# 第三十四章 高维时空有质量粒子的协变量子化

自我评述：本章将有质量粒子协变量子化推广到了一般 $N+1$ 维时空中。在 $N+1$ 维时空中与四维时空类似，对于Bargmann-Wigner方程或Dirac方程描述的粒子，一般来说既可以描述带荷的复粒子，也可以描述不带荷的马约拉纳粒子。两种情形的主对易规则形式一致，但其余对易或反对易括号，对带荷的复粒子一般为零；对不带荷的马约拉纳粒子，其余对易或反对易括号由主对易规则和马约拉纳条件自然得到，一般不为零。在本章只讨论复粒子情形，一般也只给出主对易规则，不再专门讨论马约拉纳粒子情形，若要得到马约拉纳粒子情形的量子场论，只需在复粒子情形加上马约拉纳条件即可自然得到。

# 第三十五章 高维时空无质量粒子的协变量子化

自我评述：本章将无质量粒子协变量子化推广到了一般 $N+1$ 维时空中。在特殊的 $N+1$ 维时空中与四维时空不同的是对于全对称Penrose方程描述的粒子，一般来说既可以描述带荷的复粒子，也可以描述不带荷的马约拉纳粒子。两种情形的主对易规则形式一致，但其余对易或反对易括号，对带荷的复粒子一般为零；对不带荷的马约拉纳粒子，其余对易或反对易括号由主对易规则和马约拉纳条件自然得到，一般不为零。在本章只讨论复粒子情形，一般也只给出主对易规则，不再专门讨论马约拉纳粒子情形，若要得到马约拉纳粒子情形的量子场论，只需在复粒子情形加上马约拉纳条件即可自然得到。

自我评述: 以上的证法不再基于等时对易规则, 直接基于协变对易规则, 看似更难了, 其实是更简单了, 因为不需要求出复杂的等时对易规则, 即使求出也比较难于使用, 而协变对易规则本身已知且很有规律, 也可以分解为自旋基的乘积, 整个证明过程基本上只依赖于自旋基的性质, 没有复杂的计算。其他的几个对易括号也可按同样的方法求出, 不再列出。

# 第三十六章 低维时空粒子的协变量子化

自我评述：对于Bargmann-Wigner方程或Dirac方程描述的粒子，一般来说既可以描述带荷的复粒子，也可以描述不带荷的马约拉纳粒子。两种情形的主对易规则形式一致，但其余对易或反对易括号，对带荷的复粒子一般为零；对不带荷的马约拉纳粒子，其余对易或反对易括号由主对易规则和马约拉纳条件自然得到，一般不为零。在本章只讨论复粒子情形，一般也只给出主对易规则，不再专门讨论马约拉纳粒子情形，若要得到马约拉纳粒子情形的量子场论，只需在复粒子情形加上马约拉纳条件即可自然得到。本章描述的二、三维时空粒子可以认为是四维时空粒子在y,z轴或z轴受限后的结果，因而有现实的意义，可以应用于凝聚态物理。另外二维时空粒子也可以认为是三维时空粒子在y轴进一步受限后的结果。三维时空粒子对应量子面；二维时空粒子对应量子线；一维时空粒子对应量子点。

# 第三十七章 N+1维时空B-W方程的势分析

自我评述：本章仿照四维情形，对N+1维时空中的Bargmann-Wigner方程进行了势分解和详细的数学分析。在自旋-1情形下自然而然出现了反对称张量场，并基于Bargmann-Wigner方程的对易规则推导出了反对称张量场的对易规则。与四维情形对比，N+1维时空中的B-W方程的势分析复杂好多，而且全对称的B-W方程不再描述单个自旋态，而是描述多个基本场。正是这点导致了复杂性，从而使这种推广失去了部分美感，也使这样的描述变得丑陋，这似乎暗示着这种推广变得意义不大了。比如在自旋-1情形直接研究基本的反对称张量场即可，因为它是单个基本场，更简单、更基本。本章没有对自旋 $-\frac{3}{2}, 2$ 等更高自旋情形进行详细讨论，只是给出了高自旋情形的两个猜想，严格证明等以后有时间再说。

通过本章的研究，我发现高于四维时空的全对称Bargmann-Wigner方程不再是描述物理场的好方法了，此时B-W方程不像四维时空中那样描述的是基本场，而是描述混合场，所以此时应该直接采用反对称张量场的描述方法更合适。

# 第三十八章 二阶完美常数不变张量

自我评述：本章主要是二阶完美常数不变张量的具体介绍，是对更一般完美常数不变张量的深入具体了解和具体扩展。若将全对称自旋张量提取高自旋的程序反复利用，就可以得到越来越高阶的完美常数不变张量。同时它是之前完美常数不变张量一般情形的特殊运用而已，故直接写出其结论即可，而无需再作证明。通过本章具体化的例子，更可以明确以下事实：完美常数不变张量只是反映了全对称代数结构的内在固有性质，只与全对称有关、与其它无关，因此表现出了一系列完美的代数性质和变换性质。本章符号约定符合以往规范，出了本章也不会混淆。本章节的完美常数不变张量与  $w = 1$  情形不同构。

# 第三十九章 Dirac型完美常数不变张量

自我评述：本章主要是Dirac型完美常数不变张量的具体介绍，是对更一般完美常数不变张量的深入具体了解 and 具体扩展。若将中微子自旋矩阵替换为Dirac矩阵，就可以得到Dirac型完美常数不变张量。同时它是之前完美常数不变张量一般情形的特殊运用而已，故直接写出其结论即可，而无需再作证明。本章符号约定符合以往规范，出了本章也不会混淆。本章节的完美常数不变张量与 $w = 1$ 情形同构，所以同样满足重要的复合常数不变张量那一章的展开性质，并具有完全相同的展开系数，为了节省篇幅，不再重复写出。

# 第四十章 多重完美常数不变张量

自我评述：本章主要是多重完美常数不变张量的具体介绍，是对更一般完美常数不变张量的深入具体了解和具体扩展。若将中微子自旋矩阵替换为多重矩阵，就可以得到多重完美常数不变张量。同时它是之前完美常数不变张量一般情形的特殊运用而已，故直接写出其结论即可，也无需再作证明。在此做出特别说明，本章的符号约定虽然尽量符合规范，但有些约定只限于本章，出了本章之外需重新约定，只有这样才不会出现混淆。本章节的完美常数不变张量与 $w = 1$ 情形同构，所以同样满足重要的复合常数不变张量那一章的展开性质，并具有完全相同的展开系数，为了节省篇幅，不再重复写出。

### 2.2 定义的解读

上述定义本质上是对所有  $\underbrace{0_\zeta \dots 0_\zeta}_{l_0} \underbrace{1_\zeta \dots 1_\zeta}_{l_1} \dots \underbrace{w_\zeta \dots w_\zeta}_{l_w}$  先进行排序编号。然后对每一个  $\underbrace{A_\zeta B_\zeta C_\zeta \dots}_{2s}$  赋值，即先排成  $\underbrace{0_\zeta \dots 0_\zeta}_{l_0} \underbrace{1_\zeta \dots 1_\zeta}_{l_1} \dots \underbrace{w_\zeta \dots w_\zeta}_{l_w}$  的形式，并与之前所有编号进行对比，如果与编号不一致的为零；与编号一致的不为零，并归一化，归一化系数是  $\underbrace{0_\zeta \dots 0_\zeta}_{l_0} \underbrace{1_\zeta \dots 1_\zeta}_{l_1} \dots \underbrace{w_\zeta \dots w_\zeta}_{l_w}$  全反对称化后所有种类数的倒数开方。以上常数不变张量只与旋量全反对称代数性质相关，与旋量变换性质无直接相关，是全反对称性张量内在固有的代数性质，与  $A_\zeta$  指标阶数直接本质相关。

### 2.3 常数矩阵 $\Gamma(s; w), \bar{\Gamma}(s; w)$ 的引入

定义2.3.1.  $\Gamma(s; w) \succ \Gamma_{A_\zeta \otimes B_\zeta \otimes C_\zeta \otimes \dots}^{k_\zeta}(s; w), \bar{\Gamma}(s; w) \succ \Gamma_{k_\zeta}^{\overbrace{A_\zeta \otimes B_\zeta \otimes C_\zeta \otimes \dots}^{2s}}(s; w) \simeq \Gamma^T(s; w)$

# 第四十二章 有质量粒子的高旋量场量子化方案

自我评述：本章运用Dirac型完美常数不变张量，将四维时空中的Bargmann-Wigner方程等价改造成高旋量场形式。并从高旋量场角度重新描述有质量粒子，形式上与Dirac粒子更接近，可以类比讨论，更具统一形式。并对照之前章节的内容，直接写下对应的等价高旋量场表述结果。这为高自旋有质量粒子的量子化提供了另一个视角，并结合原来的方案就可以灵活切换，从多个角度审视检验各种物理结果。事实上就是无质量粒子自旋方程量子化方案的对应，这样对有质量粒子和无质量粒子都有两套量子化方案，即高旋量场方案和分量场方案。形式上更有统一性，更有美感，同时也体现了Dirac型完美常数不变张量方法的有用之处，找到了用武之地。

# 第四十三章 基本粒子内部分量作用

自我评述：在本章中我大胆猜测提出一种新型的相互作用：粒子内部相互作用，是否正确有待实践验证。

## 1 基本粒子内部分量假设

基本粒子内部分量假设：假设基本粒子存在内部分量，每个分量对应一个几何点。标量粒子存在一个内部分量，对应一个几何点；中微子<sup>[5]</sup>存在两个内部分量，对应两个几何点；光子<sup>[7,8]</sup>存在三个内部分量，对应三个几何点；引力微子<sup>[20]</sup>存在四个内部分量，对应四个几何点；引力子<sup>[11-14]</sup>存在五个内部分量，对应五个几何点；电子<sup>[4]</sup>存在四个内部分量，对应四个几何点。

内部分量作用本质上就是量子纠缠，作用形式与传统相互作用不同，不是吸引和排斥，而是相互内部分量关联，是一种新的相互作用。但相互作用的传递速度仍为光速，而不是瞬时传递的；几个夸克形成重子就是完全内部分量作用；平时的平面波叠加就是无内部分量作用。

## 2 粒子复合理论

### 2.1 两个中微子合成一个光子的物理机制

起初有2个独立的中微子 $\chi$ 和 $\varphi$ ，然后发生一种目前还不知道的新相互作用，即内部分量间的相互作用，该作用使第一个中微子 $\chi$ 的第2分量在任何参考系下恒等于第二个中微子 $\varphi$ 的第1分量，即 $\chi_2 \equiv \varphi_1$ ，也就是内部分量的两个几何点重合，发生这个作用后，将无法维持之前独立的协变性，因为在各自独立的洛仑兹变换到其它参考系时， $\chi_2 \equiv \varphi_1$ 不能成立。所以导致的结果是使2个粒子共同形成一个新的协变性，产生新的自旋，从而变为新的粒子：光子。过程如下：

$$\begin{cases} (\sigma, -i\zeta)^a \partial_a \begin{bmatrix} \chi_1 \\ \chi_2 \end{bmatrix} = 0, \begin{bmatrix} \chi_1 \\ \chi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \\ (\sigma, -i\zeta)^a \partial_a \begin{bmatrix} \varphi_1 \\ \varphi_2 \end{bmatrix} = 0, \begin{bmatrix} \varphi_1 \\ \varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \end{cases} \Leftrightarrow (\sigma \otimes I, -i\zeta)^a \partial_a \begin{bmatrix} \chi_1 \\ \chi_2 \\ \varphi_1 \\ \varphi_2 \end{bmatrix} = 0, \begin{bmatrix} \chi_1 \\ \chi_2 \\ \varphi_1 \\ \varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \otimes I \quad (43.1)$$

两个内部分量几何点重合： $\chi_2 \equiv \varphi_1$ ，则有意义的方程变为

$$\rightarrow (\sigma \otimes I, -i\zeta)^a \partial_a \begin{bmatrix} \chi_1 \\ \chi_2 \equiv \varphi_1 \\ \varphi_1 \equiv \chi_2 \\ \varphi_2 \end{bmatrix} = 0, \begin{bmatrix} \chi_1 \\ \chi_2 \equiv \varphi_1 \\ \varphi_1 \equiv \chi_2 \\ \varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})}_{\text{原}} \otimes e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})}_{\text{新}} \quad (43.2)$$

$$\Leftrightarrow [\partial_a + S_{ab}(1, \zeta)\partial^b] \begin{bmatrix} \chi_1 \\ \chi_2 \equiv \varphi_1 \\ \varphi_2 \end{bmatrix} = 0, \begin{bmatrix} \chi_1 \\ \chi_2 \equiv \varphi_1 \\ \varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\tau(1)} \quad (43.3)$$

### 2.2 2s个中微子合成一个自旋-s粒子的物理机制

起初有2s个独立的中微子 ${}^i\varphi, i = 1, 2, \dots, 2s$ ，然后发生一种目前还不知道的新相互作用，即内部分量间的相互作用，该作用使第i个中微子 ${}^i\varphi$ 的第2分量在任何参考系下恒等于第i+1个中微子 ${}^{i+1}\varphi$ 的第1分量，即 ${}^i\varphi_2 \equiv {}^{i+1}\varphi_1$ ，也就是内部分量的两个相邻几何点重合，发生这个作用后，将无法维持之前独立的协变性，因为在各自独立的洛仑兹变换到其它参考系时， ${}^i\varphi_2 \equiv {}^{i+1}\varphi_1$ 不能成立。所以导致的结果是使2s个粒子共同形成一个新

的协变性，产生新的自旋，从而变为新的粒子：自旋-s粒子。过程如下：

$$\left\{ \begin{array}{l} (\sigma, -i\zeta)^a \partial_a \begin{bmatrix} {}^1\varphi_1 \\ {}^1\varphi_2 \end{bmatrix} = 0, \begin{bmatrix} {}^1\varphi_1 \\ {}^1\varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \\ (\sigma, -i\zeta)^a \partial_a \begin{bmatrix} {}^2\varphi_1 \\ {}^2\varphi_2 \end{bmatrix} = 0, \begin{bmatrix} {}^2\varphi_1 \\ {}^2\varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \\ \dots\dots\dots \\ (\sigma, -i\zeta)^a \partial_a \begin{bmatrix} {}^{2s}\varphi_1 \\ {}^{2s}\varphi_2 \end{bmatrix} = 0, \begin{bmatrix} {}^{2s}\varphi_1 \\ {}^{2s}\varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \end{array} \right. \quad (43.4)$$

$$\Leftrightarrow (\sigma \otimes I_{2s}, -i\zeta)^a \partial_a \begin{bmatrix} {}^1\varphi_1 \\ {}^1\varphi_2 \\ {}^2\varphi_1 \\ {}^2\varphi_2 \\ \dots \\ {}^{2s}\varphi_1 \\ {}^{2s}\varphi_2 \end{bmatrix} = 0, \begin{bmatrix} {}^1\varphi_1 \\ {}^1\varphi_2 \\ {}^2\varphi_1 \\ {}^2\varphi_2 \\ \dots \\ {}^{2s}\varphi_1 \\ {}^{2s}\varphi_2 \end{bmatrix} \sim e^{(i\omega+\zeta\epsilon)\cdot\sigma(\frac{1}{2})} \otimes I_{2s} \quad (43.5)$$

两个相邻粒子内部分量几何点重合： ${}^i\varphi_2 \equiv {}^{i+1}\varphi_1$ ，则有意义的方程变为：

以上的数学过程可以按多种方式进行正确理解，即若干个中微子先分成几组，每一组合成为一个新粒子，然后这些新粒子，再分组，每一组又合成为一个新粒子，这个过程可以循环往复，直到合成为单个自旋-s粒子为止，因此这个合成过程可以有好多组组合方式实现。所以两个中微子可以合成为一个光子；三个中微子可以合成为一个引力微子，一个中微子和一个光子可以合成为一个引力微子；四个中微子可以合成为一个引力子，两个中微子和一个光子可以合成为一个引力子，两个光子可以合成为一个引力子，一个中微子和一个引力微子可以合成为一个引力子等等。

### 4.3 左右超对称弦的超对称代数

$$\text{定义4.3.1. } \delta_\epsilon Y = [\epsilon Q + \bar{\epsilon} \bar{Q}, Y], \partial_a Y = i[P_a, Y]$$

$$\begin{aligned}

推论4.3.2.  $[\delta_{\epsilon_1}, \delta_{\epsilon_2}]Y = \{[\epsilon_1, \epsilon_2]\partial_z + [\bar{\epsilon}_1, \bar{\epsilon}_2]\partial_{\bar{z}}\}Y$

$\Leftrightarrow [[\epsilon_2 Q + \bar{\epsilon}_2 \bar{Q}, \epsilon_1 Q + \bar{\epsilon}_1 \bar{Q}], Y] = i[[\epsilon_1, \epsilon_2]P_{\bar{z}} + [\bar{\epsilon}_1, \bar{\epsilon}_2]P_z, Y]$

#### 4.4 左右超对称弦的超空间表示

推论4.4.1.  $D_\theta = \partial_\theta + \theta\partial_z, D_{\bar{\theta}} = \partial_{\bar{\theta}} + \bar{\theta}\partial_{\bar{z}}$

推论4.4.2.  $\hat{X}(z, \bar{z}, \theta, \bar{\theta}) = X + \theta\varphi + \bar{\theta}\bar{\varphi} + \theta\bar{\theta}F$

推论4.4.3.  $S = \int D_\theta \hat{X} D_{\bar{\theta}} \hat{X} d\theta d\bar{\theta} dz d\bar{z}$

### 5 局域超对称弦作用量 [44, 46, 47]

#### 5.1 世界面的超对称作用量

定理5.1.1.  $S = -\frac{1}{2} \int d\sigma d\tau e \{g^{ab} \partial_a X^u \partial_b X_u + i\bar{\psi}^u \gamma^a \partial_a \psi_u + 2i\bar{\chi}_a \gamma^b \gamma^a \psi^u [\partial_b X_u + \frac{i}{2} \bar{\psi}_u \chi_b]\}$

$$\begin{cases} \delta X^u = i\bar{\eta} \psi^u; \\ \delta e_\beta^b = -2i\bar{\eta} \gamma^b \psi_\beta; \\ \delta \psi^u = \gamma^a (\partial_a X^u + i\bar{\psi}^u \chi_a) \eta; \\ \delta \chi_\beta = -D_\beta \eta = -\partial_\beta \eta + \frac{i}{2} \omega_\beta \gamma^x \gamma^y \eta \end{cases}$$

#### 5.2 时空中的超对称作用量

定理5.2.1.  $S = -\frac{1}{2\pi} \int d\sigma d\tau e \{g^{ab} (\partial_a X^u - i \sum_A \bar{\theta}^A \gamma^u \partial_a \theta^A) (\partial_b X^u - i \sum_A \bar{\theta}^A \gamma^u \partial_b \theta^A)\}$

$+ \frac{1}{\pi} \int \{-idX^u \wedge (\bar{\theta}^1 \gamma_u d\theta^1 - \bar{\theta}^2 \gamma_u d\theta^2) + \bar{\theta}^1 \gamma^u d\theta^1 \wedge \bar{\theta}^2 \gamma_u d\theta^2\}$

$$\begin{cases} \delta \theta^A = \varepsilon^A \\ \delta X^u = \frac{i}{2} \sum_A (\bar{\varepsilon}^A \gamma^u \theta^A - \bar{\theta}^A \gamma^u \varepsilon^A) \equiv i \sum_A \bar{\varepsilon}^A \gamma^u \theta^A \end{cases}$$

#### 5.3 超对称理论的自旋表述

猜想5.3.1.

$$\begin{cases} [\frac{1}{2} \partial_a + iS_{ab}(\frac{1}{2}, \varsigma) \partial^b] \psi = 0 \\ [\partial_a + iS_{ab}(1, \varsigma) \partial^b] \hat{Q}^+ \psi = 0 \\ [\frac{3}{2} \partial_a + iS_{ab}(\frac{3}{2}, \varsigma) \partial^b] \hat{Q}^{+2} \psi = 0 \\ [2\partial_a + iS_{ab}(2, \varsigma) \partial^b] \hat{Q}^{+3} \psi = 0 \\ \dots \\ [s\partial_a + iS_{ab}(s, \varsigma) \partial^b] \hat{Q}^{+(2s-1)} \psi = 0 \end{cases}$$

是否可以找到满足以上条件的 $\hat{Q}$ 算子？但显然不是通常的超对称算子。
