## Abstract

Hundred years after the conjecture of the British astronomer *Eddington* that the sun is powered by nuclear fusion of hydrogen, new physics theory may help making energy harvesting by nuclear fusion soon a reality. Researchers as well as investors funding the fusion megaprojects are asked to deal with new relativistic corrections for mass and energy proposed by *Suleiman* in his Information Relativity Theory (*IRT*). It will help to decide whether a venture will be successful and to save big investments when in doubt. Nature is governed by the golden ratio and criticality of physical systems influenced by it, and nuclear physics is not an exception. Computer simulations of the underlying controlled nuclear fusion processes should gain profit from *IRT* corrected starting information and may tackle anew possible low energy nuclear transmutations considering the wave-like dark components of matter and energy. The assumed optimal kinetic energy for controlled nuclear fusion must be corrected to a somewhat higher level. At very high kinetic energy in the upper GeV range it remains not enough baryonic mass to be transformed in energy. The fusion probability faded out to zero already at the golden limit of the recession speed of  $v/c = \varphi = \frac{\sqrt{5}-1}{2}$  between target nucleon and projectile nucleon. Cold nuclear fusion, if ever possible, is recommended for protons rather than deuterons at highest experimental possible temperatures around 1000(K) and needs fine-tuned kinetic nucleon energy. It would be also of interest whether a golden ratio based nuclear fuel confinement chamber could be beneficial. In this connection also cold nuclear fusion setups should be discussed.

**Keywords:** Controlled Thermonuclear Fusion, Information Relativity Theory, Relativistic Corrections, Mass, Energy, Low Energy Nuclear Reaction, Golden Ratio, Golden Limit of Nuclear Fusion, Nuclear Fuel Resources.

## 1. Introduction

Big ideas often suffer from teething problems caused by the indolence with which just great scientists insists on what they have learnt and worked out. This contribution should serve to support ideas of a new physics and recommends application of these ideas to big projects of

the mankind such as thermonuclear fusion research and its technical realization. Success in application of the mentioned theory would also promote the theory itself.

Relativistic mass respectively energy corrections are very important when dealing with nuclear fusion and the dynamics of moving particles, where light atoms combine to larger ones accompanied by conversion of some mass into huge energy. A new theory of *Ramzi Suleiman*, named *Information Relativity* theory (*IRT*), has fixed an overlooked flaw in *Newton's* theory that leads to changes in relativistic corrections [1]. Many formal explanations or physical constructs that bothered long time the world of physics are overcome by the new exciting theory. Recently, the present author has performed relativistic mass corrections on the gyromagnetic factor of the electron [2] that also would change the charge of the electron a little bit [3]. It is connected with the important question whether we need at all the construct of quantization [1] [4]. Ever the golden ratio as the dominate number of nature is involved in such considerations, and so the *IRT* theory has to do with this fundamental number as will be shown below. More than this, the genetic code of the *DNA* is based on a golden mean hierarchy [5]. In this way it is stringent to deal with the new theory in every area of physics (and of life) knowing that even in fusion science and technology several disciplines of physics are combined. Especially attention must be paid to the wave-like dark component of mass energy density respectively energy density (see **Figure 1**). It is not the intention of the author to keep the reader away from studying the *IRT* theory in detail for himself. Therefore, only a sparse introduction was given. A concise overview on controlled nuclear fusion ideas and different technologies was recently summarized by *Clynes* [6] and should not be explained in detail. This isn't a review article with an almost complete reference list, but a contribution motivating others to think outside the box. In the long run we have to move away from the large energy projects towards more decentralized producers and distributors for the benefit of our environment.

During the preparation of this contribution the successful ignition of a controlled thermonuclear fusion reaction maintaining the reaction for about 10 seconds was reported from the staff of the *CFETR* reactor in Hefei, China.

## 2. New Relativistic Mass and Energy Corrections

*Suleiman* has set out to correct physical processes for time displacements between observer and moving bodies. Transformations for time duration, length, mass density as well as energy density were applied to a whole bunch of physical phenomena, which could be explained now in simple and beautiful clarity [1]. Indeed, this theory is an outstanding example for the beauty of the simple.

According to the *IRT* theory mass is transformed in dependence of the recession velocity of a moving body as [1]

$$\frac{m}{m_0} = \frac{1-\beta}{1+\beta} \quad (1)$$

where  $\beta = \frac{v}{c}$  is the recession velocity.

For the matter energy density  $e_M$  of a moving body with velocity  $v$  and rest density  $\rho_0$  on yields

$$e_M = \frac{1}{2} \rho v^2 = \frac{1}{2} \rho_0 c^2 \frac{(1-\beta)}{(1+\beta)} \beta^2 = e_0 \frac{(1-\beta)}{(1+\beta)} \beta^2, \quad (2)$$

where  $e_o = \frac{1}{2}\rho_o c^2$ .

The matter energy density reached its maximum at a recession velocity of  $\beta = \varphi$ , where  $\varphi = \frac{\sqrt{5}-1}{2} = 0.6180339887$  is the golden mean. Replacement of this special value in equation (2) gives

$$(e_M)_{max} = e_o \frac{(1-\varphi)}{(1+\varphi)} \varphi^2 = e_o \varphi^5 = e_o \cdot 0.09016994 \dots \quad (3)$$

Remembering,  $\varphi^5$  represents *Hardy's* maximum quantum entanglement probability [7]. This result was commented by the present author in a publication before mentioned [3].

*Suleiman* aptly characterized the behavior at the critical point  $\beta_{cr} = \varphi$  as phase criticality at cosmic scale [1] [8]. However,  $\varphi^5$  scaling seems to be a more general quality of phase transitions [9].

The dark matter density transforms as

$$\frac{e_{DM}}{e_o} = \frac{2\beta^3}{(1+\beta)} \quad (4)$$

If one calculates the energy density amounts (ratios) of matter and dark matter contributions at this point, one gets again a golden mean representation like *Russian dolls* nesting

$$\varphi^3 + 2\varphi^2 = 0.236067976 \dots + 0.763932023 \dots = 1 \quad (5)$$

The difference gives  $2\varphi^2 - \varphi^3 \approx (\sqrt{2} - 1) \frac{4}{\pi}$ , where  $\sqrt{2} - 1 = 0.414213 \dots$  is the silver mean. The case, where according to the *Information Relativity* theory of *Suleiman* [1][8] just at the recession velocity of  $\beta = 1/3$  the matter and the dark matter density will be the same, delivers for the density amount the reciprocal of *Lucas* number  $L_6 = 18$  [2].

The relative energy density components are depicted in **Figure 1** versus the recession velocity  $\beta$ . Also the golden mean hierarchy was displayed.

**Figure 1.** Components of relative energy density versus recession velocity  $\beta$  according to [1]. Red: baryonic matter energy density, black: dark component, green: matter energy density sum. The golden mean hierarchy was emphasized [2].

Instead of the recession velocity it may be useful to choose another variable, the redshift  $z = \frac{\beta}{1-\beta}$ . Applied matter density transformations in terms of the redshift yield [1]

$$\frac{\rho_M}{\rho_0} = \frac{1}{2z+1} \quad (6)$$

$$\frac{\rho_{DM}}{\rho_0} = \frac{2z}{2z+1} \quad (7)$$

**Figure 2.** Illustration of the complementary duality between matter density and dark matter density versus redshift. Logarithmic scale, red arrow at  $z = 1/2$ , blue arrow at  $z = \phi^{-1} = 1+\phi = 1.61803398$ .

As was demonstrated by Suleiman, an increase of the redshift  $z$  caused the matter density of the travelling corpuscular particle successively to diminish, while energy is transformed into the wave-like dark component and vice versa [1]. The complementary duality between matter density and dark matter density versus redshift was illustrated in **Figure 2**. Both figures describe precisely and elegantly what needs to be considered when dealing with colliding particles of high speed during nuclear fusion, ‘where each moving particle will be permeated by the dark matter halo of the other one making the two physically entangled’ [1].

### 3. Nuclear Fusion Reactions Reexamined

The first researcher who experimentally had demonstrated nuclear fusion was the *Australian* physicist *Oliphant* at Cambridge laboratory in 1934 [10]. The investigated nuclear fusion reactions are the basis of research and development up to now fusing nuclei of hydrogen isotopes deuterium and tritium respectively deuterium and helium-3 according to

The stability of atomic nuclei can be found in textbooks of nuclear physics, where the average binding energy per nucleon is depicted versus the atomic mass number ([Appendix Figure A1](#)).

The energy gain according to the basic exothermic fusion reaction (8), for instance, can be calculated from the difference in the rest energy of the constituents given in MeV

$$Q = (1875.6129 + 2809.4318 - 3728.3995 - 939.5653) \text{ MeV} = 17.59 \text{ MeV} \quad (10)$$

Whereas deuterium is abundantly available in seawater coming from comets that have reached the earth, for tritium there exists no sizable natural source due to its radioactive decomposition within a half-life time of about 12.3 years.

Tritium must therefore be produced by breeding from lithium [11], for instance by its reaction with neutrons produced during the fusion processes (tritium self-sufficiency).

In the near future, mankind will be able to extract by extraterrestrial mining  ${}^3\text{He}$  from the sunlit areas of the moon as a third-generation fusion fuel. This stable isotope stems from solar wind and has been stored in moon's uppermost rock layers. A possible fusion reaction between these nucleons is

An assumed cold nuclear fusion reaction, for instance, starting with two deuterons confined in an interstitial of the palladium metal lattice, would result in

The binding energy of the nucleons in the deuteron is relatively small and about 2.2 MeV. The nucleons (proton and neutron) are relatively far apart from each other by about 4 fm. Therefore, also a cascade of the following energetically more favorable reactions should be considered with three deuterons involved temporarily

Byproducts such as neutrons or sometimes tritium when excess of deuterium reacts with neutrons have been reported as observed experimentally [12]. A summing up of these reactions delivers again reaction (11). One can indeed place three neighboring deuterons in an octahedral interstitial of palladium besides nearby tetrahedral ones. In contrast to bulk  $\text{PdD}_x$ , where only octahedral sites are occupied, in the subsurface region of nanometer-sized material of  $\text{PdH}_x$ , also 30 percent of tetrahedral sites are occupied besides 70 percent of octahedral ones [13]. The same occupation scheme may be assumed for isomorphic  $\text{PdD}_x$ . For cold fusion experiments, a high deuterium loading near the ratio  $\text{Pd/D} = 1$  is of interest [14].

Now we want to set up the equation of motion for the colliding particles keeping a fuel of heavy water and lithium in the plasma state and accelerate deuterons towards the target. At very high particle speed we have to consider duality between both particles and waves (dark matter surrounding) using an elastic atomic collisions model as well as an elastic spring model associating the atomic collision model with particles and the spring model with waves. With respect to the speed probability distribution during a two-body collision between particles one can apply the *Lattice Boltzmann Method (LBM)* as a combination of the *Boltzmann* equation and the *Maxwell-Boltzmann* distribution function [15].

The tunneling probability  $P_G$  of two nuclear particles to overcome the *Coulomb* barrier was derived by *Gamov* [16] being

$$P_G(E) = \exp\left(-\sqrt{\frac{E_G}{E}}\right) \quad (15)$$

The *Gamov* energy  $E_G$  resulted in

$$E_G = (\pi\alpha Z_A Z_B)^2 2\mu c^2 \quad (16)$$

and the kinetic energy is

$$E = \frac{1}{2} \mu v^2 \quad (17)$$

where  $\alpha$  is *Sommerfeld's* fine-structure constant,  $\mu$  is the reduced mass,  $v$  is the speed between the two particles,  $c$  is the speed of light, and  $Z_A$  respectively  $Z_B$  are the proton numbers of the nucleons  $A$  respectively  $B$ . Importantly, the fine-structure constant  $\alpha$  in relation (16) has to be changed marginally [2] [3].

Using the *IRT* transformation for mass according to relation (1), the reduced mass  $\mu$  for a reaction involving two equal nuclear particles of rest mass  $m_0$  gets

$$\mu = \frac{m_0}{2} \cdot \frac{1-\beta}{1+\beta} \quad (18)$$

Finally one gets together with equation (2)

$$P_G(E) = \exp(-2\pi\alpha Z_A Z_B / \beta) \quad (19)$$

Following now *Cooley* [17] and considering that the particle's speed  $v$  is distributed by a *Maxwell-Boltzmann* function one can finally verify the probability (reactivity) for a fusion reaction to occur with two opposing energy terms under the exponential function

$$\langle \sigma v \rangle = \left(\frac{8}{\pi\mu}\right)^{1/2} \cdot \frac{S_0}{(kT)^{3/2}} \cdot \int_0^\infty \exp\left[-\left(\frac{E}{kT} + \sqrt{E_G/E}\right)\right] dE \quad (20)$$

where  $\sigma$  is the nuclear cross section expressing the likelihood of interaction between projectile particle and target

$$\sigma_{AB}(E) = \frac{S_0}{E} P_G(E) \quad (21)$$

The *Maxwell* averaged fusion cross section  $\langle\sigma v\rangle$  or reactivity has the dimension of  $cm^2 \cdot \frac{cm}{s} = \frac{cm^3}{s}$  with a constant  $S_0 (cm^2 keV)$ . It should be noticed that the upper integration limit of  $\infty$  in relation (20) is likely to be problematic because the speed of light is considered as limited. Therefore, equation (23) in the following explanation represents a more concise form using  $\beta = v/c$  instead of  $v$ .

The maximum of the non-relativistic integrant of relation (20) can be found by setting the first derivative equal to zero [17]

$$E_{max} = \left(\frac{kT}{2}\right)^{2/3} E_G^{1/3} \quad (22)$$

giving 
$$\beta_{max} = 2 \sqrt{\frac{E_{max}}{e_D}} = \sqrt[3]{4} \cdot \frac{(kT)^{1/3} E_G^{1/6}}{\sqrt{e_D}} = \sqrt[3]{4} \cdot \left(\frac{kT}{e_D}\right)^{1/3} \cdot \left(\frac{E_G}{e_D}\right)^{1/6} \quad (23)$$

Inserting relation (22) in equation (20) results in

$$\langle\sigma v\rangle_{max} = \left(\frac{8}{\pi\mu}\right)^{1/2} \cdot \frac{S_0}{(kT)^{3/2}} \cdot \exp\left(-3 \left(\frac{E_G}{4kT}\right)^{1/3}\right) \quad (24)$$

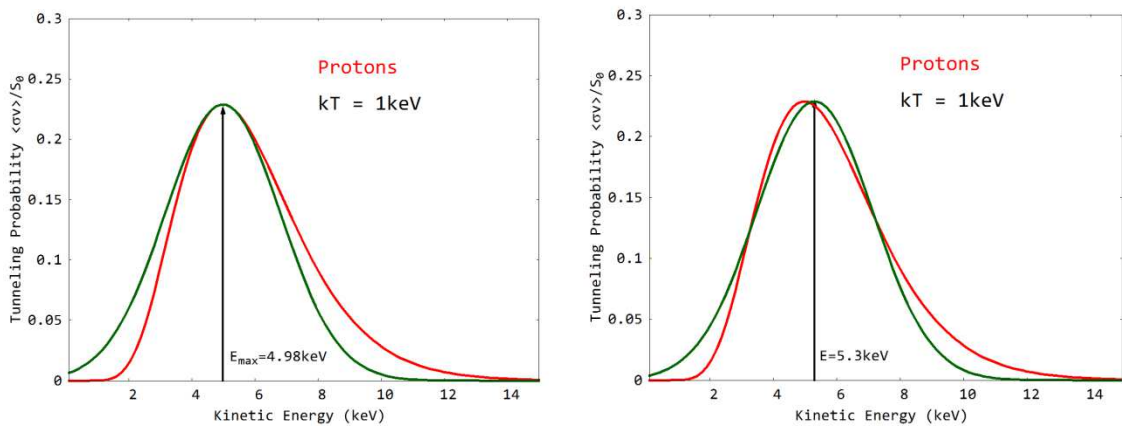

Approximating equation (20) by a *Gaussian*, one can calculate the integral width  $w_i$  yielding

$$w_i = \frac{2\sqrt{\pi}}{\sqrt{3}} kT \left(\frac{E_G}{4kT}\right)^{1/6} \quad (25)$$

and then the integral content

$$\langle\sigma v\rangle_{max} \cdot w_i = \frac{4\sqrt{2}}{\sqrt{3}} \frac{S_0}{\sqrt{kT} \cdot \sqrt{\mu}} \cdot \left(\frac{E_G}{4kT}\right)^{1/6} \cdot \exp\left(-3 \left(\frac{E_G}{4kT}\right)^{1/3}\right) \quad (26)$$

The approximation by a *Gaussian* is compared in **Figure 3** for the case of proton fusion applying  $kT = 1keV$ . A better adaption between both curves would result when the maximum of the *Gaussian* would be shifted to somewhat higher values  $> 4.98 keV$  (for example see right side of **Figure 3**).

**Figure 3.** Left: Comparison of the asymmetric fusion probability for protons (red) with a *Gaussian* (green) using maximum and integral width according to equations (24) respectively (25). Right: Shift of the *Gaussian* showing for instance its maximum now at 5.3 keV.

In [Table A1](#) of the [Appendix](#)  $\beta_{\max}$  values for selected  $kT$  have been compared for the non-relativistic case and the *IRT* corrected case. In [Figure 4](#) the tunneling probabilities and  $E_{\max}$  values at  $kT = 1\text{keV}$  for proton and deuteron nuclei have been compared. Notice the significantly higher proton probability increased by a factor of about 68.5 compared to deuterium.

**Figure 4.** Tunneling probability (arbitrary units) versus kinetic energy for non-relativistic proton respectively deuteron fusion at  $kT = 1\text{keV}$ . The right figure used a logarithmic scale.

The representation of the fusion probability in relation to the kinetic energy can be done also in logarithmic form as performed in [Figure 4](#) because  $\beta \propto \sqrt{E_{kin}}$  to compare both  $\beta$  representation and kinetic energy one. If one would translate the given result in the parlance of cold fusion it seems to be evident that proton fusion should be happen much more likely than deuterium fusion, if possible at all.

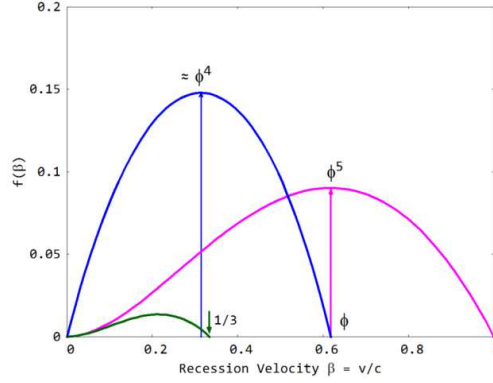

The *Information Relativity* theoretical solution based on equation (20) yielded the fusion probability in relation to the recession velocity  $\beta$  indirectly involving the golden mean, where  $\langle\sigma\beta\rangle$  has the dimension of  $(cm^2)$  and  $e_D = 1875.61294257(57)$  ( $MeV$ ) represents the rest energy of the deuteron [18] [19]. Integration is now taken within the changed limits from  $\beta = 0$  to 1

$$\begin{aligned} \langle\sigma\beta\rangle &= \frac{1}{c} \left( \frac{8 \cdot 2(1+\beta)}{\pi m_D(1-\beta)} \right)^{1/2} \cdot \frac{S_0}{(kT)^{3/2}} \cdot \int_0^1 \exp\left(-\frac{e_D}{4kT} \frac{(1-\beta)}{(1+\beta)} \beta^2 - \frac{2\pi\alpha Z_A Z_B}{\beta}\right) \frac{e_D \cdot \beta(1-\beta-\beta^2)}{2(1+\beta)^2} d\beta \\ &= \frac{2}{\sqrt{\pi}} \cdot \left( \frac{e_D}{kT} \right)^{1/2} \frac{S_0}{kT} \cdot \int_0^1 \frac{\beta(1-\beta-\beta^2)}{(1+\beta)\sqrt{(1-\beta^2)}} \exp\left(-\frac{e_D}{4kT} \frac{(1-\beta)}{(1+\beta)} \beta^2 - \frac{2\pi\alpha Z_A Z_B}{\beta}\right) d\beta \end{aligned} \quad (27)$$

The first integrand term being solely a function of  $\beta$  has a maximum of  $f(\beta) = 0.147847 \approx \varphi^4 = 0.145898 \dots$  at a recession speed of  $\beta_{\max} = 0.314026 \approx 0.30901699 = \varphi/2$  (see [Appendix](#)). It means that the maximum relative particle speed should be about a third of that of light. When following the blue outlined curve in [Figure 5](#), this parabola-like function has zeros at  $\beta = 0$  respectively  $\beta = \varphi$ , but is not fully symmetrical, when mirrored at a vertical through  $\beta = \varphi/2$ . Because we are dealing with a polynomial of third degree, a third

physically not meaningful zero is found at  $\beta = -\varphi^{-1}$ . This pre-factor is responsible for fading out of the tunneling probability of nuclear fusion to zero at the golden mean limit  $\beta = \varphi$ , just at the recession speed, where the relative energy density of baryonic matter reaches its maximum. Once more this golden limit can be assigned as a phase critical point transforming matter and energy [1] [2].

**Figure 5.** A comparison of different functions of the recession velocity  $\beta = \frac{v}{c}$ .

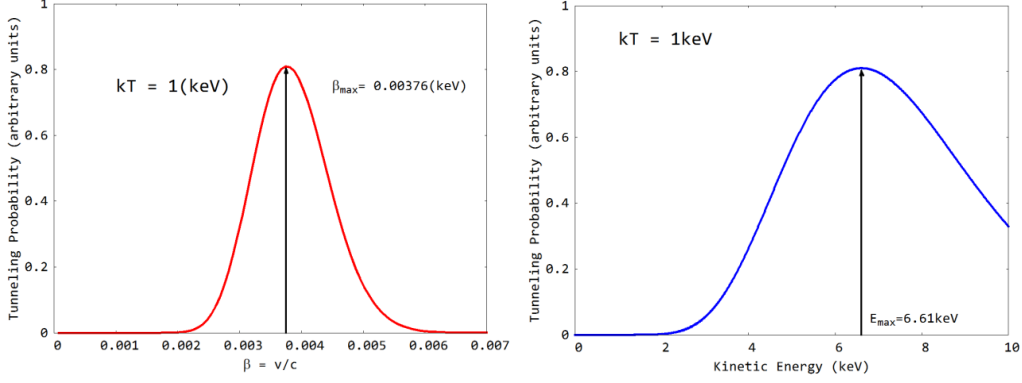

Magenta: *Hardy's* quantum probability function respectively *Suleiman's* energy density according to equation (2) with the maximum of  $\varphi^5$  at  $\beta = \varphi$ . Green: Difference curve between energy density and dark energy density. Blue: Parabola-like curve given by the first integrand term of equation (27).

The tunneling probability was calculated for the case of colliding deuterons depending of the recession speed as well as in dependence to the kinetic energy. The result was depicted in **Figure 5** for the case of  $kT = 1$  keV. The  $E_{\max} = 6.61$  keV value is slightly larger than that for the non-relativistic case with  $E_{\max} = 6.27$  keV. Also the half-width of the curve is pronounced greater using the *IRT* approach. The  $\beta$  representation is better suited to be approximated by a *Gaussian*. One can further ask at which  $kT$  the maximal probability is realized. This can be done by calculating  $\frac{d\langle\sigma\beta\rangle}{d(kT)} = 0$ . Its solution yielded

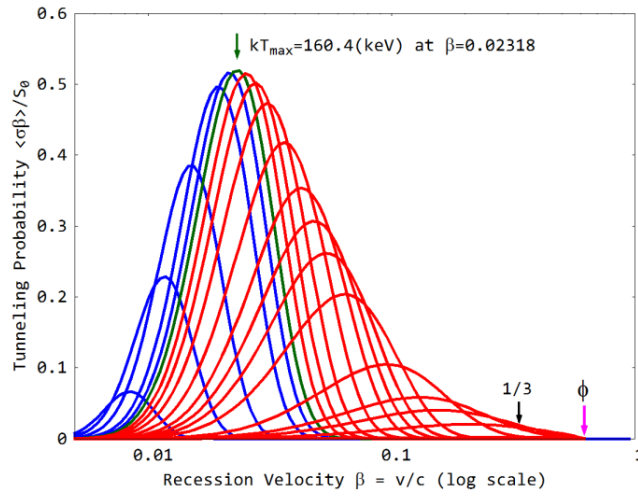

$$(kT)_{\max} = \frac{1}{6} e_D \frac{1-\beta}{1+\beta} \beta^2 \quad (28)$$

for  $\beta = \beta_{\max}$ . Inserting this result into equation (27) leads to the following simplified expression for maximum  $kT$

$$(kT)_{\max}: \quad \langle\sigma\beta\rangle_{\max} = 12 \cdot \sqrt{\frac{6}{\pi}} \cdot \exp\left(-\frac{3}{2}\right) \frac{S_0}{e_D} \cdot \frac{(1-\beta-\beta^2)}{\beta^2(1-\beta)^2} \exp\left(-\frac{2\pi\alpha Z_A Z_B}{\beta}\right) \quad (29)$$

**Figure 6.** Tunneling probability (arbitrary units) for deuterons with  $kT = 1\text{keV}$ . Left: versus recession velocity, right: versus kinetic energy (compare **Figure 4**).

**Figure 7.** Deuteron tunneling probability for a set of  $kT$  values (recession speed logarithmic scaled). The green arrow marks the green outlined maximum curve for  $kT = 160.4\text{ (keV)}$  at  $\beta = 0.02319$ , and the magenta arrow depicts the ultimate zero probability at limiting  $\beta = \phi = 0.6180339887$ .

**Figure 7** depicts a set of curves for different  $kT$  values indicating the overall maximum for  $kT = 160.4\text{ keV}$  at  $\beta_{\text{max}} = 0.023188$  ( $E_{\text{kin}} = 240.7\text{ keV}$ ) according to equation (26). Covering all maxima with an envelope shows that the limiting value is  $\beta = 1/3$ , where the probability at very high  $kT$  faded out to become completely zero. According to *IRT* at this special recession speed the amounts of matter density and dark matter density will be equal (**Figure 1**) [1] [2].

We will not write down the complex eighth degree polynomial resulting as first derivative of equation (27) to determine the zeros and maxima of that function, but instead use an approximation by modifying the simpler non-relativistic result given in equation (23). Whereas the low- $kT$  data follow the non-relativistic result, the high- $kT$  data can be approximated by a relation having the golden mean  $\phi$  in its pre-factor and exponent

$$\beta_{\text{max}}(kT) \approx \frac{\sqrt[3]{4}}{\phi^3} \cdot \left(\frac{kT}{e_D}\right)^{\phi/\sqrt{2}} \cdot \left(\frac{E_G}{e_D}\right)^{\phi/(2\cdot\sqrt{2})} \approx \frac{\sqrt[3]{4}}{2\phi} \cdot \left(\frac{kT}{e_D}\right)^{\phi/\sqrt{2}} \quad (30)$$

Another simple approximation valid over a larger  $kT$  range is given by the relation

$$\beta_{max}(kT) \approx \exp\left(\frac{3}{4}\sqrt{2} \cdot \left(\frac{kT}{e_D}\right)^{\sqrt{2}-1}\right) - 0.9993 \quad (31)$$

The different relationships were double-logarithmically documented by **Figure 8**.

**Figure 8.** Double logarithmic representation of  $kT$  versus the corresponding  $\beta_{max}$  for deuteron fusion. Magenta straight line: non-relativistic case according to equation (23). Green straight line: linear approximation of the high- $kT$  relativistic data. Cyan curve: approximation according to relation (31).

In addition, on can verify that at maximum  $kT$  it holds

$$\frac{E_{kin}}{kT_{max}} = \frac{3}{2} \quad (32)$$

as well as [20] 
$$\beta_{max} \approx \pi\alpha Z_A Z_B = 0.022935 Z_A Z_B \approx \frac{6\alpha}{5\varphi^2} Z_A Z_B \quad (33)$$

Again it should be pointed out that according to the *IRT* theory the charge of the electron respectively *Sommerfeld's* fine-structure constant have to be marginally but in view of the given high accuracy still noticeably corrected [2].

In this contribution arbitrary unit for the fusion probability were used because some parameters such as the slightly energy-dependent (astrophysical) parameter  $S_0$  are not sufficiently correct known and should be verified by a modified model calculation (see equation 21 and 23).

A more quantitative prediction of the released power  $\epsilon$  per unit mass and per second (power density) follows a non-relativistic approach already given by *Coolley* [17], but in an altered form and exemplified for protons

$$\epsilon = \frac{2^{8/3}}{\sqrt{3}} \cdot \frac{c \cdot \rho \cdot X_A X_B}{m_H^2 A_A A_B \sqrt{e_P}} Q S_0 \frac{E_G^{1/6}}{(kT)^{2/3}} \exp\left[-3 \left(\frac{E_G}{4kT}\right)^{1/3}\right] \quad (34)$$

where  $X_A$  respectively  $X_B$  are the nucleon abundances,  $\rho$  is the mass density,  $A_i$  are the atomic numbers,  $c$  is the speed of light, and  $S_0 = 4 \cdot 10^{-46} \text{cm}^2 \text{keV}$ . The proton fusion reaction [17]

delivers an energy of  $Q = 26.74 \text{ MeV} - 0.52 \text{ MeV} = 26.2 \text{ MeV}$  (36)

When identical nucleons collide,  $X_A = X_B = 0.5$ , the collision rate has in addition to be divided by 2. For conditions at the core of the sun ( $kT = 1(\text{keV})$ ,  $\rho = 150 \text{ g}\cdot\text{cm}^{-3}$ ) one can use the small energy unit of 1 (erg) =  $10^{-7}(\text{J})$  and calculate the non-relativistic power density to be about

$$\epsilon_{sun \ core} \approx 11.8 \text{ erg} \cdot \text{g}^{-1} \cdot \text{s}^{-1} \quad (37)$$

Turning now to the relativistic relation (24) and approximate the *Gaussian*-like fusion probability integral by the area given by multiplication of the height  $\langle \sigma\beta \rangle_{\max}$  with the integral width  $w_i = \frac{\sqrt{\pi}}{2\sqrt{\ln(2)}} \cdot w_{FW}$  giving [21]

$$\langle \sigma\beta \rangle / S_0 = \frac{\sqrt{\pi}}{2\sqrt{\ln(2)}} \langle \sigma\beta \rangle_{\max} \cdot w_{FW} \quad (38)$$

Again, with proton abundances  $X_A = X_B = 0.5$  and atomic number  $A_A = A_B = 1$  one finally yields for the relativistic power density

$$\epsilon^* = \frac{1}{2} \frac{\sqrt{\pi}}{2\sqrt{\ln(2)}} \frac{c \cdot \rho \cdot X_A X_B}{m_H^2 A_A A_B \sqrt{e_P}} \cdot Q \cdot S_0 \cdot \langle \sigma\beta \rangle_{\max} \cdot w_{FW} \quad (39)$$

For  $kT = 1\text{keV}$  one can estimate  $\langle \sigma\beta \rangle_{\max} = 0.001748$  respectively  $w_{FW} = 0.002039$  giving

$$\epsilon_{sun \ core}^* \approx 13.2 \text{ erg} \cdot \text{g}^{-1} \cdot \text{s}^{-1} \quad (40)$$

Specialists in the field of controlled thermo-nuclear fusion can use own experimental values such as the chosen  $kT$  and mass density of the nuclear fuel to verify result obtained with relation (39) using the different concepts of low fuel density combined with extreme temperature contrary to high fuel density and less temperature.

If one briefly summarizes the main results, the following can be noted. There exists a natural golden limit, where nuclear fusion stops down to zero probability. This happened at the recession speed between nucleons of  $\beta = \varphi$ . The probability distribution curve as a function of the nucleon speed is pronounced broader than in the case of the non-relativistic approach. The maximum probability is found at markedly enhanced speed respectively kinetic energy (see right side of [Figure 5](#)). In the GeV range of  $kT$  the maximum probability is found at  $\beta = \frac{1}{3}$ , straight at the recession speed at which baryonic matter energy and dark matter energy will become equal. It simply means the more moving matter is transformed to its wave-like

dark component, the less is available to be transformed in released energy by fusion of nucleons.

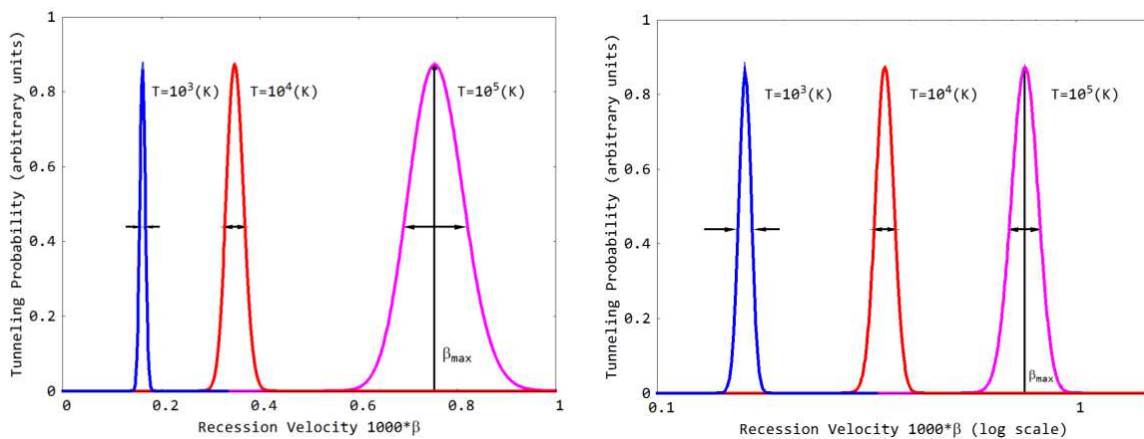

In the range of high particle speed hot fusion takes place in the halo of surrounding dark matter energy emerging from moving particles. It should be considered in an adequate way by varying equation (23). A related correction is in progress. Recently, such matter – dark matter coupling was excellently described for the case of disk galaxies by *Suleiman* [22]. Besides the action or involvement of dark matter in fusion physics also the validity of the *Gamov* approach [16] should be questioned critically.

Last but not least the probability for cold fusion remains an open question. Some *IRT* based calculations are summarized in the following chapter.

#### 4. Cold Nuclear Fusion

For the cold fusion at low  $kT$  a very sharp energy distribution around the cross section probability maximum can be expected. A cold fusion experiment must optimally meet these requirements for maximum kinetic energy in order to be successful at all. In the following calculated fusion probability curves for deuterium respectively proton nuclei are shown. In **Figure 8** the probability for deuteron fusion within the low-temperature range between  $10^3$  K and  $10^5$  K was presented depicting their small *Gaussian*-like distribution curves ( $T$  instead of  $kT$  was used). However, a further reduction of temperature failed to process the needed number of decimals with a home PC.

For the proton fusion the probability is markedly enhanced compared to deuterium fusion, and so the 500 K values could be calculated, too. If ever cold fusion is detectable, it should be realized using hydrogen at the experimentally highest possible temperature, for instance choosing about 1000 K = 727°C, for which the result is depicted in **Figure 9**. For  $T = 1000$  K one yields  $\beta_{max} = 0.20375$  corresponding to  $v_{max} \approx 60(\frac{km}{s})$  as the optimum speed with which the nuclei should be moved towards each other. The full width at half maximum is about  $\Delta\beta_{max} = 1.84 \cdot 10^{-5}$  (**Figure 9**). See also **Table A1** in the **Appendix**.

**Figure 9.** Tunneling probability for deuterons within the low-temperature range ( $10^3$ K to  $10^5$ K) indicating the extremely different half-width of the curves. The three curves of very different maxima have been adapted all to an equal height.

The draft of a more quantitative picture is currently under progress. In advance some ideas will be presented in the next chapter.

**Figure 10.** Widths of fusion probability curves for protons at ‘low’ temperatures. The 500 K curve must be reduced by a tremendously large factor of about  $3 \cdot 10^{34}$  in comparison to the 1000 K one (Table A2).

## 5. Tesla’s Energetic Pyramid Conjecture and Beyond

In connection with the Great Pyramid, mention may be made of the vision of the great inventor *Nicola Tesla* to harvest free energy from what we now characterize as dark components of matter respectively energy. Intuitive knowledge of great thinkers shouldn’t be confused with obsession. The reader can find more information about this discussion in the references [23] and [24]. Be that as it may, the golden mean based architecture of the Great Pyramid can serve as a proposal for a quite asymmetric nuclear fuel confinement chamber. In this connection the reader may also study the in-ellipsoid approach for less-symmetric solids such as the Great Pyramid to stimulate new ideas [25]. **Figure 11** shows a sketch of two opposed deuterium nucleons in an asymmetric-pyramidal micro-cage waiting for cold fusion to helium according to reaction (11), where the Great Pyramid served as a model.

Cold fusion experiments were described with atomic deuterium occluded in the cubic face-centered palladium lattice having 4 octahedral interstitials besides 8 tetrahedral ones in the unit-cell. First evidenced by *Fleischmann and Pons* [26], the reader may follow an explanation of lattice assisted low-energy nuclear fusion recently given by *Garai* [27], where two protons respectively deuterons are confined in the octahedral interstitials of the cubic Pd lattice. Theoretical considerations of *Gurbich* [28] indicate the problem of cold fusion.

Now we turn back to a pyramidal environment in contrast to the octahedral hole within the Pd lattice. If one would deposit Pd on the surface of a thin mica sheet and bend it cylindrically, the half-octahedral interstitial would be deformed towards the case described in **Figure 9**.

Possibly the occluded deuterons would be asymmetrically positioned at the interface between mica and palladium as illustrated in the **Figure 11**. It is suggested that a fusion reaction could be enhanced by such lattice deformation. However, we are still seeking for a more suitable host material. For micro-scale reactors one could deposit palladium on an atomic flat and highly reflecting (111) gold platelet [29] where the gold substrate serves also as a diffusion

barrier for hydrogen or deuterium [30]. The PdH<sub>x</sub> respectively PdD<sub>x</sub> contact layer is strained due to mismatch between the lattice parameters of gold and PdH<sub>x</sub> (PdD<sub>x</sub>) and should be able to host even more hydrogen or deuterium in the widened lattice. The upload of deuterium into the Pd lattice was estimated to be about  $1.2 \cdot 10^{23} \text{ cm}^{-3}$  [31]. Then one can calculate the mass density yielding  $\rho \approx 0.8 \text{ g} \cdot \text{cm}^{-3}$ .

The movement of the two nucleons against each other starting a fusion reaction can be supported by chaotic excessive resonance caused by focused ultrasonic energy loading of the confinement lattice bouncing back the nucleons from the walls with extremely high speed overcoming their *Coulomb* barriers [32] [33] [34] [35]. Fine-tuning of the applied cavitation energy according to the fusion probability maxima given in Chapter 4 is recommended. It is assumed that golden ratio governed geometry of the confinement can support chaotic bouncing of the nucleons against each other with a wanted distribution of collision angles. Because the particles moving with high speed are stretched in direction of the moving direction it makes a difference at which angle they collide. The relativistic longitudinal-transversal mass alteration already proposed in 1899 by *Lorentz* [36] should be recast in an *IRT* compatible version then applicable to the controlled nuclear fusion, too.

A *Lattice-Boltzmann* solution is currently in progress and should be published soon.

If one speculates about the reality of a cold fusion of atomic nuclei it may appropriate remembering the history of diamond synthesis, where *HPHT* synthesis has been successfully supplemented by cost-efficient *CVD* synthesis under sub-ambient conditions. In this sense the same success is desirable for cold fusion currently under progress.

**Figure 11.** Design of a pyramidal micro-cage containing two opposed deuterons consisting of proton (red) and neutron (blue). The yellow area is the projected maximum in-ellipsoid of such pyramid, where big  $\phi = \frac{1+\sqrt{5}}{2} = 1 + \varphi$  and  $\alpha = \arctan(\sqrt{\phi}) = 51.82729^\circ$  [24] [25].

## 6. Keeping a Watch on Nuclear Fuel Resources on Earth and Moon

This remark takes a look into the future. What would extraterrestrial powers do on earth, fight against human beings or only harvest rough materials such as deuterium from the ocean or  ${}^3_2\text{He}$  from the sunlit areas of the moon to fuel their spaceships, as yet unobserved but friendly? May be they already manage it. If so, we should start an across area monitoring of the sea water deuterium content to detect significant local variation before the ocean flow equalizes any left local difference. By the way, we had the technique to do this immediately, gaining also profit for other scientific areas besides precaution for the future. With respect to the

deuterium extraction from seawater we can assume that an extraterrestrial power surely knows processes like the archetype *Girdler-sulfide* process (*GS* process) [37], a two-temperature isotopic exchange process, or even seawater electrolysis, or a more sophisticated rapid gas effusion process.

## 7. Conclusions

There is a need of applying new physics to great technological challenges of our time such as providing the world's sustainable energy needs through controlled nuclear fusion. Large investments in this technique could soon bear fruit if new relativistic corrections for mass and energy according to the *IRT* theory would be considered in computer models as well as in the equipment. Possible changes in the equipment is a task of experts, but the recalculation of energy balances of nuclear fusion reactions can also be up to cooperating readers. When exemplarily calculating the fusion probability for deuterons or protons with *Suleiman's IRT* approach one can confirm markedly different results in comparison to the non-relativistic case. The maxima of the probability shift to somewhat higher energy and the probability versus energy respectively recession speed curves are markedly broader than compared to non-relativistic calculations. Consequently, the *IRT* corrected probability results recommend to correct the existing assumptions to somewhat higher values. There exists a golden limit where already at a recession speed of  $\beta = \varphi$  the fusion probability is zero. At extreme temperatures ( $kT > 1\text{GeV}$ ) the maximum of the fusion probability is found at  $\beta = 1/3$ , where baryonic matter energy and dark matter energy becomes equal. A more quantitative calculation depends on the availability of some values that should be accessed by an elaborated model calculation. The new approach should inspire researchers and big investors in the fusion technology proceed in this direction of new physics, touching besides physics the philosophical foundations of our world. The presented ideas may be extended to more cosmological questions such as avoiding the 'big bang' singularity hypothesis respectively the origin of the speed of light.

## Conflicts of Interest

The author declares no conflict of interests regarding the publication of this paper.

## Appendix

### Stability of Atomic Nuclei

**Figure A1.** Valley of stability for atomic nuclei explaining the nuclear fusion ability of elements left from the minimum respectively fission ability right from the minimum.

### Maximum of the Function $f(\beta)$

The maximum of the polynomial equation as part of the integrand of equation (23) can be found by setting the derivative equal to zero

$$f(\beta) = \frac{\beta(1-\beta-\beta^2)}{(1+\beta)\sqrt{(1-\beta^2)}} \quad (41)$$

$$f'(\beta) = \frac{\beta^4 + \beta^3 - \beta^2 - 3\beta + 1}{(1+\beta)(1-\beta^2)^{3/2}} = 0 \quad (42)$$

Result:  $f_{max} = 0.147847$  at  $\beta_{max} = 0.3140262767$

### Reciprocity Relation of the Function $f(\beta)$

Interestingly in the context of a previous contributions [2] [38], one can recast the function  $f(\beta)$  leading to a reciprocity relation

$$f(\beta) = \frac{\beta^{3/2}}{(1+\beta)} (\sqrt{(\beta^{-1} - \beta)} - (\sqrt{(\beta^{-1} - \beta)})^{-1}) \quad (43)$$

Furthermore, the zeros of the quadratic equation as part of equation (41)

$$\beta^2 - \beta + 1 = 0 \quad (44)$$

deliver the golden mean  $\beta_1 = \varphi$  and its negative reciprocal  $\beta_2 = -\varphi^{-1} = -(\varphi + 1)$  [9].

A further examination of this function yielded the following results that were depicted in **Figure A2**, considering the decomposition into reciprocal terms according to equation (43). The intersection point of the basic function with the magenta curve at  $\varphi = \sqrt{2} - 1 = 0.41421356 \dots$  is remarkable. The result representing the silver mean is given by solving the quadratic equation

$$\beta^2 + 2\beta - 1 = 0 \quad (45)$$

giving zeros at  $\beta_3 = \sqrt{2} - 1$  respectively  $\beta_4 = -(\sqrt{2} + 1)$ .

Furthermore interesting is the value of  $\sqrt{(\beta^{-1} - \beta)}$  at  $\beta = \varphi/2$  yielding

$$\sqrt{\frac{2}{\varphi} - \frac{\varphi}{2}} = 1.710862 \dots \approx \frac{\ln(2)}{\ln(3) - \ln(2)} = 1.709511 \dots \quad (46)$$

This numerical similarity may be important when interpreting *Suleiman's* result for rotating galaxies. When relating the galaxy's scale radius  $r_s$ , at which the rotation velocity equals half of its maximum value, to the galactic core radius  $r_c$ , where the energy densities of matter and dark matter are predicted to be equal [1], then one is faced exactly with the value  $\frac{r_s}{r_c} = 1.70951$  [21].

**Figure A2.** Illustration of the function  $f(\beta)$  according to equation (41). Green: basic function, red and magenta: decomposed reciprocal summands according to equation (34). The red circle is located at  $x = \frac{\varphi}{2}, y = \varphi^4$ .

**Table A1. IRT-Corrected Deuteron Fusion Data for selected values of  $kT$**

$\beta_{\max}$  respectively  $E$  values put in brackets were calculated for the non-relativistic case according to equation (23). The maximum of  $\langle\sigma\beta\rangle/S_0$  is given in different color.

$kT(\text{keV})$	$\beta_{\max}$	$\Delta\beta_{\max}$	$\Delta\beta_{\max}/\beta_{\max}$	$E(\text{keV})$	$\langle\sigma\beta\rangle_{\max}/S_0$

**Table A2. Full-Width of Fusion Probability Curves at ‘Low’ Temperature Comparing Deuterons with Protons**

$T(\text{K})$	Deuterons			Protons		
	$\beta_{\max}$	$\Delta\beta_{\max}$	$\Delta\beta_{\max}/\beta_{\max}$	$\beta_{\max}$	$\Delta\beta_{\max}$	$\Delta\beta_{\max}/\beta_{\max}$
$10^6$	<b>0.0016143</b>	<b>0.0004084</b>	<b>0.2489</b>			
$10^5$	0.0007538	0.0001300	0.1725	<b>0.0009423</b>	<b>0.0001315</b>	<b>0.1912</b>
$10^4$	0.0003485	0.0000414	0.1188	0.0004400	0.0000583	0.1325
$10^3$	0.0001617	0.0000131	0.0812	0.0002038	0.0000184	0.0903
$5 \cdot 10^2$				0.0001617	0.0000129	0.0800

Values of the relative width  $\Delta\beta_{\max}/\beta_{\max}$  that differ by a power of ten in temperature can be scaled by  $\ln(2)$  division. In this way further values can be generated as given in **Table A2** in brown color. In the same way one can scale down consecutive values of  $\beta_{\max}$  by  $\pi-1 =$

2.16159 division respectively  $\Delta\beta_{\max}$  by  $\pi = 3.14159$  division because  $\frac{\pi-1}{\pi} = 0.68169 \approx \ln(2) = 0.69315$ .

## Fundamental Constants and Quantities

**Table A3. Used Fundamental Constants and Quantities [3] [18] [19]**

Notation	Symbol	Quantity	Unit
Speed of light	$c$	$2.99792458 \cdot 10^8$	m/s
<i>Boltzmann</i> constant	$k$	$8.617333262 \cdot 10^{-11}$	MeV·K <sup>-1</sup>
