emphasized that there is no need to keep the phase angle  $\phi$  as a redundant variable is the interpretation as Kähler magnetic flux is accepted. In fact, Kähler magnetic fluxes are expected to appear as zero modes define external parameters in the amplitudes.

One can carry out similar calculation for  $d^4k$  assuming the representation of  $p$  as a sum of two light-like momenta  $k_1$  and  $k_2$  with another one lying in the preferred plane  $M^2$ . The representation is unique and given by

$$\begin{aligned} p &= k_1 + k , \\ k_1 &= (|p_T|\cosh(\eta), |p_T|\sinh(\eta), p_T) , \quad k = |k|(1, \epsilon, 0, 0) , \quad \epsilon = \pm 1 , \\ \exp(\eta) &= \left[ \frac{|p_T|}{p_0 - \epsilon p_z} \right]^\epsilon , \\ |k| &= p_0 - |p_T|\cosh(\eta) . \end{aligned} \quad (6.4.5)$$

Both signs of  $\epsilon = k_2^0/k_2^z$  are needed and correspond to spin up and spin down spinor  $\mu$  with an indefinite phase whereas  $k_1$  corresponds to  $\lambda$  as in previous example. The 6-dimensional volume element in the space of the spinors is

$$dV = \rho_1\rho_2\rho_3d\rho_1d\rho_2d\rho_3d\Psi d\Phi_1d\Phi_2 . \quad (6.4.6)$$

$\Phi_1$  and  $\Phi_2$  represent the phases of the spinors  $\lambda$  and  $\mu$  and are redundant variables in the momentum integration. The expression for  $d^4k$  in terms of spinor variables reads as

$$d^4k = \frac{1}{16\pi^2} [\rho_1^2(1 - \epsilon) + \rho_2^2(1 + \epsilon)] \times dV . \quad (6.4.7)$$

Here the redundant integral over  $d\Phi_i$  is included. The integration measure does not have so nice structure as in the case of light-cone. Whether one might combine the spinors to single twistor is an interesting question: conformal invariance does not encourage this. Second option is to combine spinors and their complex conjugates to twistors.

### 6.4.3 What could be the propagator in twistor space?

The mere lifting of Feynman diagrams is probably not enough since the propagator in momentum space corresponds to momentum eigen states whereas in TGD framework a more natural notion is the propagator in the space of light-rays, which correspond to states totally localized in the direction of light-like momentum and thus could be seen as superpositions of momentum eigen states with virtual momentum components in transversal directions so that all momenta would be actually space-like in standard sense. Topological light rays (massless extremals) are the direct space-time correlate for this picture and also braid picture and direct physical intuition about what particles are support the idea about ray propagator.

What could propagation mean assuming that one allows only the propagation of light-like momenta in loops in order to achieve an elegant expression of loop diagrams in terms of spinors  $\lambda$ ?

1. The points of  $M^4$  are effectively replaced with parallel light-rays for given four-momentum and so that it does not make sense to speak about propagation in the direction of light-like four-momentum. Rather, the propagation would be in the space defined by transversal degrees of freedom which can be parameterized by the points of light-cone.  $x$  is fixed uniquely if one assumes it to lie in the plane defined by  $p$  as dual of  $p$  and conservation  $p$  gives rise to conservation of  $x$  with the already suggests interpretation as a geometric representation of momentum. One could construct oscillator operators basis creating light-ray states. The task is to guess an expression for the commutators  $[a^\dagger(p_1, m_1), a(p_2, m_2)]$ .

If one accepts the parametrization of the space of parallel light rays in terms of points  $m_1$  and  $m_2$  of light-cone, one can argue that only the complete overlap of light rays occurring for  $m_1 = m_2$  should contribute to the commutator. This would give

$$[a^\dagger(p_1, m_1), a(p_2, m_2)] = i2E_1 \times 2|m_1^0| \times \delta^3(p_1 - p_2) \delta^3(m_1 - m_2) .$$

This picture is consistent with the classical intuitive picture and also with the idea that signals propagate only along light-rays. In twistor space this would give commutation relations which are completely local and there would be no propagation. Note the complete symmetry between momentum space and x-space.

2. This would give for the counterpart of massless scalar propagator  $G_-$  allowing only the propagation of light-like virtual momenta the expression

$$G_-(p_1, p_2, m_1, m_2) = i\delta^3(p_1 - p_2) \delta^3(m_1 - m_2) 4E_1 \times |m_1^0| . \quad (6.4.8)$$

3. From this one can construct the counterpart of  $G_-$  in the twistor space. This would give

$$G_-(\lambda_1, \tilde{\mu}_1, \lambda_2, \tilde{\mu}_2) = i\delta(\lambda_1 \tilde{\lambda}_1 - \lambda_2 \tilde{\lambda}_2) \delta(\mu_1 \tilde{\mu}_1 - \mu_2 \tilde{\mu}_2) \times 4E |m_1^0| . \quad (6.4.9)$$

Note that  $m_1$  and therefore also  $m_1^0$  can be fixed uniquely from the basic twistor equation by using the constraint that  $m_1 \equiv x$  is light-like so that one has  $x_{ab} = \mu_a \tilde{\mu}_b$  if  $\mu_a \lambda^a = 1$  is satisfied.

4. One can express the momentum conserving delta function in terms of delta function  $\delta^4(\lambda_1 - \lambda_2)$  if one assumes that the irrelevant phase  $\exp(i\phi)$  of  $\lambda$  (as far as ordinary Feynman diagrams are considered) is conserved. The alternative is the the propagator does not depend at all on the phase difference  $\phi_1 - \phi_2$ . The proposed interpretation of the phase in terms of Kähler magnetic flux which can be interpreted as non-quantum fluctuating zero mode given for all points of braids as classical variable would suggest that it does not make sense to speak about correlation function for  $\phi$  in quantal sense. Going to the cylindrical coordinates  $(\rho_1, \rho_2, \psi, \phi)$  repeating the calculation of the Jacobian for the transformations  $\lambda \rightarrow (\rho_1, \rho_2, \psi, \phi) \rightarrow (k_1, k_2, k_3, \phi)$  and its variant for  $m$  coordinate, one obtains that for massless virtual states the propagator for the two options is apart from normalization constants equal to

$$G_-(\lambda_1, \tilde{\mu}_1, \lambda_2, \tilde{\mu}_2) = i \frac{\delta^4(\lambda_1 - \lambda_2) \delta^4(\tilde{\mu}_1 - \tilde{\mu}_2)}{\delta(\phi_1 - \phi_2) \delta(\phi_1 - \phi_2)}. \quad (6.4.10)$$

The division by  $\delta(\phi_1 - \phi_2)$  symbolizes the assumption of that  $\phi$  is not quantum fluctuating variable. Consider next the twistor counterpart of Feynman propagator

$$G_F(p_1, p_2) = i \delta^4(p_1 - p_2) \frac{1}{p_1^2 + i\epsilon}. \quad (6.4.11)$$

$p_1$  can be expressed as a sum of  $p_1 = p_{1a} + p_{1b}$  of light-like momenta expressible in terms of  $\lambda_{1a}$  and  $\lambda_{2a}$ . One can assign to  $p_{1a}$  and  $p_{1b}$  also light-cone points  $m_{1a}$  and  $m_{1b}$  as their duals and thus also  $\tilde{\mu}_{1\dot{a}}$  and  $\mu_{2\dot{a}}$ . Note that the momentum defined by  $m$  would be conserved and provide a geometric space-time representation for the real momentum.

It is however not clear whether twistor space counterpart of Feynman propagator makes sense. Should one assume that the two light-like momenta propagate independently so that the ray propagator would be proportional to the product of delta functions  $\delta(m_{1a} - m_{2a})\delta(m_{1b} - m_{2b})$  and  $\delta(p_{1a} - p_{2a})\delta(p_{1b} - p_{2b})$ ? These expressions could be translated to delta functions in twistor degrees of freedom just as above and the only difference would be the presence of  $1/p_1^2$  factor. One could perhaps say that effectively the off mass shell particle is a state of two massless particles with correlation between them characterized by the  $1/p_1^2$  factor.

#### 6.4.4 What to do with the perturbation theory?

The basic question is whether one should replace the perturbation theory based on momentum eigenstates with a perturbation theory relying on ray momentum eigen states completely localized in transverse degrees of freedom and allowing only light-like loop momenta or just restrict the loop momenta of ordinary Feynman diagrams to be light-like? Depending on answer to this question one ends up with different scenarios raising further questions.

1. Suppose that one uses ordinary momentum eigen states. The minimum option of the ordinary perturbation theory or of its stringy variant in TGD framework means the replacement of loop momenta with light-like momenta using  $G_-$  instead of  $G_F$ . In this approach spinors  $\lambda$  are enough and one can do without  $\mu$  and  $m$ . One could of course introduce them but  $m$  would be simply the light-like dual of  $p$  in the minimal scenario and completely constrained.
2. If one introduces ray eigen states, then also  $m$  and  $\tilde{\mu}$  emerge naturally. In TGD based perturbation theory  $m$  can be assumed to reside at light-cone boundary (at  $\delta CD$ ). Since braid points at  $X^2$  vary it seems that one must allow  $m$  to be dynamical so that  $\mu$  is also dynamical. If  $m$  and  $p$  are duals then braid points come representatives of momenta and  $m$  and  $\mu$  disappear again from the theory. This hypothesis is however ad hoc and un-necessary. For this option the naive generalization of Feynman diagrammatics is not enough. A possible guess for the generalization has been already proposed.

## 6.5 Could one generalize the notion of twistor to 8-D case?

The basic problem of the twistor approach is that one cannot represent massive momenta in terms of twistors in elegant manner. I have proposed a possible representation of massive states based on the existence of preferred plane of  $M^2$  in the basic definition of theory allowing to express four-momentum as some of two light-like momenta allowing twistor description. One could however ask whether some more elegant representation of massive  $M^4$  momenta might be possible by generalizing the notion of twistor -perhaps by starting from the number theoretic vision.

The basic idea is obvious: in quantum TGD massive states in  $M^4$  can be regarded as massless states in  $M^8$  and  $CP_2$  (recall  $M^8 - H$  duality). One can therefore map any massive  $M^4$  momentum to a light-like  $M^8$  momentum and hope that this association could be made in a unique manner. One should assign to a massless 8-momentum an 8-dimensional spinor of fixed chirality. The spinor assigned with the light-like four-momentum is not unique without additional conditions. The existence of covariantly constant right-handed neutrino in  $CP_2$  degrees generating the super-conformal symmetries could allow to eliminate the non-uniqueness. 8-dimensional twistor in  $M^8$  would be a pair of this kind of spinors fixing the momentum of massless particle and the point through which the corresponding light-geodesic goes through: the set of these points forms 8-D light-cone and one can assign to each point a spinor. In  $M^4 \times CP_2$  definitions makes also in the case of  $M^4 \times CP_2$  and twistor space would also now be a lifting of the space of light-like geodesics.

The possibility to interpret  $M^8$  as hyperoctonionic space suggests also the possibility to define the 8-D counterparts of sigma matrices to hyperoctonions to obtain a representation of sigma matrix algebra which is not a matrix representation. The mapping of gamma matrices to this representation allows to define a notion of hyper-quaternionicity in terms of the modified gamma matrices both in  $M^8$  and  $H$ .

### 6.5.1 Octo-twistors defined in terms of ordinary spinors

It is possible to define octo-twistors in terms of ordinary spinors of  $M^8$  or  $H$ .

1. The condition for the octo-twistor makes sense also for ordinary spinors and the explicit representation can be obtained by using triality. The ansatz is  $p^k = \bar{\Psi}\gamma^k\Psi$ . The condition  $p^k p_k = 0$  gives Dirac equation  $p^k \gamma_k \Psi = 0$  and its conjugate solved by  $\Psi = p^k \gamma_k \Psi_0$ . The expression of  $p^k$  in turn gives the normalization condition  $\bar{\Psi}_0 \gamma^k p_k \Psi_0 = 1/2$ .
2. Without further conditions almost any  $\Psi_0$  not annihilated by  $\gamma^k p_k$  is possible solution. One can map the spinor basis to hyper-octonion basis and assume  $\Psi_0 \rightarrow 1 = \sigma_0$ . This would give octo-twistor spinors as  $\Psi = p^k \gamma_k \Psi_0$  and its conjugate and there would be natural mapping to  $p^k \sigma_k$  so that  $\Psi$  and  $p^k$  would correspond to each other in 1-1 manner apart from the phase factor of  $\Psi$ .
3. A highly unique choice for  $\Psi_0$  is the covariantly constant (with respect to  $CP_2$  coordinates) right-handed neutrino spinor of  $M^4 \times CP_2$  since the Dirac operators of  $M^8$ ,  $H$ , and  $X^4$  reduce to free Dirac operator when acting on it in both  $M^8$  and  $H$  and giving also rise to super-conformal symmetry. The choice is unique apart from  $SO(3)$  rotation but the condition that spin eigen state is in question for the choice of quantization axis fixed by the choice of hyper-octonion units and also by the definition of the hierarchy of Planck constants fixes  $\Psi_0$  apart from the sign of the spin if reality is assumed. When  $p^k \gamma_k \Psi_0 = 0$  holds true for fixed  $\Psi_0$ , the ansatz fails so that the gauge choice is not global. There are two gauge patches corresponding to the two signs of the spin of  $\Psi_0$ . Right handed neutrino spinor reflects directly the homological magnetic monopole character of the Kähler form of  $CP_2$  so that the monopole property is in well defined sense transferred from  $CP_2$  to  $M^4$ . Note that this argument fails for quark spinors which do not allow any covariantly constant spinor.
4. For ordinary twistors the existence of the antisymmetric tensor  $\epsilon$  acting as Kähler form in the space of spinors is what allows to define second spinor and these spinors together form twistor. Ordinary twistors are pairs of spinors and also in the recent case one would have pairs of octo-spinors. The geometric interpretation would be as a light-like geodesic of  $M^8$  or tangent vector of light-like geodesic of  $M^4 \times CP_2$  and the two spinors would code for the momentum associated

with the ray and the transverse position of the ray expressible in terms of a light-like vector. This would double the dimension to  $D=16$  which happens to be the dimension of complexified octonions. The standard definition of twistors would suggest that one has 2 triplets of this kind so that Dirac equation and above argument would reduce the situation to 16-dimensional one. Twistors space would be  $C^8$  and 14-D projective twistor space would correspond to  $CP_7$ .

5. 2-D spinor and its conjugate as independent representations of Lorentz group define twistor. In an analogous manner  $M^8$  vector,  $M^8$ -spinor, and its conjugate define a triplet as independent representations. One can therefore ask whether a triplet of these independent representations could define octo-twistor so that two triplets would not be needed. Together they would form an entity with 24 components when the overall complex phase is eliminated and if no gauge choice fixing  $\Psi_0$  is made apart from the assumption  $\Psi_0$  has real components. If the overall phase is allowed, the number of components is 26 (the momentum constraint of course reduces the number of degrees of freedom to 8). It seems that the magic dimensions of string models are unavoidable! Perhaps it might be a possible to reduce 26-D string theory to 8-D theory by posing triality symmetry and additional gauge symmetry. The problem of this identification is that one does not geometric interpretation as a lifting of the space of light-like geodesics. One could of course define octo-twistors as a pair of triplets with the members of triplet obtained from each other via triality symmetry.

### 6.5.2 Could right handed neutrino spinor modes define octo-twistors?

There is no absolute need to interpret induced spinor fields as parts of octo-twistors. One can however ask whether this might make sense for the solutions of the modified Dirac equation  $D\Psi = 0$  representing right-handed neutrino and expressible as  $\Psi = D\Psi_0$ .

1. In the modified Dirac equation gamma matrices are replaced by the modified gamma matrices defined by the variation of Kähler action and the massless momentum  $p^k\sigma_k$  is replaced with the modified Dirac operator  $D$ . In plane wave basis the derivatives in  $D$  reduce to an algebraic multiplication operators in the case of right handed neutrino since right-handed neutrino has no gauge couplings.
2. A non-trivial consistency condition comes from the condition  $D^2\Psi_0 = 0$  giving sum of two terms.
  - (a) The first term is the analog of scalar d'Alembertian and given by

$$G^{\mu\nu} D_\mu D_\nu \Psi_0 \quad , \quad G^{\mu\nu} = h_{kl} T^{\mu k} T^{\nu l} \quad , \quad T^{\mu k} = \frac{\partial L_K}{\partial h_\alpha^k} \quad ,$$

and has quantum numbers of right handed neutrino as it should.

- (b) Second term is given by

$$T^{\mu k} D_\mu T^{\nu l} \Sigma_{kl} D_\nu \Psi_0 \quad ,$$

and in the general case contains charged components. Only electromagnetically neutral  $CP_2$  sigma matrices having right handed neutrino as eigen state are allowed if one wants twistor interpretation. This is not be true in the general case but might be implied by the preferred extremal property.

- (c) This property would allow to choose the induced spinor fields to be eigenstates of electromagnetic charge globally and would be therefore physically very attractive. After all, one of the basic interpretational problems has been the fact that classical  $W$  fields seems to induce mixing of quarks and leptons with different electro-magnetic charges. If this is the case one could assign to each point of the space-time surface octo-twistor like abstract entity as the triplet  $(\bar{\Psi}_0 D, D, D\Psi_0)$ . This would map space-time sheet to a 4-D surface (in real sense) in the space of 8-D (in complex sense) leptonic spinors.

### 6.5.3 Octo-twistors and modified Dirac equation

Classical number fields define one vision about quantum TGD. This vision about quantum TGD has evolved gradually and involves several speculative ideas.

1. The hard core of the vision is that space-time surfaces as preferred extremals of Kähler action can be identified as what I have called hyper-quaternionic surfaces of  $M^8$  or  $M^4 \times CP_2$ . This requires only the mapping of the modified gamma matrices to octonions or to a basis of subspace of complexified octonions. This means also the mapping of spinors to octonionic spinors. There is no need to assume that imbedding space-coordinates are octonionic.
2. I have considered also the idea that quantum TGD might emerge from the mere associativity.
  - (a) Consider Clifford algebra of WCW. Treat "vibrational" degrees of freedom in terms second quantized spinor fields and add center of mass degrees of freedom by replacing 8-D gamma matrices with their octonionic counterparts - which can be constructed as tensor products of octonions providing alternative representation for the basis of 7-D Euclidian gamma matrix algebra - and of 2-D sigma matrices. Spinor components correspond to tensor products of octonions with 2-spinors: different spin states for these spinors correspond to leptons and baryons.
  - (b) Construct a local Clifford algebra by considering Clifford algebra elements depending on point of  $M^8$  or  $H$ . The octonionic 8-D Clifford algebra and its local variant are non-associative. Associative sub-algebra of 8-D Clifford algebra is obtained by restricting the elements so any quaternionic 4-plane. Doing the same for the local algebra means restriction of the Clifford algebra valued functions to any 4-D hyper-quaternionic sub-manifold of  $M^8$  or  $H$  which means that the gamma matrices span complexified quaternionic algebra at each point of space-time surface. Also spinors must be quaternionic.
  - (c) The assignment of the 4-D gamma matrix sub-algebra at each point of space-time surface can be done in many manners. If the gamma matrices correspond to the tangent space of space-time surface, one obtains just induced gamma matrices and the standard definition of quaternionic sub-manifold. In this case induced 4-volume is taken as the action principle. If Kähler action defines the space-time dynamics, the modified gamma matrices do not span the tangent space in general.
  - (d) An important additional element is involved. If the  $M^4$  projection of the space-time surface contains a preferred subspace  $M^2$  at each point, the quaternionic planes are labeled by points of  $CP_2$  and one can equivalently regard the surfaces of  $M^8$  as surfaces of  $M^4 \times CP_2$  (number-theoretical "compactification"). This generalizes:  $M^2$  can be replaced with a distribution of planes of  $M^4$  which integrates to a 2-D surface of  $M^4$  (for instance, for string like objects this is necessarily true). The presence of the preferred local plane  $M^2$  corresponds to the fact that octonionic spin matrices  $\Sigma_{AB}$  span 14-D Lie-algebra of  $G_2 \subset SO(7)$  rather than that 28-D Lie-algebra of  $SO(7, 1)$  whereas octonionic imaginary units provide 7-D fundamental representation of  $G_2$ . Also spinors must be quaternionic and this is achieved if they are created by the Clifford algebra defined by induced gamma matrices from two preferred spinors defined by real and preferred imaginary octonionic unit. Therefore the preferred plane  $M^3 \subset M^4$  and its local variant has direct counterpart at the level of induced gamma matrices and spinors.
  - (e) This framework implies the basic structures of TGD and therefore leads to the notion of world of classical worlds (WCW) and from this one ends up with the notion WCW spinor field and WCW Clifford algebra and also hyper-finite factors of type  $II_1$  and  $III_1$ . Note that  $M^8$  is exceptional: in other dimensions there is no reason for the restriction of the local Clifford algebra to lower-dimensional sub-manifold to obtain associative algebra.

The above line of ideas leads naturally to (hyper-)quaternionic sub-manifolds and to basic quantum TGD (note that the "hyper" is un-necessary if one accepts just the notion of quaternionic sub-manifold formulated in terms of modified gamma matrices). One can pose some further questions.

1. Quantum TGD reduces basically to the second quantization of the induced spinor fields. Could it be that the theory is integrable only for 4-D hyper-quaternionic space-time surfaces in  $M^8$

(equivalently in  $M^4 \times CP_2$ ) in the sense than one can solve the modified Dirac equation exactly only in these cases?

2. The construction of quantum TGD -including the construction of vacuum functional as exponent of Kähler function reducing to Kähler action for a preferred extremal - should reduce to the modified Dirac equation defined by Kähler action. Could it be that the modified Dirac equation can be solved exactly only for Kähler action.
3. Is it possible to solve the modified Dirac equation for the octonionic gamma matrices and octonionic spinors and map the solution as such to the real context by replacing gamma matrices and sigma matrices with their standard counterparts? Could the associativity conditions for octospinors and modified Dirac equation allow to pin down the form of solutions to such a high degree that the solution can be constructed explicitly?
4. Octonionic gamma matrices provide also a non-associative representation for 8-D version of Pauli sigma matrices and encourage the identification of 8-D twistors as pairs of octonionic spinors conjectured to be highly relevant also for quantum TGD. Does the quaternionicity condition imply that octo-twistors reduce to something closely related to ordinary twistors as the fact that 2-D sigma matrices provide a matrix representation of quaternions suggests?

In the following I will try to answer these questions by developing a detailed view about the octonionic counterpart of the modified Dirac equation and proposing explicit solution ansätze for the modes of the modified Dirac equation.

### The replacement of $SO(7, 1)$ with $G_2$

The basic implication of octonionization is the replacement of  $SO(7, 1)$  as the structure group of spinor connection with  $G_2$ . This has some rather unexpected consequences.

#### 1. Octonionic representation of 8-D gamma matrices

Consider first the representation of 8-D gamma matrices in terms of tensor products of 7-D gamma matrices and 2-D Pauli sigma matrices.

1. The gamma matrices are given by

$$\gamma^0 = 1 \times \sigma_1 \quad , \quad \gamma^i = \gamma^i \otimes \sigma_2 \quad , \quad i = 1, \dots, 7 \quad . \quad (6.5.1)$$

7-D gamma matrices in turn can be expressed in terms of 6-D gamma matrices by expressing  $\gamma^7$  as

$$\gamma_{i+1}^{(7)} = \gamma_i^{(6)} \quad , \quad i = 1, \dots, 6 \quad , \quad \gamma_1^{(7)} = \gamma_7^{(6)} = \prod_{i=1}^6 \gamma_i^{(6)} \quad . \quad (6.5.2)$$

2. The octonionic representation is obtained as

$$\gamma_0 = 1 \times \sigma_1 \quad , \quad \gamma_i = e_i \otimes \sigma_2 \quad . \quad (6.5.3)$$

where  $e_i$  are the octonionic units.  $e_i^2 = -1$  guarantees that the  $M^4$  signature of the metric comes out correctly. Note that  $\gamma_7 = \prod \gamma_i$  is the counterpart for choosing the preferred octonionic unit and plane  $M^2$ .

3. The octonionic sigma matrices are obtained as commutators of gamma matrices:

$$\Sigma_{0i} = e_i \times \sigma_3 \quad , \quad \Sigma_{ij} = f_{ij}{}^k e_k \otimes 1 \quad . \quad (6.5.4)$$

These matrices span  $G_2$  algebra having dimension 14 and rank 2 and having imaginary octonion units and their conjugates as the fundamental representation and its conjugate. The Cartan algebra for the sigma matrices can be chosen to be  $\Sigma_{01}$  and  $\Sigma_{23}$  and belong to a quaternionic sub-algebra.

4. The lower dimension of the  $G_2$  algebra means that some combinations of sigma matrices vanish. All left or right handed generators of the algebra are mapped to zero: this explains why the dimension is halved from 28 to 14. From the octonionic triangle expressing the multiplication rules for octonion units [22] one finds  $e_4 e_5 = e_1$  and  $e_6 e_7 = -e_1$  and analogous expressions for the cyclic permutations of  $e_4, e_5, e_6, e_7$ . From the expression of the left handed sigma matrix  $I_L^3 = \sigma_{23} + \sigma^{30}$  representing left handed weak isospin (see the Appendix about the geometry of  $CP_2$  [2], [2]) one can conclude that this particular sigma matrix and left handed sigma matrices in general are mapped to zero. The quaternionic sub-algebra  $SU(2)_L \times SU(2)_R$  is mapped to that for the rotation group  $SO(3)$  since in the case of Lorentz group one cannot speak of a decomposition to left and right handed subgroups. The elements of the complement of the quaternionic sub-algebra are expressible in terms of  $\Sigma_{ij}$  in the quaternionic sub-algebra.

## 2. Some physical implications of $SO(7, 1) \rightarrow G_2$ reduction

This has interesting physical implications if one believes that the octonionic description is equivalent with the standard one.

1. If  $SU(2)_L$  is mapped to zero only the right-handed parts of electro-weak gauge field survive octonization. The right handed part is neutral containing only photon and  $Z^0$  so that the gauge field becomes Abelian.  $Z^0$  and photon fields become proportional to each other ( $Z^0 \rightarrow \sin^2(\theta_W)\gamma$ ) so that classical  $Z^0$  field disappears from the dynamics, and one would obtain just electrodynamics. This might provide a deeper reason for why electrodynamics is an excellent description of low energy physics and of classical physics. This is consistent with the fact that  $CP_2$  coordinates define 4 field degrees of freedom so that single Abelian gauge field should be enough to describe classical physics. This would remove also the interpretational problems caused by the transitions changing the charge state of fermion induced by the classical  $W$  boson fields.

Also the realization of  $M^8 - H$  duality led to the conclusion  $M^8$  spinor connection should have only neutral components. The isospin matrix associated with the electromagnetic charge is  $e_1 \times 1$  and represents the preferred imaginary octonionic unit so that that the image of the electro-weak gauge algebra respects associativity condition. An open question is whether octonionization is part of  $M^8$ -H duality or defines a completely independent duality. The objection is that information is lost in the mapping so that it becomes questionable whether the same solutions to the modified Dirac equation can work as a solution for ordinary Clifford algebra.

2. If  $SU(2)_R$  were mapped to zero only left handed parts of the gauge fields would remain. All classical gauge fields would remain in the spectrum so that information would not be lost. The identification of the electro-weak gauge fields as three covariantly constant quaternionic units would be possible in the case of  $M^8$  allowing Hyper-Kähler structure [15], which has been speculated to be a hidden symmetry of quantum TGD at the level of WCW. This option would lead to difficulties with associativity since the action of the charged gauge potentials would lead out from the local quaternionic subspace defined by the octonionic spinor.
3. The gauge potentials and gauge fields defined by  $CP_2$  spinor connection are mapped to fields in  $SO(2) \subset SU(2) \times U(1)$  in quaternionic sub-algebra which in a well-defined sense corresponds to  $M^4$  degrees of freedom! Since the resulting interactions are of gravitational character, one might say that electro-weak interactions are mapped to manifestly gravitational interactions. Since  $SU(2)$  corresponds to rotational group one cannot say that spinor connection would give rise only to left or right handed couplings, which would be obviously a disaster.

3. Octo-spinors and their relation to ordinary imbedding space spinors

Octo-spinors are identified as octonion valued 2-spinors with basis

$$\begin{aligned} \Psi_{L,i} &= e_i \begin{pmatrix} 1 \\ 0 \end{pmatrix} , \\ \Psi_{q,i} &= e_i \begin{pmatrix} 0 \\ 1 \end{pmatrix} . \end{aligned} \tag{6.5.5}$$

One obtains quark and lepton spinors and conjugation for the spinors transforms quarks to leptons. Note that octospinors can be seen as 2-dimensional spinors with components which have values in the space of complexified octonions.

The leptonic spinor corresponding to real unit and preferred imaginary unit  $e_1$  corresponds naturally to the two spin states of the right handed neutrino. In quark sector this would mean that right handed U quark corresponds to the real unit. The octonions decompose as  $1 + 1 + 3 + \bar{3}$  as representations of  $SU(3) \subset G_2$ . The concrete representations are given by

$$\begin{aligned} \{1 \pm ie_1\} &, \quad e_R \text{ and } \nu_R \text{ with spin } 1/2 , \\ \{e_2 \pm ie_3\} &, \quad e_R \text{ and } \nu_L \text{ with spin } -1/2 , \\ \{e_4 \pm ie_5\} &, \quad e_L \text{ and } \nu_L \text{ with spin } 1/2 , \\ \{e_6 \pm ie_7\} &, \quad e_L \text{ and } \nu_L \text{ with spin } 1/2 . \end{aligned} \tag{6.5.6}$$

Instead of spin one could consider helicity. All these spinors are eigenstates of  $e_1$  (and thus of the corresponding sigma matrix) with opposite values for the sign factor  $\epsilon = \pm$ . The interpretation is in terms of vectorial isospin. States with  $\epsilon = 1$  can be interpreted as charged leptons and D type quarks and those with  $\epsilon = -1$  as neutrinos and U type quarks. The interpretation would be that the states with vanishing color isospin correspond to right handed fermions and the states with non-vanishing SU(3) isospin (to be not confused with QCD color isospin) and those with non-vanishing SU(3) isospin to left handed fermions. The only difference between quarks and leptons is that the induced Kähler gauge potentials couple to them differently.

The importance of this identification is that it allows a unique map of the candidates for the solutions of the octonionic modified Dirac equation to those of ordinary one. There are some delicacies involved due to the possibility to chose the preferred unit  $e_1$  so that the preferred subspace  $M^2$  can corresponds to a sub-manifold  $M^2 \subset M^4$ .

**Octonionic counterpart of the modified Dirac equation**

The solution ansatz for the octonionic counterpart of the modified Dirac equation discussed below makes sense also for ordinary modified Dirac equation which raises the hope that the same ansatz, and even same solution could provide a solution in both cases.

1. The general structure of the modified Dirac equation

In accordance with quantum holography and the notion of generalized Feynman diagram, the modified Dirac equation involves two equations which must be consistent with each other.

1. There is 3-dimensional generalized eigenvalue equation for which the modified gamma matrices are defined by Chern-Simons action defined by the sum  $J_{tot} = J + J_1$  of Kähler forms of  $S^2$  and  $CP_2$  [15, 28] .

$$\begin{aligned} D_3 \Psi &= [D_{C-S} + Q_{C-S}] \Psi = \lambda^k \gamma_k \Psi , \\ Q_{C-S} &= Q_\alpha \hat{\Gamma}_{C-S}^\alpha , \quad Q_\alpha = Q_{AG}{}^{AB} j_{B\alpha} . \end{aligned} \tag{6.5.7}$$

The gamma matrices  $\gamma_k$  are  $M^4$  gamma matrices in standard Minkowski coordinates and thus constant. Given eigenvalue  $\lambda_k$  defines pseudo momentum which is some function of the genuine momenta  $p_k$  and other quantum numbers via the boundary conditions associated with the generalized eigenvalue equation.

The charges  $Q_A$  correspond to real four-momentum and charges in color Cartan algebra. The term  $Q$  can be rather general since it provides a representation for the measurement interaction by mapping observables to Cartan algebra of isometry group and to the infinite hierarchy of conserved currents implied by quantum criticality. The operator  $O$  characterizes the quantum critical conserved current. The surface  $Y_l^3$  can be chosen to be any light-like 3-surface "parallel" to the wormhole throat in the slicing of  $X^4$ : this means an additional symmetry. Formally the measurement interaction term can be regarded as an addition of a gauge term to the Kähler gauge potential associated with the Kähler form  $J_{tot}$  of  $S^2 \times CP_2$ .

The square of the equation gives the spinor analog of d'Alembert equation and generalized eigenvalue as the analog of mass squared. The propagator associated with the wormhole throats is formally massless Dirac propagator so that standard twistor formalism applies also without the octonionic representation of the gamma matrices although the physical particles propagating along the opposite wormhole throats are massive on mass shell particles with both signs of energy [28] .

2. Second equation is the 4-D modified Dirac equation defined by Kähler action.

$$D_K \Psi = 0 . \quad (6.5.8)$$

The dimensional reduction of this operator to a sum corresponding to  $D_{K,3}$  acting on light-like 3-surfaces and 1-D operator  $D_{K,1}$  acting on the coordinate labeling the 3-D light-like 3-surfaces in the slicing would allow to assign eigenvalues to  $D_{K,3}$  as analogs of energy eigenvalues for ordinary Schrödinger equation. One proposal has been that Dirac determinant could be identified as the product of these eigen values. Another and more plausible identification is as the product of pseudo masses assignable to  $D_3$  defined by Chern-Simons action [1] . It must be however made clear that the identification of the exponent of the Kähler function to Chern-Simons term makes the identification as Dirac determinant un-necessary.

3. There are two options depending on whether one requires that the eigenvalue equation applies only on the wormhole throats and at the ends of the space-time surface or for all 3-surfaces in the slicing of the space-time surface by light-like 3-surfaces. In the latter case the condition that the pseudo four-momentum is same for all the light-like 3-surfaces in the slicing gives a consistency condition stating that the commutator of the two Dirac operators vanishes for the solutions in the case of preferred extremals, which depend on the momentum and color quantum numbers also:

$$[D_K, D_3] \Psi = 0 . \quad (6.5.9)$$

This condition is quite strong and there is no deep reason for it since  $\lambda_k$  does not correspond to the physical conserved momentum so that its spectrum could depend on the light-like 3-surface in the slicing. On the other hand, if the eigenvalues of  $D_3$  belong to the preferred hyper-complex plane  $M^2$ ,  $D_3$  effectively reduces to a 2-dimensional algebraic Dirac operator  $\lambda^k \gamma_k$  commuting with  $D_K$ : the values of  $\lambda^k$  cannot depend on slice since this would mean that  $D_K$  does not commute with  $D_3$ .

### 2. About the hyper-octonionic variant of the modified Dirac equation

What gives excellent hopes that the octonionic variant of modified Dirac equation could lead to a provide precise information about the solution spectrum of modified Dirac equation is the condition that everything in the equation should be associative. Hence the terms which are by there nature non-associative should vanish automatically.

1. The first implication is that besides octonionic gamma matrices also octonionic spinors should belong to the local quaternionic plane at each point of the space-time surface. Spinors are also generated by quaternionic Clifford algebra from two preferred spinors defining a preferred plane in the space of spinors. Hence spinorial dynamics seems to mimic very closely the space-time dynamics and one might even hope that the solutions of the modified Dirac action could be seen as maps of the space-time surface to surfaces of the spinor space. The reduction to quaternionic sub-algebra suggest that some variant of ordinary twistors emerges in this manner in matrix representation.
2. The octonionic sigma matrices span  $G_2$  where as ordinary sigma matrices define  $SO(7, 1)$ . On the other hand, the holonomies are identical in the two cases if right-handed charge matrices are mapped to zero so that there are indeed hopes that the solutions of the octonionic Dirac equation cannot be mapped to those of ordinary Dirac equation. If left-handed charge matrices are mapped to zero, the resulting theory is essentially the analog of electrodynamics coupled to gravitation at classical level but it is not clear whether this is physically acceptable. It is not clear whether associativity condition leaves only this option under consideration.
3. The solution ansatz to the modified Dirac equation is expected to be of the form  $\Psi = D_K(\Psi_0 u_0 + \Psi_1 u_1)$ , where  $u_0$  and  $u_1$  are constant spinors representing real unit and the preferred unit  $e_1$ . Hence constant spinors associated with right handed electron and neutrino and right-handed  $d$  and  $u$  quark would appear in  $\Psi$  and  $\Psi_i$  could correspond to scalar coefficients of spinors with different charge. This ansatz would reduce the modified Dirac equation to  $D_K^2 \Psi_i = 0$  since there are no charged couplings present. The reduction of a d'Alembert type equation for single scalar function coupling to  $U(1)$  gauge potential and  $U(1)$  "gravitation" would obviously mean a dramatic simplification raising hopes about integrable theory.
4. The condition  $D_K^2 \Psi = 0$  involves products of three octonions and involves derivatives of the modified gamma matrices which might belong to the complement of the quaternionic sub-space. The restriction of  $\Psi$  to the preferred hyper-complex plane  $M^2$  simplifies the situation dramatically but  $(D_K^2)D_K \Psi = D_K(D_K^2)\Psi = 0$  could still fail. The problem is that the action of  $D_K$  is not algebraic so that one cannot treat reduce the associativity condition to  $(AA)A = A(AA)$ .

### Could the notion of octo-twistor make sense?

Twistors have led to dramatic successes in the understanding of Feynman diagrammatics of gauge theories,  $N = 4$  SUSYs, and  $N = 8$  supergravity [61, 70, 58]. This motivated the question whether they might be applied in TGD framework too [82] - at least in the description of the QFT limit. The basic problem of the twistor program is how to overcome the difficulties caused by particle massivation and TGD framework suggests possible clues in this respect.

1. In TGD it is natural to regard particles as massless particles in 8-D sense and to introduce 8-D counterpart of twistors by relying on the geometric picture in which twistors correspond to a pair of spinors characterizing light-like momentum ray and a point of  $M^8$  through which the ray traverses. Twistors would consist of a pair of spinors and quark and lepton spinors define the natural candidate for the spinors in question. This approach would allow to handle massive on-mass-shell states but cannot cope with virtual momenta massive in 8-D sense.
2. The emergence of pseudo momentum  $\lambda_k$  from the generalized eigenvalue equation for  $D_{C-S}$  suggest a dramatically simpler solution to the problem. Since propagators are effectively massless propagators for pseudo momenta, which are functions of physical on shell momenta (with both signs of energy in zero energy ontology) and of other quantum numbers, twistor formalism can be applied in its standard form. An attractive assumption is that also  $\lambda^k$  are conserved in the vertices but a good argument justifying this is lacking. One can ask whether also  $N = 4$  SUSY,  $N = 8$  super-gravity, and even QCD could have similar interpretation.

This picture should apply also in the case of octotwistors with minor modifications and one might hope that octotwistors could provide new insights about what happens in the real case.

1. In the case of ordinary Clifford algebra unit matrix and six-dimensional gamma matrices  $\gamma_i$ ,  $i = 1, \dots, 6$  and  $\gamma_7 = \prod_i \gamma_i$  would define the variant of Pauli sigma matrices as  $\sigma_0 = 1$ ,  $\sigma_k = \gamma_k$ ,  $k = 1, \dots, 7$ . The problem is that masslessness condition does not correspond to the vanishing of the determinant for the matrix  $p_k \sigma^k$ .
2. In the case of octo-twistors Pauli sigma matrices  $\sigma^k$  would correspond to hyper-octonion units  $\{\sigma_0, \sigma_k\} = \{1, ie^k\}$  and one could assign to  $p_k \sigma^k$  a matrix by the linear map defined by the multiplication with  $P = p_k \sigma^k$ . The matrix is of form  $P_{mn} = p^k f_{kmn}$ , where  $f_{kmn}$  are the structure constants characterizing multiplication by hyper-octonion. The norm squared for octonion is the fourth root for the determinant of this matrix. Since  $p_k \sigma^k$  maps its octonionic conjugate to zero so that the determinant must vanish (as is easy to see directly by reducing the situation to that for hyper-complex numbers by considering the hyper-complex plane defined by  $P$ ).
3. Associativity condition for the octotwistors requires that the gamma matrix basis appearing in the generalized eigenvalue equation for Chern-Simons Dirac operator must differ by a local  $G_2$  rotation from the standard hyper-quaternionic gamma matrix for  $M^4$  so that it is always in the local hyper-quaternionic plane. This suggests that octo-twistor can be mapped to an ordinary twistor by mapping the basis of hyper-quaternions to Pauli sigma matrices. A stronger condition guaranteeing the commutativity of  $D_3$  with  $\lambda^k \gamma_k$  is that  $\lambda_k$  belongs to a preferred hyper-complex plane  $M^2$  assignable to a given  $CD$ . Also the two spinors should belong to this plane for the proposed solution ansatz for the modified Dirac equation. Quaternionization would also allow to assign momentum to the spinors in standard manner.

The spectrum of pseudo-momenta would be 2-dimensional (continuum at worst) and this should certainly improve dramatically the convergence properties for the sum over the non-conserved pseudo-momenta in propagators which in the worst possible of worlds might destroy the manifest finiteness of the theory based on the generalized Feynman diagrams with the throats of wormholes carrying always on mass shell momenta. This effective 2-dimensionality should apply also in the real case and would have no catastrophic consequences since pseudo momenta are in question.

As a matter fact, the assumption the decomposition of quark momenta to longitudinal and transversal parts in perturbative QCD might have interpretation in terms of pseudo-momenta if they are conserved.

4.  $M^8 - H$  duality suggests a possible interpretation of the pseudo-momenta as  $M^8$  momenta which by purely number theoretical reasons must be commutative and thus belong to  $M^2$  hyper-complex plane. One ends up with the similar outcome as one constructs a representation for the quantum states defined by WCW spinor fields as superpositions of real units constructed as ratios of infinite hyper-octonionic integers with precisely defined number theoretic anatomy and transformation properties under standard model symmetries having number theoretic interpretation [70].

#### 6.5.4 What one really means with a virtual particle?

Massive particles are the basic problem of the twistor program. The twistorialization of massive particles does not seem to be a problem in TGD framework thanks to the possibility to interpret them as massless particles in 8-D sense but the situation is unsatisfactory for virtual particles.

The ideas possibly allowing to circumvent this problem emerged from a totally unexpected direction. The inspiration came from the finding of Martin Grusenick [8] who discovered that a Mickelson-Morley interferometer rotating in plane gives rise a non-trivial interference pattern when the plane is orthogonal to the Earth's surface but no effect when parallel to the Earth's surface. The effect could be due to a contraction of the system in the vertical direction caused by the own weight of the system and would thus involve no new physics. If not, then one must try to find General Relativistic explanation for it. Schwarzschild metric predicts this kind of effect but it is by a factor  $10^{-4}$  too small.

In TGD framework one can however consider an explanation of the effect [77].

1. By relaxing the empty space assumption to the assumption that only the energy density (that is  $G^{tt}$ ) vanishes but the other diagonal components of Einstein tensor in Schwarzschild coordinates

can be non-vanishing allows to explain the effect in terms of the deviation of the radial component  $g_{rr}$  of the metric from Schwarzschild metric. The predicted deviation decreases as  $1/r$  and does not affect planetary orbits appreciably even if present for all astrophysical objects. The value of  $G$  determined from radial acceleration at the surface of Earth is predicted to deviate from the actual value as a consequence. The deviation of the metric from empty space metric could also explain the known surprisingly large variation in the measured values of  $G$  since nearby gravitational fields are involved.

2. The Einstein tensor in regions with vanishing energy density would obviously correspond to a tachyonic matter. This led to a series of ideas allowing to sharpen the physical meaning of Einstein's equations in TGD framework. The basic result would be the extension of quantum classical correspondence. The Einstein tensor in matter free regions would describe the presence of virtual particles and would fail to satisfy causality constraint since it corresponds to the space-like momentum exchange of the system with the external world (space-likeness follows if the scattering is elastic).
3. It is difficult to understand how the energy momentum tensor of matter could behave like  $G^{\alpha\beta}$  does if the latter describes tachyons. The resolution of the problem could be very simple in zero energy ontology. In zero energy ontology bosons (and their super counterparts) correspond to wormhole contacts carrying fermion and antifermion numbers at the light-like wormhole throats and having opposite signs of energy. This allows the possibility that the fermions at the throats are on mass shell and the sum of their momenta gives rise to off mass shell momentum which can be also space-like. In zero energy ontology  $G^{\alpha\beta}$  would naturally correspond to the sum of on mass shell energy energy momentum tensors  $T_{\pm}^{\alpha\beta}$  associated with positive and negative energy fermions and their super-counterparts. Note that for the energy momentum tensor  $T^{\alpha\beta} = (\rho + p)u^{\alpha}u^{\beta} - pg^{\alpha\beta}$  of fluid with  $u^{\alpha}u_{\alpha} = 1$  constraint stating on mass shell condition the allowance of virtual particles would mean giving up the condition  $u^{\alpha}u_{\alpha} = 1$  for the velocity field.

### Could virtual particles be regarded as pairs of on mass shell particles with opposite energies?

This identification suggests a concrete identification of virtual particle as pairs of positive and negative energy on mass shell particles allowing an elegant formulation of the twistor program in the case of virtual particles [82, 29] .

1. The basic idea is that massive on mass shell states can be regarded as massless states in 8-dimensional sense so that twistor program generalizes to the case of massive on mass shell states associated with the representations of super-conformal algebras. One has however allow now also off mass shell states, in particular those with space-like momenta, and the question is how to describe them in terms of generalized twistors. In the case of wormhole contacts the answer looks obvious. Bosons and their super partners could correspond to pairs of positive and negative energy on mass shell states and could be described using a pair of twistors associated with composite momenta massless in 8-D sense.
2. It took some time to realize that the most elegant identification of the on mass shall bosons would be as wormhole contacts for which both throats have either positive or negative energy. This would imply automatically on-mass shell property. The basic objection against this has been that one cannot construct massless spin 1 states in this manner. Dirac equation in  $M^4$  implies that the momenta are parallel and for fermion and antifermion the helicities are therefore opposite and only longitudinal polarization representing pure gauge degree of freedom is possible. It is amazing how long time it required to realize that I had swallowed this objection completely uncritically. After all, the first thing that I learned from the Dirac equation for massless induced spinors is that it mixes unavoidably  $M^4$  chiralities except for very special vacuum extremals like canonically imbedded  $M^4$ . Same applies to the modified Dirac equation. Therefore there is no problem! Of course, also the p-adic mass calculations involve imbedding spaced spinors for which  $M^4$  helicities are mixed strongly since only covariantly constant right handed neutrino is massless and possesses a well defined  $M^4$  helicity. At space-time level a pair of massless

extremals (topological light rays) with same (opposite) energies and connected by wormhole contacts could serve as a space-time correlate for on (off) mass shell boson.

3. How can one then identify virtual fermions and their super-counterparts? These particles have been assumed to consist of single wormhole throat associated with a deformation of  $CP_2$  vacuum extremal so that the proposed definition would allow only on mass shell states. A possible resolution of the problem is the identification of also virtual fermions and their super-counterparts as wormhole contacts in the sense that the second wormhole throats is fermionic Fock vacuum carrying purely bosonic quantum numbers and corresponds to a state generated by purely bosonic generators of the super-symplectic algebra whose elements are in 1-1 correspondence with Hamiltonians of  $\delta M_{\pm}^4 \times CP_2$ . Thus the distinction between on mass shell and of mass shell states would be purely topological for fermions and their super partners.
4. The concrete physical interpretation would be that particle scattering event involves at least two parallel space-time sheets. Incoming (outgoing) fermion is topologically condensed at positive energy (negative energy) sheet and corresponds to single throat. In the interaction region fermionic space-time sheet touches with a high probably the large space-time sheet since the distance between sheets is about  $10^4$  Planck lengths. The touching (topological sum) generates a second wormhole throat with a spherical topology and carrying no fermion number but having on mass shell momentum. Virtual fermions would be interacting fermions. Since only topological sum contacts are formed, also virtual fermions are labeled by the genus  $g$  of the 2-D wormhole throat whereas bosons are labeled by the pair  $(g_1, g_2)$  of the genera of two wormhole throats. This classification is consistent with the mechanism giving rise to virtual bosons.

The proposed identification of virtual and on mass shell particles is beautiful but it is of course far from obvious whether it really make sense. Bosonic emergence means that the fundamental loop integrals are for fermionic loops. One could in principle get rid of bosonic loop integrals by using generalized Cutkosky rules [56, 29] but it would be highly satisfying to have a concrete physical interpretation for the loops. It interesting to see whether the proposed picture works in practice. Bosonic emergence means that one path integrates first over fermions to get bosonic action as radiative corrections. Only 3-vertices (or rather, 3 momenta are associated with the vertex [29] ) are involved at the fermion level whereas at the bosonic level arbitrary high vertiecs appear.

### How to treat the new degrees of freedom?

The identification of off mass shell states as on mass shell states of positive and negative energy throats brings in new degrees of freedom. Let us first look what happens if the momenta of the two throats of wormhole contact are completely uncorrelated apart from the condition  $p_1 - p_2 = p$  coming from the energy conservation in the 3-vertex. Here  $p_1$  ( $-p_2$ ) is the momentum of on mass shell positive (negative) energy throat and  $p$  is the momentum of outgoing (incoming) wormhole contact. On mass shell conditions eliminate two degrees of freedom so that in absence of correlations the 4-D integral over loop momenta should be extended to a 6-D integral. For a given time-like virtual momentum  $p$  these degrees of freedom corresponds to 2-dimensional sphere as one finds by looking the situation in the rest system of  $p$  (the direction of  $\bar{p}_1 = -\bar{p}_2$  is arbitrary) so that additional loop integration is finite. For light-like  $p$  the additional degrees of freedom correspond to 2-D light-cone boundary  $\delta M_+^3$  defined by the condition  $t^2 - x^2 - y^2 = 0$ :  $\delta M_+^3$   $SO(1, 2)$  invariant 2-volume does not exist. This is not a catastrophe since massless momenta define lower-dimensional sub-manifold of the momentum space. For space-like  $p$  one has hyperboloid  $t^2 - x^2 - y^2 = -1$  and the 2-D loop integral would be infinite in absence of additional constraints.

A 2-dimensional integral appears at each line of Feynman diagram and if the only constraint comes from  $p_1 - p_2 = p$  one obtains new divergences for space-like momenta  $p$ . One can imagine several approaches to the problem.

1. The most conservative approach assumes that the freedom to select the decomposition  $p = p_1 + p_2$  is completely analogous to a gauge symmetry. This is the case if the propagators are just the usual ones. Although this decomposition would take place it would not have any physical consequences since scattering amplitudes do not depend on the choices of these decompositions. For each line the integral over the decompositions normalized by the volume of  $S^2$  or hyperboloid would give the same result as an arbitrary gauge choice fixing the decompositions.

2. For the second option the new degrees of freedom would be present for each line of the generalized Feynman diagram in a non-trivial manner, and the dependence of the emission vertices on the decompositions should allow to avoid the infinities for space-like  $p$ . The vertices would depend on Lorentz invariant quantities such as  $k \cdot p_1$  and  $k \cdot p_2$ , where  $k$  denotes the momentum of any line coming to the vertex, and in an optimist mood one could ask whether this dependence could allow to smooth out also the standard loop divergences by bringing in the effective momentum cutoff through the new momentum degrees of freedom. In twistorial description this kind of dependence could allow especially elegant realization. Note that also a sum over mass shells is involved and can cause divergences.
3. For the third option the new degrees of freedom would be eliminated by some physical mechanism fixing the direction of the projection of  $p_1$  (and  $p_2$ ) in the hyperplane normal to  $p$ . The minimum option would eliminate the additional 2-dimensional integral but would not pose conditions on the loop momenta  $p_1$  and  $p_2$ . One should be able to fix the direction of the projection of  $p_1$  in the hyperplane  $P(p)$  whose normal is  $p$  by some rule having a physical justification. As a matter of fact, this option would be special case of the first one.

Bosonic sector (with super partners included) poses additional conditions. N-boson vertices are defined by fermionic loops and N-boson vertices with arbitrary large value of  $N$  are possible. Bosonic propagators emerge as inverses of 2-boson vertices defined by fermionic loops. Let  $p_B = p_1 + p_2$  denote the sought for decomposition to on mass shell momenta. For the first and second options there are no obvious problems in the bosonic sector. For the third option there is a serious difficulty involved the decompositions  $p_B = p_1 + p_2$  defined by the vertices at the opposite ends of the boson line are not in general consistent. This kind of conditions lead to a hopelessly clumsy formalism.

### Could additional degrees of freedom allow natural cutoff in loop integrals?

Second option involving two new degrees of freedom for each internal line deserves a more detailed discussion. The masses assignable to on mass shell throats define an inherent momentum cutoff allowing to get rid of infinities without giving up conformal invariance. Of course, mass squared cutoff comes also from the breakdown of the QFT limit at  $CP_2$  length scale but one might hope that this cutoff is not actually needed.

1. To see what is involved, consider a BFF vertex with the fermionic momenta  $p_1 = p_{11} + p_{12}$  and  $p_2 = p_{21} + p_{22}$ , and bosonic momentum  $p_3 = p_{31} + p_{32}$ . As a concrete example, one might consider the calculation of bosonic propagator as the inverse of the bosonic 2-vertex involving fermion loop for which a model was discussed in [56]. For definiteness restrict the consideration to the decomposition of the fermionic momentum  $p_1$ . The natural direction in the orthogonal complement  $P(p_1)$  of  $p_1$  is defined by  $p_2$  (equivalently by  $p_3$ ). The corresponding momentum projections

$$P_{i1} = p_i - \frac{p_i \cdot p_1 p_1}{p_1^2}, \quad i = 2, 3$$

are the same.  $P_{i1}$  in general diverges for  $p_1^2 = 0$ .

2. Conformal invariance allows only dimensionless Lorentz invariants constructed from the momenta. Strong form of the conformal invariance does not allow dependence on the masses of the throats. For time-like (space-like)  $p_1$  the dimensionless variable

$$c_{12} \equiv \frac{p_{11} \cdot P_{21}}{\sqrt{p_{11}^2} \sqrt{P_{21}^2}} = c_{13}$$

describes the cosine (hyperbolic cosine) of the angle (hyperbolic angle) between  $p_{11}$  and  $P_{21}$ . The corresponding sine (hyperbolic sine)  $s_{i,i+1}$  vanishes when  $p_{11}$  is parallel to the projection of  $p_2$  ( $p_3$ ) in  $P(p_1)$ . Similar variables can be assigned to  $p_2$  and  $p_3$ . Together with the three analogous variables

$$c_{i,i} = \frac{p_{i1} \cdot p_i}{\sqrt{p_{i1}^2} \sqrt{p_i^2}}$$

measuring the hyperbolic angle between between  $p_{i1}$  and  $p_i$ , one has 6 variables.  $p_{i1}^2$  and  $p_i^2$  can have both signs and also vanish and this might lead difficulties if one wants Gaussians and analyticity.

3. The on mass shell property for throats allows to consider a milder form of conformal invariance for which one has variables

$$C_{12} \equiv \frac{p_{11} \cdot P_{21}}{m_1 m_2} = C_{13} \quad ,$$

where  $m_i$ ,  $i = 1, 2$  denote that throat masses. This introduces a cutoff in  $P_{21}$  when  $p_1$  is space-like. These variables have infinite values for massless throats so that massless throats cannot appear as building bricks of the virtual particles. The assumption that on mass-shell bosons involve massless wormhole throat would distinguish them from virtual bosons in a unique manner.

4. One can also identify dimensionless quantities formed from the loop momenta. Strong form of conformal invariance allows only

$$d_{ij} = \frac{p_i \cdot p_j}{\sqrt{p_i^2} \sqrt{p_j^2}}$$

possible also for ordinary loops. These variables give hope about cutoff with respect to Lorentz boost for  $p_i$  in the rest system of  $p_j$  but again the signs are problematic. The weaker form of conformal invariance allows also the variables

$$D_{ij} = \frac{p_i \cdot p_j}{m_i m_j}$$

not plagued by the sign problems and giving hopes also about mass squared cutoff. Indeed, if on mass shell throats are present they should take a key role in the physics of the virtual particles.

The following two simple examples give an idea about what might be involved.

1. Consider first a vertex factor which is a Gaussian of form  $\exp(-\sum_{ij} S_{ij}^2) = \exp(-2\sum_i (S_{i,i+1})^2 - \sum_i S_{i,i}^2)$  suppressing the the momenta  $p_{i1}$  for which the projections in  $P(p_i)$  are not parallel to those of  $p_j$  and also large boosts of  $p_{i1}$  in the rest system of  $p_i$ . Massless throats would not appear at all in internal lines. The additional 2-D integrals together with the correlation between  $p_k$  and  $p_{i1}$  do not probably smooth out the standard loop divergences in momentum squared and hyperbolic angle. The replacement of  $S_{ij}$  with  $s_{ij}$  together with analyticity leads to difficulties since  $s_{ij}$  does not have a definite sign.
2. The exponential  $\exp(-\sum_{i \neq j} D_{ij}^2)$  forces the decoupling of massless throats from virtual states, is free of the sign difficulties, and allows a stronger hyperbolic cutoff as well as mass scale cutoff. The replacement of  $D_{ij}$  with  $d_{ij}$  leads to the same problems as encountered in the first example. The simple model for the hyperbolic cutoff discussed in [56] could allow a more refined formulation in this framework. It is however important to realize that this kind of cutoffs look rather adhoc for the generalization of supersymmetric action for fermions [29]. They might be present in the radiatively generated bosonic action.

### Could quantum classical correspondence fix the correct option?

Concerning the dynamics in the new degrees of freedom the above argument lead two options under consideration. The first option assumes  $M^2$  gauge invariance and can be criticized as being somewhat ad hoc unless one can find a convincing interpretation for the restriction of the momenta  $p_1$  and  $p_2$  to  $M^2 \cap P(p)$ , where  $M^2$  denotes a sub-space of  $M^4$  defining the space of non-physical polarizations and  $P(p)$  is the orthogonal complement of  $p = p_1 + p_2$ . For both options one can argue that the decomposition  $p = p_1 + p_2$  should have same space-time correlate.

1. Preferred extremals of Kähler action are characterized by a local choice of  $M^2(x) \subset M^4$  in such a manner that the subspaces  $M^2(x)$  integrate to a 2-D surface in  $M^4$ .  $M^2(x)$  has a physical interpretation as the sub-space of non-physical polarizations. Number theoretical interpretation is as a hyper-complex plane of complexified octonions. In the generalized Feynman diagrammatics only the choice of  $M^2(x)$  at the 2-D partonic 2-surfaces  $X^2$  identified as the ends the 3-D light-like wormhole throats  $X_l^3$  matters. For a given line one can also restrict the consideration to single point  $x$  of  $X^2$  since fermion numbers is carried by a light-like curve along  $X_l^3$ : the is an integral over possible choices of course. The additional degrees of freedom would therefore have a concrete interpretation in terms of space-time surfaces. The effective two-dimensionality states that  $M$ -matrix depends only the partonic 2-surfaces and their 4-D tangent spaces containing  $M^2(x)$  at the ends of the lines of generalized Feynman diagrams.
2. The first option would mean a complete independence on  $M^2(x)$  at partonic 2-surface implied by the first option would mean actual 2-dimensionality instead of only effective one. This is not quite in spirit of quantum TGD although it might make sense at QFT limit.
3. For the second option preferred extremals would reflect in their properties the decomposition  $p = p_1 + p_2$  for the internal lines and the dependence of vertices on the decomposition could correspond to the value of the vacuum functional for a given distribution of the planes  $M^2(x)$ . The locality of the choice  $M^2(x)$  would mean that  $p_1$  and  $p_2$  are not separately conserved during the propagation along the internal line and physical picture suggests that the choice  $M^2(x)$  is constant for light-like 3-surfaces representing lines of the generalized Feynman diagrams.

### Could the formulation of SUSY limit of TGD allow the new view about off mass shell particles?

Could the proposed heuristic ideas about off mass shell particles and diagram-wise finiteness of the perturbation theory, the suggested manner to fix the direction of the projections of  $p_1$  and  $p_2$  in  $P(p)$  in terms of the preferred polarization plane  $M^2 \subset M^4$  characterizing a given line of Feynman diagram, and the formulation of super-symmetric QFT limit of TGD [29] be consistent with each other?

1. There are good arguments that the generalized SUSY based on bosonic emergence and the generalization of super field concept guarantees the cancelation of divergences associated with particles and their super-partners. The new view about off mass shell particles encourages a dream about the finiteness of the individual diagrams justifying the motivations for the primitive model of [56] .
2. The description of bosons and their superpartners as wormhole throats requires at the fundamental level the introduction of new degrees of freedom associated with  $p = p_1 - p_2$  decomposition. On mass shell property is possible and would realize twistorial dreams. If one keeps the original view about virtual fermions and their super-partners as single throated objects, there is no need to describe virtual fermions as wormhole contacts.
3. Quantum classical correspondence suggests that the projections of  $p_1$  and  $p_2$  into  $P(p)$  lie in the intersection  $M^2 \cap P(p)$ , where  $M^2$  characterizes the line of the generalized Feynman diagram. If so, then the new degrees of freedom mean integral over the planes  $M^2$  labeled by the points of  $s \in S^2$ . If also virtual fermions correspond to wormhole contacts, BFF-vertices would contain an amplitude  $f(\alpha, s_1, s_2, s_3)$  with  $s_i$  characterizing the lines. The parameters  $\alpha$  would code information about the momenta of virtual particles, about the masses of on mass shell particles comprising the virtual particles, and also about the dynamics of Kähler action

involving exponent of Kähler function for the extremal in question. If virtual fermions are single throated, one has  $f(\alpha, s)$  with  $s$  characterizing the bosonic line. The generalization would require a characterization of the form factor  $f(\alpha, s_1, s_2, s_3)$  or  $f(\alpha, s)$  in principle predicted by TGD proper but probably only modelable at QFT limit. The view about preferred extremals allows the possibility that  $s_i$  is not conserved along line. If the values of  $s_i$  at the ends of the line are not correlated, the integral over  $s_i$  gives a form factor  $F(\alpha)$ .

4. The propagators for the generalized chiral super-field describing fermions would not be affected, and the effects of  $f$  would be only seen at the level of propagators and vertices for bosons and their super-partners.  $f$  could in principle guarantee the finiteness of individual contributions to both fermionic and bosonic loops without the need for Wick rotation.

### Trying to sum up

The proposed replacement of virtual particles as a convenient mathematical abstraction with something very real suggests that the black box of the loop integrals could be opened and one might even construct concrete models for off mass shell particles using twistorial formulation. The conservative approach would interpret the non-uniqueness of the decomposition of the loop momenta to on mass shell momenta in terms of gauge invariance. A more radical approach would assign two additional degrees of freedom to each line of generalized Feynman diagram and allow vertices to depend on the decomposition. This would give even hopes about the smoothing out of the standard divergences. As a matter fact, this idea was followed already in the chapter about bosonic emergence [56], where it was proposed that natural physical cutoffs on mass squared and hyperbolic angle characterizing the energy of virtual particle could guarantee the finiteness of fermionic loops. The construction of the super-symmetric QFT limit of TGD [29] however suggests that the cancelation of infinities takes place by super-symmetry even without cutoffs. One interpretation is that this cancelation justifies the neglect of the physical cutoff as an excellent approximation. An interesting question is whether the loop integrals could make sense even without Wick rotation.

## 6.6 Does weak form of electric-magnetic duality lead to a twistorial description?

This section summarizes an further vision about how twistors might emerge from quantum TGD. It is only loosely related to the other visions and is certainly the simplest one and also very closely related to the recent picture about generalized Feynman diagrams. Of course, it is bound to be speculative just like all other considerations of this chapter and one cannot take the details of the proposal too seriously.

### 6.6.1 The simplest vision about how twistors might emerge from TGD

The vision involves the notions of bosonic emergence, the identification of virtual states as pairs of on mass shell states assignable to wormhole throats inspired by zero energy ontology and associated realization of Cutkosky rules in terms of manifestly finite Feynman diagrammatics, and as the latest piece the weak form of electric-magnetic duality and the notion of pseudo-momentum emerging from the generalized eigenstates of the Chern-Simons Dirac operator. There must be a correlation between pseudo-momenta and real momenta and the identification of the difference of pseudo-momenta of wormhole throats as the difference of corresponding on mass shell momenta is what gives a connection between ordinary virtual momenta and corresponding pseudo-momenta.

1. The weak form of electric-magnetic duality [28] has led to several developments in basic TGD. One important breakthrough was the improved understanding of the generalized eigenvalue spectrum of the Chern-Simons Dirac operator. The generalized eigenvalues have interpretation as pseudo-momenta reducing to the preferred plane  $M^2 \subset M^4$  assignable to  $CD$ . There are good arguments in favor of a discrete spectrum. There are several options between which one must choose. For the simplest option the pseudo-momenta have interpretation as hyper-complex primes and possibly also their powers. The number of the allowed momenta is finite for this

option. One can consider also a scenario in which integer multiples of a finite number of hyper-complex primes and their powers are allowed.

The summation over pseudo-momenta has nothing to do with the integration over the ordinary loop momenta. If one accepts the proposed connection with infinite hyper-octonionic (and hyper-complex) primes and corresponding arithmetic quantum field theory, one has separate conservation law for them for each hypercomplex prime defining this kind of pseudo-momentum. In arithmetic QFT the conservation law states that the number of bosons and fermions characterized by given prime is conserved in vertex. This conservation law can be interpreted also in terms of a hierarchy of Planck constants as a conservation law correlating the geometries of the partonic orbits entering the vertex and stating that the number of sheets of the covering of  $CD \times CP_2$  assigned to a given prime is conserved in the vertex although it can be shared between outgoing particles. Therefore pseudo-momenta for the modes of the modified Dirac operator would code for geometric data. This is in accordance with quantum classical correspondence.

2. By bosonic emergence [56] fermionic propagators are the fundamental objects in quantum TGD. The basic implication is that the fermionic propagators reduce to what is formally like a massless fermion propagator for the discrete  $M^2$ -valued pseudo-momenta. The close analogy with massless theory encourages to consider a possibility of a discrete number theoretic variant of the twistor formalism with  $M^4$  twistors reducing to  $M^2$  twistors. Whether this formalism has any practical value is of course an open question. Irrespective of whether the twistor philosophy is accepted, massless pseudo-momenta should characterize on mass shell states appearing in incoming lines. They would correspond to hyper-complex integers of form  $n \times (1, 1)$  with vanishing norm forming an ideal in the algebra of hyper-complex integers. These integers are expressible as powers of  $(1, 1)$  which therefore defines a prime like object.
3. One can assign to the lines of generalized Feynman diagrams also ordinary momenta and in loops also integrations over ordinary four-momenta are possible. In zero energy ontology however virtual momenta correspond to pairs of in general non-parallel on-mass-shell momenta, which can have also opposite signs of energy. On mass shell property for these momenta implies extremely strong kinematical constraints and only the simplest loops such as self energy loops remain. Super-symmetry gives good hopes that the bosonic and fermionic contributions to these loops vanish by the basic sign difference coming from fermionic statistics since momentum integrals are identical and only pseudo-momentum summations can distinguish between the diagrams.
4. Unitarity poses a crucial constraint on the perturbative approach. One would like to have unitarity in the form of generalized Cutkosky rules [30]. If one assigns ordinary momenta with the lines of the generalized Feynman diagram and if ordinary propagators are replaced with those involving pseudo-momenta, this is however far from obvious. What comes first in mind is that propagators defined by the pseudo-momenta are replaced with their sums with the ordinary on mass shell propagators. Unless pseudo-momentum is massless this modification is trivial. If pseudo-momentum becomes massless the propagator reduces to ordinary massless propagator and the  $i\epsilon$  description might allow to have the correct analytic structure.
5. One can argue that would be somewhat frustrating to have two separate loop momentum summations/integrals and that a more concrete connection between real momenta and pseudo-momenta should therefore exist. One possibility is that the sum or difference of on-mass-shell momenta associated with the wormhole throats defining the loop momentum is equal or at least proportional to the sum or difference of the corresponding pseudo-momenta. Since incoming lines must correspond to massless pseudo-momenta, the sum or difference of ordinary momenta associated with the wormhole throats must be massless. In the case of massive particles this condition makes sense only for the difference of the throat momenta. Hence pseudo-momenta must correspond to the differences of throat momenta.

In this manner the Cutkosky rules would emerge in a more convincing manner from the theory. The restriction of the net loop momenta to plane  $M^2$  and discretization would imply a spontaneous breaking of Lorentz invariance for a given  $CD$  bringing in mind the description of quarks and gluons in terms of longitudinal momenta. This restriction would also improve dramatically the UV behavior and imply finiteness of self energy diagrams even without super-symmetry. It is not clear whether the number theoretic constraints on difference of throat momenta are

consistent with the momentum conservation in vertices and it might be that a more general option for which pseudo-momenta are identified as  $M^2$  projections of hyper-octonionic primes must be allowed.

In the following the basic arguments supporting this still speculative picture are described.

### 6.6.2 Generalized eigen modes for the modified Chern-Simons Dirac equation and hydrodynamical picture

Hydrodynamical picture and the reduction of TGD to almost topological QFT discussed in detail in [28] helps to understand also the construction of generalized eigen modes of 3-D Chern-Simons Dirac equation.

### 6.6.3 Generalized Feynman diagrams at fermionic and momentum space level

Negative energy ontology has already led to the idea of interpreting the virtual particles as pairs of positive and negative energy wormhole throats. Hitherto I have taken it as granted that ordinary Feynman diagrammatics generalizes more or less as such. It is however far from clear what really happens in the vertices of the generalized Feynmann diagrams. The safest approach relies on the requirement that unitarity realized in terms of Cutkosky rules in ordinary Feynman diagrammatics allows a generalization. This requires loop diagrams. In particular, photon-photon scattering can take place only via a fermionic square loop so that it seems that loops must be present at least in the topological sense.

One must be however ready for the possibility that something unexpectedly simple might emerge. For instance, the vision about algebraic physics allows naturally only finite sums for diagrams and does not favor infinite perturbative expansions. Hence the true believer on algebraic physics might dream about finite number of diagrams for a given reaction type. For simplicity generalized Feynman diagrams without the complications brought by the magnetic confinement since by the previous arguments the generalization need not bring in anything essentially new.

The basic idea of duality in early hadronic models was that the lines of the dual diagram representing particles are only re-arranged in the vertices. This however does not allow to get rid of off mass shell momenta. Zero energy ontology encourages to consider a stronger form of this principle in the sense that the virtual momenta of particles could correspond to pairs of on mass shell momenta of particles. If also interacting fermions are pairs of positive and negative energy throats in the interaction region the idea about reducing the construction of Feynman diagrams to some kind of lego rules might work.

#### Virtual particles as pairs of on mass shell particles in ZEO

The first thing is to try to define more precisely what generalized Feynman diagrams are. The direct generalization of Feynman diagrams implies that both wormhole throats and wormhole contacts join at vertices.

1. A simple intuitive picture about what happens is provided by diagrams obtained by replacing the points of Feynman diagrams (wormhole contacts) with short lines and imagining that the throats correspond to the ends of the line. At vertices where the lines meet the incoming on mass shell quantum numbers would sum up to zero. This approach leads to a straightforward generalization of Feynman diagrams with virtual particles replaced with pairs of on mass shell throat states of type  $++$ ,  $--$ , and  $+-$ . Incoming lines correspond to  $++$  type lines and outgoing ones to  $--$  type lines. The first two line pairs allow only time like net momenta whereas  $+-$  line pairs allow also space-like virtual momenta. The sign assigned to a given throat is dictated by the the sign of the on mass shell momentum on the line. The condition that Cutkosky rules generalize as such requires  $++$  and  $--$  type virtual lines since the cut of the diagram in Cutkosky rules corresponds to on mass shell outgoing or incoming states and must therefore correspond to  $++$  or  $--$  type lines.

2. The basic difference as compared to the ordinary Feynman diagrammatics is that loop integrals are integrals over mass shell momenta and that all throats carry on mass shell momenta. In each vertex of the loop mass incoming on mass shell momenta must sum up to on mass shell momentum. These constraints improve the behavior of loop integrals dramatically and give excellent hopes about finiteness. It does not however seem that only a finite number of diagrams contribute to the scattering amplitude besides tree diagrams. The point is that if a the reactions  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ , where  $N_i$  denote particle numbers, are possible in a common kinematical region for  $N_2$ -particle states then also the diagrams  $N_1 \rightarrow N_2 \rightarrow N_2 \rightarrow N_3$  are possible. The virtual states  $N_2$  include all states in the intersection of kinematically allow regions for  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ . Hence the dream about finite number possible diagrams is not fulfilled if one allows massless particles. If all particles are massive then the particle number  $N_2$  for given  $N_1$  is limited from above and the dream is realized.
3. For instance, loops are not possible in the massless case or are highly singular (bringing in mind twistor diagrams) since the conservation laws at vertices imply that the momenta are parallel. In the massive case and allowing mass spectrum the situation is not so simple. As a first example one can consider a loop with three vertices and thus three internal lines. Three on mass shell conditions are present so that the four-momentum can vary in 1-D subspace only. For a loop involving four vertices there are four internal lines and four mass shell conditions so that loop integrals would reduce to discrete sums. Loops involving more than four vertices are expected to be impossible.
4. The proposed replacement of the elementary fermions with bound states of elementary fermions and monopoles  $X_{\pm}$  brings in the analog of stringy diagrammatics. The 2-particle wave functions in the momentum degrees of freedom of fermions and  $X_{\pm}$  might allow more flexibility and allow more loops. Note however that there are excellent hopes about the finiteness of the theory also in this case.

**Loop integrals are manifestly finite**

One can make also more detailed observations about loops.

1. The simplest situation is obtained if only 3-vertices are allowed. In this case conservation of momentum however allows only collinear momenta although the signs of energy need not be the same. Particle creation and annihilation is possible and momentum exchange is possible but is always light-like in the massless case. The scattering matrices of supersymmetric YM theories would suggest something less trivial and this raises the question whether something is missing. Magnetic monopoles are an essential element of also these theories as also massivation and symmetry breaking and this encourages to think that the formation of massive states as fermion  $X_{\pm}$  pairs is needed. Of course, in TGD framework one has also high mass excitations of the massless states making the scattering matrix non-trivial.
2. In YM theories on mass shell lines would be singular. In TGD framework this is not the case since the propagator is defined as the inverse of the 3-D dimensional reduction of the modified Dirac operator  $D$  containing also coupling to four-momentum (this is required by quantum classical correspondence and guarantees stringy propagators),

$$\begin{aligned}
 D &= i\hat{\Gamma}^{\alpha}p_{\alpha} + \hat{\Gamma}^{\alpha}D_{\alpha} \ , \\
 p_{\alpha} &= p_k\partial_{\alpha}h^k \ .
 \end{aligned}
 \tag{6.6.1}$$

The propagator does not diverge for on mass shell massless momenta and the propagator lines are well-defined. This is of course of essential importance also in general case. Only for the incoming lines one can consider the possibility that 3-D Dirac operator annihilates the induced spinor fields. All lines correspond to generalized eigenstates of the propagator in the sense that one has  $D_3\Psi = \lambda\gamma\Psi$ , where  $\gamma$  is modified gamma matrix in the direction of the stringy coordinate emanating from light-like surface and  $D_3$  is the 3-dimensional dimensional reduction of the 4-D modified Dirac operator. The eigenvalue  $\lambda$  is analogous to energy. Note that the eigenvalue spectrum depends on 4-momentum as a parameter.

3. Massless incoming momenta can decay to massless momenta with both signs of energy. The integration measure  $d^2k/2E$  reduces to  $dx/x$  where  $x \geq 0$  is the scaling factor of massless momentum. Only light-like momentum exchanges are however possible and scattering matrix is essentially trivial. The loop integrals are finite apart from the possible delicacies related to poles since the loop integrands for given massless wormhole contact are proportional to  $dx/x^3$  for large values of  $x$ .
4. Irrespective of whether the particles are massless or not, the divergences are obtained only if one allows too high vertices as self energy loops for which the number of momentum degrees of freedom is  $3N - 4$  for  $N$ -vertex. The construction of SUSY limit of TGD in [29] led to the conclusion that the parallelly propagating  $N$  fermions for given wormhole throat correspond to a product of  $N$  fermion propagators with same four-momentum so that for fermions and ordinary bosons one has the standard behavior but for  $N > 2$  non-standard so that these excitations are not seen as ordinary particles. Higher vertices are finite only if the total number  $N_F$  of fermions propagating in the loop satisfies  $N_F > 3N - 4$ . For instance, a 4-vertex from which  $N = 2$  states emanate is finite.

### Taking into account magnetic confinement

What has been said above is not quite enough. The weak form of electric-magnetic duality [10] leads to the picture about elementary particles as pairs of magnetic monopoles inspiring the notions of weak confinement based on magnetic monopole force. Also color confinement would have magnetic counterpart. This means that elementary particles would behave like string like objects in weak boson length scale. Therefore one must also consider the stringy case with wormhole throats replaced with fermion- $X_{\pm}$  pairs ( $X_{\pm}$  is electromagnetically neutral and  $\pm$  refers to the sign of the weak isospin opposite to that of fermion) and their super partners.

1. The simplest assumption in the stringy case is that fermion- $X_{\pm}$  pairs behave as coherent objects, that is scatter elastically. In more general case only their higher excitations identifiable in terms of stringy degrees of freedom would be created in vertices. The massivation of these states makes possible non-collinear vertices. An open question is how the massivation fermion- $X_{\pm}$  pairs relates to the existing TGD based description of massivation in terms of Higgs mechanism and modified Dirac operator.
2. Mass renormalization could come from self energy loops with negative energy lines as also vertex normalization. By very general arguments supersymmetry implies the cancellation of the self energy loops but would allow non-trivial vertex renormalization [29] .
3. If only 3-vertices are allowed, the loops containing only positive energy lines are possible if on mass shell fermion- $X_{\pm}$  pair (or its superpartner) can decay to a pair of positive energy pair particles of same kind. Whether this is possible depends on the masses involved. For ordinary particles these decays are not kinematically possible below intermediate boson mass scale (the decays  $F_1 \rightarrow F_2 + \gamma$  are forbidden kinematically or by the absence of flavor changing neutral currents whereas intermediate gauge bosons can decay to on mass shell fermion-antifermion pair).
4. The introduction of IR cutoff for 3-momentum in the rest system associated with the largest  $CD$  (causal diamond) looks natural as scale parameter of coupling constant evolution and p-adic length scale hypothesis favors the inverse of the size scale of  $CD$  coming in powers of two. This parameter would define the momentum resolution as a discrete parameter of the p-adic coupling constant evolution. This scale does not have any counterpart in standard physics. For electron,  $d$  quark, and  $u$  quark the proper time distance between the tips of  $CD$  corresponds to frequency of 10 Hz, 1280 Hz, and 160 Hz: all these frequencies define fundamental bio-rhythms [24] .

These considerations have left completely untouched one important aspect of generalized Feynman diagrams: the necessity to perform a functional integral over the deformations of the partonic 2-surfaces at the ends of the lines- that is integration over WCW. Number theoretical universality requires that WCW and these integrals make sense also p-adically and in the following these aspects of generalized Feynman diagrams are discussed.

**The general form of generalized eigenvalue equation for Chern-Simons Dirac action**

Consider first the the general form and interpretation of the generalized eigenvalue equation assigned with the modified Dirac equation for Chern-Simons action [15] . This is of course only an approximation since an additional contribution to the modified gamma matrices from the Lagrangian multiplier term guaranteeing the weak form of electric-magnetic duality must be included.

1. The modified Dirac equation for  $\Psi$  is consistent with that for its conjugate if the coefficient of the instanton term is real and one uses the Dirac action  $\bar{\Psi}(D^\rightarrow - D^\leftarrow)\Psi$  giving modified Dirac equation as

$$D_{C-S}\Psi + \frac{1}{2}(D_\alpha \hat{\Gamma}_{C-S}^\alpha)\Psi = 0 . \tag{6.6.2}$$

As noticed, the divergence  $D_\alpha \hat{\Gamma}_{C-S}^\alpha$  does not contain second derivatives in the case of Chern-Simons action. In the case of Kähler action they occur unless field equations equivalent with the vanishing of the divergence term are satisfied. The extremals of Chern-Simons action provide a natural manner to define effective 2-dimensionality.

Also the fermionic current is conserved in this case, which conforms with the idea that fermions flow along the light-like 3-surfaces. If one uses the action  $\bar{\Psi}D^\rightarrow\Psi$ ,  $\bar{\Psi}$  does not satisfy the Dirac equation following from the variational principle and fermion current is not conserved.

2. The generalized eigen modes of  $D_{C-S}$  should be such that one obtains the counterpart of Dirac propagator which is purely algebraic and does not therefore depend on the coordinates of the throat. This is satisfied if the generalized eigenvalues are expressible in terms of covariantly constant combinations of gamma matrices and here only  $M^4$  gamma matrices are possible. Therefore the eigenvalue equation would read as

$$D\Psi = \lambda^k \gamma_k \Psi , \quad D = D_{C-S} + \frac{1}{2}D_\alpha \hat{\Gamma}_{C-S}^\alpha , \quad D_{C-S} = \hat{\Gamma}_{C-S}^\alpha D_\alpha . \tag{6.6.3}$$

Here the covariant derivatives  $D_\alpha$  contain the measurement interaction term as an apparent gauge term. For extremals one has

$$D = D_{C-S} . \tag{6.6.4}$$

Covariant constancy allows to take the square of this equation and one has

$$(D^2 + [D, \lambda^k \gamma_k])\Psi = \lambda^k \lambda_k \Psi . \tag{6.6.5}$$

The commutator term is analogous to magnetic moment interaction.

3. The generalized eigenvalues correspond to  $\lambda = \sqrt{\lambda^k \lambda_k}$  and Dirac determinant is defined as a product of the eigenvalues and conjecture to give the exponent of Kähler action reducing to Chern-Simons term.  $\lambda$  is completely analogous to mass.  $\lambda_k$  cannot be however interpreted as ordinary four-momentum: for instance, number theoretic arguments suggest that  $\lambda_k$  must be restricted to the preferred plane  $M^2 \subset M^4$  interpreted as a commuting hyper-complex plane of complexified quaternions. For incoming lines this mass would vanish so that all incoming particles irrespective their actual quantum numbers would be massless in this sense and the propagator is indeed that for a massless particle. Note that the eigen-modes define the boundary

values for the solutions of  $D_K\Psi = 0$  so that the values of  $\lambda$  indeed define the counterpart of the momentum space.

This transmutation of massive particles to effectively massless ones might make possible the application of the twistor formalism as such in TGD framework [82].  $N = 4$  SUSY is one of the very few gauge theory which might be UV finite but it is definitely unphysical due to the masslessness of the basic quanta. Could the resolution of the interpretational problems be that the four-momenta appearing in this theory do not directly correspond to the observed four-momenta?

### Inclusion of the constraint term

As already noticed one must include also the constraint term due to the weak form of electric-magnetic duality and this changes somewhat the above simple picture.

1. At the 3-dimensional ends of the space-time sheet and at wormhole throats the 3-dimensionality allows to introduce a coordinate varying along the flow lines of Kähler magnetic field  $B = *J$ . In this case the integrability conditions state that the flow is Beltrami flow. Note that the value of  $B^\alpha$  along the flow line defining magnetic flux appearing in anti-commutation relations is constant. This suggests that the generalized eigenvalue equation for the Chern-Simons action reduces to a collection of ordinary apparently independent differential equations associated with the flow lines beginning from the partonic 2-surface. This indeed happens when the  $CP_2$  projection is 2-dimensional. In this case it however seems that the basis  $u_n$  is not of much help.
2. The conclusion is wrong: the variations of Chern-Simons action are subject to the constraint that electric-magnetic duality holds true expressible in terms of Lagrange multiplier term

$$\int \Lambda_\alpha (J^{n\alpha} - K \epsilon^{n\alpha\beta\gamma} J_{\beta\gamma}) \sqrt{g_4} d^3x . \quad (6.6.6)$$

This gives a constraint force to the field equations and also a dependence on the induced 4-metric so that one has only almost topological QFT. This term also guarantees the  $M^4$  part of WCW Kähler metric is non-trivial. The condition that the ends of space-time sheet and wormhole throats are extrema of Chern-Simons action subject to the electric-magnetic duality constraint is strongly suggested by the effective 2-dimensionality. Without the constraint term Chern-Simons action would vanish for its extremals so that Kähler function would be identically zero.

This term implies also an additional contribution to the modified gamma matrices besides the contribution coming from Chern-Simons action so that the first guess for the modified Dirac operator would not be quite correct. This contribution is of exactly of the same general form as the contribution for any general coordinate invariant action. The dependence of the induced metric on  $M^4$  degrees of freedom guarantees that also  $M^4$  gamma matrices are present. In the following this term will not be considered.

3. When the contribution of the constraint term to the modified gamma matrices is neglected, the explicit expression of the modified Dirac operator  $D_{C-S}$  associated with the Chern-Simons term is given by

$$\begin{aligned} D &= \hat{\Gamma}^\mu D_\mu + \frac{1}{2} D_\mu \hat{\Gamma}^\mu , \\ \hat{\Gamma}^\mu &= \frac{\partial L_{C-S}}{\partial_\mu h^k} \Gamma_k = \epsilon^{\mu\alpha\beta} [2J_{kl} \partial_\alpha h^l A_\beta + J_{\alpha\beta} A_k] \Gamma^k D_\mu , \\ D_\mu \hat{\Gamma}^\mu &= B_K^\alpha (J_{k\alpha} + \partial_\alpha A_k) , \\ B_K^\alpha &= \epsilon^{\alpha\beta\gamma} J_{\beta\gamma} , \quad J_{k\alpha} = J_{kl} \partial_\alpha s^l , \quad \hat{\epsilon}^{\alpha\beta\gamma} = \epsilon^{\alpha\beta\gamma} \sqrt{g_3} . \end{aligned} \quad (6.6.7)$$

For the extremals of Chern-Simons action one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ . Analogous condition holds true when the constraining contribution to the modified gamma matrices is added.

**Generalized eigenvalue equation for Chern-Simons Dirac action**

Consider now the Chern-Simons Dirac equation in more detail assuming that the inclusion of the constraint contribution to the modified gamma matrices does not induce any complications. Assume also extremal property for Chern-Simons action with constraint term and Beltrami flow property.

1. For the extremals the Chern-Simons Dirac operator (constraint term not included) reduces to a one-dimensional Dirac operator

$$D_{C-S} = \hat{\epsilon}^{r\alpha\beta} [2J_{k\alpha}A_\beta + J_{\alpha\beta}A_k] \Gamma^k D_r . \tag{6.6.8}$$

Constraint term implies only a modification of the modified gamma matrices but the form of the operator remains otherwise same when extrema are in question so that one has  $D_\alpha \hat{\Gamma}^\alpha = 0$ .

2. For the extremals of Chern-Simons action the general solution of the modified Chern-Simons Dirac equation ( $\lambda^k = 0$ ) is covariantly constant with respect to the coordinate  $r$ :

$$D_r \Psi = 0 . \tag{6.6.9}$$

The solution to this condition can be written immediately in terms of a non-integrable phase factor  $P \exp(i \int A_r dr)$ , where integration is along curve with constant transversal coordinates. If  $\hat{\Gamma}^v$  is light-like vector field also  $\hat{\Gamma}^v \Psi_0$  defines a solution of  $D_{C-S}$ . This solution corresponds to a zero mode for  $D_{C-S}$  and does not contribute to the Dirac determinant (suggested to give rise to the exponent of Kähler function identified as Kähler action). Note that the dependence of these solutions on transversal coordinates of  $X_l^3$  is arbitrary which conforms with the hydrodynamic picture. The solutions of Chern-Simons-Dirac are obtained by similar integration procedure also when extremals are not in question.

The formal solution associated with a general eigenvalue  $\lambda$  can be constructed by integrating the eigenvalue equation separately along all coordinate curves. This makes sense if  $r$  indeed assigned to possibly light-like flow lines of  $B^\alpha$  or more general Beltrami field possible induced by the constraint term. There are very strong consistency conditions coming from the conditions that  $\Psi$  in the interior is constant along the flow lines of Kähler current and continuous at the ends and throats (call them collectively boundaries), where  $\Psi$  has a non-trivial variation along the flow lines of  $B^\alpha$ .

1. This makes sense only if the flow lines of the Kähler current are transversal to the boundaries so that the spinor modes at boundaries dictate the modes of the spinor field in the interior. Effective 2-dimensionality means that the spinor modes in the interior can be calculated either by starting from the throats or from the ends so that the data at either upper or lower partonic 2-surfaces dictates everything in accordance with zero energy ontology.
2. This gives an infinite number of commuting diagrams stating that the flow-line time evolution along flow lines along wormhole throats from lower partonic 2-surface to the upper one is equivalent with the flow-line time evolution along the lower end of space-time surface to interior, then along interior to the upper end of the space-time surface and then back to the upper partonic 2-surface. If the space-time surface allows a slicing by partonic 2-surfaces these conditions can be assumed for any pair of partonic 2-surfaces connected by Chern-Simons flow evolution.
3. Since the time evolution along interior keeps the spinor field as constant in the proper gauge and since the flow evolutions at the lower and upper ends are in a reverse direction, there is a strong attemptation to assume that the spinor field at the ends of the of the flow lines of Kähler magnetic field are identical apart from a gauge transformation. This leads to a particle-in-box quantization of the values of the pseudo-mass (periodic boundary conditions). These conditions will be assumed in the sequel.

These assumptions lead to the following picture about the generalized eigen modes.

1. By choosing the gauge so that covariant derivative reduces to ordinary derivative and using the constancy of  $\hat{\Gamma}^r$ , the solution of the generalized eigenvalue equation can be written as

$$\begin{aligned}\Psi &= \exp(iL(r)\hat{\Gamma}^r\lambda^k\Gamma_k)\Psi_0 , \\ L(r) &= \int_0^r \frac{1}{\sqrt{\hat{g}^{rr}}} dr .\end{aligned}\tag{6.6.10}$$

$L(r)$  can be regarded as the along flux line as defined by the effective metric defined by modified gamma matrices. If  $\lambda_k$  is linear combination of  $\Gamma^0$  and  $\Gamma^{rM}$  it anti-commutes with  $\Gamma^r$  which contains only  $CP_2$  gamma matrices so that the pseudo-momentum is a priori arbitrary.

2. When the constraint term taking care of the electric-magnetic duality is included, also  $M^4$  gamma matrices are present. If they are in the orthogonal complement of a preferred plane  $M^2 \subset M^4$ , anti-commutativity is achieved. This assumption cannot be fully justified yet but conforms with the general physical vision. There is an obvious analogy with the condition that polarizations are in a plane orthogonal to  $M^2$ . The condition indeed states that only transversal deformations define quantum fluctuating WCW degrees of freedom contributing to the WCW Kähler metric. In  $M^8-H$  duality the preferred plane  $M^2$  is interpreted as a hyper-complex plane belonging to the tangent space of the space-time surface and defines the plane of non-physical polarizations. Also a generalization of this plane to an integrable distribution of planes  $M^2(x)$  has been proposed and one must consider also now the possibility of a varying plane  $M^2(x)$  for the pseudo-momenta. The scalar function  $\Phi$  appearing in the general solution ansatz for the field equations satisfies massless d'Alembert equation and its gradient defines a local light-like direction at space-time-level and hence a 2-D plane of the tangent space. Maybe the projection of this plane to  $M^4$  could define the preferred  $M^2$ . The minimum condition is that these planes are defined only at the ends of space-time surface and at wormhole throats.
3. If one accepts this hypothesis, one can write

$$\begin{aligned}\Psi &= \left[ \cos(L(r)\lambda) + i\sin(\lambda(r))\hat{\Gamma}^r\lambda^k\Gamma_k \right] \Psi_0 , \\ \lambda &= \sqrt{\lambda_k\lambda^k} .\end{aligned}\tag{6.6.11}$$

4. Boundary conditions should fix the spectrum of masses. If the the flow lines of Kähler current coincide with the flow lines of Kähler magnetic field or more general Beltrami current at wormhole throats one ends up with difficulties since the induced spinor fields must be constant along flow lines and only trivial eigenvalues are possible. Hence it seems that the two Beltrami fields must be transversal. This requires that at the partonic 2-surfaces the value of the induced spinor mode in the interior coincides with its value at the throat. Since the induced spinor fields in interior are constant along flow lines, one must have

$$\exp(i\lambda L(r_{max})) = 1 .\tag{6.6.12}$$

This implies that one has essentially particle in a box with size defined by the effective metric

$$\lambda_n = \frac{n2\pi}{L(r_{max})} .\tag{6.6.13}$$

5. This condition cannot however hold true simultaneously for all points of the partonic 2-surfaces since  $L(r_{max})$  depends on the point of the surface. In the most general case one can consider only a subset consisting of the points for which the values of  $L(r_{max})$  are rational multiples of the value of  $L(r_{max})$  at one of the points -call it  $L_0$ . This implies the notion of number theoretical braid. Induced spinor fields are localized to the points of the braid defined by the flow lines of the Kähler magnetic field (or equivalently, any conserved current- this resolves the longstanding issue about the identification of number theoretical braids). The number of the included points depends on measurement resolution characterized somehow by the number rationals which are allowed. Only finite number of harmonics and sub-harmonics of  $L_0$  are possible so that for integer multiples the number of points is finite. If  $n_{max}L_0$  and  $L_0/n_{min}$  are the largest and smallest lengths involved, one can argue that the rationals  $n_{max}/n, n = 1, \dots, n_{max}$  and  $n/n_{min}, n = 1, \dots, n_{min}$  are the natural ones.
6. One can consider also algebraic extensions for which  $L_0$  is scaled from its reference value by an algebraic number so that the mass scale  $m$  must be scaled up in similar manner. The spectrum comes also now in integer multiples. p-Adic mass calculations predicts mass scales to the inverses of square roots of prime and this raises the expectation that  $\sqrt{n}$  harmonics and sub-harmonics of  $L_0$  might be necessary. Notice however that pseudo-momentum spectrum is in question so that this argument is on shaky grounds.

There is also the question about the allowed values of  $(\lambda_0, \lambda_3)$  for a given value of  $\lambda$ . This issue will be discussed in the next section devoted to the attempt to calculate the Dirac determinant assignable to this spectrum: suffice it to say that integer valued spectrum is the first guess implying that the pseudo-momenta satisfy  $n_0^2 - n_3^2 = n^2$  and therefore correspond to Pythagorean triangles. What is remarkable that the notion of number theoretic braid pops up automatically from the Beltrami flow hypothesis.

### 6.6.4 Hyper-octonionic primes

Before detailed discussion of the hyper-octonionic option it is good to consider the basic properties of hyper-octonionic primes.

1. Hyper-octonionic primes are of form

$$\Pi_p = (n_0, n_3, n_1, n_2, \dots, n_7) , \quad \Pi_p^2 = n_0^2 - \sum_i n_i^2 = p \text{ or } p^2 . \quad (6.6.14)$$

2. Hyper-octonionic primes have a standard representation as hyper-complex primes. The Minkowski norm squared factorizes into a product as

$$n_0^2 - n_3^2 = (n_0 + n_3)(n_0 - n_3) . \quad (6.6.15)$$

If one has  $n_3 \neq 0$ , the prime property implies  $n_0 - n_3 = 1$  so that one obtains  $n_0 = n_3 + 1$  and  $2n_3 + 1 = p$  giving

$$(n_0, n_3) = ((p + 1)/2, (p - 1)/2) . \quad (6.6.16)$$

Note that one has  $(p + 1)/2$  odd for  $p \bmod 4 = 1$  and  $(p + 1)/2$  even for  $p \bmod 4 = 3$ . The difference  $n_0 - n_3 = 1$  characterizes prime property.

If  $n_3$  vanishes the prime property implies equivalence with ordinary prime and one has  $n_0^2 = p^2$ . These hyper-octonionic primes represent particles at rest.

3. The action of a discrete subgroup  $G(p)$  of the octonionic automorphism group  $G_2$  generates form hyper-complex primes with  $n_3 \neq 0$  further hyper-octonionic primes  $\Pi(p, k)$  corresponding to the same value of  $n_0$  and  $p$  and for these the integer valued projection to  $M^2$  satisfies  $n_0^2 - n_3^2 = n > p$ . It is also possible to have a state representing the system at rest with  $(n_0, n_3) = ((p+1)/2, 0)$  so that the pseudo-mass varies in the range  $[\sqrt{p}, (p+1)/2]$ . The subgroup  $G(n_0, n_3) \subset SU(3)$  leaving invariant the projection  $(n_0, n_3)$  generates the hyper-octonionic primes corresponding to the same value of mass for hyper-octonionic primes with same Minkowskian length  $p$  and pseudo-mass  $\lambda = n \geq \sqrt{p}$ .
4. One obtains two kinds of primes corresponding to the lengths of pseudo-momenta equal to  $p$  or  $\sqrt{p}$ . The first kind of particles are always at rest whereas the second kind of particles can be brought at rest only if one interprets the pseudo-momentum as  $M^2$  projection. This brings in mind the secondary p-adic length scales assigned to causal diamonds (CDs) and the primary p-adic lengths scales assigned to particles.

If the  $M^2$  projections of hyper-octonionic primes with length  $\sqrt{p}$  characterize the allowed basic momenta,  $\zeta_D$  is sum of zeta functions associated with various projections which must be in the limits dictated by the geometry of the orbit of the partonic surface giving upper and lower bounds  $L_{max}$  and  $L_{min}$  on the length  $L$ .  $L_{min}$  is scaled up to  $\sqrt{n_0^2 - n_3^2} L_{min}$  for a given projection  $(n_0, n_3)$ . In general a given  $M^2$  projection  $(n_0, n_3)$  corresponds to several hyper-octonionic primes since  $SU(3)$  rotations give a new hyper-octonionic prime with the same  $M^2$  projection. This leads to an inconsistency unless one has a good explanation for why some basic momentum can appear several times. One might argue that the spinor mode is degenerate due to the possibility to perform discrete color rotations of the state. For hyper complex representatives there is no such problem and it seems favored. In any case, one can look how the degeneracy factors for given projection can be calculated.

1. To calculate the degeneracy factor  $D(n)$  associated with given pseudo-mass value  $\lambda = n$  one must find all hyper-octonionic primes  $\Pi$ , which can have projection in  $M^2$  with length  $n$  and sum up the degeneracy factors  $D(n, p)$  associated with them:

$$\begin{aligned}
 D(n) &= \sum_p D(n, p) , \\
 D(n, p) &= \sum_{n_0^2 - n_3^2 = p} D(p, n_0, n_3) , \\
 n_0^2 - n_3^2 &= n , \quad \Pi_p^2(n_0, n_3) = n_0^2 - n_3^2 - \sum_i n_i^2 = n - \sum_i n_i^2 = p .
 \end{aligned} \tag{6.6.17}$$

2. The condition  $n_0^2 - n_3^2 = n$  allows only Pythagorean triangles and one must find the discrete subgroup  $G(n_0, n_3) \subset SU(3)$  producing hyper-octonions with integer valued components with length  $p$  and components  $(n_0, n_3)$ . The points at the orbit satisfy the condition

$$\sum n_i^2 = p - n . \tag{6.6.18}$$

The degeneracy factor  $D(p, n_0, n_3)$  associated with given mass value  $n$  is the number of elements of in the coset space  $G(n_0, n_3, p)/H(n_0, n_3, p)$ , where  $H(n_0, n_3, p)$  is the isotropy group of given hyper-octonionic prime obtained in this manner. For  $n_0^2 - n_3^2 = p^2$   $D(n_0, n_3, p)$  obviously equals to unity.

### 6.6.5 Generalized Feynman diagrams at fermionic and momentum space level

Negative energy ontology has already led to the idea of interpreting the virtual particles as pairs of positive and negative energy wormhole throats. Hitherto I have taken it as granted that ordinary

Feynman diagrammatics generalizes more or less as such. It is however far from clear what really happens in the vertices of the generalized Feynmann diagrams. The safest approach relies on the requirement that unitarity realized in terms of Cutkosky rules in ordinary Feynman diagrammatics allows a generalization. This requires loop diagrams. In particular, photon-photon scattering can take place only via a fermionic square loop so that it seems that loops must be present at least in the topological sense.

One must be however ready for the possibility that something unexpectedly simple might emerge. For instance, the vision about algebraic physics allows naturally only finite sums for diagrams and does not favor infinite perturbative expansions. Hence the true believer on algebraic physics might dream about finite number of diagrams for a given reaction type. For simplicity generalized Feynman diagrams without the complications brought by the magnetic confinement since by the previous arguments the generalization need not bring in anything essentially new.

The basic idea of duality in early hadronic models was that the lines of the dual diagram representing particles are only re-arranged in the vertices. This however does not allow to get rid of off mass shell momenta. Zero energy ontology encourages to consider a stronger form of this principle in the sense that the virtual momenta of particles could correspond to pairs of on mass shell momenta of particles. If also interacting fermions are pairs of positive and negative energy throats in the interaction region the idea about reducing the construction of Feynman diagrams to some kind of lego rules might work.

### Virtual particles as pairs of on mass shell particles in ZEO

The first thing is to try to define more precisely what generalized Feynman diagrams are. The direct generalization of Feynman diagrams implies that both wormhole throats and wormhole contacts join at vertices.

1. A simple intuitive picture about what happens is provided by diagrams obtained by replacing the points of Feynman diagrams (wormhole contacts) with short lines and imagining that the throats correspond to the ends of the line. At vertices where the lines meet the incoming on mass shell quantum numbers would sum up to zero. This approach leads to a straightforward generalization of Feynman diagrams with virtual particles replaced with pairs of on mass shell throat states of type  $++$ ,  $--$ , and  $+ -$ . Incoming lines correspond to  $++$  type lines and outgoing ones to  $--$  type lines. The first two line pairs allow only time like net momenta whereas  $+ -$  line pairs allow also space-like virtual momenta. The sign assigned to a given throat is dictated by the the sign of the on mass shell momentum on the line. The condition that Cutkosky rules generalize as such requires  $++$  and  $--$  type virtual lines since the cut of the diagram in Cutkosky rules corresponds to on mass shell outgoing or incoming states and must therefore correspond to  $++$  or  $--$  type lines.
2. The basic difference as compared to the ordinary Feynman diagrammatics is that loop integrals are integrals over mass shell momenta and that all throats carry on mass shell momenta. In each vertex of the loop mass incoming on mass shell momenta must sum up to on mass shell momentum. These constraints improve the behavior of loop integrals dramatically and give excellent hopes about finiteness. It does not however seem that only a finite number of diagrams contribute to the scattering amplitude besides tree diagrams. The point is that if a the reactions  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ , where  $N_i$  denote particle numbers, are possible in a common kinematical region for  $N_2$ -particle states then also the diagrams  $N_1 \rightarrow N_2 \rightarrow N_2 \rightarrow N_3$  are possible. The virtual states  $N_2$  include all all states in the intersection of kinematically allow regions for  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ . Hence the dream about finite number possible diagrams is not fulfilled if one allows massless particles. If all particles are massive then the particle number  $N_2$  for given  $N_1$  is limited from above and the dream is realized.
3. For instance, loops are not possible in the massless case or are highly singular (bringing in mind twistor diagrams) since the conservation laws at vertices imply that the momenta are parallel. In the massive case and allowing mass spectrum the situation is not so simple. As a first example one can consider a loop with three vertices and thus three internal lines. Three on mass shell conditions are present so that the four-momentum can vary in 1-D subspace only. For a loop involving four vertices there are four internal lines and four mass shell conditions so that loop

integrals would reduce to discrete sums. Loops involving more than four vertices are expected to be impossible.

4. The proposed replacement of the elementary fermions with bound states of elementary fermions and monopoles  $X_{\pm}$  brings in the analog of stringy diagrammatics. The 2-particle wave functions in the momentum degrees of freedom of fermions and  $X_{\pm}$  might allow more flexibility and allow more loops. Note however that there are excellent hopes about the finiteness of the theory also in this case.

### Loop integrals are manifestly finite

One can make also more detailed observations about loops.

1. The simplest situation is obtained if only 3-vertices are allowed. In this case conservation of momentum however allows only collinear momenta although the signs of energy need not be the same. Particle creation and annihilation is possible and momentum exchange is possible but is always light-like in the massless case. The scattering matrices of supersymmetric YM theories would suggest something less trivial and this raises the question whether something is missing. Magnetic monopoles are an essential element of also these theories as also massivation and symmetry breaking and this encourages to think that the formation of massive states as fermion  $X_{\pm}$  pairs is needed. Of course, in TGD framework one has also high mass excitations of the massless states making the scattering matrix non-trivial.
2. In YM theories on mass shell lines would be singular. In TGD framework this is not the case since the propagator is defined as the inverse of the 3-D dimensional reduction of the modified Dirac operator  $D$  containing also coupling to four-momentum (this is required by quantum classical correspondence and guarantees stringy propagators),

$$\begin{aligned} D &= i\hat{\Gamma}^{\alpha}p_{\alpha} + \hat{\Gamma}^{\alpha}D_{\alpha} \ , \\ p_{\alpha} &= p_k\partial_{\alpha}h^k \ . \end{aligned} \tag{6.6.19}$$

The propagator does not diverge for on mass shell massless momenta and the propagator lines are well-defined. This is of course of essential importance also in general case. Only for the incoming lines one can consider the possibility that 3-D Dirac operator annihilates the induced spinor fields. All lines correspond to generalized eigenstates of the propagator in the sense that one has  $D_3\Psi = \lambda\gamma\Psi$ , where  $\gamma$  is modified gamma matrix in the direction of the stringy coordinate emanating from light-like surface and  $D_3$  is the 3-dimensional dimensional reduction of the 4-D modified Dirac operator. The eigenvalue  $\lambda$  is analogous to energy. Note that the eigenvalue spectrum depends on 4-momentum as a parameter.

3. Massless incoming momenta can decay to massless momenta with both signs of energy. The integration measure  $d^2k/2E$  reduces to  $dx/x$  where  $x \geq 0$  is the scaling factor of massless momentum. Only light-like momentum exchanges are however possible and scattering matrix is essentially trivial. The loop integrals are finite apart from the possible delicacies related to poles since the loop integrands for given massless wormhole contact are proportional to  $dx/x^3$  for large values of  $x$ .
4. Irrespective of whether the particles are massless or not, the divergences are obtained only if one allows too high vertices as self energy loops for which the number of momentum degrees of freedom is  $3N - 4$  for  $N$ -vertex. The construction of SUSY limit of TGD in [29] led to the conclusion that the parallelly propagating  $N$  fermions for given wormhole throat correspond to a product of  $N$  fermion propagators with same four-momentum so that for fermions and ordinary bosons one has the standard behavior but for  $N > 2$  non-standard so that these excitations are not seen as ordinary particles. Higher vertices are finite only if the total number  $N_F$  of fermions propagating in the loop satisfies  $N_F > 3N - 4$ . For instance, a 4-vertex from which  $N = 2$  states emanate is finite.

**Taking into account magnetic confinement**

What has been said above is not quite enough. The weak form of electric-magnetic duality [10] leads to the picture about elementary particles as pairs of magnetic monopoles inspiring the notions of weak confinement based on magnetic monopole force. Also color confinement would have magnetic counterpart. This means that elementary particles would behave like string like objects in weak boson length scale. Therefore one must also consider the stringy case with wormhole throats replaced with fermion- $X_{\pm}$  pairs ( $X_{\pm}$  is electromagnetically neutral and  $\pm$  refers to the sign of the weak isospin opposite to that of fermion) and their super partners.

1. The simplest assumption in the stringy case is that fermion- $X_{\pm}$  pairs behave as coherent objects, that is scatter elastically. In more general case only their higher excitations identifiable in terms of stringy degrees of freedom would be created in vertices. The massivation of these states makes possible non-collinear vertices. An open question is how the massivation fermion- $X_{\pm}$  pairs relates to the existing TGD based description of massivation in terms of Higgs mechanism and modified Dirac operator.
2. Mass renormalization could come from self energy loops with negative energy lines as also vertex normalization. By very general arguments supersymmetry implies the cancellation of the self energy loops but would allow non-trivial vertex renormalization [29] .
3. If only 3-vertices are allowed, the loops containing only positive energy lines are possible if on mass shell fermion- $X_{\pm}$  pair (or its superpartner) can decay to a pair of positive energy pair particles of same kind. Whether this is possible depends on the masses involved. For ordinary particles these decays are not kinematically possible below intermediate boson mass scale (the decays  $F_1 \rightarrow F_2 + \gamma$  are forbidden kinematically or by the absence of flavor changing neutral currents whereas intermediate gauge bosons can decay to on mass shell fermion-antifermion pair).
4. The introduction of IR cutoff for 3-momentum in the rest system associated with the largest  $CD$  (causal diamond) looks natural as scale parameter of coupling constant evolution and p-adic length scale hypothesis favors the inverse of the size scale of  $CD$  coming in powers of two. This parameter would define the momentum resolution as a discrete parameter of the p-adic coupling constant evolution. This scale does not have any counterpart in standard physics. For electron,  $d$  quark, and  $u$  quark the proper time distance between the tips of  $CD$  corresponds to frequency of 10 Hz, 1280 Hz, and 160 Hz: all these frequencies define fundamental bio-rhythms [24] .

These considerations have left completely untouched one important aspect of generalized Feynman diagrams: the necessity to perform a functional integral over the deformations of the partonic 2-surfaces at the ends of the lines- that is integration over WCW. Number theoretical universality requires that WCW and these integrals make sense also p-adically and in the following these aspects of generalized Feynman diagrams are discussed.

**6.6.6 Three basic options for the pseudo-momentum spectrum**

The calculation of the scaling factor of the Kähler function requires the knowledge of the degeneracies of the mass squared eigen values. There are three options to consider.

**First option: all pseudo-momenta are allowed**

If the degeneracy for pseudo-momenta in  $M^2$  is same for all mass values- and formally characterizable by a number  $N$  telling how many 2-D pseudo-momenta reside on mass shell  $n_0^2 - n_3^2 = m^2$ . In this case zeta function would be proportional to a sum of Riemann Zetas with scaled arguments corresponding to scalings of the basic mass  $m$  to  $m/q$ .

$$\zeta_D(s) = N \sum_q \zeta(\log(qx)s) , \quad x = \frac{L_{min}}{R} . \tag{6.6.20}$$

This option provides no idea about the possible values of  $1 \leq q \leq L_{max}/L_{min}$ . The number  $N$  is given by the integral of relativistic density of states  $\int dk/2\sqrt{k^2 + m^2}$  over the hyperbola and is logarithmically divergent so that the normalization factor  $N$  of the Kähler function would be infinite.

### Second option: All integer valued pseudomomenta are allowed

Second option is inspired by number theoretic vision and assumes integer valued components for the momenta using  $m_{max} = 2\pi/L_{min}$  as mass unit. p-Adicization motivates also the assumption that momentum components using  $m_{max}$  as mass scale are integers. This would restrict the choice of the number theoretical braids.

Integer valuedness together with masses coming as integer multiples of  $m_{max}$  implies  $(\lambda_0, \lambda_3) = (n_0, n_3)$  with on mass shell condition  $n_0^2 - n_3^2 = n^2$ . Note that the condition is invariant under scaling. These integers correspond to Pythagorean triangles plus the degenerate situation with  $n_3 = 0$ . There exists a finite number of pairs  $(n_0, n_3)$  satisfying this condition as one finds by expressing  $n_0$  as  $n_0 = n_3 + k$  giving  $2n_3k + k^2 = p^2$  giving  $n_3 < n^2/2, n_0 < n^2/2 + 1$ . This would be enough to have a finite degeneracy  $D(n) \geq 1$  for a given value of mass squared and  $\zeta_D$  would be well defined.  $\zeta_D$  would be a modification of Riemann zeta given by

$$\begin{aligned} \zeta_D &= \sum_q \zeta_1(\log(qx)s) , \quad x = \frac{L_{min}}{R} , \\ \zeta_1(s) &= \sum g_n n^{-s} , \quad g_n \geq 1 . \end{aligned} \tag{6.6.21}$$

For generalized Feynman diagrams this option allows conservation of pseudo-momentum and for loops no divergences are possible since the integral over two-dimensional virtual momenta is replaced with a sum over discrete mass shells containing only a finite number of points. This option looks thus attractive but requires a regularization. On the other hand, the appearance of a zeta function having a strong resemblance with Riemann zeta could explain the finding that Riemann zeta is closely related to the description of critical systems. This point will be discussed later.

### Third option: Infinite primes code for the allowed mass scales

According to the proposal of [70] , [8] the hyper-complex parts of hyper-octonionic primes appearing in their infinite counterparts correspond to the  $M^2$  projections of real four-momenta. This hypothesis suggests a very detailed map between infinite primes and standard model quantum numbers and predicts a universal mass spectrum [70] . Since pseudo-momenta are automatically restricted to the plane  $M^2$ , one cannot avoid the question whether they could actually correspond to the hyper-octonionic primes defining the infinite prime. These interpretations need not of course exclude each other. This option allows several variants and at this stage it is not possible to exclude any of these options.

1. One must choose between two alternatives for which pseudo-momentum corresponds to hyper-complex prime serving as a canonical representative of a hyper-octonionic prime or a projection of hyper-octonionic prime to  $M^2$ .
2. One must decide whether one allows a) only the momenta corresponding to hyper-complex primes, b) also their powers (p-adic fractality), or c) all their integer multiples ("Riemann option").

One must also decide what hyper-octonionic primes are allowed.

1. The first guess is that all hyper-complex/hyper-octonionic primes defining length scale  $\sqrt{p}L_{min} \leq L_{max}$  or  $pL_{min} \leq L_{max}$  are allowed. p-Adic fractality suggests that also the higher p-adic length scales  $p^{n/2}L_{min} < L_{max}$  and  $p^n L_{min} < L_{max}, n \geq 1$ , are possible.

It can however happen that no primes are allowed by this criterion. This would mean vanishing Kähler function which is of course also possible since Kähler action can vanish (for instance, for massless extremals). It seems therefore safer to allow also the scale corresponding to the trivial prime  $(n_0, n_3) = (1, 0)$  (1 is formally prime because it is not divisible by any prime different

from 1) so that at least  $L_{min}$  is possible. This option also allows only rather small primes unless the partonic 2-surface contains vacuum regions in which case  $L_{max}$  is infinite: in this case all primes would be allowed and the exponent of Kähler function would vanish.

2. The hypothesis that only the hyper-complex or hyper-octonionic primes appearing in the infinite hyper-octonionic prime are possible looks more reasonable since large values of  $p$  would be possible and could be identified in terms of the  $p$ -adic length scale hypothesis. All hyper-octonionic primes appearing in infinite prime would be possible and the geometry of the orbit of the partonic 2-surface would define an infinite prime. This would also give a concrete physical interpretation for the earlier hypothesis that hyper-octonionic primes appearing in the infinite prime characterize partonic 2-surfaces geometrically. One can also identify the fermionic and purely bosonic primes appearing in the infinite prime as braid strands carrying fermion number and purely bosonic quantum numbers. This option will be assumed in the following.

## Chapter 7

# Yangian Symmetry, Twistors, and TGD

### 7.1 Introduction

Lubos [57] told for some time ago about last impressive steps in the understanding of  $\mathcal{N} = 4$  maximally supersymmetric YM theory (SYM) possessing 4-D super-conformal symmetry. This theory is related by AdS/CFT duality to certain string theory in  $AdS_5 \times S^5$  background. Second stringy representation was discovered by Witten and based on 6-D Calabi-Yau manifold defined by twistors. In the following I will discuss briefly the notion of Yangian symmetry and suggest its generalization in TGD framework by replacing conformal algebra with appropriate super-conformal algebras. Also a possible realization of twistor approach and the construction of scattering amplitudes in terms of Yangian invariants defined by Grassmannian integrals is considered in TGD framework and based on the idea that in zero energy ontology one can represent massive states as bound states of massless particles. There is also a proposal for a physical interpretation of the Cartan algebra of Yangian algebra allowing to understand at the fundamental level how the mass spectrum of n-particle bound states could be understood in terms of the n-local charges of the Yangian algebra.

Twistors were originally introduced by Penrose to characterize the solutions of Maxwell's equations. Kähler action is Maxwell action for the induced Kähler form of  $CP_2$ . The preferred extremals allow a very concrete interpretation in terms of modes of massless non-linear field. Both conformally compactified Minkowski space identifiable as so called causal diamond and  $CP_2$  allow a description in terms of twistors. These observations inspire the proposal that a generalization of Witten's twistor string theory relying on the identification of twistor string world sheets with certain holomorphic surfaces assigned with Feynman diagrams could allow a formulation of quantum TGD in terms of 3-dimensional holomorphic surfaces of  $CP_3 \times CP_3$  mapped to 6-surfaces dual  $CP_3 \times CP_3$ , which are sphere bundles so that they are projected in a natural manner to 4-D space-time surfaces. Very general physical and mathematical arguments lead to a highly unique proposal for the holomorphic differential equations defining the complex 3-surfaces conjectured to correspond to the preferred extremals of Kähler action.

#### 7.1.1 Background

I am outsider as far as concrete calculations in  $\mathcal{N} = 4$  SUSY are considered and the following discussion of the background probably makes this obvious. My hope is that the reader had patience to not care about this and try to see the big pattern.

The developments began from the observation of Parke and Taylor [60] that n-gluon tree amplitudes with less than two negative helicities vanish and those with two negative helicities have unexpectedly simple form when expressed in terms of spinor variables used to represent light-like momentum. In fact, in the formalism based on Grassmannian integrals the reduced tree amplitude for two negative helicities is just "1" and defines Yangian invariant. The article *Perturbative Gauge Theory As a String Theory In Twistor Space* [70] by Witten led to so called Britto-Cachazo-Feng-Witten (BCFW) recursion relations for tree level amplitudes [62, 35, 62] allowing to construct tree amplitudes using the

analogues of Feynman rules in which vertices correspond to maximally helicity violating tree amplitudes (2 negative helicity gluons) and propagator is massless Feynman propagator for boson. The progress inspired the idea that the theory might be completely integrable meaning the existence of infinite-dimensional un-usual symmetry. This symmetry would be so called Yangian symmetry [84] assigned to the super counterpart of the conformal group of 4-D Minkowski space.

Drumond, Henn, and Plefka represent in the article *Yangian symmetry of scattering amplitudes in  $\mathcal{N} = 4$  super Yang-Mills theory* [42] an argument suggesting that the Yangian invariance of the scattering amplitudes is an intrinsic property of planar  $\mathcal{N} = 4$  super Yang Mills at least at tree level.

The latest step in the progress was taken by Arkani-Hamed, Bourjaily, Cachazo, Carot-Huot, and Trnka and represented in the article *Yangian symmetry of scattering amplitudes in  $\mathcal{N} = 4$  super Yang-Mills theory* [33]. At the same day there was also the article of Rutger Boels entitled *On BCFW shifts of integrands and integrals* [25] in the archive. Arkani-Hamed *et al* argue that a full Yangian symmetry of the theory allows to generalize the BCFW recursion relation for tree amplitudes to all loop orders at planar limit (planar means that Feynman diagram allows imbedding to plane without intersecting lines). On mass shell scattering amplitudes are in question.

### 7.1.2 Yangian symmetry

The notion equivalent to that of Yangian was originally introduced by Faddeev and his group in the study of integrable systems. Yangians are Hopf algebras which can be assigned with Lie algebras as the deformations of their universal enveloping algebras. The elegant but rather cryptic looking definition is in terms of the modification of the relations for generating elements [84]. Besides ordinary product in the enveloping algebra there is co-product  $\Delta$  which maps the elements of the enveloping algebra to its tensor product with itself. One can visualize product and co-product in terms of particle reactions. Particle annihilation is analogous to annihilation of two particles so single one and co-product is analogous to the decay of particle to two.  $\Delta$  allows to construct higher generators of the algebra.

Lie-algebra can mean here ordinary finite-dimensional simple Lie algebra, Kac-Moody algebra or Virasoro algebra. In the case of SUSY it means conformal algebra of  $M^4$ - or rather its super counterpart. Witten, Nappi and Dolan have described the notion of Yangian for super-conformal algebra in very elegant and concrete manner in the article *Yangian Symmetry in  $D=4$  superconformal Yang-Mills theory* [46]. Also Yangians for gauge groups are discussed.

In the general case Yangian resembles Kac-Moody algebra with discrete index  $n$  replaced with a continuous one. Discrete index poses conditions on the Lie group and its representation (adjoint representation in the case of  $\mathcal{N} = 4$  SUSY). One of the conditions is that the tensor product  $R \otimes R^*$  for representations involved contains adjoint representation only once. This condition is non-trivial. For  $SU(n)$  these conditions are satisfied for any representation. In the case of  $SU(2)$  the basic branching rule for the tensor product of representations implies that the condition is satisfied for the product of any representations.

Yangian algebra with a discrete basis is in many respects analogous to Kac-Moody algebra. Now however the generators are labelled by non-negative integers labeling the light-like incoming and outgoing momenta of scattering amplitude whereas in the case of Kac-Moody algebra also negative values are allowed. Note that only the generators with non-negative conformal weight appear in the construction of states of Kac-Moody and Virasoro representations so that the extension to Yangian makes sense.

The generating elements are labelled by the generators of ordinary conformal transformations acting in  $M^4$  and their duals acting in momentum space. These two sets of elements can be labelled by conformal weights  $n = 0$  and  $n = 1$  and their mutual commutation relations are same as for Kac-Moody algebra. The commutators of  $n = 1$  generators with themselves are however something different for a non-vanishing deformation parameter  $h$ . Serre's relations characterize the difference and involve the deformation parameter  $h$ . Under repeated commutations the generating elements generate infinite-dimensional symmetric algebra, the Yangian. For  $h = 0$  one obtains just one half of the Virasoro algebra or Kac-Moody algebra. The generators with  $n > 0$  are  $n + 1$ -local in the sense that they involve  $n + 1$ -forms of local generators assignable to the ordered set of incoming particles of the scattering amplitude. This non-locality generalizes the notion of local symmetry and is claimed to be powerful enough to fix the scattering amplitudes completely.

## 7.2 How to generalize Yangian symmetry in TGD framework?

As far as concrete calculations are considered, I have nothing to say. I am just perplexed. It is however possible to keep discussion at general level and still say something interesting (as I hope!). The key question is whether it could be possible to generalize the proposed Yangian symmetry and geometric picture behind it to TGD framework.

1. The first thing to notice is that the Yangian symmetry of  $\mathcal{N} = 4$  SUSY in question is quite too limited since it allows only single representation of the gauge group and requires massless particles. One must allow all representations and massive particles so that the representation of symmetry algebra must involve states with different masses, in principle arbitrary spin and arbitrary internal quantum numbers. The candidates are obvious: Kac-Moody algebras [16] and Virasoro algebras [35] and their super counterparts. Yangians indeed exist for arbitrary super Lie algebras. In TGD framework conformal algebra of Minkowski space reduces to Poincare algebra and its extension to Kac-Moody allows to have also massive states.
2. The formal generalization looks surprisingly straightforward at the formal level. In zero energy ontology one replaces point like particles with partonic two-surfaces appearing at the ends of light-like orbits of wormhole throats located to the future and past light-like boundaries of causal diamond ( $CD \times CP_2$  or briefly  $CD$ ). Here  $CD$  is defined as the intersection of future and past directed light-cones. The polygon with light-like momenta is naturally replaced with a polygon with more general momenta in zero energy ontology and having partonic surfaces as its vertices. Non-point-likeness forces to replace the finite-dimensional super Lie-algebra with infinite-dimensional Kac-Moody algebras and corresponding super-Virasoro algebras assignable to partonic 2-surfaces.
3. This description replaces disjoint holomorphic surfaces in twistor space with partonic 2-surfaces at the boundaries of  $CD \times CP_2$  so that there seems to be a close analogy with Cachazo-Svrcek-Witten picture. These surfaces are connected by either light-like orbits of partonic 2-surface or space-like 3-surfaces at the ends of  $CD$  so that one indeed obtains the analog of polygon.

What does this then mean concretely (if this word can be used in this kind of context)?

1. At least it means that ordinary Super Kac-Moody and Super Virasoro algebras associated with isometries of  $M^4 \times CP_2$  annihilating the scattering amplitudes must be extended to a co-algebras with a non-trivial deformation parameter. Kac-Moody group is thus the product of Poincare and color groups. This algebra acts as deformations of the light-like 3-surfaces representing the light-like orbits of particles which are extremals of Chern-Simon action with the constraint that weak form of electric-magnetic duality holds true. I know so little about the mathematical side that I cannot tell whether the condition that the product of the representations of Super-Kac-Moody and Super-Virasoro algebras contains adjoint representation only once, holds true in this case. In any case, it would allow all representations of finite-dimensional Lie group in vertices whereas  $\mathcal{N} = 4$  SUSY would allow only the adjoint.
2. Besides this ordinary kind of Kac-Moody algebra there is the analog of Super-Kac-Moody algebra associated with the light-cone boundary which is metrically 3-dimensional. The finite-dimensional Lie group is in this case replaced with infinite-dimensional group of symplectomorphisms of  $\delta M_{+/-}^4$  made local with respect to the internal coordinates of the partonic 2-surface. A coset construction is applied to these two Virasoro algebras so that the differences of the corresponding Super-Virasoro generators and Kac-Moody generators annihilate physical states. This implies that the corresponding four-momenta are same: this expresses the equivalence of gravitational and inertial masses. A generalization of the Equivalence Principle is in question. This picture also justifies p-adic thermodynamics applied to either symplectic or isometry Super-Virasoro and giving thermal contribution to the vacuum conformal and thus to mass squared.
3. The construction of TGD leads also to other super-conformal algebras and the natural guess is that the Yangians of all these algebras annihilate the scattering amplitudes.
4. Obviously, already the starting point symmetries look formidable but they still act on single partonic surface only. The discrete Yangian associated with this algebra associated with the

closed polygon defined by the incoming momenta and the negatives of the outgoing momenta acts in multi-local manner on scattering amplitudes. It might make sense to speak about polygons defined also by other conserved quantum numbers so that one would have generalized light-like curves in the sense that state are massless in 8-D sense.

### 7.2.1 Is there any hope about description in terms of Grassmannians?

At technical level the successes of the twistor approach rely on the observation that the amplitudes can be expressed in terms of very simple integrals over sub-manifolds of the space consisting of  $k$ -dimensional planes of  $n$ -dimensional space defined by delta function appearing in the integrand. These integrals define super-conformal Yangian invariants appearing in twistorial amplitudes and the belief is that by a proper choice of the surfaces of the twistor space one can construct all invariants. One can construct also the counterparts of loop corrections by starting from tree diagrams and annihilating pair of particles by connecting the lines and quantum entangling the states at the ends in the manner dictated by the integration over loop momentum. These operations can be defined as operations for Grassmannian integrals in general changing the values of  $n$  and  $k$ . This description looks extremely powerful and elegant and -most importantly- involves only the external momenta.

The obvious question is whether one could use similar invariants in TGD framework to construct the momentum dependence of amplitudes.

1. The first thing to notice is that the super algebras in question act on infinite-dimensional representations and basically in the world of classical worlds assigned to the partonic 2-surfaces correlated by the fact that they are associated with the same space-time surface. This does not promise anything very practical. On the other hand, one can hope that everything related to other than  $M^4$  degrees of freedom could be treated like color degrees of freedom in  $\mathcal{N} = 4$  SYM and would boil down to indices labeling the quantum states. The Yangian conditions coming from isometry quantum numbers, color quantum numbers, and electroweak quantum numbers are of course expected to be highly non-trivial and could fix the coefficients of various singlets resulting in the tensor product of incoming and outgoing states.
2. The fact that incoming particles can be also massive seems to exclude the use of the twistor space. The following observation however raises hopes. The Dirac propagator for wormhole throat is massless propagator but for what I call pseudo momentum. It is still unclear how this momentum relates to the actual four-momentum. Could it be actually equal to it? The recent view about pseudo-momentum does not support this view but it is better to keep mind open. In any case this finding suggests that twistorial approach could work in in more or less standard form. What would be needed is a representation for massive incoming particles as bound states of massless partons. In particular, the massive states of super-conformal representations should allow this kind of description.

Could zero energy ontology allow to achieve this dream?

1. As far as divergence cancellation is considered, zero energy ontology suggests a totally new approach producing the basic nice aspects of QFT approach, in particular unitarity and coupling constant evolution. The big idea related to zero energy ontology is that all virtual particle particles correspond to wormhole throats, which are pairs of on mass shell particles. If their momentum directions are different, one obtains time-like continuum of virtual momenta and if the signs of energy are opposite one obtains also space-like virtual momenta. The on mass shell property for virtual partons (massive in general) implies extremely strong constraints on loops and one expect that only very few loops remain and that they are finite since loop integration reduces to integration over much lower-dimensional space than in the QFT approach. There are also excellent hopes about Cutkoski rules.
2. Could zero energy ontology make also possible to construct massive incoming particles from massless ones? Could one construct the representations of the super conformal algebras using only massless states so that at the fundamental level incoming particles would be massless and one could apply twistor formalism and build the momentum dependence of amplitudes using Grassmannian integrals.

One could indeed construct on mass shell massive states from massless states with momenta along the same line but with three-momenta at opposite directions. Mass squared is given by  $M^2 = 4E^2$  in the coordinate frame, where the momenta are opposite and of same magnitude. One could also argue that partonic 2-surfaces carrying quantum numbers of fermions and their superpartners serve as the analogs of point like massless particles and that topologically condensed fermions and gauge bosons plus their superpartners correspond to pairs of wormhole throats. Stringy objects would correspond to pairs of wormhole throats at the same space-time sheet in accordance with the fact that space-time sheet allows a slicing by string worlds sheets with ends at different wormhole throats and defining time like braiding.

The weak form of electric magnetic duality indeed supports this picture. To understand how, one must explain a little bit what the weak form of electric magnetic duality means.

1. Elementary particles correspond to light-like orbits of partonic 2-surfaces identified as 3-D surfaces at which the signature of the induced metric of space-time surface changes from Euclidian to Minkowskian and 4-D metric is therefore degenerate. The analogy with black hole horizon is obvious but only partial. Weak form of electric-magnetic duality states that the Kähler electric field at the wormhole throat and also at space-like 3-surfaces defining the ends of the space-time surface at the upper and lower light-like boundaries of the causal diamond is proportional to Kähler magnetic field so that Kähler electric flux is proportional Kähler magnetic flux. This implies classical quantization of Kähler electric charge and fixes the value of the proportionality constant.
2. There are also much more profound implications. The vision about TGD as almost topological QFT suggests that Kähler function defining the Kähler geometry of the "world of classical worlds" (WCW) and identified as Kähler action for its preferred extremal reduces to the 3-D Chern-Simons action evaluated at wormhole throats and possible boundary components. Chern-Simons action would be subject to constraints. Wormhole throats and space-like 3-surfaces would represent extremals of Chern-Simons action restricted by the constraint force stating electric-magnetic duality (and realized in terms of Lagrange multipliers as usual).

If one assumes that Kähler current and other conserved currents are proportional to current defining Beltrami flow whose flow lines by definition define coordinate curves of a globally defined coordinate, the Coulombic term of Kähler action vanishes and it reduces to Chern-Simons action if the weak form of electric-magnetic duality holds true. One obtains almost topological QFT. The absolutely essential attribute "almost" comes from the fact that Chern-Simons action is subject to constraints. As a consequence, one obtains non-vanishing four-momenta and WCW geometry is non-trivial in  $M^4$  degrees of freedom. Otherwise one would have only topological QFT not terribly interesting physically.

Consider now the question how one could understand stringy objects as bound states of massless particles.

1. The observed elementary particles are not Kähler monopoles and there much exist a mechanism neutralizing the monopole charge. The only possibility seems to be that there is opposite Kähler magnetic charge at second wormhole throat. The assumption is that in the case of color neutral particles this throat is at a distance of order intermediate gauge boson Compton length. This throat would carry weak isospin neutralizing that of the fermion and only electromagnetic charge would be visible at longer length scales. One could speak of electro-weak confinement. Also color confinement could be realized in analogous manner by requiring the cancellation of monopole charge for many-parton states only. What comes out are string like objects defined by Kähler magnetic fluxes and having magnetic monopoles at ends. Also more general objects with three strings branching from the vertex appear in the case of baryons. The natural guess is that the partons at the ends of strings and more general objects are massless for incoming particles but that the 3-momenta are in opposite directions so that stringy mass spectrum and representations of relevant super-conformal algebras are obtained. This description brings in mind the description of hadrons in terms of partons moving in parallel apart from transversal momentum about which only momentum squared is taken as observable.

2. Quite generally, one expects for the preferred extremals of Kähler action the slicing of space-time surface with string world sheets with stringy curves connecting wormhole throats. The ends of the stringy curves can be identified as light-like braid strands. Note that the strings themselves define a space-like braiding and the two braidings are in some sense dual. This has a concrete application in TGD inspired quantum biology, where time-like braiding defines topological quantum computer programs and the space-like braidings induced by it its storage into memory. Stringlike objects defining representations of super-conformal algebras must correspond to states involving at least two wormhole throats. Magnetic flux tubes connecting the ends of magnetically charged throats provide a particular realization of stringy on mass shell states. This would give rise to massless propagation at the parton level. The stringy quantization condition for mass squared would read as  $4E^2 = n$  in suitable units for the representations of super-conformal algebra associated with the isometries. For pairs of throats of the same wormhole contact stringy spectrum does not seem plausible since the wormhole contact is in the direction of  $CP_2$ . One can however expect generation of small mass as deviation of vacuum conformal weight from half integer in the case of gauge bosons.

If this picture is correct, one might be able to determine the momentum dependence of the scattering amplitudes by replacing free fermions with pairs of monopoles at the ends of string and topologically condensed fermions gauge bosons with pairs of this kind of objects with wormhole throat replaced by a pair of wormhole throats. This would mean suitable number of doublings of the Grassmannian integrations with additional constraints on the incoming momenta posed by the mass shell conditions for massive states.

### 7.2.2 Could zero energy ontology make possible full Yangian symmetry?

The partons in the loops are on mass shell particles have a discrete mass spectrum but both signs of energy are possible for opposite wormhole throats. This implies that in the rules for constructing loop amplitudes from tree amplitudes, propagator entanglement is restricted to that corresponding to pairs of partonic on mass shell states with both signs of energy. As emphasized in [33], it is the Grassmannian integrands and leading order singularities of  $\mathcal{N} = 4$  SYM, which possess the full Yangian symmetry. The full integral over the loop momenta breaks the Yangian symmetry and brings in IR singularities. Zero energy ontologist finds it natural to ask whether QFT approach shows its inadequacy both via the UV divergences and via the loss of full Yangian symmetry. The restriction of virtual partons to discrete mass shells with positive or negative sign of energy imposes extremely powerful restrictions on loop integrals and resembles the restriction to leading order singularities. Could this restriction guarantee full Yangian symmetry and remove also IR singularities?

### 7.2.3 Could Yangian symmetry provide a new view about conserved quantum numbers?

The Yangian algebra has some properties which suggest a new kind of description for bound states. The Cartan algebra generators of  $n = 0$  and  $n = 1$  levels of Yangian algebra commute. Since the co-product  $\Delta$  maps  $n = 0$  generators to  $n = 1$  generators and these in turn to generators with high value of  $n$ , it seems that they commute also with  $n \geq 1$  generators. This applies to four-momentum, color isospin and color hyper charge, and also to the Virasoro generator  $L_0$  acting on Kac-Moody algebra of isometries and defining mass squared operator.

Could one identify total four momentum and Cartan algebra quantum numbers as sum of contributions from various levels? If so, the four momentum and mass squared would involve besides the local term assignable to wormhole throats also  $n$ -local contributions. The interpretation in terms of  $n$ -parton bound states would be extremely attractive.  $n$ -local contribution would involve interaction energy. For instance, string like object would correspond to  $n = 1$  level and give  $n = 2$ -local contribution to the momentum. For baryonic valence quarks one would have 3-local contribution corresponding to  $n = 2$  level. The Yangian view about quantum numbers could give a rigorous formulation for the idea that massive particles are bound states of massless particles.

### 7.2.4 What about the selection of preferred $M^2 \subset M^4$ ?

The puzzling aspect of the proposed picture is the restriction of the pseudo-momenta to  $M^2$  and quite generally the the selection of preferred plane  $M^2 \subset M^4$ . This selection is one the key aspects of TGD but is not too well understood. Also the closely related physical interpretation of the 2-D pseudo-momenta in  $M^2$  is unclear.

#### The avatars of $M^2 \subset M^4$ in quantum TGD

The choice of preferred plane  $M^2 \subset M^4$  pops u again and again in quantum TGD.

1. There are very strong reasons to believe that the solutions of field equations for the preferred extremals assign  $M^2$  to each point of space-time surface and the interpretation is as the plane of non-physical polarizations. One can also consider the possibility that  $M^2$  depends on the point of space-time surface but that the different choices integrate to 2-D surface analogous to string world sheet - very naturally projection of stringy worlds sheets defining the slicing of the space-time surface.
2. The number theoretic vision- in particular  $M^8 - H$  duality ( $H = M^4 \times CP_2$ ) providing a purely number theoretic interpretation for the choice  $H = M^4 \times CP_2$  - involves also the selection of preferred  $M^2$ . The duality states that the surfaces in  $H$  can be regarded equivalently as surfaces in  $M^8$ . The induced metric and Kähler form are identical as also the value of Kähler function. The description of the duality is following.
  - (a) The points of space-time surface in  $M^8 = M^4 \times E^4$  in  $M^8$  are mapped to points of space-time surface in  $M^4 \times CP_2$ . The  $M^4$  part of the map is just a projection.
  - (b)  $CP_2$  part of the map is less trivial. The idea is that  $M^8$  is identified as a subspace of complexified octonions obtained by adding commutative imaginary unit, I call this sub-space hyper-octonionic. Suppose that space-time surface is hyper-quaternionic (in appropriate sense meaning that one can attach to its each point a hyper-quaternionic plane, not necessary tangent plane). Assume that it also contains a preferred hypercomplex plane  $M^2$  of  $M^8$  at each point -or more generally a varying plane  $M^2$  planes whose distribution however integrates to form 2-surface analogous to string world sheet. The interpretation is as a preferred plane of non-physical polarizations so that basic aspect of gauge symmetry would have a number theoretic interpretation. Note that one would thus have a local hierarchy of octonionic, quaternionic, and complex planes.
  - (c) Under these assumptions the tangent plane (if action is just the four-volume or its generalization in the case of Kähler action) is characterized by a point of  $CP_2 = SU(3)/U(2)$  where  $SU(3)$  is automorphism group of octonions respecting preferred plane  $M^2$  of polarizations and  $U(2)$  is automorphism group acting in the hyper-quaternionic plane. This point can be identified as a point of  $CP_2$  so that one obtains the duality.
3. Also the definition of  $CD$ s and the proposed construction of the hierarchy of Planck constants involve a choice of preferred  $M^2$ , which corresponds to the choice of rest frame and quantization axis of angular momentum physically. Therefore the choice of quantization axis would have direct correlates both at the level of  $CD$ s and space-time surface. The vector between the tips of  $CD$  indeed defines preferred direction of time and thus rest system. Similar considerations apply in the case of  $CP_2$ .
4. Preferred  $M^2$  -but now at this time at momentum space level - appears as the plane of pseudo-momenta associated with the generalized eigen modes of the modified Dirac equation associated with Chern-Simons action. Internally consistency requires a restriction to this plane. This looks somewhat mysterious since this would mean that all exchanged virtual momenta would be in  $M^2$  if the choice is same for all lines of the generalized Feynman graph. This would restrict momentum exchanges in particle reactions to single dimension and does not make sense. One must however notice that in the description of hadronic reactions in QCD picture one makes a choice of longitudinal momentum direction and considers only longitudinal momenta. It would seem that the only possibility is that the planes  $M^2$  are independent for independent exchanged

momenta. For instance, in  $2 \rightarrow 2$  scattering the exchange would be in plane defined by the initial and final particles of the vertex. There are also good arguments for a number theoretic quantization of the momenta in  $M^2$ .

The natural expectation from  $M^8 - H$  duality is that the selection of preferred  $M^2$  implies a reduction of symmetries to those of  $M^2 \times E^6$  and  $M^2 \times E^2 \times CP_2$ . Could the equivalence of  $M^8$  and  $H$  descriptions force the reduction of  $M^4$  momentum to  $M^2$  momentum implied also by the generalized eigen value equation for the modified Dirac operator at wormhole throats?

### The moduli space associated with the choice of $M^2$

Lorentz invariance requires that one must have moduli space of  $CD$ s with fixed tips defined as  $SO(3,1)/SO(1) \times SO(2)$  characterizing different choices of  $M^2$ . Maximal Lorentz invariance requires the association of this moduli space to all lines of the generalized Feynman graph. It is easy to deduce that this space is actually the hyperboloid of 5-D Minkowski space. The moduli space is 4-dimensional and has Euclidian signature of the metric. This follows from the fact that  $SO(3,1)$  has Euclidian signature as a surface in the four-fold Cartesian power  $H(1,3)^4$  of Lobatchevski space with points identified as four time-like unit vectors defining rows of the matrix representing Lorentz transformation. This surface is defined by the 6 orthogonality conditions for the rows of the Lorentz transformation matrix constraints stating the orthogonality of the 4 unit vectors. The Euclidian signature fixes the identification of the moduli space as  $H(1,5)$  having Euclidian signature of metric. The 10-D isometry group  $SO(1,5)$  of the moduli space acts as symmetries of 5-D Minkowski space (note that the conformal group of  $M^4$  is  $SO(2,4)$ ). The non-compactness of this space does not favor the idea of wave function in moduli degrees of freedom.

Concerning the interpretation of pseudo-momenta it is best to be cautious and make only questions. Should one assume that  $M^2$  for the exchanged particle is fixed by the initial and final momenta of the particle emitting it? How to fix in this kind of situation a unique coordinate frame in which the number theoretic quantization of exchanged momenta takes place? Could it be the rest frame for the initial state of the emitting particle so that one should allow also boosts of the number theoretically preferred momenta? Should one only assume the number theoretically preferred mass values for the exchanged particle but otherwise allow the hyperbolic angle characterizing the energy vary freely?

### 7.2.5 Does $M^8 - H$ duality generalize the duality between twistor and momentum twistor descriptions?

$M^8 - H$  duality is intuitively analogous to the duality of elementary wave mechanics meaning that one can use either x-space or momentum space to describe particles.  $M^8$  is indeed the tangent space of  $H$  and one could say that  $M^8 - H$  duality assigns to a 4-surface in  $H$  its "momentum" or tangent as a 4-surface in  $M^8$ . The more concrete identification of  $M^8$  as cotangent bundle of  $H$  so that its points would correspond to 8-momenta: this very naive picture is of course not correct.

$M^8 - H$  duality suggests that the descriptions using isometry groups of  $M^4 \times E^4$  and  $M^4 \times CP_2$  -or as the special role of  $M^2$  suggests - those of  $M^2 \times E^6$  and  $M^2 \times E^2 \times CP_2$  should be equivalent. The interpretation in hadron physics context would be that  $SO(4)$  is the counterpart of color group in low energy hadron physics acting on strong isospin degrees of freedom and  $SU(3)$  that of QCD description useful at high energies.  $SO(4)$  is indeed used in old fashioned hadron physics when quarks and gluons had not yet been introduced. Skyrme model is one example.

The obvious question is whether the duality between descriptions based on twistors and momentum space twistors generalizes to  $M^8 - H$  duality. The basic objection is that the charges and their duals should correspond to the same Lie algebra- or rather Kac-Moody algebra. This is however not the case. For the massless option one has  $SO(2) \times SU(3)$  at H-side and  $SO(2) \times SO(4)$  or  $SO(6)$  and  $M^8$  side. This suggests that  $M^8 - H$  duality is analogous to the duality between descriptions using twistors and momentum space twistors and transforms the local currents  $J_0$  to non-local currents  $J_1$  and vice versa. This duality would be however be more general in the sense that would relate Yangian symmetries with different Kac-Moody groups transforming locality to non-locality and vice versa. This interpretation is consistent with the fact that the groups  $SO(2) \times SO(4)$ ,  $SO(6)$  and  $SO(2) \times SU(3)$  have same rank and the standard construction of Kac-Moody generators in terms of exponentials of the Cartan algebra involves only different weights in the exponentials.

If  $M^8 - H$  duality has something to do with the duality between descriptions using twistors and momentum space twistors involved with Yangian symmetry, it should be consistent with the basic aspects of the latter duality. The following arguments provide support for this.

1.  $SO(4)$  should appear as a dynamical symmetry at  $M^4 \times CP_2$  side and  $SU(3)$  at  $M^8$  side (where it indeed appears as both subgroup of isometries and as tangent space group respecting the choice of  $M^2$ . One could consider the breaking of  $SO(4)$  to the subgroup corresponding to vectorial transformations and interpreted in terms of electroweak vectorial  $SU(2)$ : this would conform with conserved vector current hypothesis and partially conserved axial current hypothesis. The  $U(1)$  factor assignable to Kähler form is also present and allows Kac-Moody variant and an extension to Yangian.
2. The heuristics of twistorial approach suggests that the roles of currents  $J_0$  and their non-local duals  $J_1$  in Minkowski space are changed in the transition from  $H$  description to  $M^8$  description in the sense that the non-local currents  $J_1$  in  $H$  description become local currents in 8-momentum space (or 4-momentum +strong isospin) in  $M^8$  description and  $J_0$  becomes non-local one. In the case of hadron physics the non-local charges assignable to hadrons as collections of partons would become local charges meaning that one can assign them to partonic 2-surfaces at boundaries of  $CDs$  assigned to  $M^8$ : this says that hadrons are the only possible final states of particle reactions. By the locality it would be impossible decompose momentum and strong isospin to a collection of momenta and strong isospins assigned to partons.
3. In  $H$  description it would be impossible to do decompose quantum numbers to those of quarks and gluons at separate uncorrelated partonic 2-surfaces representing initial and final states of particle reaction. A possible interpretation would be in terms of monopole confinement accompanying electroweak and color confinement: single monopole is not a particle. In  $M^4 \times E^4$  monopoles must be also present since induced Kähler forms are identical. The Kähler form represents magnetic monopole in  $E^4$  and breaks its translational symmetry and also selects unique  $M^4 \times E^4$  decomposition.
4. Since the physics should not depend on its description, color should be confined also now. Indeed, internal quantum numbers should be assigned in  $M^8$  picture to a wave function in  $M^2 \times E^6$  and symmetries would correspond to  $SO(1,1) \times SO(6)$  or - if broken- to those of  $SO(1,1) \times G$ ,  $G = SO(2) \times SO(4)$  or  $G = SO(3) \times SO(3)$ . Color would be completely absent in accordance with the idea that fundamental observable objects are color singlets. Instead of color one would have  $SO(4)$  quantum numbers and  $SO(4)$  confinement: note that the rank of this group crucial for Kac-Moody algebra construction is same as that of  $SU(3)$ .

It is not clear whether the numbers of particle states should be same for  $SO(4)$  and  $SU(3)$ . If so, quark triplet should correspond to doublet and singlet for strong vectorial isospin in  $M^8$  picture. Gluons would correspond to  $SU(2)_V$  multiplets contained by color octet and would therefore contain also other representations than adjoint. This could make sense in composite particle interpretation.

5. For  $M^2 \times E^2$  longitudinal momentum and helicity would make sense and one could speak of massless strong isospin at  $M^8$  side and massless color at  $H$ -side: note that massless color is the only possibility. For  $M^2 \times SO(6)$  option one would have 15-D adjoint representation of  $SO(6)$  decomposing as  $3 \times 3 + 3 \times 1 + 1 \times 3$  under  $SO(3) \times SO(3)$ . This could be interpreted in terms of spin and vectorial isospin for massive particles so that the multiplets would relate to weak gauge bosons and Higgs boson singlet and triplet plus its pseudoscalar variant. For 4-D representation of  $SO(6)$  one would have  $2 \times 2$  decomposition having interpretation in terms of spin and vectorial isospin.

Massive spin would be associated as a local notion with  $M^2 \times E^3$  and would be essentially 5-D concept. At  $H$  side massive particle would make sense only as a non-local notion with four-momentum and mass represented as a non-local operator.

These arguments indeed encourage to think that  $M^8 - H$  duality could be the analog for the duality between the descriptions in terms of twistors and momentum twistors. In this case the Kac-Moody algebras are however not identical since the isometry groups are not identical.

### 7.3 Some mathematical details about Grassmannian formalism

In the following I try to summarize my amateurish understanding about the mathematical structure behind the Grassmann integral approach. The representation summarizes what I have gathered from the articles of Arkani-Hamed and collaborators [58, 33] . These articles are rather sketchy and the article of Bullimore provides additional details [28] related to soft factors. The article of Mason and Skinner provides excellent introduction to super-twistors [42] and dual super-conformal invariance. I apologize for unavoidable errors.

Before continuing a brief summary about the history leading to the articles of Arkani-Hamed and others is in order. This summary covers only those aspects which I am at least somewhat familiar with and leaves out many topics about existence which I am only half-conscious.

1. It is convenient to start by summarizing the basic facts about bi-spinors and their conjugates allowing to express massless momenta as  $p^{aa'} = \lambda_a \tilde{\lambda}_{a'}$  with  $\tilde{\lambda}$  defined as complex conjugate of  $\lambda$  and having opposite chirality. When  $\lambda$  is scaled by a complex number  $\tilde{\lambda}$  suffers an opposite scaling. The bi-spinors allow the definition of various inner products

$$\begin{aligned} \langle \lambda, \mu \rangle &= \epsilon_{ab} \lambda^a \mu^b , \\ [\tilde{\lambda}, \tilde{\mu}] &= \epsilon_{a'b'} \lambda^{a'} \mu^{b'} , \\ p \cdot q &= \langle \lambda, \mu \rangle [\tilde{\lambda}, \tilde{\mu}] , \quad (q_{aa'} = \mu_a \tilde{\mu}_{a'}) . \end{aligned} \quad (7.3.1)$$

If the particle has spin one can assign it a positive or negative helicity  $h = \pm 1$  . Positive helicity can be represented by introducing arbitrary negative (positive) helicity bispinor  $\mu_a$  ( $\mu_{a'}$ ) not parallel to  $\lambda_a$  ( $\mu_{a'}$ ) so that one can write for the polarization vector

$$\begin{aligned} \epsilon_{aa'} &= \frac{\mu_a \tilde{\lambda}_{a'}}{\langle \mu, \lambda \rangle} , \quad \text{positive helicity} , \\ \epsilon_{aa'} &= \frac{\lambda_a \tilde{\mu}_{a'}}{[\tilde{\mu}, \tilde{\lambda}]} , \quad \text{negative helicity} . \end{aligned} \quad (7.3.2)$$

In the case of momentum twistors the  $\mu$  part is determined by different criterion to be discussed later.

2. Tree amplitudes are considered and it is convenient to drop the group theory factor  $Tr(T_1 T_2 \cdots T_n)$ . The starting point is the observation that tree amplitude for which more than  $n - 2$  gluons have the same helicity vanish. MHV amplitudes have exactly  $n - 2$  gluons of same helicity- taken by a convention to be negative- have extremely simple form in terms of the spinors and reads as

$$A_n = \frac{\langle \lambda_x, \lambda_y \rangle^4}{\prod_{i=1}^n \langle \lambda_i, \lambda_{i+1} \rangle} \quad (7.3.3)$$

When the sign of the helicities is changed  $\langle \cdot \rangle$  is replaced with  $[\cdot]$ .

3. The article of Witten [70] proposed that twistor approach could be formulated as a twistor string theory with string world sheets "living" in 6-dimensional  $CP_3$  possessing Calabi-Yau structure and defining twistor space. In this article Witten introduced what is known as half Fourier transform allowing to transform momentum integrals over light-cone to twistor integrals. This operation makes sense only in space-time signature  $(2, 2)$ . Witten also demonstrated that maximal helicity violating (MHV) twistor amplitudes (two gluons with negative helicity) with  $n$  particles with  $k + 2$  negative helicities and  $l$  loops correspond in this approach to holomorphic

2-surfaces defined by polynomials defined by polynomials of degree  $D = k - 1 + l$ , where the genus of the surface satisfies  $g \leq l$ . AdS/CFT duality provides a second stringy approach to  $\mathcal{N} = 4$  theory allowing to understand the scattering amplitudes in terms of Wilson loops with light-like edges: about this I have nothing to say. In any case, the generalization of twistor string theory to TGD context is highly attractive idea and will be considered later.

4. In the article [35] Cachazo, Svrcek, and Witten propose the analog of Feynman diagrammatics in which MHV amplitudes can be used as analogs of vertices and ordinary  $1/P^2$  propagator as propagator to construct tree diagrams with arbitrary number of negative helicity gluons. This approach is not symmetric with respect to the change of the sign of helicities since the amplitudes with two positive helicities are constructed as tree diagrams. The construction is non-trivial because one must analytically continue the on mass shell tree amplitudes to off mass shell momenta. The problem is how to assign a twistor to these momenta. This is achieved by introducing an arbitrary twistor  $\eta^{a'}$  and defining  $\lambda_a$  as  $\lambda_a = p_{aa'}\eta^{a'}$ . This works for both massless and massive case. It however leads to a loss of the manifest Lorentz invariance. The paper however argues and the later paper [62, 62] shows rigorously that the loss is only apparent. In this paper also BCFW recursion formula is introduced allowing to construct tree amplitudes recursively by starting from vertices with 2 negative helicity gluons. Also the notion which has become known as BCFW bridge representing the massless exchange in these diagrams is introduced. The tree amplitudes are not tree amplitudes in gauge theory sense where correspond to leading singularities for which 4 or more lines of the loop are massless and therefore collinear. What is important that the very simple MHV amplitudes become the building blocks of more complex amplitudes.
5. The next step in the progress was the attempt to understand how the loop corrections could be taken into account in the construction BCFW formula. The calculation of loop contributions to the tree amplitudes revealed the existence of dual super-conformal symmetry which was found to be possessed also by BCFW tree amplitudes besides conformal symmetry. Together these symmetries generate infinite-dimensional Yangian symmetry [42].
6. The basic vision of Arkani-Hamed and collaborators is that the scattering amplitudes of  $\mathcal{N} = 4$  SYM are constructible in terms of leading order singularities of loop diagrams. These singularities are obtained by putting maximum number of momenta propagating in the lines of the loop on mass shell. The non-leading singularities would be induced by the leading singularities by putting smaller number of momenta on mass shell are dictated by these terms. A related idea serving as a starting point in [58] is that one can define loop integrals as residue integrals in momentum space. If I have understood correctly, this means that one can imagine the possibility that the loop integral reduces to a lower dimensional integral for on mass shell particles in the loops: this would resemble the approach to loop integrals based on unitarity and analyticity. In twistor approach these momentum integrals defined as residue integrals transform to residue integrals in twistor space with twistors representing massless particles. The basic discovery is that one can construct leading order singularities for  $n$  particle scattering amplitude with  $k + 2$  negative helicities as Yangian invariants  $Y_{n,k}$  for momentum twistors and invariants constructed from them by canonical operations changing  $n$  and  $k$ . The correspondence  $k = l$  does not hold true for the more general amplitudes anymore.

### 7.3.1 Yangian algebra and its super counterpart

The article of Witten [46] gives a nice discussion of the Yangian algebra and its super counterpart. Here only basic formulas can be listed and the formulas relevant to the super-conformal case are given.

#### Yangian algebra

Yangian algebra  $Y(G)$  is associative Hopf algebra. The elements of Yangian algebra are labelled by non-negative integers so that there is a close analogy with the algebra spanned by the generators of Virasoro algebra with non-negative conformal weight. The Yangian symmetry algebra is defined by the following relations for the generators labeled by integers  $n = 0$  and  $n = 1$ . The first half

of these relations discussed in very clear manner in [46] follows uniquely from the fact that adjoint representation of the Lie algebra is in question

$$[J^A, J^B] = f_C^{AB} J^C \quad , \quad [J^A, J^{(1)B}] = f_C^{AB} J^{(1)C} \quad . \quad (7.3.4)$$

Besides this Serre relations are satisfied. These have more complex and read as

$$\begin{aligned} & [J^{(1)A}, [J^{(1)B}, J^C]] + [J^{(1)B}, [J^{(1)C}, J^A]] + [J^{(1)C}, [J^{(1)A}, J^B]] \\ & \quad = \frac{1}{24} f^{ADK} f^{BEL} f^{CFM} f_{KLM} \{J_D, J_E, J_F\} \quad , \\ & [[J^{(1)A}, J^{(1)B}], [J^C, J^{(1)D}]] + [[J^{(1)C}, J^{(1)D}], [J^A, J^{(1)B}]] \\ & \quad = \frac{1}{24} f^{AGL} f^{BEM} f_K^{CD} \\ & \quad + f^{CGL} f^{DEM} f_K^{AB} f^{KFN} f_{LMN} \{J_G, J_E, J_F\} \quad . \end{aligned} \quad (7.3.5)$$

The indices of the Lie algebra generators are raised by invariant, non-degenerate metric tensor  $g_{AB}$  or  $g^{AB}$ .  $\{A, B, C\}$  denotes the symmetrized product of three generators.

Repeated commutators allow to generate the entire algebra whose elements are labeled by non-negative integer  $n$ . The generators obtain in this manner are  $n$ -local operators arising in  $(n-1)$ -commutator of  $J^{(1)}$ :s. For  $SU(2)$  the Serre relations are trivial. For other cases the first Serre relation implies the second one so the relations are redundant. Why Witten includes it is for the purposed of demonstrating the conditions for the existence of Yangians associated with discrete one-dimensional lattices (Yangians exists also for continuum one-dimensional index).

Discrete one-dimensional lattice provides under certain consistency conditions a representation for the Yangian algebra. One assumes that each lattice point allows a representation  $R$  of  $J^A$  so that one has  $J^A = \sum_i J_i^A$  acting on the infinite tensor power of the representation considered. The expressions for the generators  $J^{1A}$  are given as

$$J^{(1)A} = f_{BC}^A \sum_{i < j} J_i^B J_j^C \quad . \quad (7.3.6)$$

This formula gives the generators in the case of conformal algebra. This representation exists if the adjoint representation of  $G$  appears only one in the decomposition of  $R \otimes R$ . This is the case for  $SU(N)$  if  $R$  is the fundamental representation or is the representation of by  $k^{th}$  rank completely antisymmetric tensors.

This discussion does not apply as such to  $\mathcal{N} = 4$  case the number of lattice points is finite and corresponds to the number of external particles so that cyclic boundary conditions are needed guarantee that the number of lattice points reduces effectively to a finite number. Note that the Yangian in color degrees of freedom does not exist for  $SU(N)$  SYM.

As noticed, Yangian algebra is a Hopf algebra and therefore allows co-product. The co-product  $\Delta$  is given by

$$\begin{aligned} \Delta(J^A) & = J^A \otimes 1 + 1 \otimes J^A \quad , \\ \Delta(J^{(1)A}) & = J^{(1)A} \otimes 1 + 1 \otimes J^{(1)A} + f_{BC}^A J^B \otimes J^C \quad per, \end{aligned} \quad (7.3.7)$$

$\Delta$  allows to imbed Lie algebra to the tensor product in non-trivial manner and the non-triviality comes from the addition of the dual generator to the trivial co-product. In the case that the single spin representation of  $J^{(1)A}$  is trivial, the co-product gives just the expression of the dual generator using the ordinary generators as a non-local generator. This is assumed in the recent case and also for the generators of the conformal Yangian.

### Super-Yangian

Also the Yangian extensions of Lie super-algebras make sense. From the point of physics especially interesting Lie super-algebras are  $SU(m|m)$  and  $U(m|m)$ . The reason is that  $PSU(2, 2|4)$  ( $P$  refers to "projective") acting as super-conformal symmetries of  $\mathcal{N} = 4$  SYM and this super group is a real form of  $PSU(4|4)$ . The main point of interest is whether this algebra allows Yangian representation and Witten demonstrated that this is indeed the case [46].

These algebras are  $Z_2$  graded and decompose to bosonic and fermionic parts which in general correspond to  $n$ - and  $m$ -dimensional representations of  $U(n)$ . The representation associated with the fermionic part dictates the commutation relations between bosonic and fermionic generators. The anticommutator of fermionic generators can contain besides identity also bosonic generators if the symmetrized tensor product in question contains adjoint representation. This is the case if fermions are in the fundamental representation and its conjugate. For  $SU(3)$  the symmetrize tensor product of adjoint representations contains adjoint (the completely symmetric structure constants  $d_{abc}$ ) and this might have some relevance for the super  $SU(3)$  symmetry.

The elements of these algebras in the matrix representation (no Grassmann parameters involved) can be written in the form

$$x = \begin{pmatrix} a & b \\ c & d \end{pmatrix} .$$

$a$  and  $d$  representing the bosonic part of the algebra are  $n \times n$  matrices and  $m \times m$  matrices corresponding to the dimensions of bosonic and fermionic representations.  $b$  and  $c$  are fermionic matrices are  $n \times m$  and  $m \times n$  matrices, whose anticommutator is the direct sum of  $n \times n$  and  $n \times n$  matrices. For  $n = m$  bosonic generators transform like Lie algebra generators of  $SU(n) \times SU(n)$  whereas fermionic generators transform like  $n \otimes \bar{n} \oplus \bar{n} \otimes n$  under  $SU(n) \times SU(n)$ . Supertrace is defined as  $Str(x) = Tr(a) - Tr(b)$ . The vanishing of Str defines  $SU(n|m)$ . For  $n \neq m$  the super trace condition removes identity matrix and  $PU(n|m)$  and  $SU(n|m)$  are same. That this does not happen for  $n = m$  is an important delicacy since this case corresponds to  $\mathcal{N} = 4$  SYM. If any two matrices differing by an additive scalar are identified (projective scaling as now physical effect) one obtains  $PSU(n|n)$  and this is what one is interested in.

Witten shows that the condition that adjoint is contained only once in the tensor product  $R \otimes \bar{R}$  holds true for the physically interesting representations of  $PSU(2, 2|4)$  so that the generalization of the bilinear formula can be used to define the generators of  $J^{(1)A}$  of super Yangian of  $PU(2, 2|4)$ . The defining formula for the generators of the Super Yangian reads as

$$\begin{aligned} J_C^{(1)} &= g_{CC'} J^{(1)C'} = g_{CC'} f_{AB}^{C'} \sum_{i < j} J_i^A J_j^B \\ &= g_{CC'} f_{AB}^{C'} g^{AA'} g^{BB'} \sum_{i < j} J_{A'}^i J_{B'}^j . \end{aligned} \tag{7.3.8}$$

Here  $g_{AB} = Str(J_A J_B)$  is the metric defined by super trace and distinguishes between  $PSU(4|4)$  and  $PSU(2, 2|4)$ . In this formula both generators and super generators appear.

### Generators of super-conformal Yangian symmetries

The explicit formula for the generators of super-conformal Yangian symmetries in terms of ordinary twistors is given by

$$\begin{aligned} j_B^A &= \sum_{i=1}^n Z_i^A \partial_{Z_i^B} , \\ j_B^{(1)A} &= \sum_{i < j} (-1)^C \left[ Z_i^A \partial_{Z_j^C} Z_j^C \partial_{Z_j^B} \right] . \end{aligned} \tag{7.3.9}$$

This formula follows from completely general formulas for the Yangian algebra discussed above and allowing to express the dual generators  $j_N^{(1)}$  as quadratic expression of  $j_N$  involving structures constants. In this rather sketchy formula twistors are ordinary twistors. Note however that in the recent case the lattice is replaced with its finite cutoff corresponding to the external particles of the scattering amplitude. This probably corresponds to the assumption that for the representations considered only finite number of lattice points correspond to non-trivial quantum numbers or to cyclic symmetry of the representations.

In the expression for the amplitudes the action of transformations is on the delta functions and by partial integration one finds that a total divergence results. This is easy to see for the linear generators but not so for the quadratic generators of the dual super-conformal symmetries. A similar formula but with  $j_B^A$  and  $j_B^{(1)A}$  interchanged applies in the representation of the amplitudes as Grassmann integrals using ordinary twistors. The verification of the generalization of Serre formula is also straightforward.

### 7.3.2 Twistors and momentum twistors and super-symmetrization

In [42] the basics of twistor geometry are summarized. Despite this it is perhaps good to collect the basic formulas here.

#### Conformally compactified Minkowski space

Conformally compactified Minkowski space can be described as  $SO(2,4)$  invariant (Klein) quadric

$$T^2 + V^2 - W^2 - X^2 - Y^2 - Z^2 = 0 \quad . \quad (7.3.10)$$

The coordinates  $(T, V, W, X, Y, Z)$  define homogenous coordinates for the real projective space  $RP^5$ . One can introduce the projective coordinates  $X_{\alpha\beta} = -X_{\beta\alpha}$  through the formulas

$$\begin{aligned} X_{01} &= W - V \quad , & X_{02} &= Y + iX \quad , & X_{03} &= \frac{i}{\sqrt{2}}T - Z \quad , \\ X_{12} &= -\frac{i}{\sqrt{2}}(T + Z) \quad , & X_{13} &= Y - iX \quad , & X_{23} &= \frac{1}{2}(V + W) \quad . \end{aligned} \quad (7.3.11)$$

The motivation is that the equations for the quadric defining the conformally compactified Minkowski space can be written in a form which is manifestly conformally invariant:

$$\epsilon^{\alpha\beta\gamma\delta} X_{\alpha\beta} X_{\gamma\delta} = 0 \quad . \quad (7.3.12)$$

The points of the conformally compactified Minkowski space are null separated if and only if the condition

$$\epsilon^{\alpha\beta\gamma\delta} X_{\alpha\beta} Y_{\gamma\delta} = 0 \quad (7.3.13)$$

holds true.

#### Correspondence with twistors and infinity twistor

One ends up with the correspondence with twistors by noticing that the condition is equivalent with the possibility to expression  $X_{\alpha\beta}$  as

$$X_{\alpha\beta} = A_{[\alpha} B_{\beta]} \quad , \quad (7.3.14)$$

where brackets refer to antisymmetrization. The complex vectors  $A$  and  $B$  define a point in twistor space and are defined only modulo scaling and therefore define a point of twistor space  $CP_3$  defining a covering of 6-D Minkowski space with metric signature  $(2,4)$ . This corresponds to the fact that the Lie algebras of  $SO(2,4)$  and  $SU(2,2)$  are identical. Therefore the points of conformally compactified Minkowski space correspond to lines of the twistor space defining spheres  $CP_1$  in  $CP_3$ .

One can introduce a preferred scale for the projective coordinates by introducing what is called infinity twistor (actually a pair of twistors is in question) defined by

$$I_{\alpha\beta} = \begin{pmatrix} \epsilon^{A'B'} & 0 \\ 0 & 0 \end{pmatrix} . \quad (7.3.15)$$

Infinity twistor represents the projective line for which only the coordinate  $X_{01}$  is non-vanishing and chosen to have value  $X_{01} = 1$ .

One can define the contravariant form of the infinite twistor as

$$I^{\alpha\beta} = \epsilon^{\alpha\beta\gamma\delta} I_{\gamma\delta} = \begin{pmatrix} 0 & 0 \\ 0 & \epsilon^{AB} \end{pmatrix} . \quad (7.3.16)$$

Infinity twistor defines a representative for the conformal equivalence class of metrics at the Klein quadric and one can express Minkowski distance as

$$(x - y)^2 = \frac{X^{\alpha\beta} Y_{\alpha\beta}}{I_{\alpha\beta} X^{\alpha\beta} I_{\mu\nu} Y^{\mu\nu}} . \quad (7.3.17)$$

Note that the metric is necessary only in the denominator. In twistor notation the distance can be expressed as

$$(x - y)^2 = \frac{\epsilon(A, B, C, D)}{\langle AB \rangle \langle CD \rangle} . \quad (7.3.18)$$

Infinite twistor  $I_{\alpha\beta}$  and its contravariant counterpart project the twistor to its primed and unprimed parts usually denoted by  $\mu^{A'}$  and  $\lambda^A$  and defined spinors with opposite chiralities.

### Relationship between points of $M^4$ and twistors

In the coordinates obtained by putting  $X_{01} = 1$  the relationship between space-time coordinates  $x^{AA'}$  and  $X^{\alpha\beta}$  is

$$X_{\alpha\beta} = \begin{pmatrix} -\frac{1}{2}\epsilon^{A'B'} x^2 & -ix^{A'}_B \\ ix^A_{B'} & \epsilon_{A,B} \end{pmatrix} , \quad X^{\alpha\beta} = \begin{pmatrix} \epsilon_{A'B'} x^2 & -ix^B_{A'} \\ ix^A_{B'} & -\frac{1}{2}\epsilon^{AB} x^2 \end{pmatrix} , \quad (7.3.19)$$

If the point of Minkowski space represents a line defined by twistors  $(\mu_U, \lambda_U)$  and  $(\mu_V, \lambda_V)$ , one has

$$x^{AC'} = i \frac{(\mu_V \lambda_U - \mu_U \lambda_V)^{AC'}}{\langle UV \rangle} \quad (7.3.20)$$

The twistor  $\mu$  for a given point of Minkowski space in turn is obtained from  $\lambda$  by the twistor formula by

$$\mu^{A'} = -ix^{AA'} \lambda_A . \quad (7.3.21)$$

### Generalization to the super-symmetric case

This formalism has a straightforward generalization to the super-symmetric case.  $CP_3$  is replaced with  $CP_{3|4}$  so that Grassmann parameters have four components. At the level of coordinates this means the replacement  $[W_I] = [W_\alpha, \chi_\alpha]$ . Twistor formula generalizes to

$$\mu^{A'} = -ix^{AA'}\lambda_A, \quad \chi_\alpha = \theta_\alpha^A \lambda_A. \quad (7.3.22)$$

The relationship between the coordinates of chiral super-space and super-twistors generalizes to

$$(x, \theta) = \left( i \frac{(\mu_V \lambda_U - \mu_U \lambda_V)}{\langle UV \rangle}, \frac{(\chi_V \lambda_U - \chi_U \lambda_V)}{\langle UV \rangle} \right) \quad (7.3.23)$$

The above summarized formulas can be applied to super-symmetric variants of momentum twistors to deduce the relationship between region momenta  $x$  assigned with edges of polygons and twistors assigned with the ends of the light-like edges. The explicit formulas are represented in [42]. The geometric picture is following. The twistors at the ends of the edge define the twistor pair representing the region momentum as a line in twistor space and the intersection of the twistor lines assigned with the region momenta define twistor representing the external momenta of the graph in the intersection of the edges.

### Basic kinematics for momentum twistors

The supersymmetrization involves replacement of multiplets with super-multiplets

$$\Phi(\lambda, \tilde{\lambda}, \eta) = G^+(\lambda, \tilde{\lambda}) + \eta_i \Gamma^a \lambda, \tilde{\lambda} + \dots + \epsilon_{abcd} \eta^a \eta^b \eta^c \eta^d G^-(\lambda, \tilde{\lambda}). \quad (7.3.24)$$

Momentum twistors are dual to ordinary twistors and were introduced by Hodges. The light-like momentum of external particle  $a$  is expressed in terms of the vertices of the closed polygon defining the twistor diagram as

$$p_i^\mu = x_i^\mu - x_{i+1}^\mu = \lambda_i \tilde{\lambda}_i, \quad \theta_i - \theta_{i+1} = \lambda_i \eta_i. \quad (7.3.25)$$

One can say that massless momenta have a conserved super-part given by  $\lambda_i \eta_i$ . The dual of the super-conformal group acts on the region momenta exactly as the ordinary conformal group acts on space-time and one can construct twistor space for dual region momenta.

Super-momentum conservation gives the constraints

$$\sum p_i = 0, \quad \sum \lambda_i \eta_i = 0. \quad (7.3.26)$$

The twistor diagrams correspond to polygons with edges with lines carrying region momenta and external massless momenta emitted at the vertices.

This formula is invariant under overall shift of the region momenta  $x_a^\mu$ . A natural interpretation for  $x_a^\mu$  is as the momentum entering to the vertex where  $p_a$  is emitted. Overall shift would have interpretation as a shift in the loop momentum.  $x_a^\mu$  in the dual coordinate space is associated with the line  $Z_{a-1} Z_a$  in the momentum twistor space. The lines  $Z_{a-1} Z_a$  and  $Z_a Z_{a+1}$  intersect at  $Z_a$  representing a light-like momentum vector  $p_a^\mu$ .

The brackets  $\langle abcd \rangle \equiv \epsilon_{IJKL} Z_a^I Z_b^J Z_c^K Z_d^L$  define fundamental bosonic conformal invariants appearing in the tree amplitudes as basic building blocks. Note that  $Z_a$  define points of 4-D complex twistor space to be distinguished from the projective twistor space  $CP_3$ .  $Z_a$  define projective coordinates for  $CP_3$  and one of the four complex components of  $Z_a$  is redundant and one can take  $Z_a^0 = 1$  without a loss of generality.

### 7.3.3 Brief summary of the work of Arkani-Hamed and collaborators

The following comments are an attempt to summarize my far from complete understanding about what is involved with the representation as contour integrals. After that I shall describe in more detail my impressions about what has been done.

#### Limitations of the approach

Consider first the limitations of the approach.

1. The basis idea is that the representation for tree amplitudes generalizes to loop amplitudes. On other words, the amplitude defined as a sum of Yangian invariants expressed in terms of Grassmann integrals represents the sum of loops up to some maximum loop number. The problem is here that shifts of the loop momenta are essential in the UV regularization procedure. Fixing the coordinates  $x_1, \dots, x_n$  having interpretation as momenta associated with lines in the dual coordinate space allows to eliminate the non-uniqueness due to the common shift of these coordinates.
2. It is not however not possible to identify loop momentum as a loop momentum common to different loop integrals unless one restricts to planar loops. Non-planar diagrams are obtained from a planar diagram by permuting the coordinates  $x_i$  but this means that the unique coordinate assignment is lost. Therefore the representation of loop integrands as Grassmann integrals makes sense only for planar diagrams. From TGD point of view one could argue that this is one good reason for restricting the loops so that they are for on mass shell particles with non-parallel on mass shell four-momenta and possibly different sign of energies for given wormhole contact representing virtual particle.
3. IR regularization is needed even in  $\mathcal{N} = 4$  for SYM given by "moving out on the Coulomb branch theory" so that IR singularities remain the problem of the theory.

#### What has been done?

The article proposes a generalization of the BCFW recursion relation for tree diagrams of  $\mathcal{N} = 4$  for SYM so that it applies to planar diagrams with a summation over an arbitrary number of loops.

1. The basic goal of the article is to generalize the recursion relations of tree amplitudes so that they would apply to loop amplitudes. The key idea is following. One can formally represent loop integrand as a contour integral in complex plane whose coordinate parameterizes the deformations  $Z_n \rightarrow Z_n + \epsilon Z_{n-1}$  and re-interpret the integral as a contour integral with oppositely oriented contour surrounding the rest of the complex plane which can be imagined also as being mapped to Riemann sphere. What happens only the poles which correspond to lower number of loops contribute this integral. One obtains a recursion relation with respect to loop number. This recursion seems to be the counterpart for the recursive construction of the loops corrections in terms of absorptive parts of amplitudes with smaller number of loop using unitarity and analyticity.
2. The basic challenge is to deduce the Grassmann integrands as Yangian invariants. From these one can deduce loop integrals by integration over the four momenta associated with the lines of the polygonal graph identifiable as the dual coordinate variables  $x_a$ . The integration over loop momenta can induce infrared divergences breaking Yangian symmetry. The big idea here is that the operations described above allow to construct loop amplitudes from the Yangian invariants defining tree amplitudes for a larger number of particles by removing external particles by fusing them to form propagator lines and by using the BCFW bridge to fuse lower-dimensional invariants. Hence the usual iterative procedure (bottom-up) used to construct scattering amplitudes is replaced with a recursive procedure (top-down). Of course, once lower amplitudes has been constructed they can be used to construct amplitudes with higher particle number.
3. The first guess is that the recursion formula involves the same lower order contributions as in the case of tree amplitudes. These contributions have interpretation as factorization of channels involving single particle intermediate states. This would however allow to reduce loop amplitudes

to 3-particle loop amplitudes which vanish in  $\mathcal{N} = 4$  SYM by the vanishing of coupling constant renormalization. The additional contribution is necessary and corresponds to a source term identifiable as a "forward limit" of lower loop integrand. These terms are obtained by taking an amplitude with two additional particles with opposite four-momenta and forming a state in which these particles are entangled with respect to momentum and other quantum numbers. Entanglement means integral over the massless momenta on one hand. The insertion brings in two momenta  $x_a$  and  $x_b$  and one can imagine that the loop is represented by a branching of propagator line. The line representing the entanglement of the massless states with massless momentum define the second branch of the loop. One can of course ask whether only massless momentum in the second branch. A possible interpretation is that this state is expressible by unitarity in terms of the integral over light-like momentum.

4. The recursion formula for the loop amplitude  $M_{n,k,l}$  involves two terms when one neglects the possibility that particles can also suffer trivial scattering (cluster decomposition). This term basically corresponds to the Yangian invariance of  $n$  arguments identified as Yangian invariant of  $n - 1$  arguments with the same value of  $k$ .
  - (a) The first term corresponds to single particle exchange between particle groups obtained by splitting the polygon at two vertices and corresponds to the so called BCFW bridge for tree diagrams. There is a summation over different splittings as well as a sum over loop numbers and dimensions  $k$  for the Grassmann planes. The helicities in the two groups are opposite.
  - (b) Second term is obtained from an amplitude obtained by adding of two massless particles with opposite momenta and corresponds to  $n + 2, k + 1, l - 1$ . The integration over the light-like momentum together with other operations implies the reduction  $n + 2 \rightarrow n$ . Note that the recursion indeed converges. Certainly the allowance of added zero energy states with a finite number of particles is necessary for the convergence of the procedure.

### 7.3.4 The general form of Grassmannian integrals

If the recursion formula proposed in [33] is correct, the calculations reduce to the construction of  $N^k MHV$  (super) amplitudes.  $MHV$  refers to maximal helicity violating amplitudes with 2 negative helicity gluons. For  $N^k MHV$  amplitude the number of negative helicities is by definition  $k + 2$  [58]. Note that the total right handed R-charge assignable to 4 super-coordinates  $\eta_i$  of negative helicity gluons can be identified as  $R = 4k$ . BCFW recursion formula [62, 62] allows to construct from MHV amplitudes with arbitrary number of negative helicities.

The basic object of study are the leading singularities of color-stripped  $n$ -particle  $N^k MHV$  amplitudes. The discovery is that these singularities are expressible in terms Yangian invariants  $Y_{n,k}(Z_1, \dots, Z_n)$ , where  $Z_i$  are momentum super-twistors. These invariants are defined by residue integrals over the compact  $nk - 1$ -dimensional complex space  $G(n, k) = U(n)/U(k) \times U(n - k)$  of  $k$ -planes of complex  $n$ -dimensional space.  $n$  is the number of external massless particles,  $k$  is the number negative helicity gluons in the case of  $N^k MHV$  amplitudes, and  $Z_a, i = 1, \dots, n$  denotes the projective 4-coordinate of the super-variant  $CP^{3|4}$  of the momentum twistor space  $CP_3$  assigned to the massless external particles is following.  $Gl(n)$  acts as linear transformations in the  $n$ -fold Cartesian power of twistor space. Yangian invariant  $Y_{n,k}$  is a function of twistor variables  $Z^a$  having values in super-variant  $CP_{3|3}$  of momentum twistor space  $CP_3$  assigned to the massless external particles being simple algebraic functions of the external momenta.

It is also possible to define  $N^k MHV$  amplitudes in terms of Yangian invariants  $L_{n,k+2}(W_1, \dots, W_n)$  by using ordinary twistors  $W_a$  and identical defining formula. The two invariants are related by the formula  $L_{n,k+2}(W_1, \dots, W_n) = M_{MHV}^{tree} \times Y_{n,k}(Z_1, \dots, Z_n)$ . Here  $M_{MHV}^{tree}$  is the tree contribution to the maximally helicity violating amplitude for the scattering of  $n$  particles: recall that these amplitudes contain two negative helicity gluons whereas the amplitudes containing a smaller number of them vanish [35]. One can speak of a factorization to a product of  $n$ -particle amplitudes with  $k - 2$  and 2 negative helicities as the origin of the duality. The equivalence between the descriptions based on ordinary and momentum twistors states the dual conformal invariance of the amplitudes implying Yangian symmetry. It has been conjectured that Grassmannian integrals generate all Yangian invariants.

The formulas for the Grassmann integrals for twistors and momentum twistors appearing in the expressions of  $N^k MHV$  amplitudes are given by following expressions.

1. The integrals  $L_{n,k}(W_1, \dots, W_n)$  associated with  $N^{k-2} MHV$  amplitudes in the description based on ordinary twistors correspond to  $k$  negative helicities and are given by

$$\begin{aligned}
 L_{n,k}(W_1, \dots, W_n) &= \frac{1}{Vol(GL(2))} \int \frac{d^{k \times n} C_{\alpha a}}{(1 \dots k)(2 \dots k+1) \dots (n1 \dots k-1)} \times \\
 &\times \prod_{\alpha=1}^k d^{4|4} Y_{\alpha} \prod_{i=1}^n \delta^{4|4}(W_i - C_{\alpha i} Y_{\alpha}) .
 \end{aligned}
 \tag{7.3.27}$$

Here  $C_{\alpha a}$  denote the  $n \times k$  coordinates used to parametrize the points of  $G_{k,n}$ .

2. The integrals  $Y_{n,k}(W_1, \dots, W_n)$  associated with  $N^k MHV$  amplitudes in the description based on momentum twistors are defined as

$$Y_{n,k}(Z_1, \dots, Z_n) = \frac{1}{Vol(GL(k))} \times \int \frac{d^{k \times n} C_{\alpha a}}{(1 \dots k)(2 \dots k+1) \dots (n1 \dots k-1)} \times \prod_{\alpha=1}^k \delta^{4|4}(C_{\alpha a} Z_a) .
 \tag{7.3.28}$$

The possibility to select  $Z_a^0 = 1$  implies  $\sum_k C_{\alpha k} = 0$  allowing to eliminate  $C_{\alpha n}$  so that the actual number of coordinates Grassman coordinates is  $nk-1$ . As already noticed,  $L_{n,k+2}(W_1, \dots, W_n) = M_{MHV}^{tree} \times Y_{n,k}(Z_1, \dots, Z_n)$ . Momentum twistors are obviously computationally easier since the value of  $k$  is smaller by two units.

The  $4k$  delta functions reduce the number of integration variables of contour integrals from  $nk$  to  $(n-4)k$  in the bosonic sector (the definition of delta functions involves some delicacies not discussed here). The  $n$  quantities  $(m, \dots, m+k)$  are  $k \times k$ -determinants defined by subsequent columns from  $m$  to  $m+k-1$  of the  $k \times n$  matrix defined by the coordinates  $C_{\alpha a}$  and correspond geometrically to the  $k$ -volumes of the  $k$ -dimensional parallel-pipeds defined by these column vectors. The fact that the scalings of twistor space coordinates  $Z_a$  can be compensated by scalings of  $C_{\alpha a}$  deforming integration contour but leaving the residue integral invariant so that the integral depends on projective twistor coordinates only.

Since the integrand is a rational function, a multi-dimensional residue calculus allows to deduce the values of these integrals as residues associated with the poles of the integrand in a recursive manner. The poles correspond to the zeros of the  $k \times k$  determinants appearing in the integrand or equivalently to singular lower-dimensional parallel-pipeds. It can be shown that local residues are determined by  $(k-2)(n-k-2)$  conditions on the determinants in both cases. The value of the integral depends on the explicit choice of the integration contour for each variable  $C_{\alpha a}$  left when delta functions are taken into account. The condition that a correct form of tree amplitudes is obtained fixes the choice of the integration contours.

For the ordinary twistors  $W$  the residues correspond to projective configurations in  $CP_{k-1}$ , or more precisely in the space  $CP_{k-1}^n / Gl(k)$ , which is  $(k-1)n - k^2$ -dimensional space defining the support for the residues integral.  $Gl(k)$  relates to each other different complex coordinate frames for  $k$ -plane and since the choice of frame does not affect the plane itself, one has  $Gl(k)$  gauge symmetry as well as the dual  $Gl(n-k)$  gauge symmetry.

$CP_{k-1}$  comes from the fact that  $C_{\alpha k}$  are projective coordinates: the amplitudes are indeed invariant under the scalings  $W_i \rightarrow t_i W_i, C_{\alpha i} \rightarrow t C_{\alpha i}$ . The coset space structure comes from the fact that  $Gl(k)$  is a symmetry of the integrand acting as  $C_{\alpha i} \rightarrow \Lambda_{\alpha}^{\beta} C_{\beta i}$ . This analog of gauge symmetry allows to fix  $k$  arbitrarily chosen frame vectors  $C_{\alpha i}$  to orthogonal unit vectors. For instance, one can have  $C_{\alpha i} = \delta_{\alpha i}$  for  $\alpha = i \in 1, \dots, k$ . This choice is discussed in detail in [58]. The reduction to  $CP_{k-1}$  implies the

reduction of the support of the integral to line in the case of MHV amplitudes and to plane in the case of NMHV as one sees from the expression  $d\mu = \prod_{\alpha} d^{4|4}Y_{\alpha} \prod_{i=1}^n \delta^{4|4}(W_i - C_{\alpha i}Y_{\alpha})$ . For  $(i_1, \dots, i_k) = 0$  the vectors  $i_1, \dots, i_k$  belong to  $k - 2$ -dimensional plane of  $CP_{k-1}$ . In the case of NMHV ( $N^2$ MHV) amplitudes this translates at the level of twistors to the condition that the corresponding twistors  $\{i_1, i_2, i_3\}$  ( $\{i_1, i_2, i_3, i_4\}$ ) are collinear (in the same plane) in twistor space. This can be understood from the fact that the delta functions in  $d\mu$  allow to express  $W_i$  in terms of  $k - 1$   $Y_{\alpha}$ :s in this case.

The action of conformal transformations in twistor space reduces to the linear action of  $SU(2, 2)$  leaving invariant Hermitian sesquilinear form of signature  $(2, 2)$ . Therefore the conformal invariance of the Grassmannian integral and its dual variant follows from the possibility to perform a compensating coordinate change for  $C_{\alpha a}$  and from the fact that residue integral is invariant under small deformations of the integration contour. The above described relationship between representations based on twistors and momentum twistors implies the full Yangian invariance.

### 7.3.5 Canonical operations for Yangian invariants

General  $l$ -loop amplitudes can be constructed from the basic Yangian invariants defined by  $N^k$ MHV amplitudes by various operations respecting Yangian invariance apart from possible IR anomalies. There are several operations that one can perform for Yangian invariants  $Y_{n,k}$  and all these operations appear in the recursion formula for planar all loop amplitudes. These operations are described in [33] much better than I could do it so that I will not go to any details. It is possible to add and remove particles, to fuse two Yangian invariants, to merge particles, and to construct from two Yangian invariants a higher invariant containing so called BCFW bridge representing single particle exchange using only twistorial methods.

#### Inverse soft factors

Inverse soft factors add to the diagram a massless collinear particles between particles  $a$  and  $b$  and by definition one has

$$O_{n+1}(a, c, b, \dots) = \frac{\langle ab \rangle}{\langle ac \rangle \langle cb \rangle} O_n(a' b') . \quad (7.3.29)$$

At the limit when the momentum of the added particle vanishes both sides approach the original amplitude. The right-handed spinors and Grassmann parameters are shifted

$$\begin{aligned} \tilde{\lambda}'_a &= \tilde{\lambda}_a + \frac{\langle cb \rangle}{\langle ab \rangle} \tilde{\lambda}_c , & \tilde{\lambda}'_b &= \tilde{\lambda}_b + \frac{\langle ca \rangle}{\langle ba \rangle} \tilde{\lambda}_c , \\ \eta'_a &= \eta_a + \frac{\langle cb \rangle}{\langle ab \rangle} \eta_c , & \eta'_b &= \eta_b + \frac{\langle ca \rangle}{\langle ba \rangle} \eta_c . \end{aligned} \quad (7.3.30)$$

There are two kinds of inverse soft factors.

1. The addition of particle leaving the value  $k$  of negative helicity gluons unchanged means just the re-interpretation

$$Y'_{n,k}(Z_1, \dots, Z_{n-1}, Z_n) = Y_{n-1,k}(Z_1, \dots, Z_{n-1}) \quad (7.3.31)$$

without actual dependence on  $Z_n$ . There is however a dependence on the momentum of the added particle since the relationship between momenta and momentum twistors is modified by the addition obtained by applying the basic rules relating region super momenta and momentum twistors (light-like momentum determines  $\lambda_i$  and twistor equations for  $x_i$  and  $\lambda_i, \eta_i$  determine  $(\mu_i, \chi_i)$ ) is expressible assigned to the external particles [28]. Modifications are needed only for the new vertex and its neighbors.

2. The addition of a particle increasing  $k$  with single unit is a more complex operation which can be understood in terms of a residue of  $Y_{n,k}$  proportional to  $Y_{n-1,k-1}$  and Yangian invariant  $[z_1 \cdots z_5]$  with five arguments constructed from basic Yangian invariants with four arguments. The relationship between the amplitudes is now

$$Y'_{n,k}(\dots, Z_{n-1}Z_n, Z_1 \cdots) = [n-2 \ n-1 \ n \ 1 \ 2] \times Y_{n-1,k-1}(\cdots \hat{Z}_{n-1}, \hat{Z}_1, \cdots) . \quad (7.3.32)$$

Here

$$[abcde] = \frac{\delta^{0|4}(\eta_a \langle bcde \rangle + \text{cyclic})}{\langle abcd \rangle \langle bcde \rangle \langle cdea \rangle \langle deab \rangle \langle eabc \rangle} . \quad (7.3.33)$$

denoted also by  $R(a, b, c, d, e)$  is the fundamental R-invariant appearing in one loop corrections of MHV amplitudes and will appear also in the recursion formulas.  $\langle abcd \rangle$  is the fundamental super-conformal invariant associated with four super twistors defined in terms of the permutation symbol.

$\hat{Z}_{n-1}, \hat{Z}_1$  are deformed momentum twistor variables. The deformation is determined from the relationship between external momenta, region momenta and momentum twistor variables.  $\hat{Z}^1$  is the intersection  $\hat{Z}^1 = (n-2 \ n-1 \ 2) \cap (12)$  of the the line (12) with the plane  $(n-2 \ n-1 \ 2)$  and  $\hat{Z}^{n-1}$  the intersection  $\hat{Z}^{n-1} = (12n) \cap (n-2 \ n-1)$  of the the line  $(n-2 \ n-1)$  with the plane  $(12n)$ . The interpretation for the intersections at the level of ordinary Feynman diagrams is in terms of the collinearity of the four-momenta involved with the underlying box diagram with parallel on mass shell particles. These result from unitarity conditions obtained by putting maximal number of loop momenta on mass shell to give the leading singularities.

The explicit expressions for the momenta are

$$\begin{aligned} \hat{Z}^1 &\equiv (n-2 \ n-1 \ 2) \cap (12)Z_1 = \langle 2 \ n-2 \ n-1 \ n \rangle + Z_2 \langle n-2 \ n-1 \ n \ 1 \rangle , \\ \hat{Z}^{n-1} &\equiv (12n) \cap (n-2 \ n-1) = Z_{n-2} \langle n-2 \ n-1 \ n \ 2 \rangle + Z_{n-1} \langle n \ 1 \ 2 \ n-2 \rangle . \end{aligned} \quad (7.3.34)$$

These intersections also appear in the expressions defining the recursion formula.

### Removal of particles and merge operation

Particles can be also removed. The first manner to remove particle is by integrating over the twistor variable characterizing the particle. This reduces  $k$  by one unit. Merge operation preserves the number of loops but removes a particle particle by identifying the twistor variables of neighboring particles. This operation corresponds to an integral over on mass shell loop momentum at the level of tree diagrams and by Witten's half Fourier transform can be transformed to twistor integral.

The product

$$Y'(Z_1, \cdots Z_n) = Y_1(Z_1, \cdots Z_m) \times Y_2(Z_{m+1}, \cdots Z_n) \quad (7.3.35)$$

of two Yangian invariants is again a Yangian invariant. This is not quite trivial since the dependence of region momenta and momentum twistors on the momenta of external particles makes the operation non-trivial.

Merge operation allows to construct more interesting invariants from the products of Yangian invariants. One begins from a product of Yangian invariants (Yangian invariant trivially) represented cyclically as points of circle and identifies the last twistor argument of given invariant with the first twistor argument of the next invariant and performs integrals over the momentum twistor variables

appearing twice. The soft  $k$ -increasing and preserving operations can be described also in terms of this operation for Yangian invariants such that the second invariant corresponds to 3-vertex. The cyclic merge operation applied to four MHV amplitudes gives NMHV amplitudes associated with on mass shell momenta in box diagrams. By applying similar operation to NMHV amplitudes and MHV amplitudes one obtains 2-loop amplitudes. In [33] examples about these operations are described.

### BCFW bridge

BCFW bridge allows to build general tree diagrams from MHV tree diagrams [62, 62] and recursion formula of [33] generalizes this to arbitrary diagrams. At the level of Feynman diagrams it corresponds to a box diagram containing general diagrams labeled by  $L$  and  $R$  and MHV and  $\overline{MHV}$  3-vertices ( $\overline{MHV}$  3-vertex allows expression in terms of MHV diagrams) with the lines of the box on mass shell so that the three momenta emanating from the vertices are parallel and give rise to a one-loop leading singularity.

At the level of Feynman diagrams BCFW bridge corresponds to so called "two-mass hard" leading singularities associated with box diagrams with light-like momenta at the four lines of the diagram [58]. The motivation for the study of these diagrams comes from the hypothesis the leading order singularities obtained by putting as many particles as possible on mass shell contain the data needed to construct scattering amplitudes of  $\mathcal{N} = 4$  SYM completely. This representation of the leading singularities generalizes to arbitrary loops. The recent article is a continuation of this program to planar amplitudes.

Also BCFW bridge allows an interpretation as a particular kind fusion for Yang invariants and involves all the basic operations. One starts from the amplitudes  $Y_{n_L, k_L}^L$  and  $Y_{n_R, k_R}^R$  and constructs an amplitude  $Y'_{n_L+n_R, k_L+k_R+1}$  representing the amplitude which would correspond to a generalization of the MHV diagrams with the two tree diagrams connected by the MHV propagator (BCFW bridge) replaced with arbitrary loop diagrams. Particle "1" *resp.* "j+1" is added by the soft  $k$ -increasing factor to  $Y_{n_L+1, k_L+1}$  *resp.*  $Y_{n_R+1, k_R+1}$  giving amplitude with  $n+2$  particles and with  $k$ -charge equal to  $k_L+k_R+2$ . The subsequent operations must reduce  $k$ -charge by one unit. First repeated "1" and "j+1" are identified with their copies by  $k$  conserving merge operation, and after that one performs an integral over the twistor variable  $Z^I$  associated with the internal line obtained and reducing  $k$  by one unit. The soft  $k$ -increasing factors bring in the invariants  $[n-1 \ n \ 1 \ I \ j+2]$  associated with  $Y_L$  and  $[1 \ I \ j+1 \ j \ j-1]$  associated with  $Y_R$ . The integration contour is chosen so that it selects the pole defined by  $\langle n-1 \ n \ 1 \ I \rangle$  in the denominator of  $[n-1 \ n \ 1 \ I \ j+2]$  and the pole defined by  $\langle 1 \ I \ j+1 \ j \rangle$  in the denominator of  $[1 \ I \ j+1 \ j \ j-1]$ .

The explicit expression for the BCFW bridge is very simple:

$$\begin{aligned} (Y_L \otimes_{BCFW} Y_R)(1, \dots, n) &= [n-1 \ n \ 1 \ j \ j+1] \times Y_R(1, \dots, j, I) Y_L(I, j+1, \dots, n-1, \hat{n}) , \\ \hat{n} &= (n-1 \ n) \cap (j \ j+1 \ 1) , \quad I = (j \ j+1) \cap (n-1 \ n \ 1) . \end{aligned} \quad (7.3.36)$$

### Single cuts and forward limit

Forward limit operation is used to increase the number of loops by one unit. The physical picture is that one starts from say 1-loop amplitude and cuts one line by assigning to the pieces of the line opposite light-like momenta having interpretation as incoming and outgoing particles. The resulting amplitude is called forward limit. The only reasonable interpretation seems to be that the loop integration is expressed by unitarity as forward limit meaning cutting of the line carrying the loop momentum. This operation can be expressed in a manifestly Yangian invariant way as entangled removal of two particles with the merge operation meaning the replacement  $Z_n \rightarrow Z_{n-1}$ . Particle  $n+1$  is added adjacent to  $A, B$  as a  $k$ -increasing inverse soft factor and then  $A$  and  $B$  are removed by entangled integration, and after this merge operation identifies  $n+1$  and 1.

Forward limit is crucial for the existence of loops and for Yangian invariants it corresponds to the poles arising from  $\langle (AB)_q Z_n(z) Z_1 \rangle$  the integration contour  $Z_n + z Z_{n-1}$  around  $Z_b$  in the basic formula  $M = \oint (dz/z) M_n$  leading to the recursion formula.  $A$  and  $B$  denote the momentum twistors associated with opposite light-like momenta. In the generalized unitarity conditions the singularity corresponds to the cutting of line between particles  $n$  and 1 with momenta  $q$  and  $-q$ , summing over the multiplet of stats running around the loop. Between particles  $n_2$  and 1 one has particles  $n-1, n$

with momenta  $q, -q$ .  $q = x_1 - x_n = -x_n + x_{n-1}$  giving  $x_1 = x_{n-1}$ . Light-likeness of  $q$  means that the lines (71) = (76) and (15) intersect. At the forward limit giving rise to the pole  $Z_6$  and  $Z_7$  approach to the intersection point (76)  $\cap$  (15). In a generic gauge theories the forward limits are ill-defined but in super-symmetric gauge theories situation changes.

The corresponding Yangian operation removes two external particles with opposite four-momenta and involves integration over two twistor variables  $Z_a$  and  $Z_b$  and gives rise to the following expression

$$\int_{GL(2)} Y(\cdots, Z_n, Z_A, Z_B, Z_1, \cdots) . \quad (7.3.37)$$

The integration over  $GL(2)$  corresponds to integration over twistor variables associated  $Z_A$  and  $Z_B$ . This operation allows addition of a loop to a given amplitude. The line  $Z_a Z_b$  represents loop momentum on one hand and the dual  $x$ -coordinate identified as momentum propagating along the line on the other hand.

The integration over these variables is equivalent to an integration over loop momentum as the explicit calculation of [33] (see pages 12-13) demonstrates. If the integration contours are products in the product of twistor spaces associated with  $a$  and  $b$  the and gives lower order Yangian invariant as answer. It is however also possible to choose the integration contour to be entangled in the sense that it cannot be reduced to a product of integration contours in the Cartesian product of twistor spaces. In this case the integration gives a loop integral. In the removal operation Yangian invariance can be broken by IR singularities associated with the integration contour and the procedure does not produce genuine Yangian invariant always.

What is highly interesting from TGD point of view is that this integral can be expressed as a contour integral over  $CP_1 \times CP_1$  combined with integral over loop momentum. If TGD vision about generalized Feynman graphs in zero energy ontology is correct, the loop momentum integral is discretized to an an integral over discrete mass shells and perhaps also to a sum over discretized momenta and one can therefore avoid IR singularities.

### 7.3.6 Explicit formula for the recursion relation

Recall that the recursion formula is obtained by considering super-symmetric momentum-twistor deformation  $Z_n \rightarrow Z_n + zZ_{n-1}$  and by integrating over  $z$  to get the identity

$$M_{n,k,l} = \oint \frac{dz}{z} \hat{M}_{n,k,l}(z) . \quad (7.3.38)$$

This integral equals to integral with reversed integration contour enclosing the exterior of the contour. The challenge is to deduce the residues contributing to the residue integral and the claim of [33] is that these residues reduce to simple basic types.

1. The first residue corresponds to a pole at infinity and reduces the particle number by one giving a contribution  $M_{n-1,k,l}(1, \cdots, n-1)$  to  $M_{n,k,l}(1, \cdots, n-1, n)$ . This is not totally trivial since the twistor variables are related to momenta in different manner for the two amplitudes. This gives the first contribution to the right hand side of the formula below.
2. Second pole corresponds to the vanishing of  $\langle Z_n(z) Z_1 Z_j Z_{j+1} \rangle$  and corresponds to the factorization of channels. This gives the second BCFW contribution to the right hand side of the formula below. These terms are however not enough since the recursion formula would imply the reduction to expressions involving only loop corrections to 3-loop vertex which vanish in  $\mathcal{N} = 4$  SYM.
3. The third kind of pole results when  $\langle (AB)_q Z_n(z) Z_1 \rangle$  vanishes in momentum twistor space.  $(AB)_q$  denotes the line in momentum twistor space associated with  $q$ :th loop variable.

The explicit formula for the recursion relation yielding planar all loop amplitudes is obtained by putting all these pieces together and reads as

$$\begin{aligned}
M_{n,k,l}(1, \dots, n) &= M_{n-1,k,l}(1, \dots, n-1) \\
&+ \sum_{n_L, k_L, l_L; j} [j \ j+1 \ n-1 \ n \ 1] M_{n_R, k_R, l_R}^R(1, \dots, j, I_j) \times M_{n_L, k_L, l_L}^L(I_j, j+1, \dots, \hat{n}_j) \\
&+ \int_{GL(2)} [AB \ n-1 \ n \ 1] M_{n+2, k+1, n, k-1}(1, \dots, \hat{n}_{AB}, \hat{A}, B) \ , \\
n_L + n_R &= n+2 \ , \quad k_L + k_R = k-1 \ , \quad l_R + l_L = l \ .
\end{aligned} \tag{7.3.39}$$

The momentum super-twistors are given by

$$\begin{aligned}
\hat{n}_j &= (n-1 \ n) \cap (j \ j+1 \ 1) \ , \quad I_j = (j \ j+1 \ 1) \cap (n-1 \ n \ 1) \ , \\
\hat{n}_{AB} &= (n-1 \ n) \cap (AB \ 1) \ , \quad \hat{A} = (AB) \cap (n-1 \ n \ 1) \ .
\end{aligned} \tag{7.3.40}$$

The index  $l$  labels loops in  $n+2$ -particle amplitude and the expression is fully symmetrized with equal weight for all loop integration variables  $(AB)_l$ .  $A$  and  $B$  are removed by entangled integration meaning that  $GL(2)$  contour is chosen to encircle points where both points  $A, B$  on the line  $(AB)$  are located at the intersection of the line  $(AB)$  with the plane  $(n-1 \ n \ 1)$ .  $GL(2)$  integral can be done purely algebraically in terms of residues.

In [33] and [28] explicit calculations for  $N^k MHV$  amplitudes are carried out to make the formulas more concrete. For  $N^1 MHV$  amplitudes second line of the formula vanishes and the integrals are rather simple since the determinants are  $1 \times 1$  determinants.

## 7.4 Could the Grassmannian program be realized in TGD framework?

In the following the TGD based modification of the approach based on zero energy ontology is discussed in some detail. It is found that pseudo-momenta are very much analogous to region momenta and the approach leading to discretization of pseudo-mass squared for virtual particles - and even the discretization of pseudo-momenta - is consistent with the Grassmannian approach in the simple case considered and allow to get rid of IR divergences. Also the possibility that the number of generalized Feynman diagrams contributing to a given scattering amplitude is finite so that the recursion formula for the scattering amplitudes would involve only a finite number of steps (maximum number of loops) is considered. One especially promising feature of the residue integral approach with discretized pseudo-momenta is that it makes sense also in the p-adic context in the simple special case discussed since residue integral reduces to momentum integral (summation) and lower-dimensional residue integral.

### 7.4.1 What Yangian symmetry could mean in TGD framework?

The loss of the Yangian symmetry in the integrations over the region momenta  $x^a$  ( $p^a = x^{a+1} - x^a$ ) assigned to virtual momenta seems to be responsible for many ugly features. It is basically the source of IR divergences regulated by "moving out on the Coulomb branch theory" so that IR singularities remain the problem of the theory. This raises the question whether the loss of Yangian symmetry is the signature for the failure of QFT approach and whether the restriction of loop momentum integrations to avoid both kind of divergences might be a royal road beyond QFT. In TGD framework zero energy ontology indeed leads to a concrete proposal based on the vision that virtual particles are something genuinely real.

The detailed picture is of course far from clear but to get an idea about what is involved one can look what kind of assumptions are needed if one wants to realize the dream that only a finite number of generalized Feynman diagrams contribute to a scattering amplitude which is Yangian invariant allowing a description using a generalization of the Grassmannian integrals.

1. Assume the bosonic emergence and its super-symmetric generalization holds true. This means that incoming and outgoing states are bound states of massless fermions assignable to wormhole

throats but the fermions can opposite directions of three-momenta making them massive. Incoming and outgoing particles would consist of fermions associated with wormhole throats and would be characterized by a pair of twistors in the general situation and in general massive. This allows also string like mass squared spectrum for bound states having fermion and antifermion at the ends of the string as well as more general  $n$ -particle bound states. Hence one can speak also about the emergence of string like objects. For virtual particles the fermions would be massive and have discrete mass spectrum. Also super partners containing several collinear fermions and antifermions at a given throat are possible. Collinearity is required by the generalization of SUSY. The construction of these states bring strongly in mind the merge procedure involving the replacement  $Z^{n+1} \rightarrow Z^n$ .

2. The basic question is how the momentum twistor diagrams and the ordinary Feynman diagrams behind them are related to the generalized Feynman diagrams.
  - (a) It is good to start from a common problem. In momentum twistor approach the relationship of region momenta to physical momenta remains somewhat mysterious. In TGD framework in turn the relationship of pseudo-momenta identified as generalized eigenvalues of the Chern-Simons Dirac operator at the lines of Feynman diagram (light-like wormhole throats) to the physical momenta has remained unclear. The identification of the pseudo-momentum as the TGD counterpart of the region momentum  $x$  looks therefore like a natural first guess.
  - (b) The identification  $x_{a+1} - x_a = p_a$  with  $p_a$  representing light-like physical four-momentum generalizes in obvious manner. Also the identification of the light-like momentum of the external parton as pseudo-momentum looks natural. What is important is that this does not require the identification of the pseudo-momenta propagating along internal lines of generalized Feynman diagram as actual physical momenta since pseudo-momentum just like  $x$  is fixed only apart from an overall shift. The identification allows the physical four-momenta associated with the wormhole throats to be always on mass shell and massless: if the sign of the physical energy can be also negative space-like momentum exchanges become possible.
  - (c) The pseudo-momenta and light-like physical massless momenta at the lines of generalized Feynman diagrams on one hand, and region momenta and the light-like momenta associated with the collinear singularities on the other hand would be in very similar mutual relationship. Partonic 2-surfaces can carry large number of collinear light-like fermions and bosons since super-symmetry is extended. Generalized Feynman diagrams would be analogous to momentum twistor diagrams if this picture is correct and one could hope that the recursion relations of the momentum twistor approach generalize.
3. The discrete mass spectrum for pseudo-momentum would in the momentum twistor approach mean the restriction of  $x$  to discrete mass shells, and the obvious reason for worry is that this might spoil the Grassmannian approach relying heavily on residue integrals and making sense also  $p$ -adically. It seems however that there is no need to worry. In [33] the  $M_{6,4,l=0}(1234AB)$  the integration over twistor variables  $z_A$  and  $z_B$  using "entangled" integration contour leads to 1-loop MHV amplitude  $N^p MHV$ ,  $p = 1$ . The parametrization of the integration contour is  $z_A = (\lambda_A, x\lambda_A)$ ,  $z_B = (\lambda_B, x\lambda_B)$ , where  $x$  is the  $M^4$  coordinate representing the loop momentum. This boils down to an integral over  $CP_1 \times CP_1 \times M^4$  [33]. The integrals over spheres  $CP_1$ s are contour integrals so that only an ordinary integral over  $M^4$  remains. The reduction to this kind of sums occurs completely generally thanks to the recursion formula.
4. The obvious implication of the restriction of the pseudo-momenta  $x$  on massive mass shells is the absence of IR divergences and one might hope that under suitable assumptions one achieves Yangian invariance. The first question is of course whether the required restriction of  $x$  to mass shells in  $z_A$  and  $z_B$  or possibly even algebraic discretization of momenta is consistent with the Yangian invariance. This seems to be the case: the integration contour reduces to entangled integration contour in  $CP_1 \times CP_1$  not affected by the discretization and the resulting loop integral differs from the standard one by the discretization of masses and possibly also momenta with massless states excluded. Whether Yangian invariance poses also conditions on mass and momentum spectrum is an interesting question.

5. One can consider also the possibility that the incoming and outgoing particles - in general massive and to be distinguished from massless fermions appearing as their building blocks- have actually small masses presumably related to the IR cutoff defined by the size scale of the largest causal diamond involved.  $p$ -Adic thermodynamics could be responsible for this mass. Also the binding of the wormhole throats can give rise to a small contribution to vacuum conformal weight possibly responsible for gauge boson masses. This would imply that a given  $n$ -particle state can decay to  $N$ -particle states for which  $N$  is below some limit. The fermions inside loops would be also massive. This allows to circumvent the IR singularities due to integration over the phase space of the final states (say in Coulomb scattering).
6. The representation of the off mass shell particles as pairs of wormhole throats with non-parallel four-momenta (in the simplest case only the three-momenta need be in opposite directions) makes sense and that the particles in question are on mass shell with mass squared being proportional to inverse of a prime number as the number theoretic vision applied to the modified Dirac equation suggests. On mass shell property poses extremely powerful constraints on loops and when the number of the incoming momenta in the loop increases, the number of constraints becomes larger than the number of components of loop momentum for the generic values of the external momenta. Therefore there are excellent hopes of getting rid of UV divergences.

A stronger assumption encouraged by the classical space-time picture about virtual particles is that the 3-momenta associated with throats of the same wormhole contact are always in same or opposite directions. Even this allows to have virtual momentum spectrum and non-trivial mass spectrum for them assuming that the three momenta are opposite.

7. The best that one can hope is that only a finite number of generalized Feynman diagrams contributes to a given reaction. This would guarantee that amplitudes belong to a finite-dimensional algebraic extension of rational functions with rational coefficients since finite sums do not lead out from a finite algebraic extension of rationals. The first problem are self energy corrections. The assumption that the mass non-renormalization theorems of SUSYs generalize to TGD framework would guarantee that the loops contributing to fermionic propagators (and their super-counterparts) do not affect them. Also the iteration of more complex amplitudes as analogs of ladder diagrams representing sequences of reactions  $M \rightarrow M_1 \rightarrow M_2 \cdots \rightarrow N$  such that at each  $M_n$  in the sequence can appear as on mass shell state could give a non-vanishing contribution to the scattering amplitude and would mean infinite number of Feynman diagrams unless these amplitudes vanish. If  $N$  appears as a virtual state the fermions must be however massive on mass shell fermions by the assumption about on-mass shell states and one can indeed imagine a situation in which the decay  $M \rightarrow N$  is possible when  $N$  consists of states made of massless fermions is possible but not when the fermions have non-vanishing masses. This situation seems to be consistent with unitarity. The implication would be that the recursion formula for the all loop amplitudes for a given reaction would give vanishing result for some critical value of loops.

Already these assumptions give good hopes about a generalization of the momentum Grassmann approach to TGD framework. Twistors are doubled as are also the Grassmann variables and there are wave functions correlating the momenta of the the fermions associated with the opposite wormhole throats of the virtual particles as well as incoming gauge bosons which have suffered massivation. Also wave functions correlating the massless momenta at the ends of string like objects and more general many parton states are involved but do not affect the basic twistor formalism. The basic question is whether the hypothesis of unbroken Yangian symmetry could in fact imply something resembling this picture. The possibility to discretize integration contours without losing the representation as residue integral quite generally is basic prerequisite for this and should be shown to be true.

#### 7.4.2 How to achieve Yangian invariance without trivial scattering amplitudes?

In  $\mathcal{N} = 4$  SYM the Yangian invariance implies that the MHV amplitudes are constant as demonstrated in [33]. This would mean that the loop contributions to the scattering amplitudes are trivial. Therefore the breaking of the dual super-conformal invariance by IR singularities of the integrand is

absolutely essential for the non-triviality of the theory. Could the situation be different in TGD framework? Could it be possible to have non-trivial scattering amplitudes which are Yangian invariants. Maybe! The following heuristic argument is formulated in the language of super-twistors.

1. The dual conformal super generators of the super-Lie algebra  $U(2, 2)$  acting as super vector fields reducing effectively to the general form  $J = \eta_a^K \partial / \partial Z_a^J$  and the condition that they annihilate scattering amplitudes implies that they are constant as functions of twistor variables. When particles are replaced with pairs of wormhole throats the super generators are replaced by sums  $J_1 + J_2$  of these generators for the two wormhole throats and it might be possible to achieve the condition

$$(J_1 + J_2)M = 0 \quad (7.4.1)$$

with a non-trivial dependence on the momenta if the super-components of the twistors associated with the wormhole throats are in a linear relationship. This should be the case for bound states.

2. This kind of condition indeed exists. The condition that the sum of the super-momenta expressed in terms of super-spinors  $\lambda$  reduces to the sum of real momenta alone is not usually posed but in the recent case it makes sense as an additional condition to the super-components of the the spinors  $\lambda$  associated with the bound state. This quadratic condition is exactly of the same general form as the one following from the requirement that the sum of all external momenta vanishes for scattering amplitude and reads as

$$X = \lambda_1 \eta_1 + \lambda_2 \eta_2 = 0 \quad (7.4.2)$$

The action of the generators  $\eta_1 \partial_{\lambda_1} + \eta_2 \partial_{\lambda_2}$  forming basic building blocks of the super generators on  $p_1 + p_2 = \lambda_1 \lambda_1 + \lambda_2 \lambda_2$  appearing as argument in the scattering amplitude in the case of bound states gives just the quantity  $X$ , which vanishes so that one has super-symmetry. The generalization of this condition to n-parton bound state is obvious.
