

Preventing advanced eugenics and generational testosterone decline

Gabriel-Claudiu Grama 
 Sunday 20th November, 2022

I. ABSTRACT

The goal of the paper is to prevent eugenics against testosterone, by disclosing its possible shapes, because the first step of preventing it, is to know that the idea/weakness exists. We cannot protect our selves from something that we don't know exists. We should not neglect the fact that testosterone levels have been dropping a lot in the last decades [1] [2] [3] [4], across generations, and independently of age.

II. KEYWORDS

eugenics, testosterone, decline, fear, inhibitor

III. CONTEXT

The entire article is built around the fact that testosterone is a fear inhibitor and that it is not compatible with fear as fuel for motivation.

IV. INTRODUCTION

While evolution is the survival of the good enough, eugenics is a scientifically erroneous and immoral field of planned breeding and racial improvement, which became very popular in the 20th century (especially among elitists), a century at which testosterone levels apparently started to drop across generations (independent of chronological aging), by a far from negligible amount, and continues to do so, in most likely all countries. And that's a big problem, because testosterone is a fear inhibitor, which means that if you do not have enough testosterone, then you have more fear, which makes you less likely to stand up for your self (and others) against corruption, and less motivated to fight and protect your country as a soldier. In other words: fear is an obstacle, while testosterone helps prevent you from being too afraid to fend off.

If fear is the only fuel for motivation that you are compatible with, then that makes you the perfect candidate for becoming a slave (the fear of missing out might also count). We are not suggesting that fear is always bad, nor that it is good in small amounts, but we are deeply concerned that it is possible to reduce testosterone levels across generations (and maybe even make the human body less sensitive to testosterone). If testosterone level, like height and muscle mass, is a human attribute (and it is), then in theory, it is possible to have a distinct human race which has less testosterone levels (depending on where we draw the line at defining the word "race"). At the time of writing this paper, that distinct race does obviously not exist yet, not even in Democratic People's Republic of Korea (DPRK).

If risk is viewed as part of taking opportunities, then too much fear can lead to hesitation in taking opportunities, potentially leading to less progress (not suggesting why most richest people are men), and there is no coincidence that gambling (taking opportunities) is so addictive that it is exploited and turned against us via disguised/conventional slot machines (a very long time ago, humans used to gamble their time, safety and other resources to find truth: learning new skills, developing new/better technologies, discovering what is on the other side of the

river, forests, valleys, mountains and oceans, etc.). Homo Neanderthals are believed to be an extinct human race, partly because they were much less gamblers (more content) than us, Homo Sapiens (we were more reliant on technological development through gambling, while the Neanderthals were stronger thus more reliant on physical abilities, therefore less incentives to search for truth). That was another reason why it is not a good idea to replace dopamine/gambling, with fear, via eugenics.

If you happen find symptoms or evidence for the eugenic system, that doesn't mean that the system is intended (it's probably just inherited), or it might just be a symptom of something else (or other things which may or may not be artificially caused, but are collectively contributing). Or maybe it's just a symptom of being *soldiers* of the economic wars that we inherit. It's hard to tell what the root cause is.

V. METHODOLOGY

1) The system:

- A system mainly based on debt and sanctions (expectations are debt too), where the only fuel for motivation is fear (or by making other fuels scarce enough).

2) Symptoms of the eugenic system (some of them):

- Most homeless people being men.
- Boys putting less effort at school, compared to girls (a collection of disciplines is a discipline system, and not an education system; disciplines cannot exist without punishment which creates fear).

3) Why this eugenic system works:

- Artificial selection: if fear does not prevent you from standing up, then that is an opportunity of artificial selection, through passive sanctions like joblessness, homelessness, prison, capital punishment and social isolation (the others contribute for it). Notice how the following play an important role here: scarce education, lack of free speech and ignorance to cognitive biases (psychological defects that all people have).

4) Subtly isolating the subjects within the eugenic system:

- The more difficult it is for gene inheritance to compete with wealth/status inheritance, the stronger the isolation (this passively helps support planned breeding).
- Passively planned breeding: from an eugenicist's point of view, you are just as good as dead, if you are not motivated enough by fear, which makes you less likely to be productive, thus more likely to become jobless/homeless or at least live in poverty and therefore less likely to be selected by a female to help produce offsprings (because females tend to have less testosterone which is compatible with the system, and therefore they tend to be better off than the victims of the system, who are, coincidentally, mostly males).

VI. RESULTS

We found subtle and passive, possible shapes of eugenics (presented in the Methodology), such that it leads to testosterone decline, across generations, independently of age.
