

P-ADIC LENGTH SCALE HYPOTHESIS  
AND DARK MATTER HIERARCHY

Matti Pitkänen

## Preface

This book belongs to a series of online books summarizing the recent state Topological Geometro-dynamics (TGD) and its applications. TGD can be regarded as a unified theory of fundamental interactions but is not the kind of unified theory as so called GUTs constructed by graduate students at seventies and eighties using detailed recipes for how to reduce everything to group theory. Nowadays this activity has been completely computerized and it probably takes only a few hours to print out the predictions of this kind of unified theory as an article in the desired format. TGD is something different and I am not ashamed to confess that I have devoted the last 32 years of my life to this enterprise and am still unable to write The Rules.

I got the basic idea of Topological Geometro-dynamics (TGD) during autumn 1978, perhaps it was October. What I realized was that the representability of physical space-times as 4-dimensional surfaces of some higher-dimensional space-time obtained by replacing the points of Minkowski space with some very small compact internal space could resolve the conceptual difficulties of general relativity related to the definition of the notion of energy. This belief was too optimistic and only with the advent of what I call zero energy ontology the understanding of the notion of Poincare invariance has become satisfactory.

It soon became clear that the approach leads to a generalization of the notion of space-time with particles being represented by space-time surfaces with finite size so that TGD could be also seen as a generalization of the string model. Much later it became clear that this generalization is consistent with conformal invariance only if space-time is 4-dimensional and the Minkowski space factor of imbedding space is 4-dimensional.

It took some time to discover that also the geometrization of also gauge interactions and elementary particle quantum numbers could be possible in this framework: it took two years to find the unique internal space providing this geometrization involving also the realization that family replication phenomenon for fermions has a natural topological explanation in TGD framework and that the symmetries of the standard model symmetries are much more profound than pragmatic TOE builders have believed them to be. If TGD is correct, main stream particle physics chose the wrong track leading to the recent deep crisis when people decided that quarks and leptons belong to same multiplet of the gauge group implying instability of proton.

There have been also longstanding problems.

- Gravitational energy is well-defined in cosmological models but is not conserved. Hence the conservation of the inertial energy does not seem to be consistent with the Equivalence Principle. Furthermore, the imbeddings of Robertson-Walker cosmologies turned out to be vacuum extremals with respect to the inertial energy. About 25 years was needed to realize that the sign of the inertial energy can be also negative and in cosmological scales the density of inertial energy vanishes: physically acceptable universes are creatable from vacuum. Eventually this led to the notion of zero energy ontology which deviates dramatically from the standard ontology being however consistent with the crossing symmetry of quantum field theories. In this framework the quantum numbers are assigned with zero energy states located at the boundaries of so called causal diamonds defined as intersections of future and past directed light-cones. The notion of energy-momentum becomes length scale dependent since one has a scale hierarchy for causal diamonds. This allows to understand the non-conservation of energy as apparent. Equivalence Principle generalizes and has a formulation in terms of coset representations of Super-Virasoro algebras providing also a justification for p-adic thermodynamics.
- From the beginning it was clear that the theory predicts the presence of long ranged classical electro-weak and color gauge fields and that these fields necessarily accompany classical electromagnetic fields. It took about 26 years to gain the maturity to admit the obvious: these fields are classical correlates for long range color and weak interactions assignable to dark matter. The only possible conclusion is that TGD physics is a fractal consisting of an entire hierarchy of fractal copies of standard model physics. Also the understanding of electro-weak massivation and screening of weak charges has been a long standing problem, and 32 years was needed to discover that what I call weak form of electric-magnetic duality gives a satisfactory solution of the problem and provides also surprisingly powerful insights to the mathematical structure of quantum TGD.

I started the serious attempts to construct quantum TGD after my thesis around 1982. The original optimistic hope was that path integral formalism or canonical quantization might be enough to construct the quantum theory but the first discovery made already during first year of TGD was that these formalisms might be useless due to the extreme non-linearity and enormous vacuum degeneracy of the theory. This turned out to be the case.

- It took some years to discover that the only working approach is based on the generalization of Einstein's program. Quantum physics involves the geometrization of the infinite-dimensional "world of classical worlds" (WCW) identified as 3-dimensional surfaces. Still few years had to pass before I understood that general coordinate invariance leads to a more or less unique solution of the problem and implies that space-time surfaces are analogous to Bohr orbits. Still a couple of years and I discovered that quantum states of the Universe can be identified as classical spinor fields in WCW. Only quantum jump remains the genuinely quantal aspect of quantum physics.
- During these years TGD led to a rather profound generalization of the space-time concept. Quite general properties of the theory led to the notion of many-sheeted space-time with sheets representing physical subsystems of various sizes. At the beginning of 90s I became dimly aware of the importance of p-adic number fields and soon ended up with the idea that p-adic thermodynamics for a conformally invariant system allows to understand elementary particle massivation with amazingly few input assumptions. The attempts to understand p-adicity from basic principles led gradually to the vision about physics as a generalized number theory as an approach complementary to the physics as an infinite-dimensional spinor geometry of WCW approach. One of its elements was a generalization of the number concept obtained by fusing real numbers and various p-adic numbers along common rationals. The number theoretical trinity involves besides p-adic number fields also quaternions and octonions and the notion of infinite prime.
- TGD inspired theory of consciousness entered the scheme after 1995 as I started to write a book about consciousness. Gradually it became difficult to say where physics ends and consciousness theory begins since consciousness theory could be seen as a generalization of quantum measurement theory by identifying quantum jump as a moment of consciousness and by replacing the observer with the notion of self identified as a system which is conscious as long as it can avoid entanglement with environment. "Everything is conscious and consciousness can be only lost" summarizes the basic philosophy neatly. The idea about p-adic physics as physics of cognition and intentionality emerged also rather naturally and implies perhaps the most dramatic generalization of the space-time concept in which most points of p-adic space-time sheets are infinite in real sense and the projection to the real imbedding space consists of discrete set of points. One of the most fascinating outcomes was the observation that the entropy based on p-adic norm can be negative. This observation led to the vision that life can be regarded as something in the intersection of real and p-adic worlds. Negentropic entanglement has interpretation as a correlate for various positively colored aspects of conscious experience and means also the possibility of strongly correlated states stable under state function reduction and different from the conventional bound states and perhaps playing key role in the energy metabolism of living matter.
- One of the latest threads in the evolution of ideas is only slightly more than six years old. Learning about the paper of Laurent Nottale about the possibility to identify planetary orbits as Bohr orbits with a gigantic value of gravitational Planck constant made once again possible to see the obvious. Dynamical quantized Planck constant is strongly suggested by quantum classical correspondence and the fact that space-time sheets identifiable as quantum coherence regions can have arbitrarily large sizes. During summer 2010 several new insights about the mathematical structure and interpretation of TGD emerged. One of these insights was the realization that the postulated hierarchy of Planck constants might follow from the basic structure of quantum TGD. The point is that due to the extreme non-linearity of the classical action principle the correspondence between canonical momentum densities and time derivatives of the imbedding space coordinates is one-to-many and the natural description of the situation is in terms of local singular covering spaces of the imbedding space. One could speak about effective value of Planck

constant coming as a multiple of its minimal value. The implications of the hierarchy of Planck constants are extremely far reaching so that the significance of the reduction of this hierarchy to the basic mathematical structure distinguishing between TGD and competing theories cannot be under-estimated.

From the point of view of particle physics the ultimate goal is of course a practical construction recipe for the S-matrix of the theory. I have myself regarded this dream as quite too ambitious taking into account how far reaching re-structuring and generalization of the basic mathematical structure of quantum physics is required. It has indeed turned out that the dream about explicit formula is unrealistic before one has understood what happens in quantum jump. Symmetries and general physical principles have turned out to be the proper guide line here. To give some impressions about what is required some highlights are in order.

- With the emergence of zero energy ontology the notion of S-matrix was replaced with M-matrix which can be interpreted as a complex square root of density matrix representable as a diagonal and positive square root of density matrix and unitary S-matrix so that quantum theory in zero energy ontology can be said to define a square root of thermodynamics at least formally.
- A decisive step was the strengthening of the General Coordinate Invariance to the requirement that the formulations of the theory in terms of light-like 3-surfaces identified as 3-surfaces at which the induced metric of space-time surfaces changes its signature and in terms of space-like 3-surfaces are equivalent. This means effective 2-dimensionality in the sense that partonic 2-surfaces defined as intersections of these two kinds of surfaces plus 4-D tangent space data at partonic 2-surfaces code for the physics. Quantum classical correspondence requires the coding of the quantum numbers characterizing quantum states assigned to the partonic 2-surfaces to the geometry of space-time surface. This is achieved by adding to the modified Dirac action a measurement interaction term assigned with light-like 3-surfaces.
- The replacement of strings with light-like 3-surfaces equivalent to space-like 3-surfaces means enormous generalization of the super conformal symmetries of string models. A further generalization of these symmetries to non-local Yangian symmetries generalizing the recently discovered Yangian symmetry of  $\mathcal{N} = 4$  supersymmetric Yang-Mills theories is highly suggestive. Here the replacement of point like particles with partonic 2-surfaces means the replacement of conformal symmetry of Minkowski space with infinite-dimensional super-conformal algebras. Yangian symmetry provides also a further refinement to the notion of conserved quantum numbers allowing to define them for bound states using non-local energy conserved currents.
- A further attractive idea is that quantum TGD reduces to almost topological quantum field theory. This is possible if the Kähler action for the preferred extremals defining WCW Kähler function reduces to a 3-D boundary term. This takes place if the conserved currents are so called Beltrami fields with the defining property that the coordinates associated with flow lines extend to single global coordinate variable. This ansatz together with the weak form of electric-magnetic duality reduces the Kähler action to Chern-Simons term with the condition that the 3-surfaces are extremals of Chern-Simons action subject to the constraint force defined by the weak form of electric magnetic duality. It is the latter constraint which prevents the trivialization of the theory to a topological quantum field theory. Also the identification of the Kähler function of WCW as Dirac determinant finds support as well as the description of the scattering amplitudes in terms of braids with interpretation in terms of finite measurement resolution coded to the basic structure of the solutions of field equations.
- In standard QFT Feynman diagrams provide the description of scattering amplitudes. The beauty of Feynman diagrams is that they realize unitarity automatically via the so called Cutkosky rules. In contrast to Feynman's original beliefs, Feynman diagrams and virtual particles are taken only as a convenient mathematical tool in quantum field theories. QFT approach is however plagued by UV and IR divergences and one must keep mind open for the possibility that a genuine progress might mean opening of the black box of the virtual particle.

In TGD framework this generalization of Feynman diagrams indeed emerges unavoidably. Light-like 3-surfaces replace the lines of Feynman diagrams and vertices are replaced by 2-D partonic

2-surfaces. Zero energy ontology and the interpretation of parton orbits as light-like "wormhole throats" suggests that virtual particles do not differ from mass shell particles only in that the four- and three- momenta of wormhole throats fail to be parallel. The two throats of the wormhole defining virtual particle would contact carry on mass shell quantum numbers but for virtual particles the four-momenta need not be parallel and can also have opposite signs of energy. Modified Dirac equation suggests a number theoretical quantization of the masses of the virtual particles. The kinematic constraints on the virtual momenta are extremely restrictive and reduce the dimension of the sub-space of virtual momenta and if massless particles are not allowed (IR cutoff provided by zero energy ontology naturally), the number of Feynman diagrams contributing to a particular kind of scattering amplitude is finite and manifestly UV and IR finite and satisfies unitarity constraint in terms of Cutkosky rules. What is remarkable that fermionic propagators are massless propagators but for on mass shell four-momenta. This gives a connection with the twistor approach and inspires the generalization of the Yangian symmetry to infinite-dimensional super-conformal algebras.

What I have said above is strongly biased view about the recent situation in quantum TGD and I have left all about applications to the introductions of the books whose purpose is to provide a bird's eye view about TGD as it is now. This vision is single man's view and doomed to contain unrealistic elements as I know from experience. My dream is that young critical readers could take this vision seriously enough to try to demonstrate that some of its basic premises are wrong or to develop an alternative based on these or better premises. I must be however honest and tell that 32 years of TGD is a really vast bundle of thoughts and quite a challenge for anyone who is not able to cheat himself by taking the attitude of a blind believer or a light-hearted debunker trusting on the power of easy rhetoric tricks.

## Acknowledgements

Neither TGD nor these books would exist without the help and encouragement of many people. The friendship with Heikki and Raija Haila and their family have kept me in contact with the everyday world and without this friendship I would not have survived through these lonely 32 years most of which I have remained unemployed as a scientific dissident. I am happy that my children have understood my difficult position and like my friends have believed that what I am doing is something valuable although I have not received any official recognition for it.

During last decade Tapio Tammi has helped me quite concretely by providing the necessary computer facilities and being one of the few persons in Finland with whom to discuss about my work. I have had also stimulating discussions with Samuli Penttinen who has also helped to get through the economical situations in which there seemed to be no hope. The continual updating of fifteen online books means quite a heavy bureaucracy at the level of bits and without a systemization one ends up with endless copying and pasting and internal consistency is soon lost. Pekka Rapinoja has offered his help in this respect and I am especially grateful for him for my Python skills. Also Matti Vallinkoski has helped me in computer related problems.

The collaboration with Lian Sidorov was extremely fruitful and she also helped me to survive economically through the hardest years. The participation to CASYS conferences in Liege has been an important window to the academic world and I am grateful for Daniel Dubois and Peter Marcer for making this participation possible. The discussions and collaboration with Eduardo de Luna and Istvan Dienes stimulated the hope that the communication of new vision might not be a mission impossible after all. Also blog discussions have been very useful. During these years I have received innumerable email contacts from people around the world. In particular, I am grateful for Mark McWilliams and Ulla Matfolk for providing links to possibly interesting web sites and articles. These contacts have helped me to avoid the depressive feeling of being some kind of Don Quixote of Science and helped me to widen my views: I am grateful for all these people.

In the situation in which the conventional scientific communication channels are strictly closed it is important to have some loop hole through which the information about the work done can at

---

least in principle leak to the publicity through the iron wall of the academic censorship. Without any exaggeration I can say that without the world wide web I would not have survived as a scientist nor as individual. Homepage and blog are however not enough since only the formally published result is a result in recent day science. Publishing is however impossible without a direct support from power holders- even in archives like arXiv.org.

Situation changed for five years ago as Andrew Adamatsky proposed the writing of a book about TGD when I had already got used to the thought that my work would not be published during my life time. The Prespacetime Journal and two other journals related to quantum biology and consciousness - all of them founded by Huping Hu - have provided this kind of loop holes. In particular, Dainis Zeps, Phil Gibbs, and Arkadiusz Jadczyk deserve my gratitude for their kind help in the preparation of an article series about TGD catalyzing a considerable progress in the understanding of quantum TGD. Also the viXra archive founded by Phil Gibbs and its predecessor Archive Freedom have been of great help: Victor Christianto deserves special thanks for doing the hard work needed to run Archive Freedom. Also the Neuroquantology Journal founded by Sultan Tarlaci deserves a special mention for its publication policy. And last but not least: there are people who experience as a fascinating intellectual challenge to spoil the practical working conditions of a person working with something which might be called unified theory: I am grateful for the people who have helped me to survive through the virus attacks, an activity which has taken roughly one month per year during the last half decade and given a strong hue of grey to my hair.

For a person approaching his sixty year birthday it is somewhat easier to overcome the hard feelings due to the loss of academic human rights than for an inpatient youngster. Unfortunately the economic situation has become increasingly difficult during the twenty years after the economic depression in Finland which in practice meant that Finland ceased to be a constitutional state in the strong sense of the word. It became possible to depose people like me from the society without fear about public reactions and the classification as dropout became a convenient tool of ridicule to circumvent the ethical issues. During last few years when the right wing has held the political power this trend has been steadily strengthening. In this kind of situation the concrete help from individuals has been and will be of utmost importance. Against this background it becomes obvious that this kind of work is not possible without the support from outside and I apologize for not being able to mention all the people who have helped me during these years.

## Introduction

### 1.1 Basic Ideas of TGD

The basic physical picture behind TGD was formed as a fusion of two rather disparate approaches: namely TGD as a Poincare invariant theory of gravitation and TGD as a generalization of the old-fashioned string model.

#### 1.1.1 Background

*T(opological) G(eometro)D(ynamics)* is one of the many attempts to find a unified description of basic interactions. The development of the basic ideas of TGD to a relatively stable form took time of about half decade [K1]. The great challenge is to construct a mathematical theory around these physically very attractive ideas and I have devoted the last twenty-three years for the realization of this dream and this has resulted in seven online books about TGD and eight online books about TGD inspired theory of consciousness and of quantum biology.

Quantum T(opological) G(eometro)D(ynamics) as a classical spinor geometry for infinite-dimensional configuration space, p-adic numbers and quantum TGD, and TGD inspired theory of consciousness and of quantum biology have been for last decade of the second millenium the basic three strongly interacting threads in the tapestry of quantum TGD.

For few years ago the discussions with Tony Smith initiated a fourth thread which deserves the name 'TGD as a generalized number theory'. The basic observation was that classical number fields might allow a deeper formulation of quantum TGD. The work with Riemann hypothesis made time ripe for realization that the notion of infinite primes could provide, not only a reformulation, but a deep generalization of quantum TGD. This led to a thorough and extremely fruitful revision of the basic views about what the final form and physical content of quantum TGD might be. Together with the vision about the fusion of p-adic and real physics to a larger coherent structure these sub-threads fused to the "physics as generalized number theory" th

A further thread emerged from the realization that by quantum classical correspondence TGD predicts an infinite hierarchy of macroscopic quantum systems with increasing sizes, that it is not at all clear whether standard quantum mechanics can accommodate this hierarchy, and that a dynamical quantized Planck constant might be necessary and certainly possible in TGD framework. The identification of hierarchy of Planck constants whose values TGD "predicts" in terms of dark matter hierarchy would be natural. This also led to a solution of a long standing puzzle: what is the proper interpretation of the predicted fractal hierarchy of long ranged classical electro-weak and color gauge fields. Quantum classical correspondences allows only single answer: there is infinite hierarchy of p-adically scaled up variants of standard model physics and for each of them also dark hierarchy. Thus TGD Universe would be fractal in very abstract and deep sense.

Every updating of the books makes me frustrated as I see how badly the structure of the representation reflects my bird's eye of view as it is at the moment of updating. At this time I realized that the chronology based identification of the threads is quite natural but not logical and it is much more logical to see p-adic physics, the ideas related to classical number fields, and infinite primes as sub-threads of a thread which might be called "physics as a generalized number theory". In the

following I adopt this view. This reduces the number of threads to four! I am not even sure about the number of threads! Be patient!

TGD forces the generalization of physics to a quantum theory of consciousness, and represent TGD as a generalized number theory vision leads naturally to the emergence of p-adic physics as physics of cognitive representations. The seven online books [K80, K60, K48, K45, K61, K70, K68] about TGD and eight online books about TGD inspired theory of consciousness and of quantum biology [K74, K12, K53, K10, K29, K36, K40, K67] are warmly recommended to the interested reader.

### 1.1.2 TGD as a Poincare invariant theory of gravitation

The first approach was born as an attempt to construct a Poincare invariant theory of gravitation. Space-time, rather than being an abstract manifold endowed with a pseudo-Riemannian structure, is regarded as a surface in the 8-dimensional space  $H = M^4 \times CP_2$ , where  $M^4$  denotes Minkowski space and  $CP_2 = SU(3)/U(2)$  is the complex projective space of two complex dimensions [A13, A5, A10, A4].

The identification of the space-time as a submanifold [A3, A12] of  $M^4 \times CP_2$  leads to an exact Poincare invariance and solves the conceptual difficulties related to the definition of the energy-momentum in General Relativity.

It soon however turned out that submanifold geometry, being considerably richer in structure than the abstract manifold geometry, leads to a geometrization of all basic interactions. First, the geometrization of the elementary particle quantum numbers is achieved. The geometry of  $CP_2$  explains electro-weak and color quantum numbers. The different H-chiralities of  $H$ -spinors correspond to the conserved baryon and lepton numbers. Secondly, the geometrization of the field concept results. The projections of the  $CP_2$  spinor connection, Killing vector fields of  $CP_2$  and of  $H$ -metric to four-surface define classical electro-weak, color gauge fields and metric in  $X^4$ .

### 1.1.3 TGD as a generalization of the hadronic string model

The second approach was based on the generalization of the mesonic string model describing mesons as strings with quarks attached to the ends of the string. In the 3-dimensional generalization 3-surfaces correspond to free particles and the boundaries of the 3- surface correspond to partons in the sense that the quantum numbers of the elementary particles reside on the boundaries. Various boundary topologies (number of handles) correspond to various fermion families so that one obtains an explanation for the known elementary particle quantum numbers. This approach leads also to a natural topological description of the particle reactions as topology changes: for instance, two-particle decay corresponds to a decay of a 3-surface to two disjoint 3-surfaces.

This decay vertex does not however correspond to a direct generalization of trouser vertex of string models. Indeed, the important difference between TGD and string models is that the analogs of string world sheet diagrams do not describe particle decays but the propagation of particles via different routes. Particle reactions are described by generalized Feynman diagrams for which 3-D light-like surface describing particle propagating join along their ends at vertices. As 4-manifolds the space-time surfaces are therefore singular like Feynman diagrams as 1-manifolds.

### 1.1.4 Fusion of the two approaches via a generalization of the space-time concept

The problem is that the two approaches to TGD seem to be mutually exclusive since the orbit of a particle like 3-surface defines 4-dimensional surface, which differs drastically from the topologically trivial macroscopic space-time of General Relativity. The unification of these approaches forces a considerable generalization of the conventional space-time concept. First, the topologically trivial 3-space of General Relativity is replaced with a "topological condensate" containing matter as particle like 3-surfaces "glued" to the topologically trivial background 3-space by connected sum operation. Secondly, the assumption about connectedness of the 3-space is given up. Besides the "topological condensate" there could be "vapor phase" that is a "gas" of particle like 3-surfaces (counterpart of the "baby universes" of GRT) and the nonconservation of energy in GRT corresponds to the transfer of energy between the topological condensate and vapor phase.

What one obtains is what I have christened as many-sheeted space-time. One particular aspect is topological field quantization meaning that various classical fields assignable to a physical system

correspond to space-time sheets representing the classical fields to that particular system. One can speak of the field body of a particular physical system. Field body consists of topological light rays, and electric and magnetic flux quanta. In Maxwell's theory system does not possess this kind of field identity. The notion of magnetic body is one of the key players in TGD inspired theory of consciousness and quantum biology.

This picture became more detailed with the advent of zero energy ontology (ZEO). The basic notion of ZEO is causal diamond ( $CD$ ) identified as the Cartesian product of  $CP_2$  and of the intersection of future and past directed light-cones and having scale coming as an integer multiple of  $CP_2$  size is fundamental.  $CD$ s form a fractal hierarchy and zero energy states decompose to products of positive and negative energy parts assignable to the opposite boundaries of  $CD$  defining the ends of the space-time surface. The counterpart of zero energy state in positive energy ontology is in terms of initial and final states of a physical event, say particle reaction.

General Coordinate Invariance allows to identify the basic dynamical objects as space-like 3-surfaces at the ends of space-time surface at boundaries of  $CD$ : this means that space-time surface is analogous to Bohr orbit. An alternative identification is as light-like 3-surfaces at which the signature of the induced metric changes from Minkowskian to Euclidian and interpreted as lines of generalized Feynman diagrams. Also the Euclidian 4-D regions would have similar interpretation. The requirement that the two interpretations are equivalent, leads to a strong form of General Coordinate Invariance. The outcome is effective 2-dimensionality stating that the partonic 2-surfaces identified as intersections of the space-like ends of space-time surface and light-like wormhole throats are the fundamental objects. That only effective 2-dimensionality is in question is due to the effects caused by the failure of strict determinism of Kähler action. In finite length scale resolution these effects can be neglected below UV cutoff and above IR cutoff. One can also speak about strong form of holography.

There is a further generalization of the space-time concept inspired by p-adic physics forcing a generalization of the number concept through the fusion of real numbers and various p-adic number fields. Also the hierarchy of Planck constants forces a generalization of the notion of space-time.

A very concise manner to express how TGD differs from Special and General Relativities could be following. Relativity Principle (Poincare Invariance), General Coordinate Invariance, and Equivalence Principle remain true. What is new is the notion of sub-manifold geometry: this allows to realize Poincare Invariance and geometrize gravitation simultaneously. This notion also allows a geometrization of known fundamental interactions and is an essential element of all applications of TGD ranging from Planck length to cosmological scales. Sub-manifold geometry is also crucial in the applications of TGD to biology and consciousness theory.

The worst objection against TGD is the observation that all classical gauge fields are expressible in terms of four imbedding space coordinates only- essentially  $CP_2$  coordinates. The linear superposition of classical gauge fields taking place independently for all gauge fields is lost. This would be a catastrophe without many-sheeted space-time. Instead of gauge fields, only the effects such as gauge forces are superposed. Particle topologically condenses to several space-time sheets simultaneously and experiences the sum of gauge forces. This transforms the weakness to extreme economy: in a typical unified theory the number of primary field variables is countered in hundreds if not thousands, now it is just four.

## 1.2 The threads in the development of quantum TGD

The development of TGD has involved several strongly interacting threads: physics as infinite-dimensional geometry; TGD as a generalized number theory, the hierarchy of Planck constants interpreted in terms of dark matter hierarchy, and TGD inspired theory of consciousness. In the following these threads are briefly described.

### 1.2.1 Quantum TGD as spinor geometry of World of Classical Worlds

A turning point in the attempts to formulate a mathematical theory was reached after seven years from the birth of TGD. The great insight was "Do not quantize". The basic ingredients to the new approach have served as the basic philosophy for the attempt to construct Quantum TGD since then and have been the following ones:

1. Quantum theory for extended particles is free(!), classical(!) field theory for a generalized Schrödinger amplitude in the configuration space  $CH$  consisting of all possible 3-surfaces in  $H$ . "All possible" means that surfaces with arbitrary many disjoint components and with arbitrary internal topology and also singular surfaces topologically intermediate between two different manifold topologies are included. Particle reactions are identified as topology changes [A8, A14, A15]. For instance, the decay of a 3-surface to two 3-surfaces corresponds to the decay  $A \rightarrow B + C$ . Classically this corresponds to a path of configuration space leading from 1-particle sector to 2-particle sector. At quantum level this corresponds to the dispersion of the generalized Schrödinger amplitude localized to 1-particle sector to two-particle sector. All coupling constants should result as predictions of the theory since no nonlinearities are introduced.
2. During years this naive and very rough vision has of course developed a lot and is not anymore quite equivalent with the original insight. In particular, the space-time correlates of Feynman graphs have emerged from theory as Euclidian space-time regions and the strong form of General Coordinate Invariance has led to a rather detailed and in many respects un-expected visions. This picture forces to give up the idea about smooth space-time surfaces and replace space-time surface with a generalization of Feynman diagram in which vertices represent the failure of manifold property. I have also started introduced the word "world of classical worlds" (WCW) instead of rather formal "configuration space". I hope that "WCW" does not induce despair in the reader having tendency to think about the technicalities involved!
3. WCW is endowed with metric and spinor structure so that one can define various metric related differential operators, say Dirac operator, appearing in the field equations of the theory. The most ambitious dream is that zero energy states correspond to a complete solution basis for the Dirac operator of WCW so that this classical free field theory would dictate M-matrices which form orthonormal rows of what I call U-matrix. Given M-matrix in turn would decompose to a product of a hermitian density matrix and unitary S-matrix.

M-matrix would define time-like entanglement coefficients between positive and negative energy parts of zero energy states (all net quantum numbers vanish for them) and can be regarded as a hermitian square root of density matrix multiplied by a unitary S-matrix. Quantum theory would be in well-defined sense a square root of thermodynamics. The orthogonality and hermiticity of the complex square roots of density matrices commuting with S-matrix means that they span infinite-dimensional Lie algebra acting as symmetries of the S-matrix. Therefore quantum TGD would reduce to group theory in well-defined sense: its own symmetries would define the symmetries of the theory. In fact the Lie algebra of Hermitian M-matrices extends to Kac-Moody type algebra obtained by multiplying hermitian square roots of density matrices with powers of the S-matrix. Also the analog of Yangian algebra involving only non-negative powers of S-matrix is possible.

4. By quantum classical correspondence the construction of WCW spinor structure reduces to the second quantization of the induced spinor fields at space-time surface. The basic action is so called modified Dirac action in which gamma matrices are replaced with the modified gamma matrices defined as contractions of the canonical momentum currents with the imbedding space gamma matrices. In this manner one achieves super-conformal symmetry and conservation of fermionic currents among other things and consistent Dirac equation. This modified gamma matrices define as anticommutators effective metric, which might provide geometrization for some basic observables of condensed matter physics. The conjecture is that Dirac determinant for the modified Dirac action gives the exponent of Kähler action for a preferred extremal as vacuum functional so that one might talk about bosonic emergence in accordance with the prediction that the gauge bosons and graviton are expressible in terms of bound states of fermion and antifermion.

The evolution of these basic ideas has been rather slow but has gradually led to a rather beautiful vision. One of the key problems has been the definition of Kähler function. Kähler function is Kähler action for a preferred extremal assignable to a given 3-surface but what this preferred extremal is? The obvious first guess was as absolute minimum of Kähler action but could not be proven to be right or wrong. One big step in the progress was boosted by the idea that TGD should reduce to almost topological QFT in which braids would replace 3-surfaces in finite measurement resolution, which could

be inherent property of the theory itself and imply discretization at partonic 2-surfaces with discrete points carrying fermion number.

1. TGD as almost topological QFT vision suggests that Kähler action for preferred extremals reduces to Chern-Simons term assigned with space-like 3-surfaces at the ends of space-time (recall the notion of causal diamond ( $CD$ )) and with the light-like 3-surfaces at which the signature of the induced metric changes from Minkowskian to Euclidian. Minkowskian and Euclidian regions would give at wormhole throats the same contribution apart from coefficients and in Minkowskian regions the  $\sqrt{g_4}$  factor would be imaginary so that one would obtain sum of real term identifiable as Kähler function and imaginary term identifiable as the ordinary action giving rise to interference effects and stationary phase approximation central in both classical and quantum field theory. Imaginary contribution - the presence of which I realized only after 33 years of TGD - could also have topological interpretation as a Morse function. On physical side the emergence of Euclidian space-time regions is something completely new and leads to a dramatic modification of the ideas about black hole interior.
2. The manner to achieve the reduction to Chern-Simons terms is simple. The vanishing of Coulombic contribution to Kähler action is required and is true for all known extremals if one makes a general ansatz about the form of classical conserved currents. The so called weak form of electric-magnetic duality defines a boundary condition reducing the resulting 3-D terms to Chern-Simons terms. In this manner almost topological QFT results. But only "almost" since the Lagrange multiplier term forcing electric-magnetic duality implies that Chern-Simons action for preferred extremals depends on metric.
3. A further quite recent hypothesis inspired by effective 2-dimensionality is that Chern-Simons terms reduce to a sum of two 2-dimensional terms. An imaginary term proportional to the total area of Minkowskian string world sheets and a real term proportional to the total area of partonic 2-surfaces or equivalently strings world sheets in Euclidian space-time regions. Also the equality of the total areas of strings world sheets and partonic 2-surfaces is highly suggestive and would realize a duality between these two kinds of objects. String world sheets indeed emerge naturally for the proposed ansatz defining preferred extremals. Therefore Kähler action would have very stringy character apart from effects due to the failure of the strict determinism meaning that radiative corrections break the effective 2-dimensionality.

### 1.2.2 TGD as a generalized number theory

Quantum T(opological)D(ynamics) as a classical spinor geometry for infinite-dimensional configuration space, p-adic numbers and quantum TGD, and TGD inspired theory of consciousness, have been for last ten years the basic three strongly interacting threads in the tapestry of quantum TGD. The fourth thread deserves the name 'TGD as a generalized number theory'. It involves three separate threads: the fusion of real and various p-adic physics to a single coherent whole by requiring number theoretic universality discussed already, the formulation of quantum TGD in terms of hyper-counterparts of classical number fields identified as sub-spaces of complexified classical number fields with Minkowskian signature of the metric defined by the complexified inner product, and the notion of infinite prime.

#### p-Adic TGD and fusion of real and p-adic physics to single coherent whole

The p-adic thread emerged for roughly ten years ago as a dim hunch that p-adic numbers might be important for TGD. Experimentation with p-adic numbers led to the notion of canonical identification mapping reals to p-adics and vice versa. The breakthrough came with the successful p-adic mass calculations using p-adic thermodynamics for Super-Virasoro representations with the super-Kac-Moody algebra associated with a Lie-group containing standard model gauge group. Although the details of the calculations have varied from year to year, it was clear that p-adic physics reduces not only the ratio of proton and Planck mass, the great mystery number of physics, but all elementary particle mass scales, to number theory if one assumes that primes near prime powers of two are in a physically favored position. Why this is the case, became one of the key puzzles and led to a number

of arguments with a common gist: evolution is present already at the elementary particle level and the primes allowed by the p-adic length scale hypothesis are the fittest ones.

It became very soon clear that p-adic topology is not something emerging in Planck length scale as often believed, but that there is an infinite hierarchy of p-adic physics characterized by p-adic length scales varying to even cosmological length scales. The idea about the connection of p-adics with cognition motivated already the first attempts to understand the role of the p-adics and inspired 'Universe as Computer' vision but time was not ripe to develop this idea to anything concrete (p-adic numbers are however in a central role in TGD inspired theory of consciousness). It became however obvious that the p-adic length scale hierarchy somehow corresponds to a hierarchy of intelligences and that p-adic prime serves as a kind of intelligence quotient. Ironically, the almost obvious idea about p-adic regions as cognitive regions of space-time providing cognitive representations for real regions had to wait for almost a decade for the access into my consciousness.

There were many interpretational and technical questions crying for a definite answer.

1. What is the relationship of p-adic non-determinism to the classical non-determinism of the basic field equations of TGD? Are the p-adic space-time region genuinely p-adic or does p-adic topology only serve as an effective topology? If p-adic physics is direct image of real physics, how the mapping relating them is constructed so that it respects various symmetries? Is the basic physics p-adic or real (also real TGD seems to be free of divergences) or both? If it is both, how should one glue the physics in different number field together to get *The Physics*? Should one perform p-adicization also at the level of the configuration space of 3-surfaces? Certainly the p-adicization at the level of super-conformal representation is necessary for the p-adic mass calculations.
2. Perhaps the most basic and most irritating technical problem was how to precisely define p-adic definite integral which is a crucial element of any variational principle based formulation of the field equations. Here the frustration was not due to the lack of solution but due to the too large number of solutions to the problem, a clear symptom for the sad fact that clever inventions rather than real discoveries might be in question. Quite recently I however learned that the problem of making sense about p-adic integration has been for decades central problem in the frontier of mathematics and a lot of profound work has been done along same intuitive lines as I have proceeded in TGD framework. The basic idea is certainly the notion of algebraic continuation from the world of rationals belonging to the intersection of real world and various p-adic worlds.

Despite these frustrating uncertainties, the number of the applications of the poorly defined p-adic physics grew steadily and the applications turned out to be relatively stable so that it was clear that the solution to these problems must exist. It became only gradually clear that the solution of the problems might require going down to a deeper level than that represented by reals and p-adics.

The key challenge is to fuse various p-adic physics and real physics to single larger structures. This has inspired a proposal for a generalization of the notion of number field by fusing real numbers and various p-adic number fields and their extensions along rationals and possible common algebraic numbers. This leads to a generalization of the notions of imbedding space and space-time concept and one can speak about real and p-adic space-time sheets. The quantum dynamics should be such that it allows quantum transitions transforming space-time sheets belonging to different number fields to each other. The space-time sheets in the intersection of real and p-adic worlds are of special interest and the hypothesis is that living matter resides in this intersection. This leads to surprisingly detailed predictions and far reaching conjectures. For instance, the number theoretic generalization of entropy concept allows negentropic entanglement central for the applications to living matter.

The basic principle is number theoretic universality stating roughly that the physics in various number fields can be obtained as completion of rational number based physics to various number fields. Rational number based physics would in turn describe physics in finite measurement resolution and cognitive resolution. The notion of finite measurement resolution has become one of the basic principles of quantum TGD and leads to the notions of braids as representatives of 3-surfaces and inclusions of hyper-finite factors as a representation for finite measurement resolution.

### The role of classical number fields

The vision about the physical role of the classical number fields relies on the notion of number theoretic compactification stating that space-time surfaces can be regarded as surfaces of either  $M^8$  or  $M^4 \times CP_2$ . As surfaces of  $M^8$  identifiable as space of hyper-octonions they are hyper-quaternionic or co-hyper-quaternionic- and thus maximally associative or co-associative. This means that their tangent space is either hyper-quaternionic plane of  $M^8$  or an orthogonal complement of such a plane. These surface can be mapped in natural manner to surfaces in  $M^4 \times CP_2$  [K72] provided one can assign to each point of tangent space a hyper-complex plane  $M^2(x) \subset M^4$ . One can also speak about  $M^8 - H$  duality.

This vision has very strong predictive power. It predicts that the extremals of Kähler action correspond to either hyper-quaternionic or co-hyper-quaternionic surfaces such that one can assign to tangent space at each point of space-time surface a hyper-complex plane  $M^2(x) \subset M^4$ . As a consequence, the  $M^4$  projection of space-time surface at each point contains  $M^2(x)$  and its orthogonal complement. These distributions are integrable implying that space-time surface allows dual slicings defined by string world sheets  $Y^2$  and partonic 2-surfaces  $X^2$ . The existence of this kind of slicing was earlier deduced from the study of extremals of Kähler action and christened as Hamilton-Jacobi structure. The physical interpretation of  $M^2(x)$  is as the space of non-physical polarizations and the plane of local 4-momentum.

One can fairly say, that number theoretical compactification is responsible for most of the understanding of quantum TGD that has emerged during last years. This includes the realization of Equivalence Principle at space-time level, dual formulations of TGD as Minkowskian and Euclidian string model type theories, the precise identification of preferred extremals of Kähler action as extremals for which second variation vanishes (at least for deformations representing dynamical symmetries) and thus providing space-time correlate for quantum criticality, the notion of number theoretic braid implied by the basic dynamics of Kähler action and crucial for precise construction of quantum TGD as almost-topological QFT, the construction of configuration space metric and spinor structure in terms of second quantized induced spinor fields with modified Dirac action defined by Kähler action realizing automatically the notion of finite measurement resolution and a connection with inclusions of hyper-finite factors of type  $II_1$  about which Clifford algebra of configuration space represents an example.

The two most important number theoretic conjectures relate to the preferred extremals of Kähler action. The general idea is that classical dynamics for the preferred extremals of Kähler action should reduce to number theory: space-time surfaces should be either associative or co-associative in some sense.

1. The first meaning for associativity (co-associativity) would be that tangent (normal) spaces of space-time surfaces are quaternionic in some sense and thus associative. This can be formulated in terms of octonionic representation of the imbedding space gamma matrices possible in dimension  $D = 8$  and states that induced gamma matrices generate quaternionic sub-algebra at each space-time point. It seems that induced rather than modified gamma matrices must be in question.
2. Second meaning for associative (co-associativity) would be following. In the case of complex numbers the vanishing of the real part of real-analytic function defines a 1-D curve. In octonionic case one can decompose octonion to sum of quaternion and quaternion multiplied by an octonionic imaginary unit. Quaternionicity could mean that space-time surfaces correspond to the vanishing of the imaginary part of the octonion real-analytic function. Co-quaternionicity would be defined in an obvious manner. Octonionic real analytic functions form a function field closed also with respect to the composition of functions. Space-time surfaces would form the analog of function field with the composition of functions with all operations realized as algebraic operations for space-time surfaces. Co-associativity could be perhaps seen as an additional feature making the algebra in question also co-algebra.
3. The third conjecture is that these conjectures are equivalent.

### Infinite primes

The discovery of the hierarchy of infinite primes and their correspondence with a hierarchy defined by a repeatedly second quantized arithmetic quantum field theory gave a further boost for the speculations

about TGD as a generalized number theory. The work with Riemann hypothesis led to further ideas.

After the realization that infinite primes can be mapped to polynomials representable as surfaces geometrically, it was clear how TGD might be formulated as a generalized number theory with infinite primes forming the bridge between classical and quantum such that real numbers, p-adic numbers, and various generalizations of p-adics emerge dynamically from algebraic physics as various completions of the algebraic extensions of rational (hyper-)quaternions and (hyper-)octonions. Complete algebraic, topological and dimensional democracy would characterize the theory.

What is especially satisfying is that p-adic and real regions of the space-time surface could emerge automatically as solutions of the field equations. In the space-time regions where the solutions of field equations give rise to in-admissible complex values of the imbedding space coordinates, p-adic solution can exist for some values of the p-adic prime. The characteristic non-determinism of the p-adic differential equations suggests strongly that p-adic regions correspond to 'mind stuff', the regions of space-time where cognitive representations reside. This interpretation implies that p-adic physics is physics of cognition. Since Nature is probably an extremely brilliant simulator of Nature, the natural idea is to study the p-adic physics of the cognitive representations to derive information about the real physics. This view encouraged by TGD inspired theory of consciousness clarifies difficult interpretational issues and provides a clear interpretation for the predictions of p-adic physics.

### 1.2.3 Hierarchy of Planck constants and dark matter hierarchy

By quantum classical correspondence space-time sheets can be identified as quantum coherence regions. Hence the fact that they have all possible size scales more or less unavoidably implies that Planck constant must be quantized and have arbitrarily large values. If one accepts this then also the idea about dark matter as a macroscopic quantum phase characterized by an arbitrarily large value of Planck constant emerges naturally as does also the interpretation for the long ranged classical electro-weak and color fields predicted by TGD. Rather seldom the evolution of ideas follows simple linear logic, and this was the case also now. In any case, this vision represents the fifth, relatively new thread in the evolution of TGD and the ideas involved are still evolving.

#### Dark matter as large $\hbar$ phase

D. Da Rocha and Laurent Nottale [E23] have proposed that Schrödinger equation with Planck constant  $\hbar$  replaced with what might be called gravitational Planck constant  $\hbar_{gr} = \frac{GmM}{v_0}$  ( $\hbar = c = 1$ ).  $v_0$  is a velocity parameter having the value  $v_0 = 144.7 \pm .7$  km/s giving  $v_0/c = 4.6 \times 10^{-4}$ . This is rather near to the peak orbital velocity of stars in galactic halos. Also subharmonics and harmonics of  $v_0$  seem to appear. The support for the hypothesis coming from empirical data is impressive.

Nottale and Da Rocha believe that their Schrödinger equation results from a fractal hydrodynamics. Many-sheeted space-time however suggests astrophysical systems are not only quantum systems at larger space-time sheets but correspond to a gigantic value of gravitational Planck constant. The gravitational (ordinary) Schrödinger equation would provide a solution of the black hole collapse (IR catastrophe) problem encountered at the classical level. The resolution of the problem inspired by TGD inspired theory of living matter is that it is the dark matter at larger space-time sheets which is quantum coherent in the required time scale [K65].

TGD predicts correctly the value of the parameter  $v_0$  assuming that cosmic strings and their decay remnants are responsible for the dark matter. The harmonics of  $v_0$  can be understood as corresponding to perturbations replacing cosmic strings with their n-branched coverings so that tension becomes  $n^2$ -fold: much like the replacement of a closed orbit with an orbit closing only after  $n$  turns.  $1/n$ -sub-harmonic would result when a magnetic flux tube split into  $n$  disjoint magnetic flux tubes. Also a model for the formation of planetary system as a condensation of ordinary matter around quantum coherent dark matter emerges [K65].

The values of Planck constants postulated by Nottale are gigantic and it is natural to assign them to the space-time sheets mediating gravitational interaction and identifiable as magnetic flux tubes (quanta). The magnetic energy of these flux quanta would correspond to dark energy and magnetic tension would give rise to negative "pressure" forcing accelerate cosmological expansion. This leads to a rather detailed vision about the evolution of stars and galaxies identified as bubbles of ordinary and dark matter inside magnetic flux tubes identifiable as dark energy.

### Hierarchy of Planck constants from the anomalies of neuroscience biology

The quantal effects of ELF em fields on vertebrate brain have been known since seventies. ELF em fields at frequencies identifiable as cyclotron frequencies in magnetic field whose intensity is about 2/5 times that of Earth for biologically important ions have physiological effects and affect also behavior. What is intriguing that the effects are found only in vertebrates (to my best knowledge). The energies for the photons of ELF em fields are extremely low - about  $10^{-10}$  times lower than thermal energy at physiological temperatures- so that quantal effects are impossible in the framework of standard quantum theory. The values of Planck constant would be in these situations large but not gigantic.

This inspired the hypothesis that these photons correspond to so large value of Planck constant that the energy of photons is above the thermal energy. The proposed interpretation was as dark photons and the general hypothesis was that dark matter corresponds to ordinary matter with non-standard value of Planck constant. If only particles with the same value of Planck constant can appear in the same vertex of Feynman diagram, the phases with different value of Planck constant are dark relative to each other. The phase transitions changing Planck constant can however make possible interactions between phases with different Planck constant but these interactions do not manifest themselves in particle physics. Also the interactions mediated by classical fields should be possible. Dark matter would not be so dark as we have used to believe.

Also the anomalies of biology support the view that dark matter might be a key player in living matter.

### Does the hierarchy of Planck constants reduce to the vacuum degeneracy of Kähler action?

This starting point led gradually to the recent picture in which the hierarchy of Planck constants is postulated to come as integer multiples of the standard value of Planck constant. Given integer multiple  $\hbar = n\hbar_0$  of the ordinary Planck constant  $\hbar_0$  is assigned with a multiple singular covering of the imbedding space [K25]. One ends up to an identification of dark matter as phases with non-standard value of Planck constant having geometric interpretation in terms of these coverings providing generalized imbedding space with a book like structure with pages labelled by Planck constants or integers characterizing Planck constant. The phase transitions changing the value of Planck constant would correspond to leakage between different sectors of the extended imbedding space. The question is whether these coverings must be postulated separately or whether they are only a convenient auxiliary tool.

The simplest option is that the hierarchy of coverings of imbedding space is only effective. Many-sheeted coverings of the imbedding space indeed emerge naturally in TGD framework. The huge vacuum degeneracy of Kähler action implies that the relationship between gradients of the imbedding space coordinates and canonical momentum currents is many-to-one: this was the very fact forcing to give up all the standard quantization recipes and leading to the idea about physics as geometry of the "world of classical worlds". If one allows space-time surfaces for which all sheets corresponding to the same values of the canonical momentum currents are present, one obtains effectively many-sheeted covering of the imbedding space and the contributions from sheets to the Kähler action are identical. If all sheets are treated effectively as one and the same sheet, the value of Planck constant is an integer multiple of the ordinary one. A natural boundary condition would be that at the ends of space-time at future and past boundaries of causal diamond containing the space-time surface, various branches co-incide. This would raise the ends of space-time surface in special physical role.

### Dark matter as a source of long ranged weak and color fields

Long ranged classical electro-weak and color gauge fields are unavoidable in TGD framework. The smallness of the parity breaking effects in hadronic, nuclear, and atomic length scales does not however seem to allow long ranged electro-weak gauge fields. The problem disappears if long range classical electro-weak gauge fields are identified as space-time correlates for massless gauge fields created by dark matter. Also scaled up variants of ordinary electro-weak particle spectra are possible. The identification explains chiral selection in living matter and unbroken  $U(2)_{ew}$  invariance and free color in bio length scales become characteristics of living matter and of bio-chemistry and bio-nuclear physics. A possible solution of the matter antimatter asymmetry is based on the identification of also antimatter as dark matter.

### 1.2.4 TGD as a generalization of physics to a theory consciousness

General coordinate invariance forces the identification of quantum jump as quantum jump between entire deterministic quantum histories rather than time=constant snapshots of single history. The new view about quantum jump forces a generalization of quantum measurement theory such that observer becomes part of the physical system. Thus a general theory of consciousness is unavoidable outcome. This theory is developed in detail in the books [K74, K12, K53, K10, K29, K36, K40, K67]

#### Quantum jump as a moment of consciousness

The identification of quantum jump between deterministic quantum histories (configuration space spinor fields) as a moment of consciousness defines microscopic theory of consciousness. Quantum jump involves the steps

$$\Psi_i \rightarrow U\Psi_i \rightarrow \Psi_f ,$$

where  $U$  is informational "time development" operator, which is unitary like the S-matrix characterizing the unitary time evolution of quantum mechanics.  $U$  is however only formally analogous to Schrödinger time evolution of infinite duration although there is *no* real time evolution involved. It is not however clear whether one should regard U-matrix and S-matrix as two different things or not:  $U$ -matrix is a completely universal object characterizing the dynamics of evolution by self-organization whereas S-matrix is a highly context dependent concept in wave mechanics and in quantum field theories where it at least formally represents unitary time translation operator at the limit of an infinitely long interaction time. The S-matrix understood in the spirit of superstring models is however something very different and could correspond to U-matrix.

The requirement that quantum jump corresponds to a measurement in the sense of quantum field theories implies that each quantum jump involves localization in zero modes which parameterize also the possible choices of the quantization axes. Thus the selection of the quantization axes performed by the Cartesian outsider becomes now a part of quantum theory. Together these requirements imply that the final states of quantum jump correspond to quantum superpositions of space-time surfaces which are macroscopically equivalent. Hence the world of conscious experience looks classical. At least formally quantum jump can be interpreted also as a quantum computation in which matrix  $U$  represents unitary quantum computation which is however not identifiable as unitary translation in time direction and cannot be 'engineered'.

Can one say anything about the unitary process? Zero energy states correspond in positive energy ontology to physical events and break time reversal invariance. This because either the positive or negative energy part of the state is prepared whereas the second end of  $CD$  corresponds to a superposition of (negative/positive energy) states with varying particle numbers and single particle quantum numbers just as in ordinary particle physics experiment. State function reduction must change the roles of the ends of  $CD$ s. Therefore  $U$ -matrix should correspond to the unitary matrix relating zero energy state basis prepared at different ends of  $CD$  and state function reduction would be equivalent with state preparation.

The basic objection is that the arrow of geometric time alternates at imbedding space level but we know that arrow of time is universal. What one can say about the arrow of time at space-time level? Quantum classical correspondence requires that quantum mechanical irreversibility corresponds to irreversibility at space-time level. If the observer is analogous to an inhabitant of Flatland gaining information only about space-time surface, he or she is not able to discover that the arrow of time alternates at the level of imbedding space. The inhabitant of a folded bath towel is not able to observe the folding of the towel! Only by observing systems for which the imbedding space arrow of time is opposite, observer can discover the alternation. Living systems indeed behave as if they would contain space-time sheets with opposite arrow of geometric time (self-organization). Phase conjugate light beam is second example of this.

#### The notion of self

The concept of self is absolutely essential for the understanding of the macroscopic and macro-temporal aspects of consciousness. Self corresponds to a subsystem able to remain un-entangled under the

sequential informational 'time evolutions'  $U$ . Exactly vanishing entanglement is practically impossible in ordinary quantum mechanics and it might be that 'vanishing entanglement' in the condition for self-property should be replaced with 'subcritical entanglement'. On the other hand, if space-time decomposes into p-adic and real regions, and if entanglement between regions representing physics in different number fields vanishes, space-time indeed decomposes into selves in a natural manner.

It is assumed that the experiences of the self after the last 'wake-up' sum up to single average experience. This means that subjective memory is identifiable as conscious, immediate short term memory. Selves form an infinite hierarchy with the entire Universe at the top. Self can be also interpreted as mental images: our mental images are selves having mental images and also we represent mental images of a higher level self. A natural hypothesis is that self  $S$  experiences the experiences of its subselves as kind of abstracted experience: the experiences of subselves  $S_i$  are not experienced as such but represent kind of averages  $\langle S_{ij} \rangle$  of sub-subselves  $S_{ij}$ . Entanglement between selves, most naturally realized by the formation of join along boundaries bonds between cognitive or material space-time sheets, provides a possible a mechanism for the fusion of selves to larger selves (for instance, the fusion of the mental images representing separate right and left visual fields to single visual field) and forms wholes from parts at the level of mental images.

An attractive possibility suggested by zero energy ontology is that the notions of self and quantum jump reduce to each other and that a fractal hierarchy of quantum jumps within quantum jumps is enough.  $CD$ s would serve as imbedding space correlates of selves and quantum jumps would be followed by cascades of state function reductions beginning from given  $CD$  and proceeding downwards to the smaller scales (smaller  $CD$ s). State function reduction cascades could also take place in parallel branches of the quantum state. One ends up with concrete ideas about how the arrow of geometric time is induced from that of subjective time defined by the experiences induced by the sequences of quantum jumps for sub-selves of self. One ends also ends up with concrete ideas about how the localization of the contents of sensory experience and cognition to the upper boundaries of  $CD$  could take place.

### Relationship to quantum measurement theory

The third basic element relates TGD inspired theory of consciousness to quantum measurement theory. The assumption that localization occurs in zero modes in each quantum jump implies that the world of conscious experience looks classical. It also implies the state function reduction of the standard quantum measurement theory as the following arguments demonstrate (it took incredibly long time to realize this almost obvious fact!).

1. The standard quantum measurement theory a la von Neumann involves the interaction of brain with the measurement apparatus. If this interaction corresponds to entanglement between microscopic degrees of freedom  $m$  with the macroscopic effectively classical degrees of freedom  $M$  characterizing the reading of the measurement apparatus coded to brain state, then the reduction of this entanglement in quantum jump reproduces standard quantum measurement theory provide the unitary time evolution operator  $U$  acts as flow in zero mode degrees of freedom and correlates completely some orthonormal basis of configuration space spinor fields in non-zero modes with the values of the zero modes. The flow property guarantees that the localization is consistent with unitarity: it also means 1-1 mapping of quantum state basis to classical variables (say, spin direction of the electron to its orbit in the external magnetic field).
2. Since zero modes represent classical information about the geometry of space-time surface (shape, size, classical Kähler field,...), they have interpretation as effectively classical degrees of freedom and are the TGD counterpart of the degrees of freedom  $M$  representing the reading of the measurement apparatus. The entanglement between quantum fluctuating non-zero modes and zero modes is the TGD counterpart for the  $m - M$  entanglement. Therefore the localization in zero modes is equivalent with a quantum jump leading to a final state where the measurement apparatus gives a definite reading.

This simple prediction is of utmost theoretical importance since the black box of the quantum measurement theory is reduced to a fundamental quantum theory. This reduction is implied by the replacement of the notion of a point like particle with particle as a 3-surface. Also the infinite-dimensionality of the zero mode sector of the configuration space of 3-surfaces is absolutely essential. Therefore the reduction is a triumph for quantum TGD and favors TGD against string models.

Standard quantum measurement theory involves also the notion of state preparation which reduces to the notion of self measurement. Each localization in zero modes is followed by a cascade of self measurements leading to a product state. This process is obviously equivalent with the state preparation process. Self measurement is governed by the so called Negentropy Maximization Principle (NMP) stating that the information content of conscious experience is maximized. In the self measurement the density matrix of some subsystem of a given self localized in zero modes (after ordinary quantum measurement) is measured. The self measurement takes place for that subsystem of self for which the reduction of the entanglement entropy is maximal in the measurement. In p-adic context NMP can be regarded as the variational principle defining the dynamics of cognition. In real context self measurement could be seen as a repair mechanism allowing the system to fight against quantum thermalization by reducing the entanglement for the subsystem for which it is largest (fill the largest hole first in a leaking boat).

### Selves self-organize

The fourth basic element is quantum theory of self-organization based on the identification of quantum jump as the basic step of self-organization [K62]. Quantum entanglement gives rise to the generation of long range order and the emergence of longer p-adic length scales corresponds to the emergence of larger and larger coherent dynamical units and generation of a slaving hierarchy. Energy (and quantum entanglement) feed implying entropy feed is a necessary prerequisite for quantum self-organization. Zero modes represent fundamental order parameters and localization in zero modes implies that the sequence of quantum jumps can be regarded as hopping in the zero modes so that Haken's classical theory of self organization applies almost as such. Spin glass analogy is a further important element: self-organization of self leads to some characteristic pattern selected by dissipation as some valley of the "energy" landscape.

Dissipation can be regarded as the ultimate Darwinian selector of both memes and genes. The mathematically ugly irreversible dissipative dynamics obtained by adding phenomenological dissipation terms to the reversible fundamental dynamical equations derivable from an action principle can be understood as a phenomenological description replacing in a well defined sense the series of reversible quantum histories with its envelope.

### Classical non-determinism of Kähler action

The fifth basic element are the concepts of association sequence and cognitive space-time sheet. The huge vacuum degeneracy of the Kähler action suggests strongly that the absolute minimum space-time is not always unique. For instance, a sequence of bifurcations can occur so that a given space-time branch can be fixed only by selecting a finite number of 3-surfaces with time like(!) separations on the orbit of 3-surface. Quantum classical correspondence suggest an alternative formulation. Space-time surface decomposes into maximal deterministic regions and their temporal sequences have interpretation a space-time correlate for a sequence of quantum states defined by the initial (or final) states of quantum jumps. This is consistent with the fact that the variational principle selects preferred extremals of Kähler action as generalized Bohr orbits.

In the case that non-determinism is located to a finite time interval and is microscopic, this sequence of 3-surfaces has interpretation as a simulation of a classical history, a geometric correlate for contents of consciousness. When non-determinism has long lasting and macroscopic effect one can identify it as volitional non-determinism associated with our choices. Association sequences relate closely with the cognitive space-time sheets defined as space-time sheets having finite time duration and psychological time can be identified as a temporal center of mass coordinate of the cognitive space-time sheet. The gradual drift of the cognitive space-time sheets to the direction of future force by the geometry of the future light cone explains the arrow of psychological time.

### p-Adic physics as physics of cognition and intentionality

The sixth basic element adds a physical theory of cognition to this vision. TGD space-time decomposes into regions obeying real and p-adic topologies labelled by primes  $p = 2, 3, 5, \dots$ . p-Adic regions obey the same field equations as the real regions but are characterized by p-adic non-determinism since the functions having vanishing p-adic derivative are pseudo constants which are piecewise constant functions. Pseudo constants depend on a finite number of positive binary digits of arguments just like

numerical predictions of any theory always involve decimal cutoff. This means that p-adic space-time regions are obtained by gluing together regions for which integration constants are genuine constants. The natural interpretation of the p-adic regions is as cognitive representations of real physics. The freedom of imagination is due to the p-adic non-determinism. p-Adic regions perform mimicry and make possible for the Universe to form cognitive representations about itself. p-Adic physics space-time sheets serve also as correlates for intentional action.

A more precise formulation of this vision requires a generalization of the number concept obtained by fusing reals and p-adic number fields along common rationals (in the case of algebraic extensions among common algebraic numbers). This picture is discussed in [K71]. The application of this notion at the level of the imbedding space implies that imbedding space has a book like structure with various variants of the imbedding space glued together along common rationals (algebraics). The implication is that genuinely p-adic numbers (non-rationals) are strictly infinite as real numbers so that most points of p-adic space-time sheets are at real infinity, outside the cosmos, and that the projection to the real imbedding space is discrete set of rationals (algebraics). Hence cognition and intentionality are almost completely outside the real cosmos and touch it at a discrete set of points only.

This view implies also that purely local p-adic physics codes for the p-adic fractality characterizing long range real physics and provides an explanation for p-adic length scale hypothesis stating that the primes  $p \simeq 2^k$ ,  $k$  integer are especially interesting. It also explains the long range correlations and short term chaos characterizing intentional behavior and explains why the physical realizations of cognition are always discrete (say in the case of numerical computations). Furthermore, a concrete quantum model for how intentions are transformed to actions emerges.

The discrete real projections of p-adic space-time sheets serve also space-time correlate for a logical thought. It is very natural to assign to p-adic binary digits a  $p$ -valued logic but as such this kind of logic does not have any reasonable identification. p-Adic length scale hypothesis suggest that the  $p = 2^k - n$  binary digits represent a Boolean logic  $B^k$  with  $k$  elementary statements (the points of the  $k$ -element set in the set theoretic realization) with  $n$  taboos which are constrained to be identically true.

### **p-Adic and dark matter hierarchies and hierarchy of moments of consciousness**

Dark matter hierarchy assigned to a spectrum of Planck constant having arbitrarily large values brings additional elements to the TGD inspired theory of consciousness.

1. Macroscopic quantum coherence can be understood since a particle with a given mass can in principle appear as arbitrarily large scaled up copies (Compton length scales as  $\hbar$ ). The phase transition to this kind of phase implies that space-time sheets of particles overlap and this makes possible macroscopic quantum coherence.
2. The space-time sheets with large Planck constant can be in thermal equilibrium with ordinary ones without the loss of quantum coherence. For instance, the cyclotron energy scale associated with EEG turns out to be above thermal energy at room temperature for the level of dark matter hierarchy corresponding to magnetic flux quanta of the Earth's magnetic field with the size scale of Earth and a successful quantitative model for EEG results [K22].

Dark matter hierarchy leads to detailed quantitative view about quantum biology with several testable predictions [K22]. The general prediction is that Universe is a kind of inverted Mandelbrot fractal for which each bird's eye of view reveals new structures in long length and time scales representing scaled down copies of standard physics and their dark variants. These structures would correspond to higher levels in self hierarchy. This prediction is consistent with the belief that 75 per cent of matter in the universe is dark.

#### *1. Living matter and dark matter*

Living matter as ordinary matter quantum controlled by the dark matter hierarchy has turned out to be a particularly successful idea. The hypothesis has led to models for EEG predicting correctly the band structure and even individual resonance bands and also generalizing the notion of EEG [K22]. Also a generalization of the notion of genetic code emerges resolving the paradoxes related to the

standard dogma [K38, K22] . A particularly fascinating implication is the possibility to identify great leaps in evolution as phase transitions in which new higher level of dark matter emerges [K22] .

It seems safe to conclude that the dark matter hierarchy with levels labelled by the values of Planck constants explains the macroscopic and macro-temporal quantum coherence naturally. That this explanation is consistent with the explanation based on spin glass degeneracy is suggested by following observations. First, the argument supporting spin glass degeneracy as an explanation of the macro-temporal quantum coherence does not involve the value of  $\hbar$  at all. Secondly, the failure of the perturbation theory assumed to lead to the increase of Planck constant and formation of macroscopic quantum phases could be precisely due to the emergence of a large number of new degrees of freedom due to spin glass degeneracy. Thirdly, the phase transition increasing Planck constant has concrete topological interpretation in terms of many-sheeted space-time consistent with the spin glass degeneracy.

### 2. Dark matter hierarchy and the notion of self

The vision about dark matter hierarchy leads to a more refined view about self hierarchy and hierarchy of moments of consciousness [K21, K22] . The larger the value of Planck constant, the longer the subjectively experienced duration and the average geometric duration  $T(k) \propto \hbar$  of the quantum jump.

Quantum jumps form also a hierarchy with respect to p-adic and dark hierarchies and the geometric durations of quantum jumps scale like  $\hbar$ . Dark matter hierarchy suggests also a slight modification of the notion of self. Each self involves a hierarchy of dark matter levels, and one is led to ask whether the highest level in this hierarchy corresponds to single quantum jump rather than a sequence of quantum jumps. The averaging of conscious experience over quantum jumps would occur only for sub-selves at lower levels of dark matter hierarchy and these mental images would be ordered, and single moment of consciousness would be experienced as a history of events. The quantum parallel dissipation at the lower levels would give rise to the experience of flow of time. For instance, hadron as a macro-temporal quantum system in the characteristic time scale of hadron is a dissipating system at quark and gluon level corresponding to shorter p-adic time scales. One can ask whether even entire life cycle could be regarded as a single quantum jump at the highest level so that consciousness would not be completely lost even during deep sleep. This would allow to understand why we seem to know directly that this biological body of mine existed yesterday.

The fact that we can remember phone numbers with 5 to 9 digits supports the view that self corresponds at the highest dark matter level to single moment of consciousness. Self would experience the average over the sequence of moments of consciousness associated with each sub-self but there would be no averaging over the separate mental images of this kind, be their parallel or serial. These mental images correspond to sub-selves having shorter wake-up periods than self and would be experienced as being time ordered. Hence the digits in the phone number are experienced as separate mental images and ordered with respect to experienced time.

### 3. The time span of long term memories as signature for the level of dark matter hierarchy

The basic question is what time scale can one assign to the geometric duration of quantum jump measured naturally as the size scale of the space-time region about which quantum jump gives conscious information. This scale is naturally the size scale in which the non-determinism of quantum jump is localized. During years I have made several guesses about this time scales but zero energy ontology and the vision about fractal hierarchy of quantum jumps within quantum jumps leads to a unique identification.

Causal diamond as an imbedding space correlate of self defines the time scale  $\tau$  for the space-time region about which the consciousness experience is about. The temporal distances between the tips of  $CD$  as come as integer multiples of  $CP_2$  length scales and for prime multiples correspond to what I have christened as secondary p-adic time scales. A reasonable guess is that secondary p-adic time scales are selected during evolution and the primes near powers of two are especially favored. For electron, which corresponds to Mersenne prime  $M_{127} = 2^{127} - 1$  this scale corresponds to .1 seconds defining the fundamental time scale of living matter via 10 Hz biorhythm (alpha rhythm). The unexpected prediction is that all elementary particles correspond to time scales possibly relevant to living matter.

Dark matter hierarchy brings additional finesse. For the higher levels of dark matter hierarchy  $\tau$  is scaled up by  $\hbar/\hbar_0$ . One could understand evolutionary leaps as the emergence of higher levels at

the level of individual organism making possible intentionality and memory in the time scale defined  $\tau$ .

Higher levels of dark matter hierarchy provide a neat quantitative view about self hierarchy and its evolution. Various levels of dark matter hierarchy would naturally correspond to higher levels in the hierarchy of consciousness and the typical duration of life cycle would give an idea about the level in question. The level would determine also the time span of long term memories as discussed in [K22]. The emergence of these levels must have meant evolutionary leap since long term memory is also accompanied by ability to anticipate future in the same time scale. This picture would suggest that the basic difference between us and our cousins is not at the level of genome as it is usually understood but at the level of the hierarchy of magnetic bodies [K38, K22]. In fact, higher levels of dark matter hierarchy motivate the introduction of the notions of super-genome and hyper-genome. The genomes of entire organ can join to form super-genome expressing genes coherently. Hyper-genomes would result from the fusion of genomes of different organisms and collective levels of consciousness would express themselves via hyper-genome and make possible social rules and moral.

### 1.3 Bird's eye of view about the topics of the book

The book is devoted to the applications of p-adic length scale hypothesis and dark matter hierarchy.

1. p-Adic length scale hypothesis states that primes  $p \simeq 2^k$ ,  $k$  integer, in particular prime, define preferred p-adic length scales. Physical arguments supporting this hypothesis are based on the generalization of Hawking's area law for blackhole entropy so that it applies in case of elementary particles.
2. A much deeper number theory based justification for this hypothesis is based on the generalization of the number concept fusing real number fields and p-adic number fields among common rationals or numbers in their non-trivial algebraic extensions. This approach also justifies the notion of multi-p-fractality and allows to understand scaling law in terms of simultaneous  $p \simeq 2^k$ - and 2-fractality.
3. Certain anomalous empirical findings inspire in TGD framework the hypothesis about the existence of entire hierarchy of phases of matter identifiable as dark matter. The levels of dark matter hierarchy are labeled by the values of dynamical quantized Planck constant. The justification for the hypothesis provided by quantum classical correspondence and the fact the sizes of space-time sheets identifiable as quantum coherence regions can be arbitrarily large.

The organization of the book is following.

1. The first part of the book is devoted to the description of elementary particle massivation in terms of p-adic thermodynamics. In the first two chapters general theory is represented and the remaining three chapters are devoted to the detailed calculation of masses of elementary particles and hadrons, and to various new physics suggested or predicted by the resulting scenario.
2. The second part of the book is devoted to the application of p-adic length scale hypothesis above elementary particle length scales. The notions of topological condensation and evaporation are formulated. The so called leptohadron physics, originally developed on basis of experimental anomalies, is discussed as a particular instance of an infinite fractal hierarchy of copies of standard model physics, predicted by TGD and consistent with what is known about ordinary elementary particle physics.

TGD based view about nuclear physics involves light exotic quarks as a essential element, and dark nuclear physics could have implications also at the level of condensed matter physics and biology. Quite surprisingly, the model for dark 3-quarks states consisting of u and d quarks leads to the identification of quantum states of three-quark system as counterparts of 64 DNA and RNA codons and 20 amino-acids and of the analog of genetic code identical with the vertebrate genetic code. This suggests that dark nuclear physics with scaled up sizes of nucleon of order atomic size could play key role in living matter and provide the realization of genetic code at deeper level. Water memory would be one application of this vision.

TGD based view about high  $T_c$  superconductors involves also in an essential manner dark matter and is summarized in the closing chapter.

The seven online books about TGD [K80, K60, K48, K45, K61, K70, K68] and eight online books about TGD inspired theory of consciousness and quantum biology [K74, K12, K53, K10, K29, K36, K40, K67] are warmly recommended for the reader willing to get overall view about what is involved.

## 1.4 The contents of the book

### 1.4.1 Part I: p-Adic description of particle massivation

In this part of the book a p-adic description of particle massivation using p-adic thermodynamics and TGD variant of Higgs mechanism is developed.

#### Overall View About TGD from Particle Physics Perspective

Topological Geometro-dynamics is able to make rather precise and often testable predictions. In this and two other articles I want to describe the recent over all view about the aspects of quantum TGD relevant for particle physics.

In the first chapter I concentrate the heuristic picture about TGD with emphasis on particle physics.

- First I represent briefly the basic ontology: the motivations for TGD and the notion of many-sheeted space-time, the concept of zero energy ontology, the identification of dark matter in terms of hierarchy of Planck constant which now seems to follow as a prediction of quantum TGD, the motivations for p-adic physics and its basic implications, and the identification of space-time surfaces as generalized Feynman diagrams and the basic implications of this identification.
- Symmetries of quantum TGD are discussed. Besides the basic symmetries of the imbedding space geometry allowing to geometrize standard model quantum numbers and classical fields there are many other symmetries. General Coordinate Invariance is especially powerful in TGD framework allowing to realize quantum classical correspondence and implies effective 2-dimensionality realizing strong form of holography. Super-conformal symmetries of super string models generalize to conformal symmetries of 3-D light-like 3-surfaces and one can understand the generalization of Equivalence Principle in terms of coset representations for the two super Virasoro algebras associated with lightlike boundaries of so called causal diamonds defined as intersections of future and past directed lightcones ( $CDs$ ) and with light-like 3-surfaces. Super-conformal symmetries imply generalization of the space-time supersymmetry in TGD framework consistent with the supersymmetries of minimal supersymmetric variant of the standard model. Twistorial approach to gauge theories has gradually become part of quantum TGD and the natural generalization of the Yangian symmetry identified originally as symmetry of  $\mathcal{N} = 4$  SYMs is postulated as basic symmetry of quantum TGD.
- The so called weak form of electric-magnetic duality has turned out to have extremely far reaching consequences and is responsible for the recent progress in the understanding of the physics predicted by TGD. The duality leads to a detailed identification of elementary particles as composite objects of massless particles and predicts new electro-weak physics at LHC. Together with a simple postulate about the properties of preferred extremals of Kähler action the duality allows also to realized quantum TGD as almost topological quantum field theory giving excellent hopes about integrability of quantum TGD.
- There are two basic visions about the construction of quantum TGD. Physics as infinite-dimensional Kähler geometry of world of classical worlds (WCW) endowed with spinor structure and physics as generalized number theory. These visions are briefly summarized as also the practical constructing involving the concept of Dirac operator. As a matter fact, the construction of TGD involves three Dirac operators. The Kähler Dirac equation holds true in the interior of space-time surface and its solutions have a natural interpretation in terms of description of matter, in particular condensed matter. Chern-Simons Dirac action is associated with the light-like 3-surfaces and space-like 3-surfaces at ends of space-time surface at light-like boundaries

of  $CD$ . One can assign to it a generalized eigenvalue equation and the matrix valued eigenvalues correspond to the action of Dirac operator on momentum eigenstates. Momenta are however not usual momenta but pseudo-momenta very much analogous to region momenta of twistor approach. The third Dirac operator is associated with super Virasoro generators and super Virasoro conditions define Dirac equation in WCW. These conditions characterize zero energy states as modes of WCW spinor fields and code for the generalization of  $S$ -matrix to a collection of what I call  $M$ -matrices defining the rows of unitary  $U$ -matrix defining unitary process.

- Twistor approach has inspired several ideas in quantum TGD during the last years and it seems that the Yangian symmetry and the construction of scattering amplitudes in terms of Grassmannian integrals generalizes to TGD framework. This is due to ZEO allowing to assume that all particles have massless fermions as basic building blocks. ZEO inspires the hypothesis that incoming and outgoing particles are bound states of fundamental fermions associated with wormhole throats. Virtual particles would also consist of on mass shell massless particles but without bound state constraint. This implies very powerful constraints on loop diagrams and there are excellent hopes about their finiteness. Twistor approach also inspires the conjecture that quantum TGD allows also formulation in terms of 6-dimensional holomorphic surfaces in the product  $CP_3 \times CP_3$  of two twistor spaces and general arguments allow to identify the partial differential equations satisfied by these surfaces.

#### 1.4.2 The recent vision about preferred extremals and solutions of the modified Dirac equation

During years several approaches to what preferred extremals of Kähler action and solutions of the modified Dirac equation could be have been proposed and the challenge is to see whether at least some of these approaches are consistent with each other. It is good to list various approaches first.

1. For preferred extremals generalization of conformal invariance to 4-D situation is very attractive approach and leads to concrete conditions formally similar to those encountered in string model. The approach based on basic heuristics for massless equations, on effective 3-dimensionality, and weak form of electric magnetic duality is also promising. An alternative approach is inspired by number theoretical considerations and identifies space-time surfaces as associative or co-associative sub-manifolds of octonionic imbedding space.
2. There are also several approaches for solving the modified Dirac equation. The most promising approach is assumes that the solutions are restricted on 2-D stringy world sheets and/or partonic 2-surfaces. This strange looking view is a rather natural consequence of number theoretic vision. The conditions stating that electric charge is conserved for preferred extremals is an alternative very promising approach.

In this chapter the question whether these various approaches are mutually consistent is discussed. It indeed turns out that the approach based on the conservation of electric charge leads under rather general assumptions to the proposal that solutions of the modified Dirac equation are localized on 2-dimensional string world sheets and/or partonic 2-surfaces. Einstein's equations are satisfied for the preferred extremals and this implies that the earlier proposal for the realization of Equivalence Principle is not needed. This leads to a considerable progress in the understanding of super Virasoro representations for super-symplectic and super-Kac-Moody algebra. In particular, the proposal is that super-Kac-Moody currents assignable to string world sheets define duals of gauge potentials and their generalization for gravitons: in the approximation that gauge group is Abelian - motivated by the notion of finite measurement resolution - the exponents for the sum of KM charges would define non-integrable phase factors. One can also identify Yangian as the algebra generated by these charges. The approach allows also to understand the special role of the right handed neutrino in SUSY according to TGD.

#### Elementary particle vacuum functionals

Genus-generation correspondence is one of the basic ideas of TGD approach. In order to answer various questions concerning the plausibility of the idea, one should know something about the dependence

of the elementary particle vacuum functionals on the vibrational degrees of freedom for the partonic 2-surface.

The construction of the elementary particle vacuum functionals based on Diff invariance, 2-dimensional conformal symmetry, modular invariance plus natural stability requirements indeed leads to an essentially unique form of the vacuum functionals and one can understand why  $g > 0$  bosonic families are experimentally absent and why lepton numbers are conserved separately.

An argument suggesting that the number of the light fermion families is three, is developed. The crux of the argument is that the partonic 2-surfaces coding for quantum states are for the maxima of Kähler action hyper-elliptic, that is possess  $Z_2$  conformal symmetry, which for  $g > 2$  implies that elementary particle vacuum functional vanishes.

### Massless states and particle massivation

This chapter represents the most recent view about elementary particle massivation in TGD framework. This topic is necessarily quite extended since many several notions and new mathematics is involved. Therefore the calculation of particle masses involves five chapters. In the following my goal is to provide an up-to-date summary whereas the chapters are unavoidably a story about evolution of ideas.

The identification of the spectrum of light particles reduces to two tasks: the construction of massless states and the identification of the states which remain light in p-adic thermodynamics. The latter task is relatively straightforward. The thorough understanding of the massless spectrum requires however a real understanding of quantum TGD. It would be also highly desirable to understand why p-adic thermodynamics combined with p-adic length scale hypothesis works. A lot of progress has taken place in these respects during last years.

Zero energy ontology providing a detailed geometric view about bosons and fermions, the generalization of  $S$ -matrix to what I call  $M$ -matrix, the notion of finite measurement resolution characterized in terms of inclusions of von Neumann algebras, the derivation of p-adic coupling constant evolution and p-adic length scale hypothesis from the first principles, the realization that the counterpart of Higgs mechanism involves generalized eigenvalues of the modified Dirac operator: these are represent important steps of progress during last years with a direct relevance for the understanding of particle spectrum and massivation although the predictions of p-adic thermodynamics are not affected.

During 2010 a further progress took place. These steps of progress relate closely to zero energy ontology, bosonic emergence, the realization of the importance of twistors in TGD, and to the discovery of the weak form of electric-magnetic duality. Twistor approach and the understanding of the Chern-Simons Dirac operator served as a midwife in the process giving rise to the birth of the idea that all particles at fundamental level are massless and that both ordinary elementary particles and string like objects emerge from them. Even more, one can interpret virtual particles as being composed of these massless on mass shell particles assignable to wormhole throats so that four-momentum conservation poses extremely powerful constraints on loop integrals and makes them manifestly finite.

The weak form of electric-magnetic duality led to the realization that elementary particles correspond to bound states of two wormhole throats with opposite Kähler magnetic charges with second throat carrying weak isospin compensating that of the fermion state at second wormhole throat. Both fermions and bosons correspond to wormhole contacts: in the case of fermions topological condensation generates the second wormhole throat. This means that altogether four wormhole throats are involved with both fermions, gauge bosons, and gravitons (for gravitons this is unavoidable in any case). For p-adic thermodynamics the mathematical counterpart of string corresponds to a wormhole contact with size of order  $CP_2$  size with the role of its ends played by wormhole throats at which the signature of the induced 4-metric changes. The key observation is that for massless states the throats of spin 1 particle must have opposite three-momenta so that gauge bosons are necessarily massive, even photon and other particles usually regarded as massless must have small mass which in turn cancels infrared divergences and give hopes about exact Yangian symmetry generalizing that of  $\mathcal{N} = 4$  SYM. Besides this there is weak "stringy" contribution to the mass assignable to the magnetic flux tubes connecting the two wormhole throats at the two space-time sheets.

#### 1. Physical states as representations of super-symplectic and Super Kac-Moody algebras

Physical states are assumed to belong to the representation of super-symplectic algebra and Super Kac-Moody algebra assignable  $SO(2) \times SU(3) \times SU(2)_{rot} \times U(2)_{ew}$  associated with the 2-D surfaces

$X^2$  defined by the intersections of light-like 3-surfaces with  $\delta M_{\pm}^4 \times CP_2$ . These 2-surfaces have interpretation as partons.

Yangian algebras associated with the super-conformal algebras and motivated by twistorial approach generalize the super-conformal symmetry and make it multi-local in the sense that generators can act on several partonic 2-surfaces simultaneously. These partonic 2-surfaces generalize the vertices for the external massless particles in twistor Grassmann diagrams. The implications of this symmetry are yet to be deduced but one thing is clear: Yangians are tailor made for the description of massive bound states formed from several partons identified as partonic 2-surfaces.

### 2. Particle massivation

Particle massivation can be regarded as a generation of thermal conformal weight identified as mass squared and due to a thermal mixing of a state with vanishing conformal weight with those having higher conformal weights. The observed mass squared is not p-adic thermal expectation of mass squared but that of conformal weight so that there are no problems with Lorentz invariance.

One can imagine several microscopic mechanisms of massivation. The following proposal is the winner in the fight for survival between several competing scenarios.

1. Instead of energy, the Super Kac-Moody Virasoro (or equivalently super-symplectic) generator  $L_0$  (essentially mass squared) is thermalized in p-adic thermodynamics (and also in its real version assuming it exists). The fact that mass squared is thermal expectation of conformal weight guarantees Lorentz invariance. That mass squared, rather than energy, is a fundamental quantity at  $CP_2$  length scale is also suggested by a simple dimensional argument (Planck mass squared is proportional to  $\hbar$  so that it should correspond to a generator of some Lie-algebra (Virasoro generator  $L_0!$ )).
2. By Equivalence Principle the thermal average of mass squared can be calculated either in terms of thermodynamics for either super-symplectic of Super Kac-Moody Virasoro algebra and p-adic thermodynamics is consistent with conformal invariance.
3. There is also a modular contribution to the mass squared, which can be estimated using elementary particle vacuum functionals in the conformal modular degrees of freedom of the partonic 2-surface. It dominates for higher genus partonic 2-surfaces. For bosons both Virasoro and modular contributions seem to be negligible and could be due to the smallness of the p-adic temperature.
4. A long standing problem has been whether coupling to Higgs boson is needed to explain gauge boson masses via a generation of Higgs vacuum expectation having possibly interpretation in terms of a coherent state. The deviation  $\Delta h$  of the total ground state conformal weight from negative integer gives rise to Higgs type contribution to the thermal mass squared and dominates in case of gauge bosons for which p-adic temperature is small. In the case of fermions this contribution to the mass squared is small. It is natural to relate  $\Delta h$  to the generalized eigenvalues of Chern-Simons Dirac operator.
5. A natural identification of the non-integer contribution to the conformal weight is as Higgsy and stringy contributions to the vacuum conformal weight (strings are now "weak strings"). In twistor approach the generalized eigenvalues of Chern-Simons Dirac operator for external particles indeed correspond to light-like momenta and when the three-momenta are opposite this gives rise to non-vanishing mass. Higgs is necessary to give longitudinal polarizations for gauge bosons and also gauge bosons usually regarded as exactly massless particles would naturally receive small mass in this manner so that Higgs would disappear completely from the spectrum. The theoretical motivation for a small mass would be exact Yangian symmetry. Higgs vacuum expectation assignable to coherent state of Higgs bosons is not needed to explain the boson masses. Twistorial consideration suggest that Higgs disappears completely from the spectrum and this might happen also for its super counterpart.

p-Adic thermodynamics is what gives to this approach its predictive power.

1. p-Adic temperature is quantized by purely number theoretical constraints (Boltzmann weight  $\exp(-E/kT)$  is replaced with  $p^{L_0/T_p}$ ,  $1/T_p$  integer) and fermions correspond to  $T_p = 1$  whereas  $T_p = 1/n$ ,  $n > 1$ , seems to be the only reasonable choice for gauge bosons.

2. p-Adic thermodynamics forces to conclude that  $CP_2$  radius is essentially the p-adic length scale  $R \sim L$  and thus of order  $R \simeq 10^{3.5} \sqrt{\hbar G}$  and therefore roughly  $10^{3.5}$  times larger than the naive guess. Hence p-adic thermodynamics describes the mixing of states with vanishing conformal weights with their Super Kac-Moody Virasoro excitations having masses of order  $10^{-3.5}$  Planck mass.

### p-Adic particle massivation: hadron masses

In this chapter the results of the calculation of elementary particle masses will be used to construct a model predicting hadron masses.

#### 1. Topological mixing of quarks

In TGD framework CKM mixing is induced by topological mixing of quarks (that is 2-dimensional topologies characterized by genus). Number theoretical constraints on topological mixing can be realized by assuming that topological mixing leads to a thermodynamical equilibrium. This gives an upper bound of 1200 for the number of different  $U$  and  $D$  matrices and the input from top quark mass and  $\pi^+ - \pi^0$  mass difference implies that physical  $U$  and  $D$  matrices can be constructed as small perturbations of matrices expressible as direct sum of essentially unique  $2 \times 2$  and  $1 \times 1$  matrices. The maximally entropic solutions can be found numerically by using the fact that only the probabilities  $p_{11}$  and  $p_{21}$  can be varied freely. The solutions are unique in the accuracy used, which suggests that the system allows only single thermodynamical phase.

The matrices  $U$  and  $D$  associated with the probability matrices can be deduced straightforwardly in the standard gauge. The  $U$  and  $D$  matrices derived from the probabilities determined by the entropy maximization turn out to be unitary for most values of  $n_1$  and  $n_2$ . This is a highly non-trivial result and means that mass and probability constraints together with entropy maximization define a sub-manifold of  $SU(3)$  regarded as a sub-manifold in 9-D complex space. The choice  $(n(u), n(c)) = (4, n)$ ,  $n < 9$ , does not allow unitary  $U$  whereas  $(n(u), n(c)) = (5, 6)$  does. This choice is still consistent with top quark mass and together with  $n(d) = n(s) = 5$  it leads to a rather reasonable CKM matrix with a value of CP breaking invariant within experimental limits. The elements  $V_{i3}$  and  $V_{3i}$ ,  $i = 1, 2$  are however roughly twice larger than their experimental values deduced assuming standard model.  $V_{31}$  is too large by a factor 1.6. The possibility of scaled up variants of light quarks could lead to too small experimental estimates for these matrix elements. The whole parameter space has not been scanned so that better candidates for CKM matrices might well exist.

#### 2. Higgs contribution to fermion masses is negligible

There are good reasons to believe that Higgs expectation for the fermionic space-time sheets is vanishing although fermions couple to Higgs. Thus p-adic thermodynamics would explain fermion masses completely. This together with the fact that the prediction of the model for the top quark mass is consistent with the most recent limits on it, fixes the  $CP_2$  mass scale with a high accuracy to the maximal one obtained if second order contribution to electron's p-adic mass squared vanishes. This is very strong constraint on the model.

#### 3. The p-adic length scale of quark is dynamical

The assumption about the presence of scaled up variants of light quarks in light hadrons leads to a surprisingly successful model for pseudo scalar meson masses using only quark masses and the assumption mass squared is additive for quarks with same p-adic length scale and mass for quarks labelled by different primes  $p$ . This conforms with the idea that pseudo scalar mesons are Goldstone bosons in the sense that color Coulombic and magnetic contributions to the mass cancel each other. Also the mass differences between hadrons containing different numbers of strange and heavy quarks can be understood if  $s, b$  and  $c$  quarks appear as several scaled up versions.

This hypothesis yields surprisingly good fit for meson masses but for some mesons the predicted mass is slightly too high. The reduction of  $CP_2$  mass scale to cure the situation is not possible since top quark mass would become too low. In case of diagonal mesons for which quarks correspond to same p-adic prime, quark contribution to mass squared can be reduced by ordinary color interactions and in the case of non-diagonal mesons one can require that quark contribution is not larger than meson mass.

4. *Super-canonical bosons at hadronic space-time sheet can explain the constant contribution to baryonic masses*

Quarks explain only a small fraction of the baryon mass and that there is an additional contribution which in a good approximation does not depend on baryon. This contribution should correspond to the non-perturbative aspects of QCD.

A possible identification of this contribution is in terms of super-canonical gluons predicted by TGD. Baryonic space-time sheet with  $k = 107$  would contain a many-particle state of super-canonical gluons with net conformal weight of 16 units. This leads to a model of baryons masses in which masses are predicted with an accuracy better than 1 per cent. Super-canonical gluons also provide a possible solution to the spin puzzle of proton.

Hadronic string model provides a phenomenological description of non-perturbative aspects of QCD and a connection with the hadronic string model indeed emerges. Hadronic string tension is predicted correctly from the additivity of mass squared for  $J = 2$  bound states of super-canonical quanta. If the topological mixing for super-canonical bosons is equal to that for  $U$  type quarks then a 3-particle state formed by 2 super-canonical quanta from the first generation and 1 quantum from the second generation would define baryonic ground state with 16 units of conformal weight.

In the case of mesons pion could contain super-canonical boson of first generation preventing the large negative contribution of the color magnetic spin-spin interaction to make pion a tachyon. For heavier bosons super-canonical boson need not to be assumed. The preferred role of pion would relate to the fact that its mass scale is below QCD  $\Lambda$ .

5. *Description of color magnetic spin-spin splitting in terms of conformal weight*

What remains to be understood are the contributions of color Coulombic and magnetic interactions to the mass squared. There are contributions coming from both ordinary gluons and super-canonical gluons and the latter is expected to dominate by the large value of color coupling strength.

Conformal weight replaces energy as the basic variable but group theoretical structure of color magnetic contribution to the conformal weight associated with hadronic space-time sheet ( $k = 107$ ) is same as in case of energy. The predictions for the masses of mesons are not so good than for baryons, and one might criticize the application of the format of perturbative QCD in an essentially non-perturbative situation.

The comparison of the super-canonical conformal weights associated with spin 0 and spin 1 states and spin 1/2 and spin 3/2 states shows that the different masses of these states could be understood in terms of the super-canonical particle contents of the state correlating with the total quark spin. The resulting model allows excellent predictions also for the meson masses and implies that only pion and kaon can be regarded as Goldstone boson like states. The model based on spin-spin splittings is consistent with the model.

To sum up, the model provides an excellent understanding of baryon and meson masses. This success is highly non-trivial since the fit involves only the integers characterizing the p-adic length scales of quarks and the integers characterizing color magnetic spin-spin splitting plus p-adic thermodynamics and topological mixing for super-canonical gluons. The next challenge would be to predict the correlation of hadron spin with super-canonical particle content in case of long-lived hadrons.

### Higgs or something else?

Whether Higgs like particle is needed or not in TGD framework and whether TGD predicts such a particle has been one of the longstanding issues of TGD and my views about Higgs have fluctuated. What is clear that fermion massivation is due to p-adic thermodynamics in TGD framework but the group theoretic character of gauge boson massivation suggests that Higgs like particle giving masses only for weak bosons is needed.

The most recent TGD based interpretation of Higgs like boson is as a pion-like state of scaled up variant of hadron physics. The standard model Higgs - by definition a provider of also fermion masses - is not needed. Essentially one assumption, the separate conservation of quark and lepton numbers realized in terms of 8-D chiral invariance, excludes Higgs like states in this sense as also standard  $\mathcal{N} = 1$  SUSY.

The identification of Higgs like particle as Euclidian pion (assignable to the flux tube connecting opposite throats of wormhole contact having Euclidian signature of the induced metric) leads to

standard Higgs mechanism in the gauge boson sector if the Euclidian pion transforms as  $2 + \bar{2}$  under electroweak  $u(2)$  identifiable as holonomy group of  $CP_2$  and imbeddable as a subgroup to color group  $su(3)$ . The mass formulas are exactly the same. The hierarchy problem due to the instability of the tachyonic mass term for Higgs like particle is however avoided since the direct couplings to fermions proportional fermion mass are not needed since p-adic thermodynamics makes them massive. Also the basic contributions to the decay rates remain the same as for standard model Higgs.

The additional bonus is a microscopic description for the tachyonic mass term in terms of a bilinear coupling to a superposition of YM action density and instanton term - briefly  $a \times YM + b \times I$  - most naturally restricted to that for the induced Kähler form. This term predicts that - besides the ordinary decays to electro-weak gauge boson pairs mediated by same action as in the case of ordinary Higgs - there are also decays to neutral gauge boson pairs mediated by the linear perturbative couplings to  $a \times YM + b \times I$ . Instanton density brings in also CP breaking possibly related to the poorly understood CP breaking of hadronic physics. The quantitative estimate for the anomalous contribution to the decay rates gives a result consistent with experimental data under reasonable order of magnitude estimates for the parameters involved.

Besides solving the hierarchy problem, this identification could explain the failure to find the decays to  $\tau$  pairs and also the excess of two-gamma decays. Also a connection with the dark matter researches reporting signal at 130 GeV and possibly also at 110 GeV suggests itself: maybe also these signals also correspond to Minkowskian and Euclidian pion-like states. The fate of the most recent identification of Higgs as "Euclidian pion" of  $M_{89}$  hadron physics providing masses for gauge bosons depends on the data provided by LHC during next years.

In this chapter the evolution of ideas is described and in various sections often mutually conflicting arguments are represented.

## SUSY in TGD Universe

The view about space-time supersymmetry differs from the standard view in many respects. First of all, the super symmetries are not associated with Majorana spinors. Super generators correspond to the fermionic oscillator operators assignable to leptonic and quark-like induced spinors and there is in principle infinite number of them so that formally one would have  $\mathcal{N} = \infty$  SUSY.

Quite recent developments in the understanding of the modified Dirac equation (I am writing this 2012) have led to a considerable understanding of the special role of right-handed neutrino. Whereas all other fermions are localized to 2-D string world sheets and partonic 2-surfaces by the condition that electromagnetic charge defined in spinorial sense is conserved, right-handed neutrino is delocalized at entire space-time surface and there is unbroken 4-dimensional counterpart of 2-D super-conformal symmetry associated with it. The rapid experimental progress at LHC during 2011-2012 has more or less eliminated standard SUSY and this gives a powerful constraint in the attempts to understand what TGD SUSY could be.

As conjectured earlier, TGD indeed has also 2-D badly broken SUSY generated by all fermion modes of the modified Dirac equation and labelled by conformal weight. This SUSY could be also interpreted super-conformal symmetry. It also gives rise to extension of 2-D super-conformal symmetry to 4-D super-conformal symmetry much larger than the ordinary super-conformal symmetry: this space-time SUSY applies at the level of space-time surfaces but what about TGD counterpart of conventional space-time SUSY at the level of  $M^4$  and imbedding space? Could covariantly constant right-handed neutrino generate it?

What remains to be understood is the role of the covariantly constant right-handed neutrino spinor carrying no momentum: it behaves like Majorana spinor and its helicity is not constrained by Dirac equation. It is not clear whether the states defined by 2-D parton and by parton plus 4-D delocalized right-handed neutrino can be distinguished experimentally if right-handed neutrino does not carry four-momentum. This would be a trivial explanation for the failure to find evidence for SUSY at LHC. In fact, this argument can be developed to a more precise one: both fermions and sfermions exist and form representations of SUSY with second state having zero norm. Therefore fermion and sfermion candidates exist but belong to different representations of SUSY, and right-handed neutrinos remain invisible in the dynamics and the characteristic spin and momentum dependent vertex factors distinguishing between particle and sparticle are absent. The loss of space-time SUSY is not a catastrophe since it is not needed to stabilize Higgs in TGD framework since the variant of Higgs mechanism based on Higgs like pseudo-scalar is based conformally covariant Higgs potential

containing no tachyonic Higgs mass term and is free of the problems related to radiative instability of the tachyonic Higgs mass term.

In this chapter I discuss the evolution of the vision about SUSY in TGD framework. There is no attempt to represent a final outcome in a concise form because I do not have such a final view yet. I represent the arguments developed during years in roughly chronological order so that reader can see how the development has taken place. The arguments are not necessarily internally consistent and can be inaccurate.

### **p-Adic Particle Massivation: New Physics: part I**

TGD predicts a lot of new physics and it is quite possible that this new physics becomes visible at LHC. Although the calculational formalism is still lacking, p-adic length scale hypothesis allows to make precise quantitative predictions for particle masses by using simple scaling arguments.

The basic elements of quantum TGD responsible for new physics are following.

1. The new view about particles relies on their identification as partonic 2-surfaces (plus 4-D tangent space data to be precise). This effective metric 2-dimensionality implies generalization of the notion of Feynman diagram and holography in strong sense. One implication is the notion of field identity or field body making sense also for elementary particles and the Lamb shift anomaly of muonic hydrogen could be explained in terms of field bodies of quarks.
2. The topological explanation for family replication phenomenon implies genus generation correspondence and predicts in principle infinite number of fermion families. One can however develop a rather general argument based on the notion of conformal symmetry known as hyper-ellipticity stating that only the genera  $g = 0, 1, 2$  are light. What "light" means is however an open question. If light means something below  $CP_2$  mass there is no hope of observing new fermion families at LHC. If it means weak mass scale situation changes.

For bosons the implications of family replication phenomenon can be understood from the fact that they can be regarded as pairs of fermion and antifermion assignable to the opposite wormhole throats of wormhole throat. This means that bosons formally belong to octet and singlet representations of dynamical  $SU(3)$  for which 3 fermion families define 3-D representation. Singlet would correspond to ordinary gauge bosons. Also interacting fermions suffer topological condensation and correspond to wormhole contact. One can either assume that the resulting wormhole throat has the topology of sphere or that the genus is same for both throats.

3. The view about space-time supersymmetry differs from the standard view in many respects. First of all, the super symmetries are not associated with Majorana spinors. Super generators correspond to the fermionic oscillator operators assignable to leptonic and quark-like induced spinors and there is in principle infinite number of them so that formally one would have  $\mathcal{N} = \infty$  SUSY. I have discussed the required modification of the formalism of SUSY theories and it turns out that effectively one obtains just  $\mathcal{N} = 1$  SUSY required by experimental constraints. The reason is that the fermion states with higher fermion number define only short range interactions analogous to van der Waals forces. Right handed neutrino generates this super-symmetry broken by the mixing of the  $M^4$  chiralities implied by the mixing of  $M^4$  and  $CP_2$  gamma matrices for induced gamma matrices. The simplest assumption is that particles and their superpartners obey the same mass formula but that the p-adic length scale can be different for them.
4. The new view about particle massivation involves besides p-adic thermodynamics also Higgs but there is no need to assume that Higgs vacuum expectation plays any role. The most natural option favored by the assumption that elementary bosons are bound states of massless elementary fermions, by twistorial considerations, and by the fact that both gauge bosons and Higgs form  $SU(2)$  triplet and singlet, predicts that also photon and other massless gauge bosons develop small mass so that all Higgs particles and their colored variants would disappear from spectrum. Same could happen for Higgsinos.
5. One of the basic distinctions between TGD and standard model is the new view about color.
  - (a) The first implication is separate conservation of quark and lepton quantum numbers implying the stability of proton against the decay via the channels predicted by GUTs. This

does not mean that proton would be absolutely stable. p-Adic and dark length scale hierarchies indeed predict the existence of scale variants of quarks and leptons and proton could decay to hadrons of some zoomed up copy of hadrons physics. These decays should be slow and presumably they would involve phase transition changing the value of Planck constant characterizing proton. It might be that the simultaneous increase of Planck constant for all quarks occurs with very low rate.

- (b) Also color excitations of leptons and quarks are in principle possible. Detailed calculations would be required to see whether their mass scale is given by  $CP_2$  mass scale. The so called leptohadron physics proposed to explain certain anomalies associated with both electron, muon, and  $\tau$  lepton could be understood in terms of color octet excitations of leptons.
6. Fractal hierarchies of weak and hadronic physics labelled by p-adic primes and by the levels of dark matter hierarchy are highly suggestive. Ordinary hadron physics corresponds to  $M_{107} = 2^{107} - 1$ . One especially interesting candidate would be scaled up hadronic physics which would correspond to  $M_{89} = 2^{89} - 1$  defining the p-adic prime of weak bosons. The corresponding string tension is about 512 GeV and it might be possible to see the first signatures of this physics at LHC. Nuclear string model in turn predicts that nuclei correspond to nuclear strings of nucleons connected by colored flux tubes having light quarks at their ends. The interpretation might be in terms of  $M_{127}$  hadron physics. In biologically most interesting length scale range 10 nm-2.5  $\mu\text{m}$  there are four Gaussian Mersenneses and the conjecture is that these and other Gaussian Mersenneses are associated with zoomed up variants of hadron physics relevant for living matter. Cosmic rays might also reveal copies of hadron physics corresponding to  $M_{61}$  and  $M_{31}$ .
  7. Weak form of electric magnetic duality implies that the fermions and antifermions associated with both leptons and bosons are Kähler magnetic monopoles accompanied by monopoles of opposite magnetic charge and with opposite weak isospin. For quarks Kähler magnetic charge need not cancel and cancellation might occur only in hadronic length scale. The magnetic flux tubes behave like string like objects and if the string tension is determined by weak length scale, these string aspects should become visible at LHC. If the string tension is 512 GeV the situation becomes less promising.

In this chapter some aspects of the predicted new physics and possible indications for it are discussed. The evolution of the TGD based view about possible existing Higgs like particle and about space-time SUSY are discussed in separate chapters.

### p-Adic Particle Massivation: New Physics: part II

In this chapter the focus is on the hadron physics. The applications are to various anomalies discovered during years.

#### 1. Application of the many-sheeted space-time concept in hadron physics

The many-sheeted space-time concept involving also the notion of field body can be applied to hadron physics to explain findings which are difficult to understand in the framework of standard model.

1. The spin puzzle of proton is a two decades old mystery with no satisfactory explanation in QCD framework. The notion of hadronic space-time sheet which could be imagined as string like rotating object suggests a possible approach to the spin puzzle. The entanglement between valence quark spins and the angular momentum states of the rotating hadronic space-time sheet could allow natural explanation for why the average valence quark spin vanishes.
2. The notion of Pomeron was invented during the Bootstrap era preceding QCD to solve difficulties of Regge approach. There are experimental findings suggesting the reincarnation of this concept. The possibility that the newly born concept of Pomeron of Regge theory might be identified as the sea of perturbative QCD in TGD framework is considered. Geometrically Pomeron would correspond to hadronic space-time sheet without valence quarks.
3. The discovery that the charge radius of proton deduced from the muonic version of hydrogen atom is about 4 per cent smaller than from the radius deduced from hydrogen atom is in complete

conflict with the cherished belief that atomic physics belongs to the museum of science. The title of the article *Quantum electrodynamics-a chink in the armour?* of the article published in Nature expresses well the possible implications, which might actually go well extend beyond QED. TGD based model for the findings relies on the notion of color magnetic body carrying both electromagnetic and color fields and extends well beyond the size scale of the particle. This gives rather detailed constraints on the model of the magnetic body.

4. The soft photon production rate in hadronic reactions is by an average factor of about four higher than expected. In the article soft photons assignable to the decays of  $Z^0$  to quark-antiquark pairs. This anomaly has not reached the attention of particle physics which seems to be the fate of anomalies quite generally nowadays: large extra dimensions and black-holes at LHC are much more sexy topics of study than the anomalies about which both existing and speculative theories must remain silent. TGD based model is based on the notion of electric flux tube.

### 2. Quark gluon plasma

QCD predicts that at sufficiently high collision energies de-confinement phase transitions for quarks should take place leading to quark gluon plasma. In heavy ion collisions at RHIC something like this was found to happen. The properties of the quark gluon plasma were however not what was expected. There are long range correlations and the plasma seems to behave like perfect fluid with minimal viscosity/entropy ratio. The lifetime of the plasma phase is longer than expected and its density much higher than QCD would suggest. The experiments at LHC for proton proton collisions suggest also the presence of quark gluon plasma with similar properties.

TGD suggests an interpretation in terms of long color magnetic flux tubes containing the plasma. The confinement to color magnetic flux tubes would force higher density. The preferred extremals of Kähler action have interpretation as defining a flow of perfect incompressible fluid and the perfect fluid property is broken only by the many-sheeted structure of space-time with smaller space-time sheets assignable to sub- $CD$ s representing radiative corrections. The phase in question corresponds to a non-standard value of Planck constant: this could also explain why the lifetime of the phase is longer than expected.

### 3. Breaking of discrete symmetries

Zero energy ontology provides a fresh approach to discrete symmetries and provides also a general mechanism for their breaking. A general vision about breaking of discrete symmetries relies on quantum measurement theory: the quantum jump selecting the quantization axes induces localization to a single  $CD$  and therefore induces breaking of discrete symmetries due to the choice of quantization axes. The time scale of  $CD$  is excellent candidate for defining mass and time scales characterizing the symmetry breaking. Entropic gravity idea has a variant in TGD framework resulting from the fact that in ZEO quantum theory is a square root of thermodynamics in a well-defined sense. Thermodynamical stability could force the generation of the arrow of time and also force it to be different for matter and antimatter inducing in this manner matter antimatter asymmetry and breaking of discrete symmetries like CP. Also CPT could be broken spontaneously and there are experimental indications that this takes place for top quark with mass difference which is surprisingly large- few per cent of top mass.

### 4. Are exotic Super Virasoro representations relevant for hadron physics?

In p-adic context exotic representations of Super Virasoro with  $M^2 \propto p^k$ ,  $k = 1, 2, \dots, m$  are possible. For  $k = 1$  the states of these representations have same mass scale as elementary particles although in real context the masses would be gigantic. This inspires the question whether non-perturbative aspects of hadron physics could be assigned to the presence of these representations. Some intriguing numerical co-incidences suggest that the exotic representations of Super-Virasoro should be assigned with hadron and whereas ordinary Virasoro representations would be assigned with the quark-gluon plasma or possibly sea quarks.

### 1.4.3 Part II: Applications of p-adic length scale hypothesis and dark matter hierarchy

#### Recent status of lepto-hadron hypothesis

TGD suggests strongly the existence of lepto-hadron physics. Lepto-hadrons are bound states of color excited leptons and the anomalous production of  $e^+e^-$  pairs in heavy ion collisions finds a nice explanation as resulting from the decays of lepto-hadrons with basic condensate level  $k = 127$  and having typical mass scale of one  $MeV$ . The recent indications on the existence of a new fermion with quantum numbers of muon neutrino and the anomaly observed in the decay of orthopositronium give further support for the lepto-hadron hypothesis. There is also evidence for anomalous production of low energy photons and  $e^+e^-$  pairs in hadronic collisions.

The identification of lepto-hadrons as a particular instance in the predicted hierarchy of dark matters interacting directly only via graviton exchange allows to circumvent the lethal counter arguments against the lepto-hadron hypothesis ( $Z^0$  decay width and production of colored lepton jets in  $e^+e^-$  annihilation) even without assumption about the loss of asymptotic freedom.

PCAC hypothesis and its sigma model realization lead to a model containing only the coupling of the lepto-pion to the axial vector current as a free parameter. The prediction for  $e^+e^-$  production cross section is of correct order of magnitude only provided one assumes that lepto-pions decay to lepto-nucleon pair  $e_{ex}^+e_{ex}^-$  first and that lepto-nucleons, having quantum numbers of electron and having mass only slightly larger than electron mass, decay to lepton and photon. The peculiar production characteristics are correctly predicted. There is some evidence that the resonances decay to a final state containing  $n > 2$  particle and the experimental demonstration that lepto-nucleon pairs are indeed in question, would be a breakthrough for TGD.

During 18 years after the first published version of the model also evidence for colored  $\mu$  has emerged. Towards the end of 2008 CDF anomaly gave a strong support for the colored excitation of  $\tau$ . The lifetime of the light long lived state identified as a charged  $\tau$ -pion comes out correctly and the identification of the reported 3 new particles as p-adically scaled up variants of neutral  $\tau$ -pion predicts their masses correctly. The observed muon jets can be understood in terms of the special reaction kinematics for the decays of neutral  $\tau$ -pion to 3  $\tau$ -pions with mass scale smaller by a factor  $1/2$  and therefore almost at rest. A spectrum of new particles is predicted. The discussion of CDF anomaly led to a modification and generalization of the original model for lepto-pion production and the predicted production cross section is consistent with the experimental estimate.

#### TGD and Nuclear Physics

This chapter is devoted to the possible implications of TGD for nuclear physics. In the original version of the chapter the focus was in the attempt to resolve the problems caused by the incorrect interpretation of the predicted long ranged weak gauge fields. What seems to be a breakthrough in this respect came only quite recently (2005), more than a decade after the first version of this chapter, and is based on TGD based view about dark matter inspired by the developments in the mathematical understanding of quantum TGD. In this approach condensed matter nuclei can be either ordinary, that is behave essentially like standard model nuclei, or be in dark matter phase in which case they generate long ranged dark weak gauge fields responsible for the large parity breaking effects in living matter. This approach resolves trivially the objections against long range classical weak fields.

The basic criterion for the transition to dark matter phase having by definition large value of  $\hbar$  is that the condition  $\alpha Q_1 Q_2 \simeq 1$  for appropriate gauge interactions expressing the fact that the perturbation series does not converge. The increase of  $\hbar$  makes perturbation series converging since the value of  $\alpha$  is reduced but leaves lowest order classical predictions invariant.

This criterion can be applied to color force and inspires the hypothesis that valence quarks inside nucleons correspond to large  $\hbar$  phase whereas sea quark space-time sheets correspond to the ordinary value of  $\hbar$ . This hypothesis is combined with the earlier model of strong nuclear force based on the assumption that long color bonds with p-adically scaled down quarks with mass of order MeV at their ends are responsible for the nuclear strong force.

1. *Is strong force due to color bonds between exotic quark pairs?*

The basic assumptions are following.

1. Valence quarks correspond to large  $\hbar$  phase with p-adic length scale  $L(k_{eff} = 129) = L(107)/v_0 \simeq 2^{11}L(107) \simeq 5 \times 10^{-12}$  m whereas sea quarks correspond to ordinary  $\hbar$  and define the standard size of nucleons.
2. Color bonds with length of order  $L(127) \simeq 2.5 \times 10^{-12}$  m and having quarks with ordinary  $\hbar$  and p-adically scaled down masses  $m_q(dark) \simeq v_0 m_q$  at their ends define kind of rubber bands connecting nucleons. The p-adic length scale of exotic quarks differs by a factor 2 from that of dark valence quarks so that the length scales in question can couple naturally. This large length scale as also other p-adic length scales correspond to the size of the topologically quantized field body associated with system, be it quark, nucleon, or nucleus.
3. Valence quarks and even exotic quarks can be dark with respect to both color and weak interactions but not with respect to electromagnetic interactions. The model for binding energies suggests darkness with respect to weak interactions with weak boson masses scaled down by a factor  $v_0$ . Weak interactions remain still weak. Quarks and nucleons as defined by their  $k = 107$  sea quark portions condense at scaled up weak space-time sheet with  $k_{eff} = 111$  having p-adic size  $10^{-14}$  meters. The estimate for the atomic number of the heaviest possible nucleus comes out correctly.

The wave functions of the nucleons fix the boundary values of the wave functionals of the color magnetic flux tubes idealizable as strings. In the terminology of M-theory nucleons correspond to small branes and color magnetic flux tubes to strings connecting them.

### 2. General features of strong interactions

This picture allows to understand the general features of strong interactions.

1. Quantum classical correspondence and the assumption that the relevant space-time surfaces have 2-dimensional  $CP_2$  projection implies Abelianization. Strong isospin group can be identified as the  $SU(2)$  subgroup of color group acting as isotropies of space-time surfaces. and the  $U(1)$  holonomy of color gauge potential defines a preferred direction of strong isospin. Dark color isospin corresponds to strong isospin. The correlation of dark color with weak isospin of the nucleon is strongly suggested by quantum classical correspondence.
2. Both color singlet spin 0 pion type bonds and colored spin 1 bonds are allowed and the color magnetic spin-spin interaction between the exotic quark and anti-quark is negative in this case. p-p and n-n bonds correspond to oppositely colored spin 1 bonds and p-n bonds to colorless spin 0 bonds for which the binding energy is free times higher. The presence of colored bonds forces the presence of neutralizing dark gluon condensate favoring states with  $N - P > 0$ .
3. Shell model based on harmonic oscillator potential follows naturally from this picture in which the magnetic flux tubes connecting nucleons take the role of springs. Spin-orbit interaction can be understood in terms of the color force in the same way as it is understood in atomic physics.

### 3. Nuclear binding energies

1. The binding energies per nucleon for  $A \leq 4$  nuclei can be understood if they form closed string like structures, nuclear strings, so that only two color bonds per nucleon are possible. This could be understood if ordinary quarks and exotic quarks possessing much smaller mass behave as if they were identical fermions. p-Adic mass calculations support this assumption. Also the average behavior of binding energy for heavier nuclei is predicted correctly.
2. For nuclei with  $P = N$  all color bonds can be pion type bonds and have thus largest color magnetic spin-spin interaction energy. The increase of color Coulombic binding energy between colored exotic quark pairs and dark gluons however favors  $N > P$  and explains also the formation of neutron halo outside  $k = 111$  space-time sheet.
3. Spin-orbit interaction provides the standard explanation for magic numbers. If the maximum of the binding energy per nucleon is taken as a criterion for magic, also  $Z=N=4,6,12$  are magic. The alternative TGD based explanation for magic numbers  $Z = N = 4, 6, 8, 12, 20$  would be

in terms of regular Platonic solids. Experimentally also other magic numbers are known for neutrons. The linking of nuclear strings provides a possible mechanism producing new magic nuclei from lighter magic nuclei.

#### 4. *Stringy description of nuclear reactions*

The view about nucleus as a collection of linked nuclear strings suggests stringy description of nuclear reactions. Microscopically the nuclear reactions would correspond to re-distribution of exotic quarks between the nucleons in reacting nuclei.

#### 5. *Anomalies and new nuclear physics*

The TGD based explanation of neutron halo has been already mentioned. The recently observed tetra-neutron states are difficult to understand in the standard nuclear physics framework since Fermi statistics does not allow this kind of state. The identification of tetra-neutron as an alpha particle containing two negatively charged color bonds allows to circumvent the problem. A large variety of exotic nuclei containing charged color bonds is predicted.

The proposed model explains the anomaly associated with the tritium beta decay. What has been observed is that the spectrum intensity of electrons has a narrow bump near the endpoint energy. Also the maximum energy  $E_0$  of electrons is shifted downwards. I have considered two explanations for the anomaly. The original models are based on TGD variants of original models involving belt of dark neutrinos or antineutrinos along the orbit of Earth. Only recently (towards the end of year 2008) I realized that nuclear string model provides much more elegant explanation of the anomaly and has also the potential to explain much more general anomalies.

Cold fusion has not been taken seriously by the physics community but the situation has begun to change gradually. There is an increasing evidence for the occurrence of nuclear transmutations of heavier elements besides the production of  ${}^4\text{He}$  and  ${}^3\text{H}$  whereas the production rate of  ${}^3\text{He}$  and neutrons is very low. These characteristics are not consistent with the standard nuclear physics predictions. Also Coulomb wall and the absence of gamma rays and the lack of a mechanism transferring nuclear energy to the electrolyte have been used as an argument against cold fusion. TGD based model relying on the notion of charged color bonds explains the anomalous characteristics of cold fusion.

### **Nuclear String Hypothesis**

Nuclear string hypothesis is one of the most dramatic almost-predictions of TGD. The hypothesis in its original form assumes that nucleons inside nucleus form closed nuclear strings with neighboring nuclei of the string connected by exotic meson bonds consisting of color magnetic flux tube with quark and anti-quark at its ends. The lengths of flux tubes correspond to the p-adic length scale of electron and therefore the mass scale of the exotic mesons is around 1 MeV in accordance with the general scale of nuclear binding energies. The long lengths of em flux tubes increase the distance between nucleons and reduce Coulomb repulsion. A fractally scaled up variant of ordinary QCD with respect to p-adic length scale would be in question and the usual wisdom about ordinary pions and other mesons as the origin of nuclear force would be simply wrong in TGD framework as the large mass scale of ordinary pion indeed suggests.

#### 1. *$A > 4$ nuclei as nuclear strings consisting of $A \leq 4$ nuclei*

In this article a more refined version of nuclear string hypothesis is developed.

1. It is assumed  ${}^4\text{He}$  nuclei and  $A < 4$  nuclei and possibly also nucleons appear as basic building blocks of nuclear strings.  $A \leq 4$  nuclei in turn can be regarded as strings of nucleons. Large number of stable lightest isotopes of form  $A = 4n$  supports the hypothesis that the number of  ${}^4\text{He}$  nuclei is maximal. Even the weak decay characteristics might be reduced to those for  $A < 4$  nuclei using this hypothesis.
2. One can understand the behavior of nuclear binding energies surprisingly well from the assumptions that total *strong* binding energy associated with  $A \leq 4$  building blocks is *additive* for nuclear strings.

3. In TGD framework tetra-neutron is interpreted as a variant of alpha particle obtained by replacing two meson-like stringy bonds connecting neighboring nucleons of the nuclear string with their negatively charged variants. For heavier nuclei tetra-neutron is needed as an additional building brick.

### 2. Bose-Einstein condensation of color bonds as a mechanism of nuclear binding

The attempt to understand the variation of the nuclear binding energy and its maximum for  $Fe$  leads to a quantitative model of nuclei lighter than  $Fe$  as color bound Bose-Einstein condensates of pion like colored states associated with color flux tubes connecting  ${}^4He$  nuclei. The color contribution to the total binding energy is proportional to  $n^2$ , where  $n$  is the number of color bonds. Fermi statistics explains the reduction of  $E_B$  for the nuclei heavier than  $Fe$ . Detailed estimate favors harmonic oscillator model over free nucleon model with oscillator strength having interpretation in terms of string tension.

Fractal scaling argument allows to understand  ${}^4He$  and lighter nuclei as strings of nucleons with nucleons bound together by color bonds. Three fractally scaled variants of QCD corresponding  $A > 4$ ,  $A = 4$ , and  $A < 4$  nuclei are involved. The binding energies of also  $A \leq 4$  are predicted surprisingly accurately by applying simple p-adic scaling to the model of binding energies of heavier nuclei.

### 3. Giant dipole resonance as de-coherence of Bose-Einstein condensate of color bonds

Giant resonances and so called pygmy resonances are interpreted in terms of de-coherence of the Bose-Einstein condensates associated with  $A \leq 4$  nuclei and with the nuclear string formed from  $A \leq 4$  nuclei. The splitting of the Bose-Einstein condensate to pieces costs a precisely defined energy. For  ${}^4He$  de-coherence the model predicts singlet line at 12.74 MeV and triplet at  $\sim 27$  MeV spanning 4 MeV wide range.

The de-coherence at the level of nuclear string predicts 1 MeV wide bands 1.4 MeV above the basic lines. Bands decompose to lines with precisely predicted energies. Also these contribute to the width. The predictions are in rather good agreement with experimental values. The so called pygmy resonance appearing in neutron rich nuclei can be understood as a de-coherence for  $A = 3$  nuclei. A doublet at  $\sim 8$  MeV and MeV spacing is predicted. The prediction for the position is correct.

### 4. Dark nuclear strings as analogs of DNA-, RNA- and amino-acid sequences and baryonic realization of genetic code

A speculative picture proposing a connection between homeopathy, water memory, and phantom DNA effect is discussed and on basis of this connection a vision about how the tqc hardware represented by the genome is actively developed by subjecting it to evolutionary pressures represented by a virtual world representation of the physical environment. The speculation inspired by this vision is that genetic code as well as DNA-, RNA- and amino-acid sequences should have representation in terms of nuclear strings. The model for dark baryons indeed leads to an identification of these analogs and the basic numbers of genetic code including also the numbers of aminoacids coded by a given number of codons are predicted correctly. Hence it seems that genetic code is universal rather than being an accidental outcome of the biological evolution.

## Dark Nuclear Physics and Condensed Matter

In this chapter the possible effects of dark matter in nuclear physics and condensed matter physics are considered. The spirit of the discussion is necessarily rather speculative since the vision about the hierarchy of Planck constants is only 5 years old. The most general form of the hierarchy would involve both singular coverings and factors spaces of  $CD$  (causal diamond of  $M^4$ ) defined as intersection of future and past directed light-cones) and  $CP_2$ . There are grave objections against the allowance of factor spaces. In this case Planck constant could be smaller than its standard value and there are very few experimental indications for this. Quite recently came the realization that the hierarchy of Planck constants might emerge from the basic quantum TGD as a consequence of the extreme non-linearity of field equations implying that the correspondence between the derivatives of imbedding space coordinates and canonical momentum is many-to-one. This makes natural to the introduction of covering spaces of  $CD$  and  $CP_2$ . Planck constant would be effectively replaced with a multiple of ordinary Planck constant defined by the number of the sheets of the covering. The space-like 3-surfaces at the

ends of the causal diamond and light-like 3-surfaces defined by wormhole throats carrying elementary particle quantum numbers would be quantum critical in the sense of being unstable against decay to many-sheeted structures. Charge fractionization could be understood in this scenario. Biological evolution would have the increase of the Planck constant as one aspect. The crucial scaling of the size of  $CD$  by Planck constant can be justified by a simple argument. Note that primary p-adic length scales would scale as  $\sqrt{\hbar}$  rather than  $\hbar$  as assumed in the original model.

### 1. *What darkness means?*

Dark matter is identified as matter with non-standard value of Planck constant. The weak form of darkness states that only some field bodies of the particle consisting of flux quanta mediating bound state interactions between particles become dark. One can assign to each interaction a field body (em,  $Z^0$ ,  $W$ , gluonic, gravitational) and p-adic prime and the value of Planck constant characterize the size of the particular field body. One might even think that particle mass can be assigned with its em field body and that Compton length of particle corresponds to the size scale of em field body.

Nuclear string model suggests that the sizes of color flux tubes and weak flux quanta associated with nuclei can become dark in this sense and have size of order atomic radius so that dark nuclear physics would have a direct relevance for condensed matter physics. If this happens, it becomes impossible to make a reductionistic separation between nuclear physics and condensed matter physics and chemistry anymore.

### 2. *What dark nucleons are?*

The basic hypothesis is that nuclei can make a phase transition to dark phase in which the size of both quarks and nuclei is measured in Angstroms. For the less radical option this transition could happen only for the color, weak, and em field bodies. Proton connected by dark color bonds super-nuclei with inter-nucleon distance of order atomic radius might be crucial for understanding the properties of water and perhaps even the properties of ordinary condensed matter. Large  $\hbar$  phase for weak field body of  $D$  and  $Pd$  nuclei with size scale of atom would explain selection rules of cold fusion.

### 3. *Anomalous properties of water and dark nuclear physics*

A direct support for partial darkness of water comes from the  $H_{1.5}O$  chemical formula supported by neutron and electron diffraction in attosecond time scale. The explanation could be that one fourth of protons combine to form super-nuclei with protons connected by color bonds and having distance sufficiently larger than atomic radius.

The crucial property of water is the presence of molecular clusters. Tetrahedral clusters allow an interpretation in terms of magic  $Z=8$  protonic dark nuclei. The icosahedral clusters consisting of 20 tetrahedral clusters in turn have interpretation as magic dark dark nuclei: the presence of the dark dark matter explains large portion of the anomalies associated with water and explains the unique role of water in biology. In living matter also higher levels of dark matter hierarchy are predicted to be present. The observed nuclear transmutation suggest that also light weak bosons are present.

### 4. *Implications of the partial darkness of condensed matter*

The model for partially dark condensed matter inspired by nuclear string model and the model of cold fusion inspired by it allows to understand the low compressibility of the condensed matter as being due to the repulsive weak force between exotic quarks, explains large parity breaking effects in living matter, and suggests a profound modification of the notion of chemical bond having most important implications for bio-chemistry and understanding of bio-chemical evolution.

## Dark Forces and Living Matter

The unavoidable presence of classical long ranged weak (and also color) gauge fields in TGD Universe has been a continual source of worries for more than two decades. The basic question has been whether  $Z^0$  charges of elementary particles are screened in electro-weak length scale or not. Same question must be raised in the case of color charges. For a long time the hypothesis was that the charges are feeded to larger space-time sheets in this length scale rather than screened by vacuum charges so that an effective screening results in electro-weak length scale. This hypothesis turned out to be a failure and was replaced with the idea that the non-linearity of field equations (only topological half

of Maxwell's equations holds true) implies the generation of vacuum charge densities responsible for the screening.

The weak form of electric-magnetic duality led to the identification of the long sought for mechanism causing the weak screening in electroweak scales. The basic implication of the duality is that Kähler electric charges of wormhole throats representing particles are proportional to Kähler magnetic charges so that the  $CP_2$  projections of the wormhole throats are homologically non-trivial. The Kähler magnetic charges do not create long range monopole fields if they are neutralized by wormhole throats carrying opposite monopole charges and weak isospin neutralizing the axial isospin of the particle's wormhole throat. One could speak of confinement of weak isospin. The weak field bodies of elementary fermions would be replaced with string like objects with a length of order W boson Compton length. Electro-magnetic flux would be feeded to electromagnetic field body where it would be feeded to larger space-time sheets. Similar mechanism could apply in the case of color quantum numbers. Weak charges would be therefore screened for ordinary matter in electro-weak length scale but dark electro-weak bosons correspond to much longer symmetry breaking length scale for weak field body. Large values of Planck constant would make it possible to zoop up elementary particles and study their internal structure without any need for gigantic accelerators.

In this chapter possible implications of the dark weak force for the understanding of living matter are discussed. The basic question is how classical  $Z^0$  fields could make itself visible. Large parity breaking effects in living matter suggests which direction one should look for the answer to the question. One possible answer is based on the observation that for vacuum extremals classical electromagnetic and  $Z^0$  fields are proportional to each other and this means that the electromagnetic charges of dark fermions standard are replaced with effective couplings in which the contribution of classical  $Z^0$  force dominates. This modifies dramatically the model for the cell membrane as a Josephson junction and raises the scale of Josephson energies from IR range just above thermal threshold to visible and ultraviolet. The amazing finding is that the Josephson energies for biologically important ions correspond to the energies assigned to the peak frequencies in the biological activity spectrum of photoreceptors in retina suggesting. This suggests that almost vacuum extremals and thus also classical  $Z^0$  fields are in a central role in the understanding of the functioning of the cell membrane and of sensory qualia. This would also explain the large parity breaking effects in living matter.

A further conjecture is that EEG and its predicted fractally scaled variants which same energies in visible and UV range but different scales of Josephson frequencies correspond to Josephson photons with various values of Planck constant. The decay of dark ELF photons with energies of visible photons would give rise to bunches of ordinary ELF photons. Biophotons in turn could correspond to ordinary visible photons resulting in the phase transition of these photons to photons with ordinary value of Planck constant. This leads to a very detailed view about the role of dark electromagnetic radiation in biomatter and also to a model for how sensory qualia are realized. The general conclusion might be that most effects due to the dark weak force are associated with almost vacuum extremals.

### Super-Conductivity in Many-Sheeted Space-Time

In this chapter a model for high  $T_c$  super-conductivity as quantum critical phenomenon is developed. The relies on the notions of quantum criticality, dynamical quantized Planck constant requiring a generalization of the 8-D imbedding space to a book like structure, and many-sheeted space-time. In particular, the notion of magnetic flux tube as a carrier of supra current of central concept.

With a sufficient amount of twisting and weaving these basic ideas one ends up to concrete model for high  $T_c$  superconductors as quantum critical superconductors consistent with the qualitative facts that I am personally aware. The following minimal model looks the most realistic option found hitherto.

1. The general idea is that magnetic flux tubes are carriers of supra currents. In anti-ferromagnetic phases these flux tube structures form small closed loops so that the system behaves as an insulator. Some mechanism leading to a formation of long flux tubes must exist. Doping creates holes located around stripes, which become positively charged and attract electrons to the flux tubes.
2. The higher critical temperature  $T_{c1}$  corresponds to a formation local configurations of parallel spins assigned to the holes of stripes giving rise to a local dipole fields with size scale of the order of the length of the stripe. Conducting electrons form Cooper pairs at the magnetic flux

tube structures associated with these dipole fields. The elongated structure of the dipoles favors angular momentum  $L = 2$  for the pairs. The presence of magnetic field favors Cooper pairs with spin  $S = 1$ .

3. Stripes can be seen as 1-D metals with delocalized electrons. The interaction responsible for the energy gap corresponds to the transversal oscillations of the magnetic flux tubes inducing oscillations of the nuclei of the stripe. These transverse phonons have spin and their exchange is a good candidate for the interaction giving rise to a mass gap. This could explain the BCS type aspects of high  $T_c$  super-conductivity.
4. Above  $T_c$  supra currents are possible only in the length scale of the flux tubes of the dipoles which is of the order of stripe length. The reconnections between neighboring flux tube structures induced by the transverse fluctuations give rise to longer flux tubes structures making possible finite conductivity. These occur with certain temperature dependent probability  $p(T, L)$  depending on temperature and distance  $L$  between the stripes. By criticality  $p(T, L)$  depends on the dimensionless variable  $x = TL/\hbar$  only:  $p = p(x)$ . At critical temperature  $T_c$  transverse fluctuations have large amplitude and makes  $p(x_c)$  so large that very long flux tubes are created and supra currents can run. The phenomenon is completely analogous to percolation.
5. The critical temperature  $T_c = x_c \hbar/L$  is predicted to be proportional to  $\hbar$  and inversely proportional to  $L$  (, which is indeed to be the case). If flux tubes correspond to a large value of  $\hbar$ , one can understand the high value of  $T_c$ . Both Cooper pairs and magnetic flux tube structures represent dark matter in TGD sense.
6. The model allows to interpret the characteristic spectral lines in terms of the excitation energy of the transversal fluctuations and gap energy of the Cooper pair. The observed 50 meV threshold for the onset of photon absorption suggests that below  $T_c$  also  $S = 0$  Cooper pairs are possible and have gap energy about 9 meV whereas  $S = 1$  Cooper pairs would have gap energy about 27 meV. The flux tube model indeed predicts that  $S = 0$  Cooper pairs become stable below  $T_c$  since they cannot anymore transform to  $S = 1$  pairs. Their presence could explain the BCS type aspects of high  $T_c$  super-conductivity. The estimate for  $\hbar/\hbar_0 = r$  from critical temperature  $T_{c1}$  is about  $r = 3$  contrary to the original expectations inspired by the model of living system as a super-conductor suggesting much higher value. An unexpected prediction is that coherence length is actually  $r$  times longer than the coherence length predicted by conventional theory so that type I super-conductor could be in question with stripes serving as duals for the defects of type I super-conductor in nearly critical magnetic field replaced now by ferromagnetic phase.
7. TGD suggests preferred values for  $r = \hbar/\hbar_0$ . For the most general option the values of  $\hbar$  are products and ratios of two integers  $n_a$  and  $n_b$ . Ruler and compass integers defined by the products of distinct Fermat primes and power of two are number theoretically favored values for these integers because the phases  $\exp(i2\pi/n_i)$ ,  $i \in \{a, b\}$ , in this case are number theoretically very simple and should have emerged first in the number theoretical evolution via algebraic extensions of p-adics and of rationals. p-Adic length scale hypothesis favors powers of two as values of  $r$ . The hypothesis that Mersenne primes  $M_k = 2^k - 1$ ,  $k \in \{89, 107, 127\}$ , and Gaussian Mersennes  $M_{G,k} = (1 + i)k - 1$ ,  $k \in \{113, 151, 157, 163, 167, 239, 241.. \}$  (the number theoretical miracle is that all the four p-adic length scales with  $k \in \{151, 157, 163, 167\}$  are in the biologically highly interesting range 10 nm-2.5  $\mu\text{m}$ ) define scaled up copies of electro-weak and QCD type physics with ordinary value of  $\hbar$  and that these physics are induced by dark variants of each other leads to a prediction for the preferred values of  $r = 2^{k_d}$ ,  $k_d = k_i - k_j$ , and the resulting picture finds support from the ensuing models for biological evolution and for EEG.

At qualitative level the model explains various strange features of high  $T_c$  superconductors. One can understand the high value of  $T_c$  and ambivalent character of high  $T_c$  super conductors, the existence of pseudogap and scalings laws for observables above  $T_c$ , the role of stripes and doping and the existence of a critical doping, etc...

### Quantum Hall effect and Hierarchy of Planck Constants

In this chapter I try to formulate more precisely the recent TGD based view about fractional quantum Hall effect (FQHE). This view is much more realistic than the original rough scenario, which neglected

the existing rather detailed understanding. The spectrum of  $\nu$ , and the mechanism producing it is the same as in composite fermion approach. The new elements relate to the not so well-understood aspects of FQHE, namely charge fractionalization, the emergence of braid statistics, and non-abelianity of braid statistics.

1. The starting point is composite fermion model so that the basic predictions are same. Now magnetic vortices correspond to (Kähler) magnetic flux tubes carrying unit of magnetic flux. The magnetic field inside flux tube would be created by delocalized electron at the boundary of the vortex. One can raise two questions.

Could the boundary of the macroscopic system carrying anyonic phase have identification as a macroscopic analog of partonic 2-surface serving as a boundary between Minkowskian and Euclidian regions of space-time sheet? If so, the space-time sheet assignable to the macroscopic system in question would have Euclidian signature, and would be analogous to blackhole or to a line of generalized Feynman diagram.

Could the boundary of the vortex be identifiable a light-like boundary separating Minkowskian magnetic flux tube from the Euclidian interior of the macroscopic system and be also analogous to wormhole throat? If so, both macroscopic objects and magnetic vortices would be rather exotic geometric objects not possible in general relativity framework.

2. Taking composite model as a starting point one obtains standard predictions for the filling fractions. One should also understand charge fractionalization and fractional braiding statistics. Here the vacuum degeneracy of Kähler action suggests the explanation. Vacuum degeneracy implies that the correspondence between the normal component of the canonical momentum current and normal derivatives of imbedding space coordinates is 1- to- $n$ . These kind of branchings result in multi-furcations induced by variations of the system parameters and the scaling of external magnetic field represents one such variation.
3. At the orbits of wormhole throats, which can have even macroscopic  $M^4$  projections, one has  $1 \rightarrow n_a$  correspondence and at the space-like ends of the space-time surface at light-like boundaries of causal diamond one has  $1 \rightarrow n_b$  correspondence. This implies that at partonic 2-surfaces defined as the intersections of these two kinds of 3-surfaces one has  $1 \rightarrow n_a \times n_b$  correspondence. This correspondence can be described by using a local singular  $n$ -fold covering of the imbedding space. Unlike in the original approach, the covering space is only a convenient auxiliary tool rather than fundamental notion.
4. The fractionalization of charge can be understood as follows. A delocalization of electron charge to the  $n$  sheets of the multi-furcation takes place and single sheet is analogous to a sheet of Riemann surface of function  $z^{1/n}$  and carries fractional charge  $q = e/n$ ,  $n = n_a n_b$ . Fractionalization applies also to other quantum numbers. One can have also many-electron stats of these states with several delocalized electrons: in this case one obtains more general charge fractionalization:  $q = \nu e$ .
5. Also the fractional braid statistics can be understood. For ordinary statistics rotations of  $M^4$  rotate entire partonic 2-surfaces. For braid statistics rotations of  $M^4$  (and particle exchange) induce a flow braid ends along partonic 2-surface. If the singular local covering is analogous to the Riemann surface of  $z^{1/n}$ , the braid rotation by  $\Delta\Phi = 2\pi$ , where  $\Phi$  corresponds to  $M^4$  angle, leads to a second branch of multi-furcation and one can give up the usual quantization condition for angular momentum. For the natural angle coordinate  $\phi$  of the  $n$ -branched covering  $\Delta\phi = 2/\pi$  corresponds to  $\Delta\Phi = n \times 2\pi$ . If one identifies the sheets of multi-furcation and therefore uses  $\Phi$  as angle coordinate, single valued angular momentum eigenstates become in general  $n$ -valued, angular momentum in braid statistics becomes fractional and one obtains fractional braid statistics for angular momentum.
6. How to understand the exceptional values  $\nu = 5/2, 7/2$  of the filling fraction? The non-abelian braid group representations can be interpreted as higher-dimensional projective representations of permutation group: for ordinary statistics only Abelian representations are possible. It seems that the minimum number of braids is  $n > 2$  from the condition of non-abelianity of braid group representations. The condition that ordinary statistics is fermionic, gives  $n > 3$ . The minimum value is  $n = 4$  consistent with the fractional charge  $e/4$ .

The model introduces  $Z_4$  valued topological quantum number characterizing flux tubes. This also makes possible non-Abelian braid statistics. The interpretation of this quantum number as a  $Z_4$  valued momentum characterizing the four delocalized states of the flux tube at the sheets of the 4-furcation suggests itself strongly. Topology would correspond to that of 4-fold covering space serving as a convenient auxiliary tool. The more standard explanation is that  $Z_4 = Z_2 \times Z_2$  such that  $Z_2$ 's correspond to the presence or absence of neutral Majorana fermion in the two Cooper pair like states formed by flux tubes.

What remains to be understood is the emergence of non-abelian gauge group realizing non-Abelian fractional statistics in gauge theory framework. TGD predicts the possibility of dynamical gauge groups and maybe this kind of gauge group indeed emerges. Dynamical gauge groups emerge also for stacks of  $N$  branes and the  $n$  sheets of multifurcation are analogous to the  $N$  sheets in the stack for many-electron states.

### A Possible Explanation of Shnoll Effect

Shnoll and collaborators have discovered strange repeating patterns of random fluctuations of physical observables such as the number  $n$  of nuclear decays in a given time interval. Periodically occurring peaks for the distribution of the number  $N(n)$  of measurements producing  $n$  events in a series of measurements as a function of  $n$  is observed instead of a single peak. The positions of the peaks are not random and the patterns depend on position and time varying periodically in time scales possibly assignable to Earth-Sun and Earth-Moon gravitational interaction.

These observations suggest a modification of the expected probability distributions but it is very difficult to imagine any physical mechanism in the standard physics framework. Rather, a universal deformation of predicted probability distributions would be in question requiring something analogous to the transition from classical physics to quantum physics.

The hint about the nature of the modification comes from the TGD inspired quantum measurement theory proposing a description of the notion of finite measurement resolution in terms of inclusions of so called hyper-finite factors of type II<sub>1</sub> (HFFs) and closely related quantum groups. Also p-adic physics -another key element of TGD- is expected to be involved. A modification of a given probability distribution  $P(n|\lambda_i)$  for a positive integer valued variable  $n$  characterized by rational-valued parameters  $\lambda_i$  is obtained by replacing  $n$  and the integers characterizing  $\lambda_i$  with so called quantum integers depending on the quantum phase  $q_m = \exp(i2\pi/m)$ . Quantum integer  $n_q$  must be defined as the product of quantum counterparts  $p_q$  of the primes  $p$  appearing in the prime decomposition of  $n$ . One has  $p_q = \sin(2\pi p/m)/\sin(2\pi/m)$  for  $p \neq P$  and  $p_q = P$  for  $p = P$ .  $m$  must satisfy  $m \geq 3$ ,  $m \neq p$ , and  $m \neq 2p$ .

The quantum counterparts of positive integers can be negative. Therefore quantum distribution is defined first as p-adic valued distribution and then mapped by so called canonical identification  $I$  to a real distribution by the map taking p-adic  $-1$  to  $P$  and powers  $P^n$  to  $P^{-n}$  and other quantum primes to themselves and requiring that the mean value of  $n$  is for distribution and its quantum variant. The map  $I$  satisfies  $I(\sum P_n) = \sum I(P_n)$ . The resulting distribution has peaks located periodically with periods coming as powers of  $P$ . Also periodicities with peaks corresponding to  $n = n^+ n^-$ ,  $n_q^+ > 0$  with fixed  $n_q^- < 0$ , are predicted. These predictions are universal and easily testable. The prime  $P$  and integer  $m$  characterizing the quantum variant of distribution can be identified from data. The shapes of the distributions obtained are qualitatively consistent with the findings of Shnoll but detailed tests are required to see whether the number theoretic predictions are correct.

The periodic dependence of the distributions would be most naturally assignable to the gravitational interaction of Earth with Sun and Moon and therefore to the periodic variation of Earth-Sun and Earth-Moon distances. The TGD inspired proposal is that the p-adic prime  $P$  and integer  $m$  characterizing the quantum distribution are determined by a process analogous to a state function reduction and their most probably values depend on the deviation of the distance  $R$  through the formulas  $\Delta p/p \simeq k_p \Delta R/R$  and  $\Delta m/m \simeq k_m \Delta R/R$ . The p-adic primes assignable to elementary particles are very large unlike the primes which could characterize the empirical distributions. The hierarchy of Planck constants allows the gravitational Planck constant assignable to the space-time sheets mediating gravitational interactions to have gigantic values and this allows p-adicity with small values of the p-adic prime  $P$ .

Part I

**P-ADIC DESCRIPTION OF  
PARTICLE MASSIVATION**

## Chapter 2

# Overall View About TGD from Particle Physics Perspective

### 2.1 Introduction

Topological Geometroynamics is able to make rather precise and often testable predictions. In this and two other articles I want to describe the recent over all view about the aspects of quantum TGD relevant for particle physics.

During these 32 years TGD has become quite an extensive theory involving also applications to quantum biology and quantum consciousness theory. Therefore it is difficult to decide in which order to proceed. Should one represent first the purely mathematical theory as done in the articles in Prespacetime Journal [?, ?, ?, ?, ?, ?, ?, ?]? Or should one start from the TGD inspired heuristic view about space-time and particle physics and represent the vision about construction of quantum TGD briefly after that? In this and other two chapters I have chosen the latter approach since the emphasis is on the applications on particle physics.

Second problem is to decide about how much material one should cover. If the representation is too brief no-one understands and if it is too detailed no-one bothers to read. I do not know whether the outcome was a success or whether there is any way to success but in any case I have been sweating a lot in trying to decide what would be the optimum dose of details.

In the first chapter I concentrate the heuristic picture about TGD with emphasis on particle physics.

- First I represent briefly the basic ontology: the motivations for TGD and the notion of many-sheeted space-time, the concept of zero energy ontology, the identification of dark matter in terms of hierarchy of Planck constant which now seems to follow as a prediction of quantum TGD, the motivations for p-adic physics and its basic implications, and the identification of space-time surfaces as generalized Feynman diagrams and the basic implications of this identification.
- Symmetries of quantum TGD are discussed. Besides the basic symmetries of the imbedding space geometry allowing to geometrize standard model quantum numbers and classical fields there are many other symmetries. General Coordinate Invariance is especially powerful in TGD framework allowing to realize quantum classical correspondence and implies effective 2-dimensionality realizing strong form of holography. Super-conformal symmetries of super string models generalize to conformal symmetries of 3-D light-like 3-surfaces and one can understand the generalization of Equivalence Principle in terms of coset representations for the two super Virasoro algebras associated with lightlike boundaries of so called causal diamonds defined as intersections of future and past directed lightcones (*CDs*) and with light-like 3-surfaces. Super-conformal symmetries imply generalization of the space-time supersymmetry in TGD framework consistent with the supersymmetries of minimal supersymmetric variant of the standard model. Twistorial approach to gauge theories has gradually become part of quantum TGD and the natural generalization of the Yangian symmetry identified originally as symmetry of  $\mathcal{N} = 4$  SYMs is postulated as basic symmetry of quantum TGD.

- The so called weak form of electric-magnetic duality has turned out to have extremely far reaching consequences and is responsible for the recent progress in the understanding of the physics predicted by TGD. The duality leads to a detailed identification of elementary particles as composite objects of massless particles and predicts new electro-weak physics at LHC. Together with a simple postulate about the properties of preferred extremals of Kähler action the duality allows also to realize quantum TGD as almost topological quantum field theory giving excellent hopes about integrability of quantum TGD.
- There are two basic visions about the construction of quantum TGD. Physics as infinite-dimensional Kähler geometry of world of classical worlds (WCW) endowed with spinor structure and physics as generalized number theory. These visions are briefly summarized as also the practical constructing involving the concept of Dirac operator. As a matter fact, the construction of TGD involves three Dirac operators. The Kähler Dirac equation holds true in the interior of space-time surface and its solutions have a natural interpretation in terms of description of matter, in particular condensed matter. Chern-Simons Dirac action is associated with the light-like 3-surfaces and space-like 3-surfaces at ends of space-time surface at light-like boundaries of  $CD$ . One can assign to it a generalized eigenvalue equation and the matrix valued eigenvalues correspond to the the action of Dirac operator on momentum eigenstates. Momenta are however not usual momenta but pseudo-momenta very much analogous to region momenta of twistor approach. The third Dirac operator is associated with super Virasoro generators and super Virasoro conditions define Dirac equation in WCW. These conditions characterize zero energy states as modes of WCW spinor fields and code for the generalization of  $S$ -matrix to a collection of what I call  $M$ -matrices defining the rows of unitary  $U$ -matrix defining unitary process.
- Twistor approach has inspired several ideas in quantum TGD during the last years and it seems that the Yangian symmetry and the construction of scattering amplitudes in terms of Grassmannian integrals generalizes to TGD framework. This is due to ZEO allowing to assume that all particles have massless fermions as basic building blocks. ZEO inspires the hypothesis that incoming and outgoing particles are bound states of fundamental fermions associated with wormhole throats. Virtual particles would also consist of on mass shell massless particles but without bound state constraint. This implies very powerful constraints on loop diagrams and there are excellent hopes about their finiteness. Twistor approach also inspires the conjecture that quantum TGD allows also formulation in terms of 6-dimensional holomorphic surfaces in the product  $CP_3 \times CP_3$  of two twistor spaces and general arguments allow to identify the partial differential equations satisfied by these surfaces.

The discussion of this chapter is rather sketchy and the reader interesting in details can consult the books about TGD [K80, K60, K48, K45, K61, K70, K76] .

## 2.2 Some aspects of quantum TGD

In the following I summarize very briefly those basic notions of TGD which are especially relevant for the applications to particle physics. The representation will be practically formula free. The article series published in Prespacetime Journal [?, ?, ?, ?, ?, ?, ?, ?] describes the mathematical theory behind TGD. The seven books about TGD [K80, K60, K48, K61, K68] provide a detailed summary about the recent state of TGD.

### 2.2.1 New space-time concept

The physical motivation for TGD was what I have christened the energy problem of General Relativity. The notion of energy is ill-defined because the basic symmetries of empty space-time are lost in the presence of gravity. The way out is based on assumption that space-times are imbeddable as 4-surfaces to certain 8-dimensional space by replacing the points of 4-D empty Minkowski space with 4-D very small internal space. This space -call it  $S$ - is unique from the requirement that the theory has the symmetries of standard model:  $S = CP_2$ , where  $CP_2$  is complex projective space with 4 real dimensions [?] , is the unique choice.

The replacement of the abstract manifold geometry of general relativity with the geometry of surfaces brings the shape of surface as seen from the perspective of 8-D space-time and this means additional degrees of freedom giving excellent hopes of realizing the dream of Einstein about geometrization of fundamental interactions.

The work with the generic solutions of the field equations assignable to almost any general coordinate invariant variational principle led soon to the realization that the space-time in this framework is much more richer than in general relativity.

1. Space-time decomposes into space-time sheets with finite size: this lead to the identification of physical objects that we perceive around us as space-time sheets. For instance, the outer boundary of the table is where that particular space-time sheet ends. Besides sheets also string like objects and elementary particle like objects appear so that TGD can be regarded also as a generalization of string models obtained by replacing strings with 3-D surfaces.
2. Elementary particles are identified as topological inhomogenities glued to these space-time sheets. In this conceptual framework material structures and shapes are not due to some mysterious substance in slightly curved space-time but reduce to space-time topology just as energy-momentum currents reduce to space-time curvature in general relativity.
3. Also the view about classical fields changes. One can assign to each material system a field identity since electromagnetic and other fields decompose to topological field quanta. Examples are magnetic and electric flux tubes and flux sheets and topological light rays representing light propagating along tube like structure without dispersion and dissipation making em ideal tool for communications [K49] . One can speak about field body or magnetic body of the system.

Field body indeed becomes the key notion distinguishing TGD inspired model of quantum biology from competitors but having applications also in particle physics since also leptons and quarks possess field bodies. The is evidence for the Lamb shift anomaly of muonic hydrogen [?] and the color magnetic body of u quark whose size is somethat larger than the Bohr radius could explain the anomaly [K43] .

### 2.2.2 Zero energy ontology

In standard ontology of quantum physics physical states are assumed to have positive energy. In zero energy ontology physical states decompose to pairs of positive and negative energy states such that all net values of the conserved quantum numbers vanish. The interpretation of these states in ordinary ontology would be as transitions between initial and final states, physical events. By quantum classical correspondences zero energy states must have space-time and imbedding space correlates.

1. Positive and negative energy parts reside at future and past light-like boundaries of causal diamond (*CD*) defined as intersection of future and past directed light-cones and visualizable as double cone. The analog of *CD* in cosmology is big bang followed by big crunch. *CDs* for a fractal hierarchy containing *CDs* within *CDs*. Disjoint *CDs* are possible and *CDs* can also intersect.
2. p-Adic length scale hypothesis [?] motivates the hypothesis that the temporal distances between the tips of the intersecting light-cones come as octaves  $T = 2^n T_0$  of a fundamental time scale  $T_0$  defined by  $CP_2$  size  $R$  as  $T_0 = R/c$ . One prediction is that in the case of electron this time scale is .1 seconds defining the fundamental biorhythm. Also in the case  $u$  and  $d$  quarks the time scales correspond to biologically important time scales given by 10 ms for  $u$  quark and by and 2.5 ms for  $d$  quark [K4] . This means a direct coupling between microscopic and macroscopic scales.

Zero energy ontology conforms with the crossing symmetry of quantum field theories meaning that the final states of the quantum scattering event are effectively negative energy states. As long as one can restrict the consideration to either positive or negative energy part of the state ZEO is consistent with positive energy ontology. This is the case when the observer characterized by a particular *CD* studies the physics in the time scale of much larger *CD* containing observer's *CD* as a sub-*CD*. When the time scale sub-*CD* of the studied system is much shorter that the time scale of

sub- $CD$  characterizing the observer, the interpretation of states associated with sub- $CD$  is in terms of quantum fluctuations.

ZEO solves the problem which results in any theory assuming symmetries giving rise to conservation laws. The problem is that the theory itself is not able to characterize the values of conserved quantum numbers of the initial state. In ZEO this problem disappears since in principle any zero energy state is obtained from any other state by a sequence of quantum jumps without breaking of conservation laws. The fact that energy is not conserved in general relativity based cosmologies can be also understood since each  $CD$  is characterized by its own conserved quantities. As a matter fact, one must be speak about average values of conserved quantities since one can have a quantum superposition of zero energy states with the quantum numbers of the positive energy part varying over some range.

For thermodynamical states this is indeed the case and this leads to the idea that quantum theory in ZEO can be regarded as a "complex square root" of thermodynamics obtained as a product of positive diagonal square root of density matrix and unitary  $S$ -matrix.  $M$ -matrix defines time-like entanglement coefficients between positive and negative energy parts of the zero energy state and replaces  $S$ -matrix as the fundamental observable. In standard quantum measurement theory this time-like entanglement would be reduced in quantum measurement and regenerated in the next quantum jump if one accepts Negentropy Maximization Principle (NMP) [K42] as the fundamental variational principle. Various  $M$ -matrices define the rows of the unitary  $U$  matrix characterizing the unitary process part of quantum jump. From the point of view of consciousness theory the importance of ZEO is that conservation laws in principle pose no restrictions for the new realities created in quantum jumps: free will is maximal.

### 2.2.3 The hierarchy of Planck constants

The motivations for the hierarchy of Planck constants come from both astrophysics and biology [K55, K22]. In astrophysics the observation of Nottale [E23] that planetary orbits in solar system seem to correspond to Bohr orbits with a gigantic gravitational Planck constant motivated the proposal that Planck constant might not be constant after all [K65, K50].

This led to the introduction of the quantization of Planck constant as an independent postulate. It has however turned that quantized Planck constant in effective sense could emerge from the basic structure of TGD alone. Canonical momentum densities and time derivatives of the imbedding space coordinates are the field theory analogs of momenta and velocities in classical mechanics. The extreme non-linearity and vacuum degeneracy of Kähler action imply that the correspondence between canonical momentum densities and time derivatives of the imbedding space coordinates is 1-to-many: for vacuum extremals themselves 1-to-infinite.

A convenient technical manner to treat the situation is to replace imbedding space with its  $n$ -fold singular covering. Canonical momentum densities to which conserved quantities are proportional would be same at the sheets corresponding to different values of the time derivatives. At each sheet of the covering Planck constant is effectively  $\hbar = n\hbar_0$ . This splitting to multisheeted structure can be seen as a phase transition reducing the densities of various charges by factor  $1/n$  and making it possible to have perturbative phase at each sheet (gauge coupling strengths are proportional to  $1/\hbar$  and scaled down by  $1/n$ ). The connection with fractional quantum Hall effect [D1] is almost obvious. At the more detailed level one finds that the spectrum of Planck constants would be given by  $\hbar = n_a n_b \hbar_0$  [K25].

This has many profound implications, which are wellcome from the point of view of quantum biology but the implications would be profound also from particle physics perspective and one could say that living matter represents zoomed up version of quantum world at elementary particle length scales.

1. Quantum coherence and quantum superposition become possible in arbitrary long length scales. One can speak about zoomed up variants of elementary particles and zoomed up sizes make it possible to satisfy the overlap condition for quantum length parameters used as a criterion for the presence of macroscopic quantum phases. In the case of quantum gravitation the length scale involved are astrophysical. This would conform with Penrose's intuition that quantum gravity is fundamental for the understanding of consciousness and also with the idea that consciousness cannot be localized to brain.

2. Photons with given frequency can in principle have arbitrarily high energies by  $E = hf$  formula, and this would explain the strange anomalies associated with the interaction of ELF em fields with living matter [J9] . Quite generally the cyclotron frequencies which correspond to energies much below the thermal energy for ordinary value of Planck constant could correspond to energies above thermal threshold.
3. The value of Planck constant is a natural characterizer of the evolutionary level and biological evolution would mean a gradual increase of the largest Planck constant in the hierarchy characterizing given quantum system. Evolutionary leaps would have interpretation as phase transitions increasing the maximal value of Planck constant for evolving species. The space-time correlate would be the increase of both the number and the size of the sheets of the covering associated with the system so that its complexity would increase.
4. The phase transitions changing Planck constant change also the length of the magnetic flux tubes. The natural conjecture is that biomolecules form a kind of Indra's net connected by the flux tubes and  $\hbar$  changing phase transitions are at the core of the quantum bio-dynamics. The contraction of the magnetic flux tube connecting distant biomolecules would force them near to each other making possible for the bio-catalysis to proceed. This mechanism could be central for DNA replication and other basic biological processes. Magnetic Indra's net could be also responsible for the coherence of gel phase and the phase transitions affecting flux tube lengths could induce the contractions and expansions of the intracellular gel phase. The reconnection of flux tubes would allow the restructuring of the signal pathways between biomolecules and other subsystems and would be also involved with ADP-ATP transformation inducing a transfer of negentropic entanglement [K26] . The braiding of the magnetic flux tubes could make possible topological quantum computation like processes and analog of computer memory realized in terms of braiding patterns [K24] .
5. p-Adic length scale hypothesis and hierarchy of Planck constants suggest entire hierarchy of zoomed up copies of standard model physics with range of weak interactions and color forces scaling like  $\hbar$ . This is not conflict with the known physics for the simple reason that we know very little about dark matter (partly because we might be making misleading assumptions about its nature). One implication is that it might be someday to study zoomed up variants particle physics at low energies using dark matter.

Dark matter would make possible the large parity breaking effects manifested as chiral selection of bio-molecules [?] . What is required is that classical  $Z^0$  and  $W$  fields responsible for parity breaking effects are present in cellular length scale. If the value of Planck constant is so large that weak scale is some biological length scale, weak fields are effectively massless below this scale and large parity breaking effects become possible.

For the solutions of field equations which are almost vacuum extremals  $Z^0$  field is non-vanishing and proportional to electromagnetic field. The hypothesis that cell membrane corresponds to a space-time sheet near a vacuum extremal (this corresponds to criticality very natural if the cell membrane is to serve as an ideal sensory receptor) leads to a rather successful model for cell membrane as sensory receptor with lipids representing the pixels of sensory qualia chart. The surprising prediction is that bio-photons [?] and bundles of EEG photons can be identified as different decay products of dark photons with energies of visible photons. Also the peak frequencies of sensitivity for photoreceptors are predicted correctly [K55] .

#### 2.2.4 p-Adic physics and number theoretic universality

p-Adic physics [K45, K72] has become gradually a key piece of TGD inspired biophysics. Basic quantitative predictions relate to p-adic length scale hypothesis and to the notion of number theoretic entropy. Basic ontological ideas are that life resides in the intersection of real and p-adic worlds and that p-adic space-time sheets serve as correlates for cognition and intentionality. Number theoretical universality requires the fusion of real physics and various p-adic physics to single coherent whole. On implication is the generalization of the notion of number obtained by fusing real and p-adic numbers to a larger structure.

### p-Adic number fields

p-Adic number fields  $Q_p$  [?] -one for each prime  $p$ - are analogous to reals in the sense that one can speak about p-adic continuum and that also p-adic numbers are obtained as completions of the field of rational numbers. One can say that rational numbers belong to the intersection of real and p-adic numbers. p-Adic number field  $Q_p$  allows also an infinite number of its algebraic extensions. Also transcendental extensions are possible. For reals the only extension is complex numbers.

p-Adic topology defining the notions of nearness and continuity differs dramatically from the real topology. An integer which is infinite as a real number can be completely well defined and finite as a p-adic number. In particular, powers  $p^n$  of prime  $p$  have p-adic norm (magnitude) equal to  $p^{-n}$  in  $Q_p$  so that at the limit of very large  $n$  real magnitude becomes infinite and p-adic magnitude vanishes.

p-Adic topology is rough since p-adic distance  $d(x, y) = d(x - y)$  depends on the lowest binary digit of  $x - y$  only and is analogous to the distance between real points when approximated by taking into account only the lowest digit in the decimal expansion of  $x - y$ . A possible interpretation is in terms of a finite measurement resolution and resolution of sensory perception. p-Adic topology looks somewhat strange. For instance, p-adic spherical surface is not infinitely thin but has a finite thickness and p-adic surfaces possess no boundary in the topological sense. Ultrametricity is the technical term characterizing the basic properties of p-adic topology and is coded by the inequality  $d(x - y) \leq \text{Min}\{d(x), d(y)\}$ . p-Adic topology brings in mind the decomposition of perceptive field to objects.

### Motivations for p-adic number fields

The physical motivations for p-adic physics came from the observation that p-adic thermodynamics -not for energy but infinitesimal scaling generator of so called super-conformal algebra [?] acting as symmetries of quantum TGD [K60] - predicts elementary particle mass scales and also masses correctly under very general assumptions [K45] . The calculations are discussed in more detail in the second article of the series. In particular, the ratio of proton mass to Planck mass, the basic mystery number of physics, is predicted correctly. The basic assumption is that the preferred primes characterizing the p-adic number fields involved are near powers of two:  $p \simeq 2^k$ ,  $k$  positive integer. Those nearest to power of two correspond to Mersenne primes  $M_n = 2^n - 1$ . One can also consider complex primes known as Gaussian primes, in particular Gaussian Mersennes  $M_{G,n} = (1 + i)^n - 1$ .

It turns out that Mersennes and Gaussian Mersennes are in a preferred position physically in TGD based world order. What is especially interesting that the length scale range 10 nm-2.5  $\mu$  assignable to DNA contains as many as 4 Gaussian Mersennes corresponding to  $n = 151, 157, 163, 167$  [K55] . This number theoretical miracle supports the view that p-adic physics is especially important for the understanding of living matter.

The philosophical for p-adic numbers fields come from the question about the possible physical correlates of cognition and intention [K47] . Cognition forms representations of the external world which have finite cognitive resolution and the decomposition of the perceptive field to objects is an essential element of these representations. Therefore p-adic space-time sheets could be seen as candidates of thought bubbles, the mind stuff of Descartes. One can also consider p-adic space-time sheets as correlates of intentions. The quantum jump in which p-adic space-time sheet is replaced with a real one could serve as a quantum correlate of intentional action. This process is forbidden by conservation laws in standard ontology: one cannot even compare real and p-adic variants of the conserved quantities like energy in the general case. In zero energy ontology the net values of conserved quantities for zero energy states vanish so that conservation laws allow these transitions.

Rational numbers belong to the intersection of real and p-adic continua. An obvious generalization of this statement applies to real manifolds and their p-adic variants. When extensions of p-adic numbers are allowed, also some algebraic numbers can belong to the intersection of p-adic and real worlds. The notion of intersection of real and p-adic worlds has actually two meanings.

1. The intersection could consist of the rational and possibly some algebraic points in the intersection of real and p-adic partonic 2-surfaces at the ends of  $CD$ . This set is in general discrete. The interpretation could be as discrete cognitive representations.
2. The intersection could also have a more abstract meaning. For instance, the surfaces defined by rational functions with rational coefficients have a well-defined meaning in both real and p-adic

context and could be interpreted as belonging to this intersection. There is strong temptation to assume that intentions are transformed to actions only in this intersection. One could say that life resides in the intersection of real and p-adic worlds in this abstract sense.

Additional support for the idea comes from the observation that Shannon entropy  $S = -\sum p_n \log(p_n)$  allows a p-adic generalization if the probabilities are rational numbers by replacing  $\log(p_n)$  with  $-\log(|p_n|_p)$ , where  $|x|_p$  is p-adic norm. Also algebraic numbers in some extension of p-adic numbers can be allowed. The unexpected property of the number theoretic Shannon entropy is that it can be negative and its unique minimum value as a function of the p-adic prime  $p$  it is always negative. Entropy transforms to information!

In the case of number theoretic entanglement entropy there is a natural interpretation for this. Number theoretic entanglement entropy would measure the information carried by the entanglement whereas ordinary entanglement entropy would characterize the uncertainty about the state of either entangled system. For instance, for  $p$  maximally entangled states both ordinary entanglement entropy and number theoretic entanglement negentropy are maximal with respect to  $R_p$  norm. Entanglement carries maximal information. The information would be about the relationship between the systems, a rule. Schrödinger cat would be dead enough to know that it is better to not open the bottle completely.

Negentropy Maximization Principle [K42] coding the basic rules of quantum measurement theory implies that negentropic entanglement can be stable against the effects of quantum jumps unlike entropic entanglement. Therefore living matter could be distinguished from inanimate matter also by negentropic entanglement possible in the intersection of real and p-adic worlds. In consciousness theory negentropic entanglement could be seen as a correlate for the experience of understanding or any other positively colored experience, say love.

Negentropically entangled states are stable but binding energy and effective loss of relative translational degrees of freedom is not responsible for the stability. Therefore bound states are not in question. The distinction between negentropic and bound state entanglement could be compared to the difference between unhappy and happy marriage. The first one is a social jail but in the latter case both parties are free to leave but do not want to. The special characteristics of negentropic entanglement raise the question whether the problematic notion of high energy phosphate bond [?] central for metabolism could be understood in terms of negentropic entanglement. This would also allow an information theoretic interpretation of metabolism since the transfer of metabolic energy would mean a transfer of negentropy [K26] .

## 2.3 Symmetries of quantum TGD

Symmetry principles play key role in the construction of WCW geometry have become and deserve a separate explicit treatment even at the risk of repetitions.

### 2.3.1 General Coordinate Invariance

General coordinate invariance is certainly of the most important guidelines and is much more powerful in TGD framework than in GRT context.

1. General coordinate transformations as a gauge symmetry so that the diffeomorphic slices of space-time surface equivalent physically. 3-D light-like 3-surfaces defined by wormhole throats define preferred slices and allows to fix the gauge partially apart from the remaining 3-D variant of general coordinate invariance and possible gauge degeneracy related to the choice of the light-like 3-surface due to the Kac-Moody invariance. This would mean that the random light-likeness represents gauge degree of freedom except at the ends of the light-like 3-surfaces.
2. GCI can be strengthened so that the pairs of space-like ends of space-like 3-surfaces at  $CD$ s are equivalent with light-like 3-surfaces connecting them. The outcome is effective 2-dimensionality because their intersections at the boundaries of  $CD$ s must carry the physically relevant information.

### 2.3.2 Generalized conformal symmetries

One can assign Kac-Moody type conformal symmetries to light-like 3-surfaces as isometries of  $H$  localized with respect to light-like 3-surfaces. Kac Moody algebra essentially the Lie algebra of gauge group with central extension meaning that projective representation in which representation matrices are defined only modulo a phase factor. Kac-Moody symmetry is not quite a pure gauge symmetry.

One can assign a generalization of Kac-Moody symmetries to the boundaries of  $CD$  by replacing Lie-group of Kac Moody algebra with the group of symplectic (contact-) transformations [?, ?, ?] of  $H_+$  provided with a degenerate Kähler structure made possible by the effective 2-dimensionality of  $\delta M_+^4$ . The light-like radial coordinate of  $\delta M_+^4$  plays the role of the complex coordinate of conformal transformations or their hyper-complex analogs. These symmetries are also localized with respect to the internal coordinates of the partonic 2-surface so that rather huge symmetry group is in question. The basic hypothesis is that these transformations with possible some restrictions on the dependence on the coordinates of  $X^2$  define the isometries of  $WCW$ .

A further physically well-motivated hypothesis inspired by holography and extended GCI is that these symmetries extend so that they apply at the entire space-time sheet. This requires the slicing of space-time surface by partonic 2- surfaces and by stringy world sheets such that each point of stringy world sheet defines a partonic 2-surface and vice versa. This slicing has deep physical motivations since it realizes geometrically standard facts about gauge invariance (partonic 2-surface defines the space of physical polarizations and stringy space-time sheet corresponds to non-physical polarizations) and its existence is a hypothesis about the properties of the preferred extremals of Kähler action. There is a similar decomposition also at the level of  $CD$  and so called Hamilton-Jacobi coordinates for  $M_+^4$  [K9] define this kind of slicings. This slicing can induced the slicing of the space-time sheet. The number theoretic vision gives a further justification for this hypothesis and also strengthens it by postulating the presence of the preferred time direction having interpretation in terms of real unit of octonions. In ZEO this time direction corresponds to the time-like vector connecting the tips of  $CD$ .

Conformal symmetries would provide the realization of  $WCW$  as a union of symmetric spaces. Symmetric spaces are coset spaces of form  $G/H$ . The natural identification of  $G$  and  $H$  is as groups of  $X^2$ -local symplectic transformations and local Kac-Moody group of  $X^2$ -local  $H$  isometries. Quantum fluctuating (metrically non-trivial) degrees of freedom would correspond to symplectic transformations of  $H_+$  and induced Kähler form at  $X^2$  would define a local representation for zero modes: not necessarily all of them.

### 2.3.3 Equivalence Principle and super-conformal symmetries

Equivalence Principle (EP) is a second corner stone of General Relativity and together with GCI leads to Einstein's equations. What EP states is that inertial and gravitational masses are identical. In this form it is not well-defined even in GRT since the definition of gravitational and inertial four-momenta is highly problematic because Noether theorem is not available. The realization is in terms of local equations identifying energy momentum tensor with Einstein tensor.

Whether EP is realized in TGD has been a longstanding open question [K77] . The problem has been that at the classical level EP in its GRT form can hold true only in long enough length scales and it took long to time to realize that only the stringy form of this principle is required. The first question is how to identify the gravitational and inertial four-momenta. This is indeed possible. One can assign to the two types super-conformal symmetries assigned with light-like 3-surfaces and space-like 3-surfaces four-momenta to both. EP states that these four momenta are identical and is equivalent with the generalization of GCI and effective 2-dimensionality. The condition generalizes so that it applies to the generators of super-conformal algebras associated with the two super-conformal symmetries. This leads to a generalization of a standard mathematical construction of super-conformal theories known as coset representation [?] . What the construction states is that the differences of super-conformal generators defined by super-symmetric algebra and Kac-Moody algebra annihilate physical states.

### 2.3.4 Extension to super-conformal symmetries

The original idea behind the extension of conformal symmetries to super-conformal symmetries was the observation that isometry currents defining infinitesimal isometries of  $WCW$  have natural super-

counterparts obtained by contracting the Killing vector fields with the complexified gamma matrices of the imbedding space.

This vision has generalized considerably as the construction of WCW spinor structure in terms of modified Dirac action has developed. The basic philosophy behind this idea is that configuration space spinor structure must relate directly to the fermionic sector of quantum physics. In particular, modified gamma matrices should be expressible in terms of the fermionic oscillator operators associated with the second quantized induced spinor fields. The explicit realization of this program leads to an identification of rich spectrum of super-conformal symmetries and generalization of the ordinary notion of space-time supersymmetry. What happens that all fermionic oscillator operators generate broken super-symmetries whereas in SUSYs there is only finite number of them. One can however identify sub-algebra of super-conformal symmetries associated with right handed neutrino and this gives  $\mathcal{N} = 1$  super-symmetry [?] of SUSYs [?] .

### 2.3.5 Space-time supersymmetry in TGD Universe

It has been clear from the beginning that the notion of super-conformal symmetry crucial for the successes of super-string models generalizes in TGD framework. The answer to the question whether space-time SUSY makes sense in TGD framework has not been obvious at all but it seems now that the answer is affirmative. The evolution of the ideas relevant for the formulation of SUSY in TGD framework is summarized in the chapters of [K61] . The chapters devoted to the notion of bosonic emergence [?] , to the SUSY QFT limit of TGD [?] , to twistor approach to TGD [?] , and to the generalization of Yangian symmetry of  $\mathcal{N} = 4$  SYM manifest in the Grassmannian twistor approach [?] to a multi-local variant of super-conformal symmetries [?] represent a gradual development of the ideas about how super-symmetric  $M$ -matrix could be constructed in TGD framework. A warning to the reader is in order. In their recent form these chapters do not represent the final outcome but just an evolution of ideas proceeding by trial and error. There are however good reasons to believe that the chapter about Yangian symmetry is nearest to the correct physical interpretation and mathematical formulation.

Contrary to the original expectations, TGD seems to allow a generalization of the space-time super-symmetry. This became clear with the increased understanding of the modified Dirac action [K15, ?, ?] . The appearance of the momentum and color quantum numbers in the measurement interaction part of the modified Dirac action associated with the light-like wormhole throats [?] couples space-time degrees of freedom to quantum numbers and allows also to define SUSY algebra at fundamental level as anti-commutation relations of fermionic oscillator operators. Depending on the situation  $\mathcal{N} = 2N$  SUSY algebra (an inherent cutoff on the number of fermionic modes at light-like wormhole throat) or fermionic part of super-conformal algebra with infinite number of oscillator operators results. The addition of fermion in particular mode would define particular super-symmetry. This super-symmetry is badly broken due to the dynamics of the modified Dirac operator which also mixes  $M^4$  chiralities inducing massivation. Since right-handed neutrino has no electro-weak couplings the breaking of the corresponding super-symmetry should be weakest.

Zero energy ontology combined with the analog of the twistor approach to  $\mathcal{N} = 4$  SYMs and weak form of electric-magnetic duality has actually led to this kind of formulation [?] . What is new that also virtual particles have massless fermions as their building blocks. This implies manifest finiteness of loop integrals so that the situation simplifies dramatically. What is also new element that physical particles and also string like objects correspond to bound states of massless fermions.

The question is whether this SUSY has a realization as a SUSY algebra at space-time level and whether the QFT limit of TGD could be formulated as a generalization of SUSY QFT. There are several problems involved.

1. In TGD framework super-symmetry means addition of fermion to the state and since the number of spinor modes is larger states with large spin and fermion numbers are obtained. This picture does not fit to the standard view about super-symmetry. In particular, the identification of theta parameters as Majorana spinors and super-charges as Hermitian operators is not possible.
2. The belief that Majorana spinors are somehow an intrinsic aspect of super-symmetry is however only a belief. Weyl spinors meaning complex theta parameters are also possible. Theta parameters can also carry fermion number meaning only the supercharges carry fermion number and

are non-hermitian. The general classification of super-symmetric theories indeed demonstrates that for  $D = 8$  Weyl spinors and complex and non-hermitian super-charges are possible. The original motivation for Majorana spinors might come from MSSM assuming that right handed neutrino does not exist. This belief might have also led to string theories in  $D = 10$  and  $D = 11$  as the only possible candidates for TOE after it turned out that chiral anomalies cancel. It indeed turns out that TGD view about space-time SUSY is internally consistent. Even more, the separate conservation of quark and lepton number is essential for the internal consistency of this view [?].

3. The massivation of particles is the basic problem of both SUSYs and twistor approach. I have discussed several solutions to this problem [?, ?]. The simplest and most convincing solution of the problem is following and inspired by twistor Grassmannian approach to  $\mathcal{N} = 4$  SYM and the generalization of the Yangian symmetry of this theory. In zero energy ontology one can construct physical particles as bound states of massless particles associated with the opposite wormhole throats. If the particles have opposite 3-momenta the resulting state is automatically massive. In fact, this forces massivation of also spin one bosons since the fermion and antifermion must move in opposite directions for their spins to be parallel so that the net mass is non-vanishing: note that this means that even photon, gluons, and graviton have small mass. This mechanism makes topologically condensed fermions massive and p-adic thermodynamics allows to describe the massivation in terms of zero energy states and  $M$ -matrix. Bosons receive to their mass besides the small mass coming from thermodynamics also a contribution which is counterpart of the contribution coming from Higgs vacuum expectation value and Higgs gives rise to longitudinal polarizations. No Higgs potential is however needed. The cancellation of infrared divergences necessary for exact Yangian symmetry and the observation that even photon receives small mass suggest that scalar Higgs would disappear completely from the spectrum.

### Basic data bits

Let us first summarize the data bits about possible relevance of super-symmetry for TGD before the addition of the 3-D measurement interaction term to the modified Dirac action [K15, ?].

1. Right-handed covariantly constant neutrino spinor  $\nu_R$  defines a super-symmetry in  $CP_2$  degrees of freedom in the sense that Dirac equation is satisfied by covariant constancy and there is no need for the usual ansatz  $\Psi = D\Psi_0$  giving  $D^2\Psi = 0$ . This super-symmetry allows to construct solutions of Dirac equation in  $CP_2$  [A13, A5, A10, A4].
2. In  $M^4 \times CP_2$  this means the existence of massless modes  $\Psi = \not{p}\Psi_0$ , where  $\Psi_0$  is the tensor product of  $M^4$  and  $CP_2$  spinors. For these solutions  $M^4$  chiralities are not mixed unlike for all other modes which are massive and carry color quantum numbers depending on the  $CP_2$  chirality and charge. As matter fact, covariantly constant right-handed neutrino spinor mode is the only color singlet. The mechanism leading to non-colored states for fermions is based on super-conformal representations for which the color is neutralized [K39, ?]. The negative conformal weight of the vacuum also cancels the enormous contribution to mass squared coming from mass in  $CP_2$  degrees of freedom.
3. Right-handed covariantly constant neutrino allows to construct the gamma matrices of the world of classical worlds (WCW) as fermionic counterparts of Hamiltonians of WCW. This gives rise super-symplectic symmetry algebra having interpretation also as a conformal algebra. Also more general super-conformal symmetries exist.
4. Space-time (in the sense of Minkowski space  $M^4$ ) super-symmetry in the conventional sense of the word is impossible in TGD framework since it would require require Majorana spinors. In 8-D space-time with Minkowski signature of metric Majorana spinors are definitely ruled out by the standard argument leading to super string model. Majorana spinors would also break separate conservation of lepton and baryon numbers in TGD framework.

### Could one generalize super-symmetry?

Could one then consider a more general space-time super-symmetry with "space-time" identified as space-time surface rather than Minkowski space?

1. The TGD variant of the super-symmetry could correspond quite concretely to the addition to fermion and boson states right-handed neutrinos. Since right-handed neutrinos do not have electro-weak interactions, the addition might not appreciably affect the mass formula although it could affect the p-adic prime defining the mass scale.
2. The problem is to understand what this addition of the right-handed neutrino means. To begin with, notice that in TGD Universe fermions reside at light-like 3-surfaces at which the signature of induced metric changes. Bosons correspond to pairs of light-like wormhole throats with wormhole contact having Euclidian signature of the induced metric. The long standing problem has been that for bosons with parallel light-like four-momenta with same sign of energy the spins of fermion and antifermion are opposite so that one would obtain only scalar bosons!

I have considered several solutions to the problem but the final solution came from the basic problem of twistor approach to  $\mathcal{N} = 4$  SUSY. This theory is believed to be UV finite but has IR divergences spoiling the Yangian SUSY. These infinities cancel if the physical particles are bound states of pairs of wormhole throats with light-like momenta. Just the requirement that spin is equal to one forces massivation. This is true for all spin 1 particles, also those regarded as massless. Massivation of the photon is not a problem if the mass corresponds to the IR cutoff determined by the largest causal diamond ( $CD$ ) defining the measurement resolution. For electron the size of  $CD$  corresponds to the size scale of Earth. The basic prediction is that Higgs disappears completely from the spectrum so that this mechanism is testable at LHC.

The first proposal to the solution of problem was that either fermion or antifermion in the boson state carries what might be called un-physical polarization in the standard conceptual framework. This means that it has negative energy but three-momentum parallel to that of the second wormhole throat. The assumption that the bosonic wormhole throats correspond to positive and negative energy space-time sheets realizes this constraint in the framework of zero energy ontology. It however turned out that for light-like momenta these states have more natural interpretation in terms of virtual bosons able to have space-like momenta. This means that one can realize virtual particles as pairs of on mass shell wormhole throats with either sign of energy and 3-momentum so that the basic condition of twistorial approach is satisfied. The conservation of 4-momentum at vertices gives extremely powerful kinematical constraints so that there are excellent hopes about cancellation of UV divergences of loop integrals.

3. The super-symmetry as an addition to the fermion state a second wormhole throats carrying right handed neutrino quantum numbers does not make sense since the resulting state cannot be distinguished from gauge boson or Higgs type particle. The light-like 3-surfaces can however carry fermion numbers up to the number of modes of the induced spinor field, which is expected to be infinite inside string like objects having wormhole throats at ends and finite when one has space time sheets containing the throats [?]. In very general sense one could say that each mode defines a very large broken  $N$ -super-symmetry with the value of  $N$  depending on state and light-like 3-surface. The breaking of this super-symmetry would come from electro-weak -, color -, and gravitational interactions. Right-handed neutrino would by its electro-weak and color inertness define a minimally broken super-symmetry.
4. What this addition of the right handed neutrinos or more general fermion modes could precisely mean? One cannot assign fermionic oscillator operators to right handed neutrinos which are covariantly constant in both  $M^4$  and  $CP_2$  degrees of freedom since the modes with vanishing energy (frequency) cannot correspond to fermionic oscillator operator creating a physical state since one would have  $a = a^\dagger$ . The intuitive view is that all the spinor modes move in an exactly collinear manner -somewhat like quarks inside hadron do approximately.

### Modified Dirac equation briefly

The answer to the question what "collinear motion" means mathematically emerged from the recent progress in the understanding of the modified Dirac equation.

1. The modified Dirac action involves two terms. Besides the original 4-D modified Dirac action there is measurement interaction which can be localized to wormhole throat or to any light-like 3-surfaces "parallel" to it in the slicing of space-time sheet by light-like 3-surfaces. This term

correlates space-time geometry with quantum numbers assignable to super-conformal representations and is also necessary to obtain almost-stringy propagator.

2. The modified Dirac equation with measurement action added reads as

$$\begin{aligned} D_K \Psi &= 0 , \\ D_3 \Psi &= (D_{C-S} + Q \times O) \Psi = 0 , \\ [D_3, D_K] \Psi &= 0 . \end{aligned} \tag{2.3.1}$$

- (a)  $D_K$  corresponds formally to 4-D massless Dirac equation in  $X^4$ .  $D_3$  realizes measurement interaction.  $D_{C-S}$  is the 3-D modified Dirac action defined by Chern-Simons action.
- (b)  $Q$  is linear in Cartan algebra generators of the isometry algebra of imbedding space (color isospin and hypercharge plus four-momentum or two components of four momentum and spin and boost in direction of 3-momentum).  $Q$  is expressible as

$$Q = Q_A \partial_\alpha h^k g^{AB} j_{Bk} \hat{\Gamma}_{CS}^\alpha . \tag{2.3.2}$$

Here  $Q_A$  is Cartan algebra generator acting on physical states. Physical states must be eigen states of  $Q_A$  since otherwise the equations do not make sense.  $g^{AB}$  is the inverse of the matrix defined by the imbedding space inner product of Killing vector fields  $j_A^k$  and  $j_B^l$ : its existence allows only Cartan algebra charges.  $\hat{\Gamma}_{CS}^\alpha$  is the modified gamma matrix associated with the Chern-Simons action.

- (c) In general case the modified gamma matrices are defined in terms of action density  $L$  as

$$\hat{\Gamma}^\alpha = \frac{\partial L}{\partial_\alpha h^k} \gamma^k . \tag{2.3.3}$$

$\gamma^k$  denotes imbedding space gamma matrices.

- (d) The operator  $O$  characterizes the conserved fermionic current to which Cartan algebra generators of isometries couple. The simplest conserved currents correspond to quark or lepton currents and corresponding vectorial isospin- and spin currents [?] . Besides this there is an infinite hierarchy of conserved currents relating to quantum criticality and in one-one correspondence with vanishing second variations of Kähler action for preferred extremal. These couplings allow to represent measurement interaction for any observable.
3. The equation  $D_3 \nu_R = 0$  would reduce for vanishing color charges and covariantly constant spinor to the analog of algebraic fermionic on mass shell condition  $p_A \gamma^A \nu_R = 0$  since  $Q$  is obtained by projecting the total four-momentum of the parton state interpreted as a vector-field of  $H$  to the space-time surface and by replacing ordinary gamma matrices with the modified ones. This equation cannot be exact since  $Q$  depends on the point of the light-like 3-surface so that covariant constancy fails and  $D_{C-S}$  cannot annihilate the state. This is the space-time correlate for the breaking of super-symmetry. The action of the Cartan algebra generators is purely algebraic and on the state of super-conformal representations rather than that of a differential operator on spinor field. The modified equation implies that all spinor modes represent fermions moving collinearly in the sense an equation with the same total four-momentum and total color quantum numbers is satisfied by all of them. Note that  $p_A$  represents the total four-momentum of the state rather than individual four-momenta of fermions.

### TGD counterpart of space-time super-symmetry

This picture allows to define more precisely what one means with the approximate super-symmetries in TGD framework.

1. One can in principle construct many-fermion states containing both fermions and anti-fermions at given light-like 3-surface. The four-momenta of states related by super-symmetry need not be same. Super-symmetry breaking is present and has as the space-time correlate the deviation of the modified gamma matrices from the ordinary  $M^4$  gamma matrices. In particular, the fact that  $\hat{\Gamma}^\alpha$  possesses  $CP_2$  part in general means that different  $M^4$  chiralities are mixed: a space-time correlate for the massivation of the elementary particles.
2. For right-handed neutrino super-symmetry breaking is expected to be smallest but also in the case of the right-handed neutrino mode mixing of  $M^4$  chiralities takes place and breaks the TGD counterpart of super-symmetry.
3. The fact that all helicities in the state are physical for a given light-like 3-surface has important implications. For instance, the addition of a right-handed antineutrino to right-handed (left-handed) electron state gives scalar (spin 1) state. Also states with fermion number two are obtained from fermions. For instance, for  $e_R$  one obtains the states  $\{e_R, e_R\nu_R\bar{\nu}_R, e_R\bar{\nu}_R, e_R\nu_R\}$  with lepton numbers  $(1, 1, 0, 2)$  and spins  $(1/2, 1/2, 0, 1)$ . For  $e_L$  one obtains the states  $\{e_L, e_L\nu_R\bar{\nu}_R, e_L\bar{\nu}_R, e_L\nu_R\}$  with lepton numbers  $(1, 1, 0, 2)$  and spins  $(1/2, 1/2, 1, 0)$ . In the case of gauge boson and Higgs type particles -allowed by TGD but not required by p-adic mass calculations- gauge boson has 15 super partners with fermion numbers  $[2, 1, 0, -1, -2]$ .

The cautious conclusion is that the recent view about quantum TGD allows the analog of super-symmetry which is necessary broken and for which the multiplets are much more general than for the ordinary super-symmetry. Right-handed neutrinos might however define something resembling ordinary super-symmetry to a high extent. The question is how strong prediction one can deduce using quantum TGD and proposed super-symmetry.

1. For a minimal breaking of super-symmetry only the p-adic length scale characterizing the super-partner differs from that for partner but the mass of the state is same. This would allow only a discrete set of masses for various super-partners coming as half octaves of the mass of the particle in question. A highly predictive model results.
2. The quantum field theoretic description should be based on QFT limit of TGD formulated in terms of bosonic emergence [?] . This formulation should allow to calculate the propagators of the super-partners in terms of fermionic loops.
3. This TGD variant of space-time super-symmetry resembles ordinary super-symmetry in the sense that selection rules due to the right-handed neutrino number conservation and analogous to the conservation of R-parity hold true. The states inside super-multiplets have identical electro-weak and color quantum numbers but their p-adic mass scales can be different. It should be possible to estimate reaction rates using rules very similar to those of super-symmetric gauge theories.
4. It might be even possible to find some simple generalization of standard super-symmetric gauge theory to get rough estimates for the reaction rates. There are however problems. The fact that spins  $J = 0, 1, 2, 3/2, 2$  are possible for super-partners of gauge bosons forces to ask whether these additional states define an analog of non-stringy strong gravitation. Note that graviton in TGD framework corresponds to a pair of wormhole throats connected by flux tube (counterpart of string) and for gravitons one obtains  $2^8$ -fold degeneracy.

### 2.3.6 Twistorial approach, Yangian symmetry, and generalized Feynman diagrams

There has been impressive steps in the understanding of  $\mathcal{N} = 4$  maximally supersymmetric YM theory possessing 4-D super-conformal symmetry. This theory is related by AdS/CFT duality to certain string theory in  $AdS_5 \times S^5$  background. Second stringy representation was discovered by Witten and is based on 6-D Calabi-Yau manifold defined by twistors. The unifying proposal is that so called Yangian symmetry is behind the mathematical miracles involved.

The notion of Yangian symmetry would have a generalization in TGD framework obtained by replacing conformal algebra with appropriate super-conformal algebras. Also a possible realization

of twistor approach and the construction of scattering amplitudes in terms of Yangian invariants defined by Grassmannian integrals is considered in TGD framework and based on the idea that in zero energy ontology one can represent massive states as bound states of massless particles. There is also a proposal for a physical interpretation of the Cartan algebra of Yangian algebra allowing to understand at the fundamental level how the mass spectrum of n-particle bound states could be understood in terms of the n-local charges of the Yangian algebra.

Twistors were originally introduced by Penrose to characterize the solutions of Maxwell's equations. Kähler action is Maxwell action for the induced Kähler form of  $CP_2$ . The preferred extremals allow a very concrete interpretation in terms of modes of massless non-linear field. Both conformally compactified Minkowski space identifiable as so called causal diamond and  $CP_2$  allow a description in terms of twistors. These observations inspire the proposal that a generalization of Witten's twistor string theory relying on the identification of twistor string world sheets with certain holomorphic surfaces assigned with Feynman diagrams could allow a formulation of quantum TGD in terms of 3-dimensional holomorphic surfaces of  $CP_3 \times CP_3$  mapped to 6-surfaces dual  $CP_3 \times CP_3$ , which are sphere bundles so that they are projected in a natural manner to 4-D space-time surfaces. Very general physical and mathematical arguments lead to a highly unique proposal for the holomorphic differential equations defining the complex 3-surfaces conjectured to correspond to the preferred extremals of Kähler action.

## Background

I am outsider as far as concrete calculations in  $\mathcal{N} = 4$  SUSY are considered and the following discussion of the background probably makes this obvious. My hope is that the reader had patience to not care about this and try to see the big pattern.

The developments began from the observation of Parke and Taylor [?] that n-gluon tree amplitudes with less than two negative helicities vanish and those with two negative helicities have unexpectedly simple form when expressed in terms of spinor variables used to represent light-like momentum. In fact, in the formalism based on Grassmannian integrals the reduced tree amplitude for two negative helicities is just "1" and defines Yangian invariant. The article *Perturbative Gauge Theory As a String Theory In Twistor Space* [?] by Witten led to so called Britto-Cachazo-Feng-Witten (BCFW) recursion relations for tree level amplitudes [?, ?, ?] allowing to construct tree amplitudes using the analogs of Feynman rules in which vertices correspond to maximally helicity violating tree amplitudes (2 negative helicity gluons) and propagator is massless Feynman propagator for boson. The progress inspired the idea that the theory might be completely integrable meaning the existence of infinite-dimensional un-usual symmetry. This symmetry would be so called Yangian symmetry [?] assigned to the super counterpart of the conformal group of 4-D Minkowski space.

Drumond, Henn, and Plefka represent in the article *Yangian symmetry of scattering amplitudes in  $\mathcal{N} = 4$  super Yang-Mills theory* [?] an argument suggesting that the Yangian invariance of the scattering amplitudes is an intrinsic property of planar  $\mathcal{N} = 4$  super Yang Mills at least at tree level.

The latest step in the progress was taken by Arkani-Hamed, Bourjaily, Cachazo, Carot-Huot, and Trnka and represented in the article *Yangian symmetry of scattering amplitudes in  $\mathcal{N} = 4$  super Yang-Mills theory* [?]. At the same day there was also the article of Rutger Boels entitled *On BCFW shifts of integrands and integrals* [?] in the archive. Arkani-Hamed *et al* argue that a full Yangian symmetry of the theory allows to generalize the BCFW recursion relation for tree amplitudes to all loop orders at planar limit (planar means that Feynman diagram allows imbedding to plane without intersecting lines). On mass shell scattering amplitudes are in question.

## Yangian symmetry

The notion equivalent to that of Yangian was originally introduced by Faddeev and his group in the study of integrable systems. Yangians are Hopf algebras which can be assigned with Lie algebras as the deformations of their universal enveloping algebras. The elegant but rather cryptic looking definition is in terms of the modification of the relations for generating elements [?]. Besides ordinary product in the enveloping algebra there is co-product  $\Delta$  which maps the elements of the enveloping algebra to its tensor product with itself. One can visualize product and co-product in terms of particle reactions. Particle annihilation is analogous to annihilation of two particle so single one and

co-product is analogous to the decay of particle to two.  $\Delta$  allows to construct higher generators of the algebra.

Lie-algebra can mean here ordinary finite-dimensional simple Lie algebra, Kac-Moody algebra or Virasoro algebra. In the case of SUSY it means conformal algebra of  $M^4$ - or rather its super counterpart. Witten, Nappi and Dolan have described the notion of Yangian for super-conformal algebra in very elegant and concrete manner in the article *Yangian Symmetry in D=4 superconformal Yang-Mills theory* [?]. Also Yangians for gauge groups are discussed.

In the general case Yangian resembles Kac-Moody algebra with discrete index  $n$  replaced with a continuous one. Discrete index poses conditions on the Lie group and its representation (adjoint representation in the case of  $\mathcal{N} = 4$  SUSY). One of the conditions is that the tensor product  $R \otimes R^*$  for representations involved contains adjoint representation only once. This condition is non-trivial. For  $SU(n)$  these conditions are satisfied for any representation. In the case of  $SU(2)$  the basic branching rule for the tensor product of representations implies that the condition is satisfied for the product of any representations.

Yangian algebra with a discrete basis is in many respects analogous to Kac-Moody algebra. Now however the generators are labelled by non-negative integers labeling the light-like incoming and outgoing momenta of scattering amplitude whereas in the case of Kac-Moody algebra also negative values are allowed. Note that only the generators with non-negative conformal weight appear in the construction of states of Kac-Moody and Virasoro representations so that the extension to Yangian makes sense.

The generating elements are labelled by the generators of ordinary conformal transformations acting in  $M^4$  and their duals acting in momentum space. These two sets of elements can be labelled by conformal weights  $n = 0$  and  $n = 1$  and their mutual commutation relations are same as for Kac-Moody algebra. The commutators of  $n = 1$  generators with themselves are however something different for a non-vanishing deformation parameter  $h$ . Serre's relations characterize the difference and involve the deformation parameter  $h$ . Under repeated commutations the generating elements generate infinite-dimensional symmetric algebra, the Yangian. For  $h = 0$  one obtains just one half of the Virasoro algebra or Kac-Moody algebra. The generators with  $n > 0$  are  $n + 1$ -local in the sense that they involve  $n + 1$ -forms of local generators assignable to the ordered set of incoming particles of the scattering amplitude. This non-locality generalizes the notion of local symmetry and is claimed to be powerful enough to fix the scattering amplitudes completely.

### How to generalize Yangian symmetry in TGD framework?

As far as concrete calculations are considered, I have nothing to say. I am just perplexed. It is however possible to keep discussion at general level and still say something interesting (as I hope!). The key question is whether it could be possible to generalize the proposed Yangian symmetry and geometric picture behind it to TGD framework.

1. The first thing to notice is that the Yangian symmetry of  $\mathcal{N} = 4$  SUSY in question is quite too limited since it allows only single representation of the gauge group and requires massless particles. One must allow all representations and massive particles so that the representation of symmetry algebra must involve states with different masses, in principle arbitrary spin and arbitrary internal quantum numbers. The candidates are obvious: Kac-Moody algebras [?] and Virasoro algebras [?] and their super counterparts. Yangians indeed exist for arbitrary super Lie algebras. In TGD framework conformal algebra of Minkowski space reduces to Poincare algebra and its extension to Kac-Moody allows to have also massive states.
2. The formal generalization looks surprisingly straightforward at the formal level. In zero energy ontology one replaces point like particles with partonic two-surfaces appearing at the ends of light-like orbits of wormhole throats located to the future and past light-like boundaries of causal diamond ( $CD \times CP_2$  or briefly  $CD$ ). Here  $CD$  is defined as the intersection of future and past directed light-cones. The polygon with light-like momenta is naturally replaced with a polygon with more general momenta in zero energy ontology and having partonic surfaces as its vertices. Non-point-likeness forces to replace the finite-dimensional super Lie-algebra with infinite-dimensional Kac-Moody algebras and corresponding super-Virasoro algebras assignable to partonic 2-surfaces.

3. This description replaces disjoint holomorphic surfaces in twistor space with partonic 2-surfaces at the boundaries of  $CD \times CP_2$  so that there seems to be a close analogy with Cachazo-Svrcek-Witten picture. These surfaces are connected by either light-like orbits of partonic 2-surface or space-like 3-surfaces at the ends of  $CD$  so that one indeed obtains the analog of polygon.

What does this then mean concretely (if this word can be used in this kind of context;-)?

1. At least it means that ordinary Super Kac-Moody and Super Virasoro algebras associated with isometries of  $M^4 \times CP_2$  annihilating the scattering amplitudes must be extended to a co-algebras with a non-trivial deformation parameter. Kac-Moody group is thus the product of Poincare and color groups. This algebra acts as deformations of the light-like 3-surfaces representing the light-like orbits of particles which are extremals of Chern-Simon action with the constraint that weak form of electric-magnetic duality holds true. I know so little about the mathematical side that I cannot tell whether the condition that the product of the representations of Super-Kac-Moody and Super-Virasoro algebras contains adjoint representation only once, holds true in this case. In any case, it would allow all representations of finite-dimensional Lie group in vertices whereas  $\mathcal{N} = 4$  SUSY would allow only the adjoint.
2. Besides this ordinary kind of Kac-Moody algebra there is the analog of Super-Kac-Moody algebra associated with the light-cone boundary which is metrically 3-dimensional. The finite-dimensional Lie group is in this case replaced with infinite-dimensional group of symplectomorphisms of  $\delta M^4_{+/-}$  made local with respect to the internal coordinates of partonic 2-surface. A coset construction is applied to these two Virasoro algebras so that the differences of the corresponding Super-Virasoro generators and Kac-Moody generators annihilate physical states. This implies that the corresponding four-momenta are same: this expresses the equivalence of gravitational and inertial masses. A generalization of the Equivalence Principle is in question. This picture also justifies p-adic thermodynamics applied to either symplectic or isometry Super-Virasoro and giving thermal contribution to the vacuum conformal and thus to mass squared.
3. The construction of TGD leads also to other super-conformal algebras and the natural guess is that the Yangians of all these algebras annihilate the scattering amplitudes.
4. Obviously, already the starting point symmetries look formidable but they still act on single partonic surface only. The discrete Yangian associated with this algebra associated with the closed polygon defined by the incoming momenta and the negatives of the outgoing momenta acts in multi-local manner on scattering amplitudes. It might make sense to speak about polygons defined also by other conserved quantum numbers so that one would have generalized light-like curves in the sense that state are massless in 8-D sense.

### Is there any hope about description in terms of Grassmannians?

At technical level the successes of the twistor approach rely on the observation that the amplitudes can be expressed in terms of very simple integrals over sub-manifolds of the space consisting of  $k$ -dimensional planes of  $n$ -dimensional space defined by delta function appearing in the integrand. These integrals define super-conformal Yangian invariants appearing in twistorial amplitudes and the belief is that by a proper choice of the surfaces of the twistor space one can construct all invariants. One can construct also the counterparts of loop corrections by starting from tree diagrams and annihilating pair of particles by connecting the lines and quantum entangling the states at the ends in the manner dictated by the integration over loop momentum. These operations can be defined as operations for Grassmannian integrals in general changing the values of  $n$  and  $k$ . This description looks extremely powerful and elegant and most importantly involves only the external momenta.

The obvious question is whether one could use similar invariants in TGD framework to construct the momentum dependence of amplitudes.

1. The first thing to notice is that the super algebras in question act on infinite-dimensional representations and basically in the world of classical worlds assigned to the partonic 2-surfaces correlated by the fact that they are associated with the same space-time surface. This does not promise anything very practical. On the other hand, one can hope that everything related to other than  $M^4$  degrees of freedom could be treated like color degrees of freedom in  $\mathcal{N} = 4$  SYM

and would boil down to indices labeling the quantum states. The Yangian conditions coming from isometry quantum numbers, color quantum numbers, and electroweak quantum numbers are of course expected to be highly non-trivial and could fix the coefficients of various singlets resulting in the tensor product of incoming and outgoing states.

2. The fact that incoming particles can be also massive seems to exclude the use of the twistor space. The following observation however raises hopes. The Dirac propagator for wormhole throat is massless propagator but for what I call pseudo momentum. It is still unclear how this momentum relates to the actual four-momentum. Could it be actually equal to it? The recent view about pseudo-momentum does not support this view but it is better to keep mind open. In any case this finding suggests that twistorial approach could work in in more or less standard form. What would be needed is a representation for massive incoming particles as bound states of massless partons. In particular, the massive states of super-conformal representations should allow this kind of description.

Could zero energy ontology allow to achieve this dream?

1. As far as divergence cancellation is considered, zero energy ontology suggests a totally new approach producing the basic nice aspects of QFT approach, in particular unitarity and coupling constant evolution. The big idea related to zero energy ontology is that all virtual particle particles correspond to wormhole throats, which are pairs of on mass shell particles. If their momentum directions are different, one obtains time-like continuum of virtual momenta and if the signs of energy are opposite one obtains also space-like virtual momenta. The on mass shell property for virtual partons (massive in general) implies extremely strong constraints on loops and one expect that only very few loops remain and that they are finite since loop integration reduces to integration over much lower-dimensional space than in the QFT approach. There are also excellent hopes about Cutkoski rules.
2. Could zero energy ontology make also possible to construct massive incoming particles from massless ones? Could one construct the representations of the super conformal algebras using only massless states so that at the fundamental level incoming particles would be massless and one could apply twistor formalism and build the momentum dependence of amplitudes using Grassmannian integrals.

One could indeed construct on mass shell massive states from massless states with momenta along the same line but with three-momenta at opposite directions. Mass squared is given by  $M^2 = 4E^2$  in the coordinate frame, where the momenta are opposite and of same magnitude. One could also argue that partonic 2-surfaces carrying quantum numbers of fermions and their superpartners serve as the analogs of point like massless particles and that topologically condensed fermions and gauge bosons plus their superpartners correspond to pairs of wormhole throats. Stringy objects would correspond to pairs of wormhole throats at the same space-time sheet in accordance with the fact that space-time sheet allows a slicing by string worlds sheets with ends at different wormhole throats and defining time like braiding.

The weak form of electric magnetic duality indeed supports this picture. To understand how, one must explain a little bit what the weak form of electric magnetic duality means.

1. Elementary particles correspond to light-like orbits of partonic 2-surfaces identified as 3-D surfaces at which the signature of the induced metric of space-time surface changes from Euclidian to Minkowskian and 4-D metric is therefore degenerate. The analogy with black hole horizon is obvious but only partial. Weak form of electric-magnetic duality states that the Kähler electric field at the wormhole throat and also at space-like 3-surfaces defining the ends of the space-time surface at the upper and lower light-like boundaries of the causal diamond is proportional to Kähler magnetic field so that Kähler electric flux is proportional Kähler magnetic flux. This implies classical quantization of Kähler electric charge and fixes the value of the proportionality constant.
2. There are also much more profound implications. The vision about TGD as almost topological QFT suggests that Kähler function defining the Kähler geometry of the "world of classical

worlds" (WCW) and identified as Kähler action for its preferred extremal reduces to the 3-D Chern-Simons action evaluated at wormhole throats and possible boundary components. Chern-Simons action would be subject to constraints. Wormhole throats and space-like 3-surfaces would represent extremals of Chern-Simons action restricted by the constraint force stating electric-magnetic duality (and realized in terms of Lagrange multipliers as usual).

If one assumes that Kähler current and other conserved currents are proportional to current defining Beltrami flow whose flow lines by definition define coordinate curves of a globally defined coordinate, the Coulombic term of Kähler action vanishes and it reduces to Chern-Simons action if the weak form of electric-magnetic duality holds true. One obtains almost topological QFT. The absolutely essential attribute "almost" comes from the fact that Chern-Simons action is subject to constraints. As a consequence, one obtains non-vanishing four-momenta and WCW geometry is non-trivial in  $M^4$  degrees of freedom. Otherwise one would have only topological QFT not terribly interesting physically.

Consider now the question how one could understand stringy objects as bound states of massless particles.

1. The observed elementary particles are not Kähler monopoles and there much exist a mechanism neutralizing the monopole charge. The only possibility seems to be that there is opposite Kähler magnetic charge at second wormhole throat. The assumption is that in the case of color neutral particles this throat is at a distance of order intermediate gauge boson Compton length. This throat would carry weak isospin neutralizing that of the fermion and only electromagnetic charge would be visible at longer length scales. One could speak of electro-weak confinement. Also color confinement could be realized in analogous manner by requiring the cancellation of monopole charge for many-parton states only. What comes out are string like objects defined by Kähler magnetic fluxes and having magnetic monopoles at ends. Also more general objects with three strings branching from the vertex appear in the case of baryons. The natural guess is that the partons at the ends of strings and more general objects are massless for incoming particles but that the 3-momenta are in opposite directions so that stringy mass spectrum and representations of relevant super-conformal algebras are obtained. This description brings in mind the description of hadrons in terms of partons moving in parallel apart from transversal momentum about which only momentum squared is taken as observable.
2. Quite generally, one expects for the preferred extremals of Kähler action the slicing of space-time surface with string world sheets with stringy curves connecting wormhole throats. The ends of the stringy curves can be identified as light-like braid strands. Note that the strings themselves define a space-like braiding and the two braidings are in some sense dual. This has a concrete application in TGD inspired quantum biology, where time-like braiding defines topological quantum computer programs and the space-like braidings induced by it its storage into memory. Stringlike objects defining representations of super-conformal algebras must correspond to states involving at least two wormhole throats. Magnetic flux tubes connecting the ends of magnetically charged throats provide a particular realization of stringy on mass shell states. This would give rise to massless propagation at the parton level. The stringy quantization condition for mass squared would read as  $4E^2 = n$  in suitable units for the representations of super-conformal algebra associated with the isometries. For pairs of throats of the same wormhole contact stringy spectrum does not seem plausible since the wormhole contact is in the direction of  $CP_2$ . One can however expect generation of small mass as deviation of vacuum conformal weight from half integer in the case of gauge bosons.

If this picture is correct, one might be able to determine the momentum dependence of the scattering amplitudes by replacing free fermions with pairs of monopoles at the ends of string and topologically condensed fermions gauge bosons with pairs of this kind of objects with wormhole throat replaced by a pair of wormhole throats. This would mean suitable number of doublings of the Grassmannian integrations with additional constraints on the incoming momenta posed by the mass shell conditions for massive states.

### Could zero energy ontology make possible full Yangian symmetry?

The partons in the loops are on mass shell particles have a discrete mass spectrum but both signs of energy are possible for opposite wormhole throats. This implies that in the rules for constructing loop amplitudes from tree amplitudes, propagator entanglement is restricted to that corresponding to pairs of partonic on mass shell states with both signs of energy. As emphasized in [?], it is the Grassmannian integrands and leading order singularities of  $\mathcal{N} = 4$  SYM, which possess the full Yangian symmetry. The full integral over the loop momenta breaks the Yangian symmetry and brings in IR singularities. Zero energy ontologist finds it natural to ask whether QFT approach shows its inadequacy both via the UV divergences and via the loss of full Yangian symmetry. The restriction of virtual partons to discrete mass shells with positive or negative sign of energy imposes extremely powerful restrictions on loop integrals and resembles the restriction to leading order singularities. Could this restriction guarantee full Yangian symmetry and remove also IR singularities?

### Could Yangian symmetry provide a new view about conserved quantum numbers?

The Yangian algebra has some properties which suggest a new kind of description for bound states. The Cartan algebra generators of  $n = 0$  and  $n = 1$  levels of Yangian algebra commute. Since the co-product  $\Delta$  maps  $n = 0$  generators to  $n = 1$  generators and these in turn to generators with high value of  $n$ , it seems that they commute also with  $n \geq 1$  generators. This applies to four-momentum, color isospin and color hyper charge, and also to the Virasoro generator  $L_0$  acting on Kac-Moody algebra of isometries and defining mass squared operator.

Could one identify total four momentum and Cartan algebra quantum numbers as sum of contributions from various levels? If so, the four momentum and mass squared would involve besides the local term assignable to wormhole throats also  $n$ -local contributions. The interpretation in terms of  $n$ -parton bound states would be extremely attractive.  $n$ -local contribution would involve interaction energy. For instance, string like object would correspond to  $n = 1$  level and give  $n = 2$ -local contribution to the momentum. For baryonic valence quarks one would have 3-local contribution corresponding to  $n = 2$  level. The Yangian view about quantum numbers could give a rigorous formulation for the idea that massive particles are bound states of massless particles.

## 2.4 Weak form electric-magnetic duality and color and weak forces

The notion of electric-magnetic duality [?] was proposed first by Olive and Montonen and is central in  $\mathcal{N} = 4$  supersymmetric gauge theories. It states that magnetic monopoles and ordinary particles are two different phases of theory and that the description in terms of monopoles can be applied at the limit when the running gauge coupling constant becomes very large and perturbation theory fails to converge. The notion of electric-magnetic self-duality is more natural since for  $CP_2$  geometry Kähler form is self-dual and Kähler magnetic monopoles are also Kähler electric monopoles and Kähler coupling strength is by quantum criticality renormalization group invariant rather than running coupling constant. The notion of electric-magnetic (self-)duality emerged already two decades ago in the attempts to formulate the Kähler geometric of world of classical worlds. Quite recently a considerable step of progress took place in the understanding of this notion [?]. What seems to be essential is that one adopts a weaker form of the self-duality applying at partonic 2-surfaces. What this means will be discussed in the sequel.

Every new idea must be of course taken with a grain of salt but the good sign is that this concept leads to precise predictions. The point is that elementary particles do not generate monopole fields in macroscopic length scales: at least when one considers visible matter. The first question is whether elementary particles could have vanishing magnetic charges: this turns out to be impossible. The next question is how the screening of the magnetic charges could take place and leads to an identification of the physical particles as string like objects identified as pairs magnetic charged wormhole throats connected by magnetic flux tubes.

1. The first implication is a new view about electro-weak massivation reducing it to weak confinement in TGD framework. The second end of the string contains particle having electroweak isospin neutralizing that of elementary fermion and the size scale of the string is electro-weak

scale would be in question. Hence the screening of electro-weak force takes place via weak confinement realized in terms of magnetic confinement.

2. This picture generalizes to the case of color confinement. Also quarks correspond to pairs of magnetic monopoles but the charges need not vanish now. Rather, valence quarks would be connected by flux tubes of length of order hadron size such that magnetic charges sum up to zero. For instance, for baryonic valence quarks these charges could be  $(2, -1, -1)$  and could be proportional to color hyper charge.
3. The highly non-trivial prediction making more precise the earlier stringy vision is that elementary particles are string like objects in electro-weak scale: this should become manifest at LHC energies.
4. The weak form electric-magnetic duality together with Beltrami flow property of Kähler leads to the reduction of Kähler action to Chern-Simons action so that TGD reduces to almost topological QFT and that Kähler function is explicitly calculable. This has enormous impact concerning practical calculability of the theory.
5. One ends up also to a general solution ansatz for field equations from the condition that the theory reduces to almost topological QFT. The solution ansatz is inspired by the idea that all isometry currents are proportional to Kähler current which is integrable in the sense that the flow parameter associated with its flow lines defines a global coordinate. The proposed solution ansatz would describe a hydrodynamical flow with the property that isometry charges are conserved along the flow lines (Beltrami flow). A general ansatz satisfying the integrability conditions is found. The solution ansatz applies also to the extremals of Chern-Simons action and to the conserved currents associated with the modified Dirac equation defined as contractions of the modified gamma matrices between the solutions of the modified Dirac equation. The strongest form of the solution ansatz states that various classical and quantum currents flow along flow lines of the Beltrami flow defined by Kähler current (Kähler magnetic field associated with Chern-Simons action). Intuitively this picture is attractive. A more general ansatz would allow several Beltrami flows meaning multi-hydrodynamics. The integrability conditions boil down to two scalar functions: the first one satisfies massless d'Alembert equation in the induced metric and the the gradients of the scalar functions are orthogonal. The interpretation in terms of momentum and polarization directions is natural.
6. The general solution ansatz works for induced Kähler Dirac equation and Chern-Simons Dirac equation and reduces them to ordinary differential equations along flow lines. The induced spinor fields are simply constant along flow lines of induced spinor field for Dirac equation in suitable gauge. Also the generalized eigen modes of the modified Chern-Simons Dirac operator can be deduced explicitly if the throats and the ends of space-time surface at the boundaries of  $CD$  are extremals of Chern-Simons action. Chern-Simons Dirac equation reduces to ordinary differential equations along flow lines and one can deduce the general form of the spectrum and the explicit representation of the Dirac determinant in terms of geometric quantities characterizing the 3-surface (eigenvalues are inversely proportional to the lengths of strands of the flow lines in the effective metric defined by the modified gamma matrices).

### 2.4.1 Could a weak form of electric-magnetic duality hold true?

Holography means that the initial data at the partonic 2-surfaces should fix the configuration space metric. A weak form of this condition allows only the partonic 2-surfaces defined by the wormhole throats at which the signature of the induced metric changes. A stronger condition allows all partonic 2-surfaces in the slicing of space-time sheet to partonic 2-surfaces and string world sheets. Number theoretical vision suggests that hyper-quaternionicity *resp.* co-hyperquaternionicity constraint could be enough to fix the initial values of time derivatives of the imbedding space coordinates in the space-time regions with Minkowskian *resp.* Euclidian signature of the induced metric. This is a condition on modified gamma matrices and hyper-quaternionicity states that they span a hyper-quaternionic sub-space.

### Definition of the weak form of electric-magnetic duality

One can also consider alternative conditions possibly equivalent with this condition. The argument goes as follows.

1. The expression of the matrix elements of the metric and Kähler form of  $WCW$  in terms of the Kähler fluxes weighted by Hamiltonians of  $\delta M_{\pm}^4$  at the partonic 2-surface  $X^2$  looks very attractive. These expressions however carry no information about the 4-D tangent space of the partonic 2-surfaces so that the theory would reduce to a genuinely 2-dimensional theory, which cannot hold true. One would like to code to the  $WCW$  metric also information about the electric part of the induced Kähler form assignable to the complement of the tangent space of  $X^2 \subset X^4$ .
2. Electric-magnetic duality of the theory looks a highly attractive symmetry. The trivial manner to get electric magnetic duality at the level of the full theory would be via the identification of the flux Hamiltonians as sums of of the magnetic and electric fluxes. The presence of the induced metric is however troublesome since the presence of the induced metric means that the simple transformation properties of flux Hamiltonians under symplectic transformations -in particular color rotations- are lost.
3. A less trivial formulation of electric-magnetic duality would be as an initial condition which eliminates the induced metric from the electric flux. In the Euclidian version of 4-D YM theory this duality allows to solve field equations exactly in terms of instantons. This approach involves also quaternions. These arguments suggest that the duality in some form might work. The full electric magnetic duality is certainly too strong and implies that space-time surface at the partonic 2-surface corresponds to piece of  $CP_2$  type vacuum extremal and can hold only in the deep interior of the region with Euclidian signature. In the region surrounding wormhole throat at both sides the condition must be replaced with a weaker condition.
4. To formulate a weaker form of the condition let us introduce coordinates  $(x^0, x^3, x^1, x^2)$  such  $(x^1, x^2)$  define coordinates for the partonic 2-surface and  $(x^0, x^3)$  define coordinates labeling partonic 2-surfaces in the slicing of the space-time surface by partonic 2-surfaces and string world sheets making sense in the regions of space-time sheet with Minkowskian signature. The assumption about the slicing allows to preserve general coordinate invariance. The weakest condition is that the generalized Kähler electric fluxes are apart from constant proportional to Kähler magnetic fluxes. This requires the condition

$$J^{03}\sqrt{g_4} = K J_{12} . \quad (2.4.1)$$

A more general form of this duality is suggested by the considerations of [?] reducing the hierarchy of Planck constants to basic quantum TGD and also reducing Kähler function for preferred extremals to Chern-Simons terms [?] at the boundaries of  $CD$  and at light-like wormhole throats. This form is following

$$J^{n\beta}\sqrt{g_4} = K \epsilon \times \epsilon^{n\beta\gamma\delta} J_{\gamma\delta}\sqrt{g_4} . \quad (2.4.2)$$

Here the index  $n$  refers to a normal coordinate for the space-like 3-surface at either boundary of  $CD$  or for light-like wormhole throat.  $\epsilon$  is a sign factor which is opposite for the two ends of  $CD$ . It could be also opposite of opposite at the opposite sides of the wormhole throat. Note that the dependence on induced metric disappears at the right hand side and this condition eliminates the potentials singularity due to the reduction of the rank of the induced metric at wormhole throat.

5. Information about the tangent space of the space-time surface can be coded to the configuration space metric with loosing the nice transformation properties of the magnetic flux Hamiltonians

if Kähler electric fluxes or sum of magnetic flux and electric flux satisfying this condition are used and  $K$  is symplectic invariant. Using the sum

$$J_e + J_m = (1 + K)J , \quad (2.4.3)$$

where  $J$  can denote the Kähler magnetic flux, makes it possible to have a non-trivial configuration space metric even for  $K = 0$ , which could correspond to the ends of a cosmic string like solution carrying only Kähler magnetic fields. This condition suggests that it can depend only on Kähler magnetic flux and other symplectic invariants. Whether local symplectic coordinate invariants are possible at all is far from obvious, If the slicing itself is symplectic invariant then  $K$  could be a non-constant function of  $X^2$  depending on string world sheet coordinates. The light-like radial coordinate of the light-cone boundary indeed defines a symplectically invariant slicing and this slicing could be shifted along the time axis defined by the tips of  $CD$ .

### Electric-magnetic duality physically

What could the weak duality condition mean physically? For instance, what constraints are obtained if one assumes that the quantization of electro-weak charges reduces to this condition at classical level?

1. The first thing to notice is that the flux of  $J$  over the partonic 2-surface is analogous to magnetic flux

$$Q_m = \frac{e}{\hbar} \oint B dS = n .$$

$n$  is non-vanishing only if the surface is homologically non-trivial and gives the homology charge of the partonic 2-surface.

2. The expressions of classical electromagnetic and  $Z^0$  fields in terms of Kähler form [?] , [?] read as

$$\begin{aligned} \gamma &= \frac{eF_{em}}{\hbar} = 3J - \sin^2(\theta_W)R_{03} , \\ Z^0 &= \frac{g_Z F_Z}{\hbar} = 2R_{03} . \end{aligned} \quad (2.4.4)$$

Here  $R_{03}$  is one of the components of the curvature tensor in vielbein representation and  $F_{em}$  and  $F_Z$  correspond to the standard field tensors. From this expression one can deduce

$$J = \frac{e}{3\hbar} F_{em} + \sin^2(\theta_W) \frac{g_Z}{6\hbar} F_Z . \quad (2.4.5)$$

3. The weak duality condition when integrated over  $X^2$  implies

$$\begin{aligned} \frac{e^2}{3\hbar} Q_{em} + \frac{g_Z^2 p}{6} Q_{Z,V} &= K \oint J = Kn , \\ Q_{Z,V} &= \frac{I_V^3}{2} - Q_{em} , \quad p = \sin^2(\theta_W) . \end{aligned} \quad (2.4.6)$$

Here the vectorial part of the  $Z^0$  charge rather than as full  $Z^0$  charge  $Q_Z = I_L^3 + \sin^2(\theta_W)Q_{em}$  appears. The reason is that only the vectorial isospin is same for left and right handed components of fermion which are in general mixed for the massive states.

The coefficients are dimensionless and expressible in terms of the gauge coupling strengths and using  $\hbar = r\hbar_0$  one can write

$$\begin{aligned} \alpha_{em} Q_{em} + p \frac{\alpha_Z}{2} Q_{Z,V} &= \frac{3}{4\pi} \times rnK , \\ \alpha_{em} &= \frac{e^2}{4\pi\hbar_0} , \quad \alpha_Z = \frac{g_Z^2}{4\pi\hbar_0} = \frac{\alpha_{em}}{p(1-p)} . \end{aligned} \quad (2.4.7)$$

4. There is a great temptation to assume that the values of  $Q_{em}$  and  $Q_Z$  correspond to their quantized values and therefore depend on the quantum state assigned to the partonic 2-surface. The linear coupling of the modified Dirac operator to conserved charges implies correlation between the geometry of space-time sheet and quantum numbers assigned to the partonic 2-surface. The assumption of standard quantized values for  $Q_{em}$  and  $Q_Z$  would be also seen as the identification of the fine structure constants  $\alpha_{em}$  and  $\alpha_Z$ . This however requires weak isospin invariance.

#### The value of $K$ from classical quantization of Kähler electric charge

The value of  $K$  can be deduced by requiring classical quantization of Kähler electric charge.

1. The condition that the flux of  $F^{03} = (\hbar/g_K)J^{03}$  defining the counterpart of Kähler electric field equals to the Kähler charge  $g_K$  would give the condition  $K = g_K^2/\hbar$ , where  $g_K$  is Kähler coupling constant which should invariant under coupling constant evolution by quantum criticality. Within experimental uncertainties one has  $\alpha_K = g_K^2/4\pi\hbar_0 = \alpha_{em} \simeq 1/137$ , where  $\alpha_{em}$  is finite structure constant in electron length scale and  $\hbar_0$  is the standard value of Planck constant.
2. The quantization of Planck constants makes the condition highly non-trivial. The most general quantization of  $r$  is as rationals but there are good arguments favoring the quantization as integers corresponding to the allowance of only singular coverings of  $CD$  and  $CP_2$ . The point is that in this case a given value of Planck constant corresponds to a finite number pages of the "Big Book". The quantization of the Planck constant implies a further quantization of  $K$  and would suggest that  $K$  scales as  $1/r$  unless the spectrum of values of  $Q_{em}$  and  $Q_Z$  allowed by the quantization condition scales as  $r$ . This is quite possible and the interpretation would be that each of the  $r$  sheets of the covering carries (possibly same) elementary charge. Kind of discrete variant of a full Fermi sphere would be in question. The interpretation in terms of anyonic phases [?] supports this interpretation.
3. The identification of  $J$  as a counterpart of  $eB/\hbar$  means that Kähler action and thus also Kähler function is proportional to  $1/\alpha_K$  and therefore to  $\hbar$ . This implies that for large values of  $\hbar$  Kähler coupling strength  $g_K^2/4\pi$  becomes very small and large fluctuations are suppressed in the functional integral. The basic motivation for introducing the hierarchy of Planck constants was indeed that the scaling  $\alpha \rightarrow \alpha/r$  allows to achieve the convergence of perturbation theory: Nature itself would solve the problems of the theoretician. This of course does not mean that the physical states would remain as such and the replacement of single particles with anyonic states in order to satisfy the condition for  $K$  would realize this concretely.
4. The condition  $K = g_K^2/\hbar$  implies that the Kähler magnetic charge is always accompanied by Kähler electric charge. A more general condition would read as

$$K = n \times \frac{g_K^2}{\hbar}, n \in Z . \quad (2.4.8)$$

This would apply in the case of cosmic strings and would allow vanishing Kähler charge possible when the partonic 2-surface has opposite fermion and antifermion numbers (for both leptons and quarks) so that Kähler electric charge should vanish. For instance, for neutrinos the vanishing of electric charge strongly suggests  $n = 0$  besides the condition that abelian  $Z^0$  flux contributing to em charge vanishes.

It took a year to realize that this value of  $K$  is natural at the Minkowskian side of the wormhole throat. At the Euclidian side much more natural condition is

$$K = \frac{1}{\hbar c} . \quad (2.4.9)$$

In fact, the self-duality of  $CP_2$  Kähler form favours this boundary condition at the Euclidian side of the wormhole throat. Also the fact that one cannot distinguish between electric and magnetic charges in Euclidian region since all charges are magnetic can be used to argue in favor of this form. The same constraint arises from the condition that the action for  $CP_2$  type vacuum extremal has the value required by the argument leading to a prediction for gravitational constant in terms of the square of  $CP_2$  radius and  $\alpha_K$  the effective replacement  $g_K^2 \rightarrow 1$  would spoil the argument.

The boundary condition  $J_E = J_B$  for the electric and magnetic parts of Kähler form at the Euclidian side of the wormhole throat inspires the question whether all Euclidian regions could be self-dual so that the density of Kähler action would be just the instanton density. Self-duality follows if the deformation of the metric induced by the deformation of the canonically imbedded  $CP_2$  is such that in  $CP_2$  coordinates for the Euclidian region the tensor  $(g^{\alpha\beta} g^{\mu\nu} - g^{\alpha\nu} g^{\mu\beta})/\sqrt{g}$  remains invariant. This is certainly the case for  $CP_2$  type vacuum extremals since by the light-likeness of  $M^4$  projection the metric remains invariant. Also conformal scalings of the induced metric would satisfy this condition. Conformal scaling is not consistent with the degeneracy of the 4-metric at the wormhole throat. Full self-duality is indeed an un-necessarily strong condition.

### Reduction of the quantization of Kähler electric charge to that of electromagnetic charge

The best manner to learn more is to challenge the form of the weak electric-magnetic duality based on the induced Kähler form.

1. Physically it would seem more sensible to pose the duality on electromagnetic charge rather than Kähler charge. This would replace induced Kähler form with electromagnetic field, which is a linear combination of induced Kähler field and classical  $Z^0$  field

$$\begin{aligned} \gamma &= 3J - \sin^2\theta_W R_{03} , \\ Z^0 &= 2R_{03} . \end{aligned} \quad (2.4.10)$$

Here  $Z_0 = 2R_{03}$  is the appropriate component of  $CP_2$  curvature form [?]. For a vanishing Weinberg angle the condition reduces to that for Kähler form.

2. For the Euclidian space-time regions having interpretation as lines of generalized Feynman diagrams Weinberg angle should be non-vanishing. In Minkowskian regions Weinberg angle could however vanish. If so, the condition guaranteeing that electromagnetic charge of the partonic 2-surfaces equals to the above condition stating that the em charge assignable to the fermion content of the partonic 2-surfaces reduces to the classical Kähler electric flux at the Minkowskian side of the wormhole throat. One can argue that Weinberg angle must increase smoothly from a vanishing value at both sides of wormhole throat to its value in the deep interior of the Euclidian region.
3. The vanishing of the Weinberg angle in Minkowskian regions conforms with the physical intuition. Above elementary particle length scales one sees only the classical electric field reducing to the induced Kähler form and classical  $Z^0$  fields and color gauge fields are effectively absent. Only in phases with a large value of Planck constant classical  $Z^0$  field and other classical weak fields and color gauge field could make themselves visible. Cell membrane could be one such system [K55]. This conforms with the general picture about color confinement and weak massivation.

The GRT limit of TGD suggests a further reason for why Weinberg angle should vanish in Minkowskian regions.

1. The value of the Kähler coupling strength must be very near to the value of the fine structure constant in electron length scale and these constants can be assumed to be equal.
2. GRT limit of TGD with space-time surfaces replaced with abstract 4-geometries would naturally correspond to Einstein-Maxwell theory with cosmological constant which is non-vanishing only in Euclidian regions of space-time so that both Reissner-Nordström metric and  $CP_2$  are allowed as simplest possible solutions of field equations [K77]. The extremely small value of the observed cosmological constant needed in GRT type cosmology could be equal to the large cosmological constant associated with  $CP_2$  metric multiplied with the 3-volume fraction of Euclidian regions.
3. Also at GRT limit quantum theory would reduce to almost topological QFT since Einstein-Maxwell action reduces to 3-D term by field equations implying the vanishing of the Maxwell current and of the curvature scalar in Minkowskian regions and curvature scalar + cosmological constant term in Euclidian regions. The weak form of electric-magnetic duality would guarantee also now the preferred extremal property and prevent the reduction to a mere topological QFT.
4. GRT limit would make sense only for a vanishing Weinberg angle in Minkowskian regions. A non-vanishing Weinberg angle would make sense in the deep interior of the Euclidian regions where the approximation as a small deformation of  $CP_2$  makes sense.

The weak form of electric-magnetic duality has surprisingly strong implications for the basic view about quantum TGD as following considerations show.

### 2.4.2 Magnetic confinement, the short range of weak forces, and color confinement

The weak form of electric-magnetic duality has surprisingly strong implications if one combines it with some very general empirical facts such as the non-existence of magnetic monopole fields in macroscopic length scales.

#### How can one avoid macroscopic magnetic monopole fields?

Monopole fields are experimentally absent in length scales above order weak boson length scale and one should have a mechanism neutralizing the monopole charge. How electroweak interactions become short ranged in TGD framework is still a poorly understood problem. What suggests itself is the neutralization of the weak isospin above the intermediate gauge boson Compton length by neutral Higgs bosons. Could the two neutralization mechanisms be combined to single one?

1. In the case of fermions and their super partners the opposite magnetic monopole would be a wormhole throat. If the magnetically charged wormhole contact is electromagnetically neutral but has vectorial weak isospin neutralizing the weak vectorial isospin of the fermion only the electromagnetic charge of the fermion is visible on longer length scales. The distance of this wormhole throat from the fermionic one should be of the order weak boson Compton length. An interpretation as a bound state of fermion and a wormhole throat state with the quantum numbers of a neutral Higgs boson would therefore make sense. The neutralizing throat would have quantum numbers of  $X_{-1/2} = \nu_L \bar{\nu}_R$  or  $X_{1/2} = \bar{\nu}_L \nu_R$ .  $\nu_L \bar{\nu}_R$  would not be neutral Higgs boson (which should correspond to a wormhole contact) but a super-partner of left-handed neutrino obtained by adding a right handed neutrino. This mechanism would apply separately to the fermionic and anti-fermionic throats of the gauge bosons and corresponding space-time sheets and leave only electromagnetic interaction as a long ranged interaction.
2. One can of course wonder what is the situation for the bosonic wormhole throats feeding gauge fluxes between space-time sheets. It would seem that these wormhole throats must always appear as pairs such that for the second member of the pair monopole charges and  $I_V^3$  cancel each other at both space-time sheets involved so that one obtains at both space-time sheets magnetic dipoles of size of weak boson Compton length. The proposed magnetic character of fundamental particles should become visible at TeV energies so that LHC might have surprises in store!

### Magnetic confinement and color confinement

Magnetic confinement generalizes also to the case of color interactions. One can consider also the situation in which the magnetic charges of quarks (more generally, of color excited leptons and quarks) do not vanish and they form color and magnetic singlets in the hadronic length scale. This would mean that magnetic charges of the state  $q_{\pm 1/2} - X_{\mp 1/2}$  representing the physical quark would not vanish and magnetic confinement would accompany also color confinement. This would explain why free quarks are not observed. To how degree then quark confinement corresponds to magnetic confinement is an interesting question.

For quark and antiquark of meson the magnetic charges of quark and antiquark would be opposite and meson would correspond to a Kähler magnetic flux so that a stringy view about meson emerges. For valence quarks of baryon the vanishing of the net magnetic charge takes place provided that the magnetic net charges are  $(\pm 2, \mp 1, \mp 1)$ . This brings in mind the spectrum of color hyper charges coming as  $(\pm 2, \mp 1, \mp 1)/3$  and one can indeed ask whether color hyper-charge correlates with the Kähler magnetic charge. The geometric picture would be three strings connected to single vertex. Amusingly, the idea that color hypercharge could be proportional to color hyper charge popped up during the first year of TGD when I had not yet discovered  $CP_2$  and believed on  $M^4 \times S^2$ .

p-Adic length scale hypothesis and hierarchy of Planck constants defining a hierarchy of dark variants of particles suggest the existence of scaled up copies of QCD type physics and weak physics. For p-adically scaled up variants the mass scales would be scaled by a power of  $\sqrt{2}$  in the most general case. The dark variants of the particle would have the same mass as the original one. In particular, Mersenne primes  $M_k = 2^k - 1$  and Gaussian Mersennes  $M_{G,k} = (1 + i)^k - 1$  has been proposed to define zoomed copies of these physics. At the level of magnetic confinement this would mean hierarchy of length scales for the magnetic confinement.

One particular proposal is that the Mersenne prime  $M_{89}$  should define a scaled up variant of the ordinary hadron physics with mass scaled up roughly by a factor  $2^{(107-89)/2} = 512$ . The size scale of color confinement for this physics would be same as the weak length scale. It would look more natural that the weak confinement for the quarks of  $M_{89}$  physics takes place in some shorter scale and  $M_{61}$  is the first Mersenne prime to be considered. The mass scale of  $M_{61}$  weak bosons would be by a factor  $2^{(89-61)/2} = 2^{14}$  higher and about  $1.6 \times 10^4$  TeV.  $M_{89}$  quarks would have virtually no weak interactions but would possess color interactions with weak confinement length scale reflecting themselves as new kind of jets at collisions above TeV energies.

In the biologically especially important length scale range 10 nm -2500 nm there are as many as four Gaussian Mersennes corresponding to  $M_{G,k}$ ,  $k = 151, 157, 163, 167$ . This would suggest that the existence of scaled up scales of magnetic-, weak- and color confinement. An especially interesting possibly testable prediction is the existence of magnetic monopole pairs with the size scale in this range. There are recent claims about experimental evidence for magnetic monopole pairs [?].

### Magnetic confinement and stringy picture in TGD sense

The connection between magnetic confinement and weak confinement is rather natural if one recalls that electric-magnetic duality in super-symmetric quantum field theories means that the descriptions in terms of particles and monopoles are in some sense dual descriptions. Fermions would be replaced by string like objects defined by the magnetic flux tubes and bosons as pairs of wormhole contacts would correspond to pairs of the flux tubes. Therefore the sharp distinction between gravitons and physical particles would disappear.

The reason why gravitons are necessarily stringy objects formed by a pair of wormhole contacts is that one cannot construct spin two objects using only single fermion states at wormhole throats. Of course, also super partners of these states with higher spin obtained by adding fermions and anti-fermions at the wormhole throat but these do not give rise to graviton like states [?]. The upper and lower wormhole throat pairs would be quantum superpositions of fermion anti-fermion pairs with sum over all fermions. The reason is that otherwise one cannot realize graviton emission in terms of joining of the ends of light-like 3-surfaces together. Also now magnetic monopole charges are necessary but now there is no need to assign the entities  $X_{\pm}$  with gravitons.

Graviton string is characterized by some p-adic length scale and one can argue that below this length scale the charges of the fermions become visible. Mersenne hypothesis suggests that some Mersenne prime is in question. One proposal is that gravitonic size scale is given by electronic

Mersenne prime  $M_{127}$ . It is however difficult to test whether graviton has a structure visible below this length scale.

What happens to the generalized Feynman diagrams is an interesting question. It is not at all clear how closely they relate to ordinary Feynman diagrams. All depends on what one is ready to assume about what happens in the vertices. One could of course hope that zero energy ontology could allow some very simple description allowing perhaps to get rid of the problematic aspects of Feynman diagrams.

1. Consider first the recent view about generalized Feynman diagrams which relies zero energy ontology. A highly attractive assumption is that the particles appearing at wormhole throats are on mass shell particles. For incoming and outgoing elementary bosons and their super partners they would be positive it resp. negative energy states with parallel on mass shell momenta. For virtual bosons they the wormhole throats would have opposite sign of energy and the sum of on mass shell states would give virtual net momenta. This would make possible twistor description of virtual particles allowing only massless particles (in 4-D sense usually and in 8-D sense in TGD framework). The notion of virtual fermion makes sense only if one assumes in the interaction region a topological condensation creating another wormhole throat having no fermionic quantum numbers.
2. The addition of the particles  $X^\pm$  replaces generalized Feynman diagrams with the analogs of stringy diagrams with lines replaced by pairs of lines corresponding to fermion and  $X_{\pm 1/2}$ . The members of these pairs would correspond to 3-D light-like surfaces glued together at the vertices of generalized Feynman diagrams. The analog of 3-vertex would not be splitting of the string to form shorter strings but the replication of the entire string to form two strings with same length or fusion of two strings to single string along all their points rather than along ends to form a longer string. It is not clear whether the duality symmetry of stringy diagrams can hold true for the TGD variants of stringy diagrams.
3. How should one describe the bound state formed by the fermion and  $X^\pm$ ? Should one describe the state as superposition of non-parallel on mass shell states so that the composite state would be automatically massive? The description as superposition of on mass shell states does not conform with the idea that bound state formation requires binding energy. In TGD framework the notion of negentropic entanglement has been suggested to make possible the analogs of bound states consisting of on mass shell states so that the binding energy is zero [K42]. If this kind of states are in question the description of virtual states in terms of on mass shell states is not lost. Of course, one cannot exclude the possibility that there is infinite number of this kind of states serving as analogs for the excitations of string like object.
4. What happens to the states formed by fermions and  $X_{\pm 1/2}$  in the internal lines of the Feynman diagram? Twistor philosophy suggests that only the higher on mass shell excitations are possible. If this picture is correct, the situation would not change in an essential manner from the earlier one.

The highly non-trivial prediction of the magnetic confinement is that elementary particles should have stringy character in electro-weak length scales and could behaving to become manifest at LHC energies. This adds one further item to the list of non-trivial predictions of TGD about physics at LHC energies [K43].

## 2.5 Quantum TGD very briefly

There are two basic approaches to the construction of quantum TGD. The first approach relies on the vision of quantum physics as infinite-dimensional Kähler geometry [?] for the "world of classical worlds" (WCW) identified as the space of 3-surfaces in in certain 8-dimensional space. Essentially a generalization of the Einstein's geometrization of physics program is in question. The second vision is the identification of physics as a generalized number theory involving p-adic number fields and the fusion of real numbers and p-adic numbers to a larger structure, classical number fields, and the notion of infinite prime.

With a better resolution one can distinguish also other visions crucial for quantum TGD. Indeed, the notion of finite measurement resolution realized in terms of hyper-finite factors, TGD as almost topological quantum field theory, twistor approach, zero energy ontology, and weak form of electric-magnetic duality play a decisive role in the actual construction and interpretation of the theory. One can however argue that these visions are not so fundamental for the formulation of the theory than the first two.

### 2.5.1 Physics as infinite-dimensional geometry

It is good to start with an attempt to give overall view about what the dream about physics as infinite-dimensional geometry is. The basic vision is generalization of the Einstein's program for the geometrization of classical physics so that entire quantum physics would be geometrized. Finite-dimensional geometry is certainly not enough for this purposed but physics as infinite-dimensional geometry of what might be called world of classical worlds (WCW) -or more neutrally configuration space of 3-surfaces of some higher-dimensional imbeddign space- might make sense. The requirement that the Hermitian conjugation of quantum theories has a geometric realization forces Kähler geometry for WCW. WCW defines the fixed arena of quantum physics and physical states are identified as spinor fields in WCW. These spinor fields are classical and no second quantization is needed at this level. The justification comes from the observation that infinite-dimensional Clifford algebra [?] generated by gamma matrices allows a natural identification as fermionic oscillator algebra.

The basic challenges are following.

1. Identify WCW.
2. Provide WCW with Kähler metric and spinor structure
3. Define what spinors and spinor fields in WCW are.

There is huge variety of finite-dimensional geometries and one might think that in infinite-dimensional case one might be drowned with the multitude of possibilities. The situation is however exactly opposite. The loop spaces associated with groups have a unique Kähler geometry due to the simple condition that Riemann connection exists mathematically [?]. This condition requires that the metric possesses maximal symmetries. Thus raises the vision that infinite-dimensional Kähler geometric existence is unique once one poses the additional condition that the resulting geometry satisfies some basic constraints forced by physical considerations.

The observation about the uniqueness of loop geometries leads also to a concrete vision about what this geometry could be. Perhaps WCW could be refarded as a union of symmetric spaces [?] for which every point is equivalent with any other. This would simplify the construction of the geometry immensely and would mean a generalization of cosmological principle to infinite-D context [?], [?].

This still requires an answer to the question why  $M^4 \times CP_2$  is so unique. Something in the structure of this space must distinguish it in a unique manner from any other candidate. The uniqueness of  $M^4$  factor can be understood from the miraculous conformal symmetries of the light-cone boundary but in the case of  $CP_2$  there is no obvious mathematical argument of this kind although physically  $CP_2$  is unique [?]. The observation that  $M^4 \times CP_2$  has dimension 8, the space-time surfaces have dimension 4, and partonic 2-surfaces, which are the fundamental objects by holography have dimension 2, suggests that classical number fields [?, ?, ?] are involved and one can indeed end up to the choice  $M^4 \times CP_2$  from physics as generalized number theory vision by simple arguments [K72], [?]. In particular, the choices  $M^8$  -a subspace of complexified octonions (for octonions see [?]), which I have used to call hyper-octonions- and  $M^4 \times CP_2$  can be regarded as physically equivalent: this "number theoretical compactification" is analogous to spontaneous compactification in M-theory. No dynamical compactification takes place so that  $M^8 - H$  duality is a more appropriate term.

### 2.5.2 Physics as generalized number theory

Physics as a generalized number theory (for an overview about number theory see [?]) program consists of three separate threads: various p-adic physics and their fusion together with real number based physics to a larger structure [K71], [?], the attempt to understand basic physics in terms of classical number fields [K72], [?] (in particular, identifying associativity condition as the basic

dynamical principle), and infinite primes [?] , [?] , whose construction is formally analogous to a repeated second quantization of an arithmetic quantum field theory. In this article a summary of the philosophical ideas behind this dream and a summary of the technical challenges and proposed means to meet them are discussed.

The construction of p-adic physics and real physics poses formidable looking technical challenges: p-adic physics should make sense both at the level of the imbedding space, the "world of classical worlds" (WCW), and space-time and these physics should allow a fusion to a larger coherent whole. This forces to generalize the notion of number by fusing reals and p-adics along rationals and common algebraic numbers. The basic problem that one encounters is definition of the definite integrals and harmonic analysis [?] in the p-adic context [?] . It turns out that the representability of WCW as a union of symmetric spaces [?] provides a universal group theoretic solution not only to the construction of the Kähler geometry of WCW but also to this problem. The p-adic counterpart of a symmetric space is obtained from its discrete invariant by replacing discrete points with p-adic variants of the continuous symmetric space. Fourier analysis [?] reduces integration to summation. If one wants to define also integrals at space-time level, one must pose additional strong constraints which effectively reduce the partonic 2-surfaces and perhaps even space-time surfaces to finite geometries and allow assign to a given partonic 2-surface a unique power of a unique p-adic prime characterizing the measurement resolution in angle variables. These integrals might make sense in the intersection of real and p-adic worlds defined by algebraic surfaces.

The dimensions of partonic 2-surface, space-time surface, and imbedding space suggest that classical number fields might be highly relevant for quantum TGD. The recent view about the connection is based on hyper-octonionic representation of the imbedding space gamma matrices, and the notions of associative and co-associative space-time regions defined as regions for which the modified gamma matrices span quaternionic or co-quaternionic plane at each point of the region. A further condition is that the tangent space at each point of space-time surface contains a preferred hyper-complex (and thus commutative) plane identifiable as the plane of non-physical polarizations so that gauge invariance has a purely number theoretic interpretation. WCW can be regarded as the space of sub-algebras of the local octonionic Clifford algebra [?] of the imbedding space defined by space-time surfaces with the property that the local sub-Clifford algebra spanned by Clifford algebra valued functions restricted at them is associative or co-associative in a given region.

The recipe for constructing infinite primes is structurally equivalent with a repeated second quantization of an arithmetic super-symmetric quantum field theory. At the lowest level one has fermionic and bosonic states labeled by finite primes and infinite primes correspond to many particle states of this theory. Also infinite primes analogous to bound states are predicted. This hierarchy of quantizations can be continued indefinitely by taking the many particle states of the previous level as elementary particles at the next level. Construction could make sense also for hyper-quaternionic and hyper-octonionic primes although non-commutativity and non-associativity pose technical challenges. One can also construct infinite number of real units as ratios of infinite integers with a precise number theoretic anatomy. The fascinating finding is that the quantum states labeled by standard model quantum numbers allow a representation as wave functions in the discrete space of these units. Space-time point becomes infinitely richly structured in the sense that one can associate to it a wave function in the space of real (or octonionic) units allowing to represent the WCW spinor fields. One can speak about algebraic holography or number theoretic Brahman=Atman identity and one can also say that the points of imbedding space and space-time surface are subject to a number theoretic evolution.

### 2.5.3 Questions

The experience has shown repeatedly that a correct question and identification of some weakness of existing vision is what can only lead to a genuine progress. In the following I discuss the basic questions, which have stimulated progress in the challenge of constructing WCW geometry.

#### What is WCW?

Concerning the identification of WCW I have made several guesses and the progress has been basically due to the gradual realization of various physical constraints and the fact that standard physics ontology is not enough in TGD framework.

1. The first guess was that WCW corresponds to all possible space-like 3-surfaces in  $H = M^4 \times CP_2$ , where  $M^4$  denotes Minkowski space and  $CP_2$  denotes complex projective space of two complex dimensions having also representation as coset space  $SU(3)/U(2)$  (see the separate article summarizing the basic facts about  $CP_2$  and how it codes for standard model symmetries [?] , [?, ?] ). What led to the this particular choice  $H$  was the observation that the geometry of  $H$  codes for standard model quantum numbers and that the generalization of particle from point like particle to 3-surface allows to understand also remaining quantum numbers having no obvious explanation in standard model (family replication phenomenon). What is important to notice is that Poincare symmetries act as exact symmetries of  $M^4$  rather than space-time surface itself: this realizes the basic vision about Poincare invariant theory of gravitation. This lifting of symmetries to the level of imbedding space and the new dynamical degrees of freedom brought by the sub-manifold geometry of space-time surface are absolutely essential for entire quantum TGD and distinguish it from general relativity and string models. There is however a problem: it is not obvious how to get cosmology.
2. The second guess was that WCW consists of space-like 3-surfaces in  $H_+ = M_+^4 \times CP_2$ , where  $M_+^4$  future light-cone having interpretation as Big Bang cosmology at the limit of vanishing mass density with light-cone property time identified as the cosmic time. One obtains cosmology but loses exact Poincare invariance in cosmological scales since translations lead out of future light-cone. This as such has no practical significance but due to the metric 2-dimensionality of light-cone boundary  $\delta M_+^4$  the conformal symmetries of string model assignable to finite-dimensional Lie group generalize to conformal symmetries assignable to an infinite-dimensional symplectic group of  $S^2 \times CP_2$  and also localized with respect to the coordinates of 3-surface. These symmetries are simply too beautiful to be important only at the moment of Big Bang and must be present also in elementary particle length scales. Note that these symmetries are present only for 4-D Minkowski space so that a partial resolution of the old conundrum about why space-time dimension is just four emerges.
3. The third guess was that the light-like 3-surfaces in  $H$  or  $H_+$  are more attractive than space-like 3-surfaces. The reason is that the infinite-D conformal symmetries characterize also light-like 3-surfaces because they are metrically 2-dimensional. This leads to a generalization of Kac-Moody symmetries [?] of super string models with finite-dimensional Lie group replaced with the group of isometries of  $H$ . The natural identification of light-like 3-surfaces is as 3-D surfaces defining the regions at which the signature of the induced metric changes from Minkowskian  $(1, -1, -1, -1)$  to Euclidian  $(-1 - 1 - 1 - 1)$ - I will refer these surfaces as throats or wormhole throats in the sequel. Light-like 3-surfaces are analogous to blackhole horizons and are static because strong gravity makes them light-like. Therefore also the dimension 4 for the space-time surface is unique.

This identification leads also to a rather unexpected physical interpretation. Single lightlike wormhole throat carries elementary particle quantum numbers. Fermions and their superpartners are obtained by glueing Euclidian regions (deformations of so called  $CP_2$  type vacuum extremals of Kähler action) to the background with Minkowskian signature. Bosons are identified as wormhole contacts with two throats carrying fermion *resp.* antifermionic quantum numbers. These can be identified as deformations of  $CP_2$  vacuum extremals between two parallel Minkowskian space-time sheets. One can say that bosons and their superpartners emerge. This has dramatic implications for quantum TGD [K17] and QFT limit of TGD [?] .

The question is whether one obtains also a generalization of Feynman diagrams. The answer is affirmative. Light-like 3-surfaces or corresponding Euclidian regions of space-time are analogous to the lines of Feynman diagram and vertices are replaced by 2-D surface at which these surfaces glued together. One can speak about Feynman diagrams with lines thickened to light-like 3-surfaces and vertices to 2-surfaces. The generalized Feynman diagrams are singular as 3-manifolds but the vertices are non-singular as 2-manifolds. Same applies to the corresponding space-time surfaces and space-like 3-surfaces. Therefore one can say that WCW consists of generalized Feynman diagrams- something rather different from the original identification as space-like 3-surfaces and one can wonder whether these identification could be equivalent.

4. The fourth guess was a generalization of the WCW combining the nice aspects of the identifications  $H = M^4 \times CP_2$  (exact Poincare invariance) and  $H = M_+^4 \times CP_2$  (Big Bang cosmology).

The idea was to generalize *WCW* to a union of basic building bricks -causal diamonds (*CDs*) - which themselves are analogous to Big Bang-Big Crunch cosmologies breaking Poincare invariance, which is however regained by the allowance of union of Poincare transforms of the causal diamonds.

The starting point is General Coordinate Invariance (GCI). It does not matter, which 3-D slice of the space-time surface one choose to represent physical data as long as slices are related by a diffeomorphism of the space-time surface. This condition implies holography in the sense that 3-D slices define holograms about 4-D reality.

The question is whether one could generalize GCI in the sense that the descriptions using space-like and light-like 3-surfaces would be equivalent physically. This requires that finite-sized space-like 3-surfaces are somehow equivalent with light-like 3-surfaces. This suggests that the light-like 3-surfaces must have ends. Same must be true for the space-time surfaces and must define preferred space-like 3-surfaces just like wormhole throats do. This makes sense only if the 2-D intersections of these two kinds of 3-surfaces -call them partonic 2-surfaces- and their 4-D tangent spaces carry the information about quantum physics. A strengthening of holography principle would be the outcome. The challenge is to understand, where the intersections defining the partonic 2-surfaces are located.

Zero energy ontology (ZEO) allows to meet this challenge.

- (a) Assume that *WCW* is union of sub-*WCWs* identified as the space of light-like 3-surfaces assignable to  $CD \times CP_2$  with given *CD* defined as an intersection of future and past directed lightcones of  $M^4$ . The tips of *CDs* have localization in  $M^4$  and one can perform for *CD* both translations and Lorentz boost for *CDs*. Space-time surfaces inside *CD* define the basic building brick of *WCW*. Also unions of *CDs* allowed and the *CDs* belonging to the union can intersect. One can of course consider the possibility of intersections and analogy with the set theoretic realization of topology.
- (b) ZEO property means that the light-like boundaries of these objects carry positive and negative energy states, whose quantum numbers are opposite. Everything can be created from vacuum and can be regarded as quantum fluctuations in the standard vocabulary of quantum field theories.
- (c) Space-time surfaces inside *CDs* begin from the lower boundary and end to the upper boundary and in ZEO it is natural to identify space-like 3-surfaces as pairs of space-like 3-surfaces at these boundaries. Light-like 3-surfaces connect these boundaries.
- (d) The generalization of GCI states that the descriptions based on space-like 3-surfaces must be equivalent with that based on light-like 3-surfaces. Therefore only the 2-D intersections of light-like and space-like 3-surfaces - partonic 2-surfaces- and their 4-D tangent spaces (4-surface is there!) matter. Effective 2-dimensionality means a strengthened form of holography but does not imply exact 2-dimensionality, which would reduce the theory to a mere string model like theory. Once these data are given, the 4-D space-time surface is fixed and is analogous to a generalization of Bohr orbit to infinite-D context. This is the first guess. The situation is actually more delicate due to the non-determinism of Kähler action motivating the interaction of the hierarchy of *CDs* within *CDs*.

In this framework one obtains cosmology: *CDs* represent a fractal hierarchy of big bang-big crunch cosmologies. One obtains also Poincare invariance. One can also interpret the non-conservation of gravitational energy in cosmology which is an empirical fact but in conflict with exact Poincare invariance as it is realized in positive energy ontology [K77, K66] . The reason is that energy and four-momentum in zero energy ontology correspond to those assignable to the positive energy part of the zero energy state of a particular *CD*. The density of energy as cosmologist defines it is the statistical average for given *CD*: this includes the contributions of sub-*CDs*. This average density is expected to depend on the size scale of *CD* density is should therefore change as quantum dispersion in the moduli space of *CDs* takes place and leads to large time scale for any fixed sub-*CD*.

Even more, one obtains actually quantum cosmology! There is large variety of *CDs* since they have position in  $M^4$  and Lorentz transformations change their shape. The first question is

whether the  $M^4$  positions of both tips of  $CD$  can be free so that one could assign to both tips of  $CD$  momentum eigenstates with opposite signs of four-momentum. The proposal, which might look somewhat strange, is that this not the case and that the proper time distance between the tips is quantized in octaves of a fundamental time scale  $T = R/c$  defined by  $CP_2$  size  $R$ . This would explain p-adic length scale hypothesis which is behind most quantitative predictions of TGD. That the time scales assignable to the  $CD$  of elementary particles correspond to biologically important time scales [K22] forces to take this hypothesis very seriously.

The interpretation for  $T$  could be as a cosmic time quantized in powers of two. Even more general quantization is proposed to take place. The relative position of the second tip with respect to the first defines a point of the proper time constant hyperboloid of the future light cone. The hypothesis is that one must replace this hyperboloid with a lattice like structure. This implies very powerful cosmological predictions finding experimental support from the quantization of redshifts for instance [K66]. For quite recent further empirical support see [?].

One should not take this argument without a grain of salt. Can one really realize zero energy ontology in this framework? The geometric picture is that translations correspond to translations of  $CD$ s. Translations should be done independently for the upper and lower tip of  $CD$  if one wants to speak about zero energy states but this is not possible if the proper time distance is quantized. If the relative  $M^4_{\pm}$  coordinate is discrete, this pessimistic conclusion is strengthened further.

The manner to get rid of problem is to assume that translations are represented by quantum operators acting on states at the light-like boundaries. This is just what standard quantum theory assumes. An alternative- purely geometric- way out of difficulty is the Kac-Moody symmetry associated with light-like 3-surfaces meaning that local  $M^4$  translations depending on the point of partonic 2-surface are gauge symmetries. For a given translation leading out of  $CD$  this gauge symmetry allows to make a compensating transformation which allows to satisfy the constraint.

This picture is roughly the recent view about  $WCW$ . What deserves to be emphasized is that a very concrete connection with basic structures of quantum field theory emerges already at the level of basic objects of the theory and GCI implies a strong form of holography and almost stringy picture.

### Some Why's

In the following I try to summarize the basic motivations behind quantum TGD in form of various Why's.

#### 1. Why $WCW$ ?

Einstein's program has been extremely successful at the level of classical physics. Fusion of general relativity and quantum theory has however failed. The generalization of Einstein's geometrization program of physics from classical physics to quantum physics gives excellent hopes about the success in this project. Infinite-dimensional geometries are highly unique and this gives hopes about fixing the physics completely from the uniqueness of the infinite-dimensional Kähler geometric existence.

#### 2. Why spinor structure in $WCW$ ?

Gamma matrices defining the Clifford algebra [?] of  $WCW$  are expressible in terms of fermionic oscillator operators. This is obviously something new as compared to the view about gamma matrices as bosonic objects. There is however no deep reason denying this kind of identification. As a consequence, a geometrization of fermionic oscillator operator algebra and fermionic statistics follows as also geometrization of super-conformal symmetries [?, ?] since gamma matrices define super-generators of the algebra of  $WCW$  isometries extended to a super-algebra.

#### 3. Why Kähler geometry?

Geometrization of the bosonic oscillator operators in terms of  $WCW$  vector fields and fermionic oscillator operators in terms of gamma matrices spanning Clifford algebra. Gamma matrices span hyper-finite factor of type  $II_1$  and the extremely beautiful properties of these von Neuman

algebras [?] (one of the three von Neuman algebras that von Neumann suggests as possible mathematical frameworks behind quantum theory) lead to a direct connection with the basic structures of modern physics (quantum groups, non-commutative geometries,.. [?]).

A further reason why is the finiteness of the theory.

- (a) In standard QFTs there are two kinds of divergences. Action is a local functional of fields in 4-D sense and one performs path integral over **all** 4-surfaces to construct S-matrix. Mathematically path integration is a poorly defined procedure and one obtains diverging Gaussian determinants and divergences due to the local interaction vertices. Regularization provides the manner to get rid of the infinities but makes the theory very ugly.
- (b) Kähler function defining the Kähler geometry is expected to be non-local functional of the partonic 2-surface (Kähler action for a preferred extremal having as its ends the positive and negative energy 3-surfaces). Path integral is replaced with a functional integral which is mathematically well-defined procedure and one performs functional integral only over the partonic 2-surfaces rather than all 4-surfaces (holography). The exponent of Kähler function defines a unique vacuum functional. The local divergences of local quantum field theories since there are no local interaction vertices. Also the divergences associated with the Gaussian determinant and metric determinant cancel since these two determinants cancel each other in the integration over WCW. As a matter fact, symmetric space property suggest a much more elegant manner to perform the functional integral by reducing it to harmonic analysis in infinite-dimensional symmetric space [?].
- (c) One can imagine also the possibility of divergences in fermionic degrees of freedom but it has turned out that the generalized Feynman diagrams in ZEO are manifestly finite. Even more: it is quite possible that only finite number of these diagrams give non-vanishing contributions to the scattering amplitude. This is essentially due to the new view about virtual particles, which are identified as bound states of on mass shell states assigned with the throats of wormhole contacts so that the integration over loop momenta of virtual particles is extremely restricted [?].

#### 4. Why infinite-dimensional symmetries?

WCW must be a union of symmetric spaces in order that the Riemann connection exists (this generalizes the finding of Freed for loop groups [?]). Since the points of symmetric spaces are metrically equivalent, the geometrization becomes tractable although the dimension is infinite. A union of symmetric spaces is required because 3-surfaces with a size of galaxy and electron cannot be metrically equivalent. Zero modes distinguish these surfaces and can be regarded as purely classical degrees of freedom whereas the degrees of freedom contributing to the WCW line element are quantum fluctuating degrees of freedom.

One immediate implication of the symmetric space property is constant curvature space property meaning that the Ricci tensor proportional to metric tensor. Infinite-dimensionality means that Ricci scalar either vanishes or is infinite. This implies vanishing of Ricci tensor and vacuum Einstein equations for WCW.

#### 5. Why $M^4 \times CP_2$ ?

This choice provides an explanation for standard model quantum numbers. The conjecture is that infinite-D geometry of 3-surfaces exists only for this choice. As noticed, the dimension of space-time surfaces and  $M^4$  fixed by the requirement of generalized conformal invariance [?] making possible to achieve symmetric space property. If  $M^4 \times CP_2$  is so special, there must be a good reason for this. Number theoretical vision [K72], [?] indeed leads to the identification of this reason. One can assign the hierarchy of dimensions associated with partonic 2-surfaces, space-time surfaces and imbedding space to classical number fields and can assign to imbedding space what might be called hyper-octonionic structure. "Hyper" comes from the fact that the tangent space of  $H$  corresponds to the subspaces of complexified octonions with octonionic imaginary units multiplied by a commuting imaginary unit. The space-time regions would be either hyper-quaternionic or co-hyper-quaternionic so that associativity/co-associativity would become the basic dynamical principle at the level of space-time dynamics. Whether this dynamical principle is equivalent with the preferred extremal property of Kähler action remains an open conjecture.

#### 6. Why zero energy ontology and why causal diamonds?

The consistency between Poincare invariance and GRT requires ZEO. In positive energy ontology only one of the infinite number of classical solutions is realized and partially fixed by the values of conserved quantum numbers so that the theory becomes obsolete. Even in quantum theory conservation laws mean that only those solutions of field equations with the quantum numbers of the initial state of the Universe are interesting and one faces the problem of understanding what the the initial state of the universe was. In ZEO these problems disappear. Everything is creatable from vacuum: if the physical state is mathematically realizable it is in principle reachable by a sequence of quantum jumps. There are no physically non-reachable entities in the theory. Zero energy ontology leads also to a fusion of thermodynamics with quantum theory. Zero energy states are defined as entangled states of positive and negative energy states and entanglement coefficients define what I call  $M$ -matrix identified as "complex square root" of density matrix expressible as a product of diagonal real and positive density matrix and unitary  $S$ -matrix [K17] .

There are several good reasons why for causal diamonds. ZEO requires  $CD$ s, the generalized form of GCI and strong form of holography (light-like and space-like 3-surfaces are physically equivalent representations) require  $CD$ s, and also the view about light-like 3-surfaces as generalized Feynman diagrams requires  $CD$ s. Also the classical non-determinism of Kähler action can be understood using the hierarchy  $CD$ s and the addition of  $CD$ s inside  $CD$ s to obtain a fractal hierarchy of them provides an elegant manner to understand radiative corrections and coupling constant evolution in TGD framework.

A strong physical argument in favor of  $CD$ s is the finding that the quantized proper time distance between the tips of  $CD$  fixed to be an octave of a fundamental time scale defined by  $CP_2$  happens to define fundamental biological time scale for electron,  $u$  quark and  $d$  quark [K22] : there would be a deep connection between elementary particle physics and living matter leading to testable predictions.

### 2.5.4 Modified Dirac action

The construction of the spinor structure for the world of classical worlds (WCW) leads to the vision that second quantized modified Dirac equation codes for the entire quantum TGD. Among other things this would mean that Dirac determinant would define the vacuum functional of the theory having interpretation as the exponent of Kähler function of WCW and Kähler function would reduce to Kähler action for a preferred extremal of Kähler action. In this chapter the recent view about the modified Dirac action are explained in more detail.

#### Identification of the modified Dirac action

The modified Dirac action involves several terms. The first one is 4-dimensional assignable to Kähler action. Second term is instanton term reducible to an expression restricted to wormhole throats or any light-like 3-surfaces parallel to them in the slicing of space-time surface by light-like 3-surfaces. The third term is assignable to Chern-Simons term and has interpretation as a measurement interaction term linear in Cartan algebra of the isometry group of the imbedding space in order to obtain stringy propagators and also to realize coupling between the quantum numbers associated with super-conformal representations and space-time geometry required by quantum classical correspondence.

This means that 3-D light-like wormhole throats carry induced spinor field which can be regarded as independent degrees of freedom having the spinor fields at partonic 2-surfaces as sources and acting as 3-D sources for the 4-D induced spinor field. The most general measurement interaction would involve the corresponding coupling also for Kähler action but is not physically motivated. There are good arguments in favor of Chern-Simons Dirac action and corresponding measurement interaction.

1. A correlation between 4-D geometry of space-time sheet and quantum numbers is achieved by the identification of exponent of Kähler function as Dirac determinant making possible the entanglement of classical degrees of freedom in the interior of space-time sheet with quantum numbers.

2. Cartan algebra plays a key role not only at quantum level but also at the level of space-time geometry since quantum critical conserved currents vanish for Cartan algebra of isometries and the measurement interaction terms giving rise to conserved currents are possible only for Cartan algebras. Furthermore, modified Dirac equation makes sense only for eigen states of Cartan algebra generators. The hierarchy of Planck constants realized in terms of the book like structure of the generalized imbedding space assigns to each  $CD$  (causal diamond) preferred Cartan algebra: in case of Poincare algebra there are two of them corresponding to linear and cylindrical  $M^4$  coordinates.
3. Quantum holography and dimensional reduction hierarchy in which partonic 2-surface defined fermionic sources for 3-D fermionic fields at light-like 3-surfaces  $Y_l^3$  in turn defining fermionic sources for 4-D spinors find an elegant realization. Effective 2-dimensionality is achieved if the replacement of light-like wormhole throat  $X_l^3$  with light-like 3-surface  $Y_l^3$  "parallel" with it in the definition of Dirac determinant corresponds to the  $U(1)$  gauge transformation  $K \rightarrow K + f + \bar{f}$  for Kähler function of WCW so that WCW Kähler metric is not affected. Here  $f$  is holomorphic function of WCW ("world of classical worlds") complex coordinates and arbitrary function of zero mode coordinates.
4. An elegant description of the interaction between super-conformal representations realized at partonic 2-surfaces and dynamics of space-time surfaces is achieved since the values of Cartan charges are feeded to the 3-D Dirac equation which also receives mass term at the same time. Almost topological QFT at wormhole throats results at the limit when four-momenta vanish: this is in accordance with the original vision about TGD as almost topological QFT.
5. A detailed view about the physical role of quantum criticality results. Quantum criticality fixes the values of Kähler coupling strength as the analog of critical temperature. Quantum criticality implies that second variation of Kähler action vanishes for critical deformations and the existence of conserved current except in the case of Cartan algebra of isometries. Quantum criticality allows to fix the values of couplings appearing in the measurement interaction by using the condition  $K \rightarrow K + f + \bar{f}$ . p-Adic coupling constant evolution can be understood also and corresponds to scale hierarchy for the sizes of causal diamonds ( $CD$ s).
6. The inclusion of imaginary instanton term to the definition of the modified gamma matrices is not consistent with the conjugation of the induced spinor fields. Measurement interaction can be however assigned to both Kähler action and its instanton term. CP breaking, irreversibility and the space-time description of dissipation are closely related and the CP and T oddness of the instanton part of the measurement interaction term could provide first level description for dissipative effects. It must be however emphasized that the mere addition of instanton term to Kähler function could be enough.
7. A radically new view about matter antimatter asymmetry based on zero energy ontology emerges and one could understand the experimental absence of antimatter as being due to the fact antimatter corresponds to negative energy states. The identification of bosons as wormhole contacts is the only possible option in this framework.
8. Almost stringy propagators and a consistency with the identification of wormhole throats as lines of generalized Feynman diagrams is achieved. The notion of bosonic emergence leads to a long sought general master formula for the  $M$ -matrix elements. The counterpart for fermionic loop defining bosonic inverse propagator at QFT limit is wormhole contact with fermion and cutoffs in mass squared and hyperbolic angle for loop momenta of fermion and antifermion in the rest system of emitting boson have precise geometric counterpart.

### Hyper-quaternionicity and quantum criticality

The conjecture that quantum critical space-time surfaces are hyper-quaternionic in the sense that the modified gamma matrices span a quaternionic subspace of complexified octonions at each point of the space-time surface is consistent with what is known about preferred extremals. The condition that both the modified gamma matrices and spinors are quaternionic at each point of the space-time surface leads to a precise ansatz for the general solution of the modified Dirac equation making sense

also in the real context. The octonionic version of the modified Dirac equation is very simple since  $SO(7, 1)$  vielbein group is replaced with  $G_2$  acting as automorphisms of octonions so that only the neutral Abelian part of the classical electro-weak gauge fields survives the map.

Octonionic gamma matrices provide also a non-associative representation for the 8-D version of Pauli sigma matrices and encourage the identification of 8-D twistors as pairs of octonionic spinors conjectured to be highly relevant also for quantum TGD. Quaternionicity condition implies that octo-twistors reduce to something closely related to ordinary twistors.

### The exponent of Kähler function as Dirac determinant for the modified Dirac action

Although quantum criticality in principle predicts the possible values of Kähler coupling strength, one might hope that there exists even more fundamental approach involving no coupling constants and predicting even quantum criticality and realizing quantum gravitational holography.

1. The Dirac determinant defined by the product of Dirac determinants associated with the light-like partonic 3-surfaces  $X_l^3$  associated with a given space-time sheet  $X^4$  is the simplest candidate for vacuum functional identifiable as the exponent of the Kähler function. Individual Dirac determinant is defined as the product of eigenvalues of the dimensionally reduced modified Dirac operator  $D_{K,3}$  and there are good arguments suggesting that the number of eigenvalues is finite. p-Adicization requires that the eigenvalues belong to a given algebraic extension of rationals. This restriction would imply a hierarchy of physics corresponding to different extensions and could automatically imply the finiteness and algebraic number property of the Dirac determinants if only finite number of eigenvalues would contribute. The regularization would be performed by physics itself if this were the case.
2. It remains to be proven that the product of eigenvalues gives rise to the exponent of Kähler action for the preferred extremal of Kähler action. At this moment the only justification for the conjecture is that this the only thing that one can imagine.
3. A long-standing conjecture has been that the zeros of Riemann Zeta are somehow relevant for quantum TGD. Riemann zeta is however naturally replaced Dirac zeta defined by the eigenvalues of  $D_{K,3}$  and closely related to Riemann Zeta since the spectrum consists essentially for the cyclotron energy spectra for localized solutions region of non-vanishing induced Kähler magnetic field and hence is in good approximation integer valued up to some cutoff integer. In zero energy ontology the Dirac zeta function associated with these eigenvalues defines "square root" of thermodynamics assuming that the energy levels of the system in question are expressible as logarithms of the eigenvalues of the modified Dirac operator defining kind of fundamental constants. Critical points correspond to approximate zeros of Dirac zeta and if Kähler function vanishes at criticality as it indeed should, the thermal energies at critical points are in first order approximation proportional to zeros themselves so that a connection between quantum criticality and approximate zeros of Dirac zeta emerges.
4. The discretization induced by the number theoretic braids reduces the world of classical worlds to effectively finite-dimensional space and configuration space Clifford algebra reduces to a finite-dimensional algebra. The interpretation is in terms of finite measurement resolution represented in terms of Jones inclusion  $\mathcal{M} \subset \mathcal{N}$  of HFFs with  $\mathcal{M}$  taking the role of complex numbers. The finite-D quantum Clifford algebra spanned by fermionic oscillator operators is identified as a representation for the coset space  $\mathcal{N}/\mathcal{M}$  describing physical states modulo measurement resolution. In the sectors of generalized imbedding space corresponding to non-standard values of Planck constant quantum version of Clifford algebra is in question.

#### 2.5.5 Three Dirac operators and their interpretation

The physical interpretation of Kähler Dirac equation is not at all straightforward. The following arguments inspired by effective 2-dimensionality suggest that the modified gamma matrices and corresponding effective metric could allow dual gravitational description of the physics associated with wormhole throats. This applies in particular to condensed matter physics.

### Three Dirac equations

To begin with, Dirac equation appears in three forms in TGD.

1. The Dirac equation in world of classical worlds codes for the super Virasoro conditions for the super Kac-Moody and similar representations formed by the states of wormhole contacts forming the counterpart of string like objects (throats correspond to the ends of the string. This Dirac generalizes the Dirac of 8-D imbedding space by bringing in vibrational degrees of freedom. This Dirac equation should give as its solutions zero energy states and corresponding M-matrices generalizing S-matrix and their collection defining the unitary U-matrix whose natural application appears in consciousness theory as a coder of what Penrose calls U-process.
2. There is generalized eigenvalue equation for Chern-Simons Dirac operator at light-like wormhole throats. The generalized eigenvalue is  $p^k \gamma_k$ . The interpretation of pseudo-momentum  $p^k$  has been a problem but twistor Grassmannian approach suggests strongly that it can be interpreted as the counterpart of equally mysterious region momentum appearing in momentum twistor Grassmannian approach to  $\mathcal{N} = 4$  SYM. The pseudo-/region momentum  $p$  is quantized (this does not spoil the basics of Grassmannian residues integral approach) and  $1/p^k \gamma_k$  defines propagator in lines of generalized Feynman diagrams. The Yangian symmetry discovered generalizes in a very straightforward manner and leads also to the realization that TGD could allow also a twistorial formulation in terms of product  $CP_3 \times CP_3$  of two twistor spaces [?]. General arguments lead to a proposal for explicit form for the solutions of field equation represented identified as holomorphic 6-surfaces in this space subject to additional partial differential equations for homogenous functions of projective twistor coordinates suggesting strongly the quantal interpretation as analogs of partial waves. Therefore quantum-classical correspondence would be realized in beautiful manner.
3. There is Kähler Dirac equation in the interior of space-time. In this equation the gamma matrices are replaced with modified gamma matrices defined by the contractions of canonical momentum currents  $T_k^\alpha = \partial L / \partial_\alpha h^k$  with imbedding space gamma matrices  $\Gamma_k$ . This replacement is required by internal consistency and by super-conformal symmetries.

Could Kähler Dirac equation provide a first principle justification for the light-hearted use of effective mass and the analog of Dirac equation in condensed matter physics? This would conform with the holographic philosophy. Partonic 2-surfaces with tangent space data and their light-like orbits would give hologram like representation of physics and the interior of space-time the 4-D representation of physics. Holography would have in the recent situation interpretation also as quantum classical correspondence between representations of physics in terms of quantized spinor fields at the light-like 3-surfaces on one hand and in terms of classical fields on the other hand.

The resulting dispersion relation for the square of the Kähler-Dirac operator assuming that induced like metric, Kähler field, etc. are very slowly varying contains quadratic and linear terms in momentum components plus a term corresponding to magnetic moment coupling. In general massive dispersion relation is obtained as is also clear from the fact that Kähler Dirac gamma matrices are combinations of  $M^4$  and  $CP_2$  gammas so that modified Dirac mixes different  $M^4$  chiralities (basic signal for massivation). If one takes into account the dependence of the induced geometric quantities on space-time point dispersion relations become non-local.

### Does energy metric provide the gravitational dual for condensed matter systems?

The modified gamma matrices define an effective metric via their anticommutators which are quadratic in components of energy momentum tensor (canonical momentum densities). This effective metric vanishes for vacuum extremals. Note that the use of modified gamma matrices guarantees among other things internal consistency and super-conformal symmetries of the theory. The physical interpretation has remained obscure hitherto although corresponding effective metric for Chern-Simons Dirac action has now a clear physical interpretation.

If the above argument is on the right track, this effective metric should have applications in condensed matter theory. In fact, energy metric has a natural interpretation in terms of effective light velocities which depend on direction of propagation. One can diagonalize the energy metric  $g_e^{\alpha\beta}$  (contravariant form results from the anticommutators) and one can denote its eigenvalues by  $(v_0, v_i)$  in

the case that the signature of the effective metric is  $(1, -1, -1, -1)$ . The 3-vector  $v_i/v_0$  has interpretation as components of effective light velocity in various directions as becomes clear by thinking the d'Alembert equation for the energy metric. This velocity field could be interpreted as that of hydrodynamic flow. The study of the extremals of Kähler action shows that if this flow is actually Beltrami flow so that the flow parameter associated with the flow lines extends to global coordinate, Kähler action reduces to a 3-D Chern-Simons action and one obtains effective topological QFT. The conserved fermion current  $\bar{\Psi}\Gamma_e^\alpha\Psi$  has interpretation as incompressible hydrodynamical flow.

This would give also a nice analogy with AdS/CFT correspondence allowing to describe various kinds of physical systems in terms of higher-dimensional gravitation and black holes are introduced quite routinely to describe condensed matter systems. In TGD framework one would have an analogous situation but with 10-D space-time replaced with the interior of 4-D space-time and the boundary of AdS representing Minkowski space with the light-like 3-surfaces carrying matter. The effective gravitation would correspond to the "energy metric". One can associate with it curvature tensor, Ricci tensor and Einstein tensor using standard formulas and identify effective energy momentum tensor associated as Einstein tensor with effective Newton's constant appearing as constant of proportionality. Note however that the besides ordinary metric and "energy" metric one would have also the induced classical gauge fields having purely geometric interpretation and action would be Kähler action. This 4-D holography would provide a precise, dramatically simpler, and also a very concrete dual description. This cannot be said about model of graphene based on the introduction of 10-dimensional black holes, branes, and strings chosen in more or less ad hoc manner.

This raises questions. Does this give a general dual gravitational description of dissipative effects in terms of the "energy" metric and induced gauge fields? Does one obtain the counterparts of black holes? Do the general theorems of general relativity about the irreversible evolution leading to black holes generalize to describe analogous fate of condensed matter systems caused by dissipation? Can one describe non-equilibrium thermodynamics and self-organization in this manner?

One might argue that the incompressible Beltrami flow defined by the dynamics of the preferred extremals is dissipationless and viscosity must therefore vanish locally. The failure of complete non-determinism of Kähler action however means generation of entropy since the knowledge about the state decreases gradually. This in turn should have a phenomenological local description in terms of viscosity which characterizes the transfer of energy to shorter scales and eventually to radiation. The deeper description should be non-local and basically topological and might lead to quantization rules. For instance, one can imagine the quantization of the ratio  $\eta/s$  of the viscosity to entropy density as multiples of a basic unit defined by its lower bound (note that this would be analogous to Quantum Hall effect). For the first M-theory inspired derivation of the lower bound of  $\eta/s$  [?]. The lower bound for  $\eta/s$  is satisfied in good approximation by what should have been QCD plasma but found to be something different (RHIC and the first evidence for new physics from LHC [K43]).

An encouraging sign comes from the observation that for so called massless extremals representing classically arbitrarily shaped pulses of radiation propagating without dissipation and dispersion along single direction the canonical momentum currents are light-like. The effective contravariant metric vanishes identically so that fermions cannot propagate in the interior of massless extremals! This is of course the case also for vacuum extremals. Massless extremals are purely bosonic and represent bosonic radiation. Many-sheeted space-time decomposes into matter containing regions and radiation containing regions. Note that when wormhole contact (particle) is glued to a massless extremal, it is deformed so that  $CP_2$  projection becomes 4-D guaranteeing that the weak form of electric magnetic duality can be satisfied. Therefore massless extremals can be seen as asymptotic regions. Perhaps one could say that dissipation corresponds to a decoherence process creating space-time sheets consisting of matter and radiation. Those containing matter might be even seen as analogs blackholes as far as energy metric is considered.

### Preferred extremals as perfect fluids

Almost perfect fluids seems to be abundant in Nature. For instance, QCD plasma was originally thought to behave like gas and therefore have a rather high viscosity to entropy density ratio  $x = \eta/s$ . Already RHIC found that it however behaves like almost perfect fluid with  $x$  near to the minimum predicted by AdS/CFT. The findings from LHC gave additional confirm the discovery [?]. Also Fermi gas is predicted on basis of experimental observations to have at low temperatures a low viscosity roughly 5-6 times the minimal value [?]. In the following the argument that the preferred extremals

of Kähler action are perfect fluids apart from the symmetry breaking to space-time sheets is developed. The argument requires some basic formulas summarized first.

The detailed definition of the viscous part of the stress energy tensor linear in velocity (oddness in velocity relates directly to second law) can be found in [?] .

1. The symmetric part of the gradient of velocity gives the viscous part of the stress-energy tensor as a tensor linear in velocity. Velocity gradient decomposes to a term traceless tensor term and a term reducing to scalar.

$$\partial_i v_j + \partial_j v_i = \frac{2}{3} \partial_k v^k g_{ij} + (\partial_i v_j + \partial_j v_i - \frac{2}{3} \partial_k v^k g_{ij}) . \quad (2.5.1)$$

The viscous contribution to stress tensor is given in terms of this decomposition as

$$\sigma_{visc;ij} = \zeta \partial_k v^k g_{ij} + \eta (\partial_i v_j + \partial_j v_i - \frac{2}{3} \partial_k v^k g_{ij}) . \quad (2.5.2)$$

From  $dF^i = T^{ij} S_j$  it is clear that bulk viscosity  $\zeta$  gives to energy momentum tensor a pressure like contribution having interpretation in terms of friction opposing. Shear viscosity  $\eta$  corresponds to the traceless part of the velocity gradient often called just viscosity. This contribution to the stress tensor is non-diagonal and corresponds to momentum transfer in directions not parallel to momentum and makes the flow rotational. This term is essential for the thermal conduction and thermal conductivity vanishes for ideal fluids.

2. The 3-D total stress tensor can be written as

$$\sigma_{ij} = \rho v_i v_j - p g_{ij} + \sigma_{visc;ij} . \quad (2.5.3)$$

The generalization to a 4-D relativistic situation is simple. One just adds terms corresponding to energy density and energy flow to obtain

$$T^{\alpha\beta} = (\rho - p) u^\alpha u^\beta + p g^{\alpha\beta} - \sigma_{visc}^{\alpha\beta} . \quad (2.5.4)$$

Here  $u^\alpha$  denotes the local four-velocity satisfying  $u^\alpha u_\alpha = 1$ . The sign factors relate to the conventions in the definition of Minkowski metric  $((1, -1, -1, -1))$ .

3. If the flow is such that the flow parameters associated with the flow lines integrate to a global flow parameter one can identify new time coordinate  $t$  as this flow parameter. This means a transition to a coordinate system in which fluid is at rest everywhere (comoving coordinates in cosmology) so that energy momentum tensor reduces to a diagonal term plus viscous term.

$$T^{\alpha\beta} = (\rho - p) g^{tt} \delta_t^\alpha \delta_t^\beta + p g^{\alpha\beta} - \sigma_{visc}^{\alpha\beta} . \quad (2.5.5)$$

In this case the vanishing of the viscous term means that one has perfect fluid in strong sense. The existence of a global flow parameter means that one has

$$v_i = \Psi \partial_i \Phi . \quad (2.5.6)$$

$\Psi$  and  $\Phi$  depend on space-time point. The proportionality to a gradient of scalar  $\Phi$  implies that  $\Phi$  can be taken as a global time coordinate. If this condition is not satisfied, the perfect fluid property makes sense only locally.

AdS/CFT correspondence allows to deduce a lower limit for the coefficient of shear viscosity as

$$x = \frac{\eta}{s} \geq \frac{\hbar}{4\pi} . \quad (2.5.7)$$

This formula holds true in units in which one has  $k_B = 1$  so that temperature has unit of energy.

What makes this interesting from TGD view is that in TGD framework perfect fluid property in appropriately generalized sense indeed characterizes locally the preferred extremals of Kähler action defining space-time surface.

1. Kähler action is Maxwell action with U(1) gauge field replaced with the projection of  $CP_2$  Kähler form so that the four  $CP_2$  coordinates become the dynamical variables at QFT limit. This means enormous reduction in the number of degrees of freedom as compared to the ordinary unifications. The field equations for Kähler action define the dynamics of space-time surfaces and this dynamics reduces to conservation laws for the currents assignable to isometries. This means that the system has a hydrodynamic interpretation. This is a considerable difference to ordinary Maxwell equations. Notice however that the "topological" half of Maxwell's equations (Faraday's induction law and the statement that no non-topological magnetic are possible) is satisfied.
2. Even more, the resulting hydrodynamical system allows an interpretation in terms of a perfect fluid. The general ansatz for the preferred extremals of field equations assumes that various conserved currents are proportional to a vector field characterized by so called Beltrami property. The coefficient of proportionality depends on space-time point and the conserved current in question. Beltrami fields by definition is a vector field such that the time parameters assignable to its flow lines integrate to single global coordinate. This is highly non-trivial and one of the implications is almost topological QFT property due to the fact that Kähler action reduces to a boundary term assignable to wormhole throats which are light-like 3-surfaces at the boundaries of regions of space-time with Euclidian and Minkowskian signatures. The Euclidian regions (or wormhole throats, depends on one's tastes ) define what I identify as generalized Feynman diagrams.

Beltrami property means that if the time coordinate for a space-time sheet is chosen to be this global flow parameter, all conserved currents have only time component. In TGD framework energy momentum tensor is replaced with a collection of conserved currents assignable to various isometries and the analog of energy momentum tensor complex constructed in this manner has no counterparts of non-diagonal components. Hence the preferred extremals allow an interpretation in terms of perfect fluid without any viscosity.

This argument justifies the expectation that TGD Universe is characterized by the presence of low-viscosity fluids. Real fluids of course have a non-vanishing albeit small value of  $x$ . What causes the failure of the exact perfect fluid property?

1. Many-sheetedness of the space-time is the underlying reason. Space-time surface decomposes into finite-sized space-time sheets containing topologically condensed smaller space-time sheets containing.... Only within given sheet perfect fluid property holds true and fails at wormhole contacts and because the sheet has a finite size. As a consequence, the global flow parameter exists only in given length and time scale. At imbedding space level and in zero energy ontology the phrasing of the same would be in terms of hierarchy of causal diamonds (CDs).
2. The so called eddy viscosity is caused by eddies (vortices) of the flow. The space-time sheets glued to a larger one are indeed analogous to eddies so that the reduction of viscosity to eddy viscosity could make sense quite generally. Also the phase slippage phenomenon of super-conductivity meaning that the total phase increment of the super-conducting order parameter is reduced by a multiple of  $2\pi$  in phase slippage so that the average velocity proportional to the increment of the phase along the channel divided by the length of the channel is reduced by a quantized amount.

The standard arrangement for measuring viscosity involves a lipid layer flowing along plane. The velocity of flow with respect to the surface increases from  $v = 0$  at the lower boundary to

$v_{upper}$  at the upper boundary of the layer: this situation can be regarded as outcome of the dissipation process and prevails as long as energy is feeded into the system. The reduction of the velocity in direction orthogonal to the layer means that the flow becomes rotational during dissipation leading to this stationary situation.

This suggests that the elementary building block of dissipation process corresponds to a generation of vortex identifiable as cylindrical space-time sheets parallel to the plane of the flow and orthogonal to the velocity of flow and carrying quantized angular momentum. One expects that vortices have a spectrum labelled by quantum numbers like energy and angular momentum so that dissipation takes in discrete steps by the generation of vortices which transfer the energy and angular momentum to environment and in this manner generate the velocity gradient.

3. The quantization of the parameter  $x$  is suggestive in this framework. If entropy density and viscosity are both proportional to the density  $n$  of the eddies, the value of  $x$  would equal to the ratio of the quanta of entropy and kinematic viscosity  $\eta/n$  for single eddy if all eddies are identical. The quantum would be  $\hbar/4\pi$  in the units used and the suggestive interpretation is in terms of the quantization of angular momentum. One of course expects a spectrum of eddies so that this simple prediction should hold true only at temperatures for which the excitation energies of vortices are above the thermal energy. The increase of the temperature would suggest that gradually more and more vortices come into play and that the ratio increases in a stepwise manner bringing in mind quantum Hall effect. In TGD Universe the value of  $\hbar$  can be large in some situations so that the quantal character of dissipation could become visible even macroscopically. Whether this a situation with large  $\hbar$  is encountered even in the case of QCD plasma is an interesting question.

The following poor man's argument tries to make the idea about quantization a little bit more concrete.

1. The vortices transfer momentum parallel to the plane from the flow. Therefore they must have momentum parallel to the flow given by the total cm momentum of the vortex. Before continuing some notations are needed. Let the densities of vortices and absorbed vortices be  $n$  and  $n_{abs}$  respectively. Denote by  $v_{\parallel}$  resp.  $v_{\perp}$  the components of cm momenta parallel to the main flow resp. perpendicular to the plane boundary plane. Let  $m$  be the mass of the vortex. Denote by  $S$  parallel to the boundary plane.
2. The flow of momentum component parallel to the main flow due to the absorbed at  $S$  is

$$n_{abs} m v_{\parallel} v_{\perp} S .$$

This momentum flow must be equal to the viscous force

$$F_{visc} = \eta \frac{v_{\parallel}}{d} \times S .$$

From this one obtains

$$\eta = n_{abs} m v_{\perp} d .$$

If the entropy density is due to the vortices, it equals apart from possible numerical factors to

$$s = n$$

so that one has

$$\frac{\eta}{s} = m v_{\perp} d .$$

This quantity should have lower bound  $x = \hbar/4\pi$  and perhaps even quantized in multiples of  $x$ , Angular momentum quantization suggests strongly itself as origin of the quantization.

3. Local momentum conservation requires that the comoving vortices are created in pairs with opposite momenta and thus propagating with opposite velocities  $v_{\perp}$ . Only one half of vortices is absorbed so that one has  $n_{abs} = n/2$ . Vortex has quantized angular momentum associated with its internal rotation. Angular momentum is generated to the flow since the vortices flowing downwards are absorbed at the boundary surface.

Suppose that the distance of their center of mass lines parallel to plane is  $D = \epsilon d$ ,  $\epsilon$  a numerical constant not too far from unity. The vortices of the pair moving in opposite direction have same angular momentum  $mv D/2$  relative to their center of mass line between them. Angular momentum conservation requires that the sum these relative angular momenta cancels the sum of the angular momenta associated with the vortices themselves. Quantization for the total angular momentum for the pair of vortices gives

$$\frac{\eta}{s} = \frac{n\hbar}{\epsilon}$$

Quantization condition would give

$$\epsilon = 4\pi .$$

One should understand why  $D = 4\pi d$  - four times the circumference for the largest circle contained by the boundary layer- should define the minimal distance between the vortices of the pair. This distance is larger than the distance  $d$  for maximally sized vortices of radius  $d/2$  just touching. This distance obviously increases as the thickness of the boundary layer increases suggesting that also the radius of the vortices scales like  $d$ .

4. One cannot of course take this detailed model too literally. What is however remarkable that quantization of angular momentum and dissipation mechanism based on vortices identified as space-time sheets indeed could explain why the lower bound for the ratio  $\eta/s$  is so small.

### Is the effective metric one- or two-dimensional?

The following argument suggests that the effective metric defined by the anti-commutators of the modified gamma matrices is effectively one- or two-dimensional. Effective one-dimensionality would conform with the observation that the solutions of the modified Dirac equations can be localized to one-dimensional world lines in accordance with the vision that finite measurement resolution implies discretization reducing partonic many-particle states to quantum superpositions of braids. This localization to 1-D curves occurs always at the 3-D orbits of the partonic 2-surfaces.

The argument is based on the following assumptions.

1. The modified gamma matrices for Kähler action are contractions of the canonical momentum densities  $T_k^{\alpha}$  with the gamma matrices of  $H$ .
2. The strongest assumption is that the isometry currents

$$J^{A\alpha} = T_k^{\alpha} j^{Ak}$$

for the preferred extremals of Kähler action are of form

$$J^{A\alpha} = \Psi^A (\nabla \Phi)^{\alpha} \tag{2.5.8}$$

with a common function  $\Phi$  guaranteeing that the flow lines of the currents integrate to coordinate lines of single global coordinate variables (Beltrami property). Index raising is carried out by using the ordinary induced metric.

3. A weaker assumption is that one has two functions  $\Phi_1$  and  $\Phi_2$  assignable to the isometry currents of  $M^4$  and  $CP_2$  respectively.:

$$\begin{aligned} J_1^{A\alpha} &= \Psi_1^A (\nabla \Phi_1)^\alpha , \\ J_2^{A\alpha} &= \Psi_2^A (\nabla \Phi_2)^\alpha . \end{aligned} \quad (2.5.9)$$

The two functions  $\Phi_1$  and  $\Phi_2$  could define dual light-like curves spanning string world sheet. In this case one would have effective 2-dimensionality and decomposition to string world sheets [?] . Isometry invariance does not allow more than two independent scalar functions  $\Phi_i$ .

Consider now the argument.

1. One can multiply both sides of this equation with  $j^{Ak}$  and sum over the index  $A$  labeling isometry currents for translations of  $M^4$  and  $SU(3)$  currents for  $CP_2$ . The tensor quantity  $\sum_A j^{Ak} j^{Al}$  is invariant under isometries and must therefore satisfy

$$\sum_A \eta_{AB} j^{Ak} j^{Al} = h^{kl} , \quad (2.5.10)$$

where  $\eta_{AB}$  denotes the flat tangent space metric of  $H$ . In  $M^4$  degrees of freedom this statement becomes obvious by using linear Minkowski coordinates. In the case of  $CP_2$  one can first consider the simpler case  $S^2 = CP_1 = SU(2)/U(1)$ . The coset space property implies in standard complex coordinate transforming linearly under  $U(1)$  that only the the isometry currents belonging to the complement of  $U(1)$  in the sum contribute to the identity holds true at the origin and by the symmetric space property everywhere. Identity can be verified also directly in standard spherical coordinates. The argument generalizes to the case of  $CP_2 = SU(3)/U(2)$  in an obvious manner.

2. In the most general case one obtains

$$\begin{aligned} T_1^{\alpha k} &= \sum_A \Psi_1^A j^{Ak} \times (\nabla \Phi_1)^\alpha \equiv f_1^k (\nabla \Phi_1)^\alpha , \\ T_2^{\alpha k} &= \sum_A \Psi_2^A j^{Ak} \times (\nabla \Phi_2)^\alpha \equiv f_2^k (\nabla \Phi_2)^\alpha . \end{aligned} \quad (2.5.11)$$

3. The effective metric given by the anti-commutator of the modified gamma matrices is in turn is given by

$$G^{\alpha\beta} = m_{kl} f_1^k f_1^l (\nabla \Phi_1)^\alpha (\nabla \Phi_1)^\beta + s_{kl} f_2^k f_2^l (\nabla \Phi_2)^\alpha (\nabla \Phi_2)^\beta . \quad (2.5.12)$$

The covariant form of the effective metric is effectively 1-dimensional for  $\Phi_1 = \Phi_2$  in the sense that the only non-vanishing component of the covariant metric  $G_{\alpha\beta}$  is diagonal component along the coordinate line defined by  $\Phi \equiv \Phi_1 = \Phi_2$ . Also the contravariant metric is effectively 1-dimensional since the index raising does not affect the rank of the tensor but depends on the other space-time coordinates. This would correspond to an effective reduction to a dynamics of point-like particles for given selection of braid points. For  $\Phi_1 \neq \Phi_2$  the metric is effectively 2-dimensional and would correspond to stringy dynamics.

One can also develop an objection to effective 1- or 2-dimensionality. The proposal for what preferred extremals of Kähler action as deformations of the known extremals of Kähler action could be leads to a beautiful ansatz relying on generalization of conformal invariance and minimal surface equations of string model [K9]. The field equations of TGD reduce to those of classical string model generalized to 4-D context.

If the proposed picture is correct, field equations reduce to purely algebraically conditions stating that the Maxwellian energy momentum tensor for the Kähler action has no common index pairs with the second fundamental form. For the deformations of  $CP_2$  type vacuum extremals  $T$  is a complex tensor of type (1,1) and second fundamental form  $H^k$  a tensor of type (2,0) and (0,2) so that  $Tr(TH^k) = 0$  is true. This requires that second light-like coordinate of  $M^4$  is constant so that the  $M^4$  projection is 3-dimensional. For Minkowskian signature of the induced metric Hamilton-Jacobi structure replaces conformal structure. Here the dependence of  $CP_2$  coordinates on second light-like coordinate of  $M^2(m)$  only plays a fundamental role. Note that now  $T^{vv}$  is non-vanishing (and light-like). This picture generalizes to the deformations of cosmic strings and even to the case of vacuum extremals.

There is however an important consistency condition involved. The Maxwell energy momentum tensor for Kähler action must have vanishing covariant divergence. This is satisfied if it is linear combination of Einstein tensor and metric. This gives Einstein's equations with cosmological term in the general case. By the algebraic character of field equations also minimal surface equations are satisfied and Einstein's General Relativity would be exact part of TGD.

In the case of modified Dirac equation the result means that modified gamma matrices are contractions of linear combination of Einstein tensor and metric tensor with the induced gamma matrices so that the TGD counterpart of ordinary Dirac equation would be modified by the addition of a term proportional to Einstein tensor. The condition of effective 1- or 2-dimensionality seems to pose too strong conditions on this combination.

## 2.6 The role of twistors in quantum TGD

### 2.6.1 Could the Grassmannian program be realized in TGD framework?

In the following the TGD based modification of the approach based on zero energy ontology is discussed in some detail. It is found that pseudo-momenta are very much analogous to region momenta and the approach leading to discretization of pseudo-mass squared for virtual particles - and even the discretization of pseudo-momenta - is consistent with the Grassmannian approach in the simple case considered and allow to get rid of IR divergences. Also the possibility that the number of generalized Feynman diagrams contributing to a given scattering amplitude is finite so that the recursion formula for the scattering amplitudes would involve only a finite number of steps (maximum number of loops) is considered. One especially promising feature of the residue integral approach with discretized pseudo-momenta is that it makes sense also in the p-adic context in the simple special case discussed since residue integral reduces to momentum integral (summation) and lower-dimensional residue integral.

#### What Yangian symmetry could mean in TGD framework?

The loss of the Yangian symmetry in the integrations over the region momenta  $x^a$  ( $p^a = x^{a+1} - x^a$ ) assigned to virtual momenta seems to be responsible for many ugly features. It is basically the source of IR divergences regulated by "moving out on the Coulomb branch theory" so that IR singularities remain the problem of the theory. This raises the question whether the loss of Yangian symmetry is the signature for the failure of QFT approach and whether the restriction of loop momentum integrations to avoid both kind of divergences might be a royal road beyond QFT. In TGD framework zero energy ontology indeed leads to to a concrete proposal based on the vision that virtual particles are something genuinely real.

The detailed picture is of course far from clear but to get an idea about what is involved one can look what kind of assumptions are needed if one wants to realize the dream that only a finite number of generalized Feynman diagrams contribute to a scattering amplitude which is Yangian invariant allowing a description using a generalization of the Grassmannian integrals.

1. Assume the bosonic emergence and its super-symmetric generalization holds true. This means that incoming and outgoing states are bound states of massless fermions assignable to wormhole throats but the fermions can opposite directions of three-momenta making them massive. Incoming and outgoing particles would consist of fermions associated with wormhole throats and would be characterized by a pair of twistors in the general situation and in general massive. This allows also string like mass squared spectrum for bound states having fermion and antifermion at the ends of the string as well as more general  $n$ -particle bound states. Hence one can speak also about the emergence of string like objects. For virtual particles the fermions would be massive and have discrete mass spectrum. Also super partners containing several collinear fermions and antifermions at a given throat are possible. Collinearity is required by the generalization of SUSY. The construction of these states bring strongly in mind the merge procedure involving the replacement  $Z^{n+1} \rightarrow Z^n$ .
2. The basic question is how the momentum twistor diagrams and the ordinary Feynman diagrams behind them are related to the generalized Feynman diagrams.
  - (a) It is good to start from a common problem. In momentum twistor approach the relationship of region momenta to physical momenta remains somewhat mysterious. In TGD framework in turn the relationship of pseudo-momenta identified as generalized eigenvalues of the Chern-Simons Dirac operator at the lines of Feynman diagram (light-like wormhole throats) to the physical momenta has remained unclear. The identification of the pseudo-momentum as the TGD counterpart of the region momentum  $x$  looks therefore like a natural first guess.
  - (b) The identification  $x_{a+1} - x_a = p_a$  with  $p_a$  representing light-like physical four-momentum generalizes in obvious manner. Also the identification of the light-like momentum of the external parton as pseudo-momentum looks natural. What is important is that this does not require the identification of the pseudo-momenta propagating along internal lines of generalized Feynman diagram as actual physical momenta since pseudo-momentum just like  $x$  is fixed only apart from an overall shift. The identification allows the physical four-momenta associated with the wormhole throats to be always on mass shell and massless: if the sign of the physical energy can be also negative space-like momentum exchanges become possible.
  - (c) The pseudo-momenta and light-like physical massless momenta at the lines of generalized Feynman diagrams on one hand, and region momenta and the light-like momenta associated with the collinear singularities on the other hand would be in very similar mutual relationship. Partonic 2-surfaces can carry large number of collinear light-like fermions and bosons since super-symmetry is extended. Generalized Feynman diagrams would be analogous to momentum twistor diagrams if this picture is correct and one could hope that the recursion relations of the momentum twistor approach generalize.
3. The discrete mass spectrum for pseudo-momentum would in the momentum twistor approach mean the restriction of  $x$  to discrete mass shells, and the obvious reason for worry is that this might spoil the Grassmannian approach relying heavily on residue integrals and making sense also  $p$ -adically. It seems however that there is no need to worry. In [?] the  $M_{6,4,l=0}(1234AB)$  the integration over twistor variables  $z_A$  and  $z_B$  using "entangled" integration contour leads to 1-loop MHV amplitude  $N^p MHV$ ,  $p = 1$ . The parametrization of the integration contour is  $z_A = (\lambda_A, x\lambda_A)$ ,  $z_B = (\lambda_B, x\lambda_B)$ , where  $x$  is the  $M^4$  coordinate representing the loop momentum. This boils down to an integral over  $CP_1 \times CP_1 \times M^4$  [?]. The integrals over spheres  $CP_1$ s are contour integrals so that only an ordinary integral over  $M^4$  remains. The reduction to this kind of sums occurs completely generally thanks to the recursion formula.
4. The obvious implication of the restriction of the pseudo-momenta  $x$  on massive mass shells is the absence of IR divergences and one might hope that under suitable assumptions one achieves Yangian invariance. The first question is of course whether the required restriction of  $x$  to mass shells in  $z_A$  and  $z_B$  or possibly even algebraic discretization of momenta is consistent with the Yangian invariance. This seems to be the case: the integration contour reduces to entangled integration contour in  $CP_1 \times CP_1$  not affected by the discretization and the resulting loop integral differs from the standard one by the discretization of masses and possibly also momenta

with massless states excluded. Whether Yangian invariance poses also conditions on mass and momentum spectrum is an interesting question.

5. One can consider also the possibility that the incoming and outgoing particles - in general massive and to be distinguished from massless fermions appearing as their building blocks- have actually small masses presumably related to the IR cutoff defined by the size scale of the largest causal diamond involved. p-Adic thermodynamics could be responsible for this mass. Also the binding of the wormhole throats can give rise to a small contribution to vacuum conformal weight possibly responsible for gauge boson masses. This would imply that a given n-particle state can decay to N-particle states for which  $N$  is below some limit. The fermions inside loops would be also massive. This allows to circumvent the IR singularities due to integration over the phase space of the final states (say in Coulomb scattering).
6. The representation of the off mass shell particles as pairs of wormhole throats with non-parallel four-momenta (in the simplest case only the three-momenta need be in opposite directions) makes sense and that the particles in question are on mass shell with mass squared being proportional to inverse of a prime number as the number theoretic vision applied to the modified Dirac equation suggests. On mass shell property poses extremely powerful constraints on loops and when the number of the incoming momenta in the loop increases, the number of constraints becomes larger than the number of components of loop momentum for the generic values of the external momenta. Therefore there are excellent hopes of getting rid of UV divergences.

A stronger assumption encouraged by the classical space-time picture about virtual particles is that the 3-momenta associated with throats of the same wormhole contact are always in same or opposite directions. Even this allows to have virtual momentum spectrum and non-trivial mass spectrum for them assuming that the three momenta are opposite.

7. The best that one can hope is that only a finite number of generalized Feynman diagrams contributes to a given reaction. This would guarantee that amplitudes belong to a finite-dimensional algebraic extension of rational functions with rational coefficients since finite sums do not lead out from a finite algebraic extension of rationals. The first problem are self energy corrections. The assumption that the mass non-renormalization theorems of SUSYs generalize to TGD framework would guarantee that the loops contributing to fermionic propagators (and their super-counterparts) do not affect them. Also the iteration of more complex amplitudes as analogs of ladder diagrams representing sequences of reactions  $M \rightarrow M_1 \rightarrow M_2 \cdots \rightarrow N$  such that at each  $M_n$  in the sequence can appear as on mass shell state could give a non-vanishing contribution to the scattering amplitude and would mean infinite number of Feynman diagrams unless these amplitudes vanish. If  $N$  appears as a virtual state the fermions must be however massive on mass shell fermions by the assumption about on-mass shell states and one can indeed imagine a situation in which the decay  $M \rightarrow N$  is possible when  $N$  consists of states made of massless fermions is possible but not when the fermions have non-vanishing masses. This situation seems to be consistent with unitarity. The implication would be that the recursion formula for the all loop amplitudes for a given reaction would give vanishing result for some critical value of loops.

Already these assumptions give good hopes about a generalization of the momentum Grassmann approach to TGD framework. Twistors are doubled as are also the Grassmann variables and there are wave functions correlating the momenta of the the fermions associated with the opposite wormhole throats of the virtual particles as well as incoming gauge bosons which have suffered massivation. Also wave functions correlating the massless momenta at the ends of string like objects and more general many parton states are involved but do not affect the basic twistor formalism. The basic question is whether the hypothesis of unbroken Yangian symmetry could in fact imply something resembling this picture. The possibility to discretize integration contours without losing the representation as residue integral quite generally is basic prerequisite for this and should be shown to be true.

### How to achieve Yangian invariance without trivial scattering amplitudes?

In  $\mathcal{N} = 4$  SYM the Yangian invariance implies that the MHV amplitudes are constant as demonstrated in [?]. This would mean that the loop contributions to the scattering amplitudes are trivial. Therefore the breaking of the dual super-conformal invariance by IR singularities of the integrand is absolutely

essential for the non-triviality of the theory. Could the situation be different in TGD framework? Could it be possible to have non-trivial scattering amplitudes which are Yangian invariants. Maybe! The following heuristic argument is formulated in the language of super-twistors.

1. The dual conformal super generators of the super-Lie algebra  $U(2, 2)$  acting as super vector fields reducing effectively to the general form  $J = \eta_a^K \partial / \partial Z_a^J$  and the condition that they annihilate scattering amplitudes implies that they are constant as functions of twistor variables. When particles are replaced with pairs of wormhole throats the super generators are replaced by sums  $J_1 + J_2$  of these generators for the two wormhole throats and it might be possible to achieve the condition

$$(J_1 + J_2)M = 0 \quad (2.6.1)$$

with a non-trivial dependence on the momenta if the super-components of the twistors associated with the wormhole throats are in a linear relationship. This should be the case for bound states.

2. This kind of condition indeed exists. The condition that the sum of the super-momenta expressed in terms of super-spinors  $\lambda$  reduces to the sum of real momenta alone is not usually posed but in the recent case it makes sense as an additional condition to the super-components of the the spinors  $\lambda$  associated with the bound state. This quadratic condition is exactly of the same general form as the one following from the requirement that the sum of all external momenta vanishes for scattering amplitude and reads as

$$X = \lambda_1 \eta_1 + \lambda_2 \eta_2 = 0 \quad (2.6.2)$$

The action of the generators  $\eta_1 \partial_{\lambda_1} + \eta_2 \partial_{\lambda_2}$  forming basic building blocks of the super generators on  $p_1 + p_2 = \lambda_1 \lambda_1 + \lambda_2 \lambda_2$  appearing as argument in the scattering amplitude in the case of bound states gives just the quantity  $X$ , which vanishes so that one has super-symmetry. The generalization of this condition to n-parton bound state is obvious.

3. The argument does not apply to free fermions which have not suffered topological condensation and are therefore represented by  $CP_2$  type vacuum extremal with single wormhole throat. If one accepts the weak form of electric-magnetic duality, one can circumvent this difficulty. The free fermions carry Kähler magnetic charge whereas physical fermions are accompanied by a bosonic wormhole throat carrying opposite Kähler magnetic charge and opposite electroweak isospin so that a ground state of string like object with size of order electroweak length scale is in question. In the case of quarks the Kähler magnetic charges need not be opposite since color confinement could involve Kähler magnetic confinement: electro-weak confinement holds however true also now. The above argument generalizes as such to the pairs formed by wormhole throats at the ends of string like object. One can of course imagine also more complex hybrids of these basic options but the general idea remains the same.

Note that the argument involves in an essential manner non-locality, which is indeed the defining property of the Yangian algebra and also the fact that physical particles are bound states. The massivation of the physical particles brings in the IR cutoff.

### Number theoretical constraints on the pseudo-momenta

One can consider also further assumptions motivated by the recent view about the generalized eigenvalues of Chern-Simons Dirac operator having interpretation as pseudo-momentum. The details of this view need not of course be final.

1. Assume that the pseudo-momentum assigned to fermion lines by the modified Dirac equation [?] is the counterpart of region momentum as already explained and therefore does not directly correspond to the actual light-like four-momentum associated with partonic line of the generalized Feynman diagram. This assumption conforms with the assumption that incoming particles are built out of massless partonic fermions. It also implies that the propagators are massless propagators as required by twistorialization and Yangian generalization of super-conformal invariance.
2. Since (pseudo)-mass squared is number theoretically quantized as the length of a hyper-complex prime in preferred plane  $M^2$  of pseudo-momentum space fermionic propagators are massless propagators with pseudo-masses restricted on discrete mass shells. Lorentz invariance suggests that  $M^2$  cannot be common to all particles but corresponds to preferred reference frame for the virtual particle having interpretation as plane spanned by the quantization axes of energy and spin.
3. Hyper-complex primeness means also the quantization of pseudo-momentum components so that one has hyper-complex primes of form  $\pm((p+1)/2, \pm(p-1)/1)$  corresponding to pseudo-mass squared  $M^2 = p$  and hypercomplex primes  $\pm(p, 0)$  with pseudo-mass squared  $M^2 = p^2$ . Space-like fermionic momenta are not needed since for opposite signs of energy wormhole throats can have space-like net momenta. If space-like pseudo-momenta are allowed/needed for some reason, they could correspond to space-like hyper-complex primes  $\pm((p-1)/2, \pm(p+1)/1)$  and  $\pm(0, p)$  so that one would obtain also discretization of space-like mass shells also. The number theoretical mass squared is proportional to  $p$ , whereas p-adic mass squared is proportional to  $1/p$ . For p-adic mass calculations canonical identification  $\sum x_n p^n$  maps p-adic mass squared to its real counterpart. The simplest mapping consistent with this would be  $(p_0, p_1) \rightarrow (p_0, p_1)/p$ . This could be assumed from the beginning in real context and would mean that the mass squared scale is proportional to  $1/p$ .
4. Lorentz invariance requires that the preferred coordinate system in which this holds must be analogous to the rest system of the virtual fermion and thus depends on the virtual particle. In accordance with the general vision discussed in [?] Lorentz invariance could correspond to a discrete algebraic subgroup of Lorentz group spanned by transformation matrices expressible in terms of roots of unity. This would give a discrete version of mass shell and the preferred coordinate system would have a precise meaning also in the real context. Unless one allows algebraic extension of p-adic numbers p-adic mass shell reduces to the set of above number-theoretic momenta. For algebraic extensions of p-adic numbers the same algebraic mass shell is obtained as in real correspondence and is essential for the number theoretic universality. The interpretation for the algebraic discretization would be in terms of a finite measurement resolution. In real context this would mean discretization inducing a decomposition of the mass shell to cells. In the p-adic context each discrete point would be replaced with a p-adic continuum. As far as loop integrals are considered, this vision means that they make sense in both real and p-adic context and reduce to summations in p-adic context. This picture is discussed in detail in [?] .
5. Concerning p-adicization the beautiful aspect of residue integral is that it makes sense also in p-adic context provided one can circumvent the problems related to the identification of p-adic counterpart of  $\pi$  requiring infinite-dimensional transcendental extension coming in powers of  $\pi$ . Together with the discretization of both real and virtual four-momenta this would allow to define also p-adic variants of the scattering amplitudes.

### Could recursion formula allow interpretation in terms of zero energy ontology?

The identification of pseudo-momentum as a counterpart of region momentum suggests that generalized Feynman diagrams could be seen as a generalization of momentum twistor diagrams. Of course, the generalization from  $\mathcal{N} = 4$  SYM to TGD is an enormous step in complexity and one must take all proposals in the following with a big grain of salt. For instance, the replacement of point-like particles with wormhole throats and the decomposition of gauge bosons to pairs of wormhole throats means that naive generalizations are dangerous.

With this in firmly in mind one can ask whether the recursion formula could allow interpretation in terms of zero energy states assigned to causal diamonds (*CDs*) containing *CDs* containing  $\dots$ . In this framework loops could be assigned with sub-*CDs*.

The interpretation of the leading order singularities forming the basic building blocks of the twistor approach in zero ontology is the basic source of questions. Before posing these questions recall the basic proposal that partonic fermions are massless but opposite signs of energy are possible for the opposite throats of wormhole contacts. Partons would be on mass shell but besides physical states identified as bound states formed from partons also more general intermediate states would be possible but restricted by momentum conservation and mass shell conditions for partons at vertices. Consider now the questions.

1. Suppose that the massivation of virtual fermions and their super partners allows only ladder diagrams in which the intermediate states contain on mass shell massless states. Should one allow this kind of ladder diagrams? Can one identify them in terms of leading order singularities? Could one construct the generalized Feynman diagrams from Yangian invariant tree diagrams associated with the hierarchy of sub-*CDs* and using BCFW bridges and entangled pairs of massless states having interpretation as box diagrams with on mass shell momenta at microscopic level? Could it make sense to say that scattering amplitudes are represented by tree diagrams inside *CDs* in various scales and that the fermionic momenta associated with throats and emerging from sub-*CDs* are always massless?
2. Could BCFW bridge generalizes as such and could the interpretation of BCFW bridge be in terms of a scattering in which the four on mass shell massless partonic states (partonic throats have arbitrary fermion number) are exchanged between four sub-*CDs*. This admittedly looks somewhat artificial.
3. Could the addition of 2-particle zero energy state responsible for addition of loop in the recursion relations and having interpretation in terms of the cutting of line carrying loop momentum correspond to an addition of sub-*CD* such that the 2-particle zero energy state has its positive and negative energy part on its past and future boundaries? Could this mean that one cuts a propagator line by adding *CD* and leaves only the portion of the line within *CD*. Could the reverse operation mean to the addition of zero energy "thermally entangled" states in shorter time and length scales and assignable as a zero energy state to a sub-*CD*. Could one interpret the Cutkosky rule for propagator line in terms of this cutting or its reversal. Why only pairs would be needed in the recursion formula? Why not more general states? Does the recursion formula imply that they are included? Does this relate to the fact that these zero energy states have interpretation as single particle states in the positive energy ontology and that the basic building block of Feynman diagrams is single particle state? Could one regard the unitarity as an identity which states that the discontinuity of T-matrix characterizing zero energy state over cut is expressible in terms of  $TT^\dagger$  and  $T$  matrix is the relevant quantity?

Maybe it is again dangerous to try to draw too detailed correspondences: after all, point like particles are replaced by partonic two-surfaces in TGD framework.

4. If I have understood correctly the genuine  $l$ -loop term results from  $l - 1$ -loop term by the addition of the zero energy pair and integration over  $GL(2)$  as a representative of loop integral reducing  $n + 2$  to  $n$  and calculating the added loop at the same time [?] . The integrations over the two momentum twistor variables associated with a line in twistor space defining off mass shell four-momentum and integration over the lines represent the integration over loop momentum. The reduction to  $GL(2)$  integration should result from the delta functions relating the additional momenta to  $GL(2)$  variables (note that  $GL(2)$  performs linear transformations in the space spanned by the twistors  $Z_A$  and  $Z_B$  and means integral over the positions of  $Z_A$  and  $Z_B$ ). The resulting object is formally Yangian invariant but IR divergences along some contours of integration breaks Yangian symmetry.

The question is what happens in TGD framework. The previous arguments suggests that the reduction of the the loop momentum integral to integrals over discrete mass shells and possibly to a sum over their discrete subsets does not spoil the reduction to contour integrals for loop integrals in the example considered in [?] . Furthermore, the replacement of mass continuum

with a discrete set of mass shells should eliminate IR divergences and might allow to preserve Yangian symmetry. One can however wonder whether the loop corrections with on mass shell massless fermions are needed. If so, one would have at most finite number of loop diagrams with on mass shell fermionic momenta and one of the TGD inspired dreams already forgotten would be realized.

### What about unitarity?

The approach of Arkani-Hamed and collaborators means that loop integral over four-momenta are replaced with residue integrals around a small sphere  $p^2 = \epsilon$ . This is very much reminiscent of my own proposal for a few years ago based on the idea that the condition of twistorialization forces to accept only massless virtual states [?, ?]. I of course soon gave up this proposal as too childish.

This idea seems to however make a comeback in a modified form. At this time one would have only massive and quantized pseudo-momenta located at discrete mass shells. Can this picture be consistent with unitarity?

Before trying to answer this question one must make clear what one could assume in TGD framework.

1. Physical particles are in the general case massive and consist of collinear fermions at wormhole throats. External partons at wormhole throats must be massless to allow twistorial interpretation. Therefore massive states emerge. This applies also to stringy states.
2. The simplest assumption generalizing the childish idea is that on mass shell massless states for partons appear as both virtual particles and external particles. Space-like virtual momentum exchanges are possible if the virtual particles can consist of pairs of positive and negative energy fermions at opposite wormhole throats. Hence also partons at internal lines should be massless and this raises the question about the identification of propagators.
3. Generalized eigenvalue equation for Chern-Simons Dirac operator implies that virtual elementary fermions have massive and quantized pseudo-momenta whereas external elementary fermions are massless. The massive pseudo-momentum assigned with the Dirac propagator of a parton line cannot be identified with the massless real momentum assigned with the fermionic propagator line. The region momenta introduced in Grassmannian approach are something analogous.

As already explained, this brings in mind is the identification of this pseudo momentum as the counterpart of the region momentum of momentum twistor diagrams so that the external massless fermionic momenta would be differences of the pseudo-momenta. Indeed, since region momenta are determined apart from a common shift, they need not correspond to real momenta. Same applies to pseudo-momenta and one could assume that both internal and external fermion lines carry light-like pseudo-momenta and that external pseudo-momenta are equal to real momenta.

4. This picture has natural correspondence with twistor diagrams. For instance, the region momentum appearing in BCFW bridge defining effective propagator is in general massive although the underlying Feynman diagram would contain on-line massless momenta. In TGD framework massless lines of Feynman graphs associated with singularities would correspond to real momenta of massless fermions at wormhole throats. Also other canonical operations for Yangian invariants involve light-like momenta at the level of Feynman diagrams and would in TGD framework have a natural identification in terms of partonic momenta. Hence partonic picture would provide a microscopic description for the lines of twistor diagrams.

Let us assume being virtual particle means only that the discretized pseudo-momentum is on shell but massive whereas all real momenta of partons are light-like, and that negative partonic energies are possible. Can one formulate Cutkosky rules for unitarity in this framework? What could the unitarity condition

$$iDisc(T - T^\dagger) = -TT^\dagger$$

mean now? In particular, are the cuts associated with mass shells of physical particles or with mass shells of pseudo-momenta? Could these two assignments be equivalent?

1. The restriction of the partons to be massless but having both signs of energy means that the spectrum of intermediate states contains more states than the external states identified as bound states of partons with the same sign of energy. Therefore the summation over intermediate states does not reduce to a mere summation over physical states but involves a summation over states formed from massless partons with both signs of energy so that also space-like momentum exchanges become possible.
2. The understanding of the unitarity conditions in terms of Cutkosky rules would require that the cuts of the loop integrands correspond to mass shells for the virtual states which are also physical states. Therefore real momenta have a definite sign and should be massless. Besides this bound state conditions guaranteeing that the mass spectrum for physical states is discrete must be assumed. With these assumptions the unitary cuts would not be assigned with the partonic light-cones but with the mass shells associated of physical particles.
3. There is however a problem. The pseudo-momenta of partons associated with the external partons are assumed to be light-like and equal to the physical momenta.
  - (a) If this holds true also for the intermediate physical states appearing in the unitarity conditions, the pseudo-momenta at the cuts are light-like and cuts must be assigned with pseudo-momentum light-cones. This could bring in IR singularities and spoil Yangian symmetry. The formation of bound states could eliminate them and the size scale of the largest  $CD$  involved would bring in a natural IR cutoff as the mass scale of the lightest particle. This assumption would however force to give up the assumption that only massive pseudo-momenta appear at the lines of the generalized Feynman diagrams.
  - (b) On the other hand, if pseudo-momenta are not regarded as a property of physical state and are thus allowed to be massive for the real intermediate states in Cutkosky rules, the cuts at parton level correspond to on mass shell hyperboloids and IR divergences are absent.

### 2.6.2 Could TGD allow formulation in terms of twistors

There are many questions to be asked. There would be innumerable questions upwelling from my very incomplete understanding of the technical issues. In the following I restrict only to the questions which relate to the relationship of TGD approach to Witten's twistor string approach [?] and M-theory like frameworks. The arguments lead to an explicit proposal how the preferred extremals of Kähler action could correspond to holomorphic 4-surfaces in  $CP_3 \times CP_3$ . The basic motivation for this proposal comes from the observation that Kähler action is Maxwell action for the induced Kähler form and metric. Hence Penrose's original twistorial representation for the solutions of linear Maxwell's equations could have a generalization to TGD framework.

#### $M^4 \times CP_2$ from twistor approach

The first question which comes to mind relates to the origin of the Grassmannians. Do they have some deeper interpretation in TGD context. In twistor string theory Grassmannians relate to the moduli spaces of holomorphic surfaces defined by string world sheets in twistor space. Could partonic 2-surfaces have analogous interpretation and could one assign Grassmannians to their moduli spaces? If so, one could have rather direct connection with topological QFT defining twistor strings [?] and the almost topological QFT defining TGD. There are some hints to this direction which could be of course seen as figments of a too wild imagination.

1. The geometry of  $CD$  brings strongly in mind Penrose diagram for the conformally compactified Minkowski space [?], which indeed becomes  $CD$  when its points are replaced with spheres. This would suggest the information theoretic idea about interaction between observer and externals as a map in which  $M^4$  is mapped to its conformal compactification represented by  $CD$ . Compactification means that the light-like points at the light-like boundaries of  $CD$  are identified and the physical counterpart for this in TGD framework is conformal invariance along light-rays along the boundaries of  $CD$ . The world of conscious observer for which  $CD$  is identified as a geometric correlate would be conformally compactified  $M^4$  (plus  $CP_2$  or course).

2. Since the points of the conformally compactified  $M^4$  correspond to twistor pairs [?], which are unique only apart from opposite complex scalings, it would be natural to assign twistor space to  $CD$  and represent its points as pairs of twistors. This suggests an interpretation for the basic formulas of Grassmannian approach involving integration over twistors. The incoming and outgoing massless particles could be assigned at point-like limit light-like points at the lower and upper boundaries of  $CD$  and the lifting of the points of the light-cone boundary at partonic surfaces would give rise to the description in terms of ordinary twistors. The assumption that massless collinear fermions at partonic 2-surfaces are the basic building blocks of physical particles at partonic 2-surfaces defined as many particles states involving several partonic 2-surfaces would lead naturally to momentum twistor description in which massless momenta and described by twistors and virtual momenta in terms of twistor pairs. It is important to notice that in TGD framework string like objects would emerge from these massless fermions.
3. Partonic 2-surfaces are located at the upper and lower light-like boundaries of the causal diamond ( $CD$ ) and carry energies of opposite sign in zero energy ontology. Quite generally, one can assign to the point of the conformally compactified Minkowski space a twistor pair using the standard description. The pair of twistors is determined apart from  $Gl(2)$  rotation. At the light-cone boundary  $M^4$  points are light-like so that the two spinors of the two twistors differ from each other only by a complex scaling and single twistor is enough to characterize the space-time point this degenerate situation. The components of the twistor are related by the well known twistor equation  $\mu^{a'} = -ix^{aa'}\lambda_a$ . One can therefore lift each point of the partonic 2-surface to single twistor determined apart from opposite complex scalings of  $\mu$  and  $\lambda$  so that the lift of the point would be 2-sphere. In the general case one must lift the point of  $CD$  to a twistor pair. The degeneracy of the points is given by  $Gl(2)$  and each point corresponds to a 2-sphere in projective twistor space.
4. The new observation is that one can understand also  $CP_2$  factor in twistor framework. The basic observation about which I learned in [?] (giving also a nice description of basics of twistor geometry) is that a pair  $(X, Y)$  of twistors defines a point of  $CD$  on one hand and complex 2-planes of the dual twistor space -which is nothing but  $CP_2$ - by the equations

$$X_\alpha W^\alpha = 0 \quad , \quad Y_\alpha W^\alpha = 0 \quad .$$

The intersection of these planes is the complex line  $CP_1 = S^2$ . The action of  $G(2)$  on the twistor pair affects the pair of surfaces  $CP_2$  determined by these equations since it transforms the equations to their linear combination but not the the point of conformal  $CD$  resulting as projection of the sphere. Therefore twistor pair defines both a point of  $M^4$  and assigns with it pair of  $CP_2$ :s represented as holomorphic surfaces of the projective dual twistor space. Hence the union over twistor pairs defines  $M^4 \times CP_2$  via this assignment if it is possible to choose "the other"  $CP_2$  in a unique manner for all points of  $M^4$ . The situation is similar to the assignment of a twistor to a point in the Grassmannian diagrams forming closed polygons with light-like edges. In this case one assigns to the the "region momenta" associated with the edge the twistor at the either end of the edge. One possible interpretation is that the two  $CP_2$ :s correspond to the opposite ends of the  $CD$ . My humble hunch is that this observation might be something very deep.

Recall that the assignment of  $CP_2$  to  $M^4$  point works also in another direction.  $M^8 - H$  duality associates with so called hyper-quaternionic 4-surface of  $M^8$  allowing preferred hyper-complex plane at each point 4-surfaces of  $M^4 \times CP_2$ . The basic observation behind this duality is that the hyper-quaternionic planes (copies of  $M^4$ ) with preferred choices of hyper-complex plane  $M^2$  are parameterized by points of  $CP_2$ . One can therefore assign to a point of  $CP_2$  a copy of  $M^4$ . Maybe these both assignments indeed belong to the core of quantum TGD. There is also an interesting analogy with Uncertainty Principle: complete localization in  $M^4$  implies maximal uncertainty of the point in  $CP_2$  and vice versa.

### Does twistor string theory generalize to TGD?

With this background the key speculative questions seem to be the following ones.

1. Could one relate twistor string theory to TGD framework? Partonic 2-surfaces at the boundaries of  $CD$  are lifted to 4-D sphere bundles in twistor space. Could they serve as a 4-D counterpart for Witten's holomorphic twistor strings assigned to point like particles? Could these surfaces be actually lifts of the holomorphic curves of twistor space replaced with the product  $CP_3 \times CP_2$  to 4-D sphere bundles? If I have understood correctly, the Grassmannians  $G(n, k)$  can be assigned to the moduli spaces of these holomorphic curves characterized by the degree of the polynomial expressible in terms of genus, number of negative helicity gluons, and the number of loops for twistor diagram.

Could one interpret  $G(n, k)$  as a moduli space for the  $\delta CD$  projections of  $n$  partonic 2-surfaces to which  $k$  negative helicity gluons and  $n - k$  positive helicity gluons are assigned (or something more complex when one considers more general particle states)? Could quantum numbers be mapped to integer valued algebraic invariants? If so, there would be a correlation between the geometry of the partonic 2-surface and quantum numbers in accordance with quantum classical correspondence.

2. Could one understand light-like orbits of partonic 2-surfaces and space-time surfaces in terms of twistors? To each point of the 2-surface one can assign a 2-sphere in twistor space  $CP_3$  and  $CP_2$  in its dual. These  $CP_2$ s can be identified. One should be able to assign to each sphere  $S^2$  at least one point of corresponding  $CP_2$ s associated with its points in the dual twistor space and identified as single  $CP_2$  union of  $CP_2$ :s in the dual twistor space a point of  $CP_2$  or even several of them. One should be also able to continue this correspondence so that it applies to the light-like orbit of the partonic 2-surface and to the space-time surface defining a preferred extremal of Kähler action. For space-time sheets representable as graph of a map  $M^4 \rightarrow CP_2$  locally one should select from a  $CP_2$  assigned with a particular point of the space-time sheet a unique point of corresponding  $CP_2$  in a manner consistent with field equations. For surfaces with lower dimensional  $M^4$  projection one must assign a continuum of points of  $CP_2$  to a given point of  $M^4$ . What kind equations-could allow to realize this assignment? Holomorphy is strongly favored also by the number theoretic considerations since in this case one has hopes of performing integrals using residue calculus.

- (a) Could two holomorphic equations in  $CP_3 \times CP_2$  defining 6-D surfaces as sphere bundles over  $M^4 \times CP_2$  characterize the preferred extremals of Kähler action? Could partonic 2-surfaces be obtained by posing an additional holomorphic equation reducing twistors to null twistors and thus projecting to the boundaries of  $CD$ ? A philosophical justification for this conjecture comes from effective 2-dimensionality stating that partonic 2-surfaces plus their 4-D tangent space data code for physics. That the dynamics would reduce to holomorphy would be an extremely beautiful result. Of course this is only an additional item in the list of general conjectures about the classical dynamics for the preferred extremals of Kähler action.
- (b) One could also work in  $CP_3 \times CP_3$ . The first  $CP_3$  would represent twistors endowed with a metric conformally equivalent to that of  $M^{2,4}$  and having the covering of  $SU(2, 2)$  of  $SO(2, 4)$  as isometries. The second  $CP_3$  defining its dual would have a metric consistent with the Calabi-Yau structure (having holonomy group  $SU(3)$ ). Also the induced metric for canonically imbedded  $CP_2$ s should be the standard metric of  $CP_2$  having  $SU(3)$  as its isometries. In this situation the linear equations assigning to  $M^4$  points twistor pairs and  $CP_2 \subset CP_3$  as a complex plane would hold always true. Besides this two holomorphic equations coding for the dynamics would be needed.
- (c) The issues related to the induced metric are important. The conformal equivalence class of  $M^4$  metric emerges from the 5-D light-cone of  $M^{2,4}$  under projective identification. The choice of a proper projective gauge would select  $M^4$  metric locally. Twistors inherit the conformal metric with signature  $(2, 4)$  from the metric of 4+4 component spinors with metric having  $(4, 4)$  signature. One should be able to assign a conformal equivalence class of Minkowski metric with the orbits of pairs of twistors modulo  $GL(2)$ . The metric of conformally compactified  $M^4$  would be obtained from this metric by dropping from the line element the contribution to the  $S^2$  fiber associated with  $M^4$  point.

- (d) Witten related [?] the degree  $d$  of the algebraic curve describing twistor string, its genus  $g$ , the number  $k$  of negative helicity gluons, and the number  $l$  of loops by the following formula

$$d = k - 1 + l \quad , \quad g \leq l \quad . \quad (2.6.3)$$

One should generalize the definition of the genus so that it applies to 6-D surfaces. For projective complex varieties of complex dimension  $n$  this definition indeed makes sense. Algebraic genus [?] is expressible in terms of the dimensions of the spaces of closed holomorphic forms known as Hodge numbers  $h^{p,q}$  as

$$g = \sum (-1)^{n-k} h^{k,0} \quad . \quad (2.6.4)$$

The first guess is that the formula of Witten generalizes by replacing genus with its algebraic counterpart . This requires that the allowed holomorphic surfaces are projective curves of twistor space, that is described in terms of homogenous polynomials of the 4+4 projective coordinates of  $CP_3 \times CP_3$ .

### What is the relationship of TGD to M-theory and F-theory?

There are also questions relating to the possible relationship to M-theory and F-theory.

1. Calabi-Yau-manifolds [?, ?] are central for the compactification in super string theory and emerge from the condition that the super-symmetry breaks down to  $\mathcal{N} = 1$  SUSY. The dual twistor space  $CP_3$  with Euclidian signature of metric is a Calabi-Yau manifold [?] . Could one have in some sense two Calabi-Yaus! Twistorial  $CP_3$  can be interpreted as a four-fold covering and conformal compactification of  $M^{2,4}$ . I do not know whether Calabi-Yau property has a generalization to the situation when Euclidian metric is replaced with a conformal equivalence class of flat metrics with Minkowskian signature and thus having a vanishing Ricci tensor. As far as differential forms (no dependence on metric) are considered there should be no problems. Whether the replacement of the maximal holonomy group  $SU(3)$  with its non-compact version  $SU(1,2)$  makes sense is not clear to me.
2. The lift of the  $CD$  to projective twistor space would replace  $CD \times CP_2$  with 10-dimensional space which inspires the familiar questions about connection between TGD and M-theory. If Calabi-Yau with a Minkowskian signature of metric makes sense then the Calabi-Yau of the standard M-theory would be replaced with its Minkowskian counterpart! Could it really be that M-theory like theory based on  $CP_3 \times CP_2$  reduces to TGD in  $CD \times CP_2$  if an additional symmetry mapping 2-spheres of  $CP_3$  to points of  $CD$  is assumed? Could the formulation based on 12-D  $CP_3 \times CP_3$  correspond to F-theory which also has two time-like dimensions. Of course, the additional conditions defined by the maps to  $M^4$  and  $CP_2$  would remove the second time-like dimension which is very difficult to justify on purely physical grounds.
3. One can actually challenge the assumption that the first  $CP_3$  should have a conformal metric with signature (2,4). Metric appears nowhere in the definition holomorphic functions and once the projections to  $M^4$  and  $CP_2$  are known, the metric of the space-time surface is obtained from the metric of  $M^4 \times CP_2$ . The previous argument for the necessity of the presence of the information about metric in the second order differential equation however suggests that the metric is needed.
4. The beginner might ask whether the 6-D 2-sphere bundles representing space-time sheets could have interpretation as Calabi-Yau manifolds. In fact, the Calabi-Yau manifolds defined as complete intersections in  $CP_3 \times CP_3$  discovered by Tian and Yau are defined by three polynomials [?] . Two of them have degree 3 and depend on the coordinates of single  $CP_3$  only whereas the third is bilinear in the coordinates of the  $CP_3$ :s. Obviously the number of these manifolds is quite too small (taking into account scaling the space defined by the coefficients is 6-dimensional). All these manifolds are deformation equivalent. These manifolds have Euler characteristic  $\chi = \pm 18$

and a non-trivial fundamental group. By dividing this manifold by  $Z_3$  one obtains  $\chi = \pm 6$ , which guarantees that the number of fermion generations is three in heterotic string theory. This manifold was the first one proposed to give rise to three generations and  $\mathcal{N} = 1$  SUSY.

### What could the field equations be in twistorial formulation?

The fascinating question is whether one can identify the equations determining the 3-D complex surfaces of  $CP_3 \times CP_3$  in turn determining the space-time surfaces.

The first thing is to clarify in detail how space-time  $M^4 \times CP_2$  results from  $CP_3 \times CP_3$ . Each point  $CP_3 \times CP_3$  define a line in third  $CP_3$  having interpretation as a point of conformally compactified  $M^4$  obtained by sphere bundle projection. Each point of either  $CP_3$  in turn defines  $CP_2$  in in fourth  $CP_3$  as a 2-plane. Therefore one has  $(CP_3 \times CP_3) \times (CP_3 \times CP_3)$  but one can reduce the consideration to  $CP_3 \times CP_3$  fixing  $M^4 \times CP_2$ . In the generic situation 6-D surface in 12-D  $CP_3 \times CP_3$  defines 4-D surface in the dual  $CP_3 \times CP_3$  and its sphere bundle projection defines a 4-D surface in  $M^4 \times CP_2$ .

1. The vanishing of three holomorphic functions  $f^i$  would characterize 3-D holomorphic surfaces of 6-D  $CP_3 \times CP_3$ . These are determined by three real functions of three real arguments just like a holomorphic function of single variable is dictated by its values on a one-dimensional curve of complex plane. This conforms with the idea that initial data are given at 3-D surface. Note that either the first or second  $CP_3$  can determine the  $CP_2$  image of the holomorphic 3-surface unless one assumes that the holomorphic functions are symmetric under the exchange of the coordinates of the two  $CP_3$ s. If symmetry is not assumed one has some kind of duality.
2. Effective 2-dimensionality means that 2-D partonic surfaces plus 4-D tangent space data are enough. This suggests that the 2 holomorphic functions determining the dynamics satisfy some second order differential equation with respect to their three complex arguments: the value of the function and its derivative would correspond to the initial values of the imbedding space coordinates and their normal derivatives at partonic 2-surface. Since the effective 2-dimensionality brings in dependence on the induced metric of the space-time surface, this equation should contain information about the induced metric.
3. The no-where vanishing holomorphic 3-form  $\Omega$ , which can be regarded as a "complex square root" of volume form characterizes 6-D Calabi-Yau manifold [?, ?], indeed contains this information albeit in a rather implicit manner but in spirit with TGD as almost topological QFT philosophy. Both  $CP_3$ s are characterized by this kind of 3-form if Calabi-Yau with (2, 4) signature makes sense.
4. The simplest second order- and one might hope holomorphic- differential equation that one can imagine with these ingredients is of the form

$$\Omega_1^{i_1 j_1 k_1} \Omega_2^{i_2 j_2 k_2} \partial_{i_1 i_2} f^1 \partial_{j_1 j_2} f^2 \partial_{k_1 k_2} f^3 = 0, \quad \partial_{ij} \equiv \partial_i \partial_j. \quad (2.6.5)$$

Since  $\Omega_i$  is by its antisymmetry equal to  $\Omega_i^{123} \epsilon^{ijk}$ , one can divide  $\Omega^{123}$ s away from the equation so that one indeed obtains holomorphic solutions. Note also that one can replace ordinary derivatives in the equation with covariant derivatives without any effect so that the equations are general coordinate invariant.

One can consider more complex equations obtained by taking instead of  $(f^1, f^2, f^3)$  arbitrary combinations  $(f^i, f^j, f^k)$  which results uniquely if one assumes anti-symmetrization in the labels (1, 2, 3). In the sequel only this equation is considered.

5. The metric disappears completely from the equations and skeptic could argue that this is inconsistent with the fact that it appears in the equations defining the weak form of electric-magnetic duality as a Lagrange multiplier term in Chern-Simons action. Optimist would respond that the representation of the 6-surfaces as intersections of three hyper-surfaces is different from the representation as imbedding maps  $X^4 \rightarrow H$  used in the usual formulation so that the argument does not bite, and continue by saying that the metric emerges in any case when one endows space-time with the induced metric given by projection to  $M^4$ .

6. These equations allow infinite families of obvious solutions. For instance, when some  $f^i$  depends on the coordinates of either  $CP_3$  only, the equations are identically satisfied. As a special case one obtains solutions for which  $f^1 = Z \cdot W$  and  $(f^2, f^3) = (f^2(Z), f^3(W))$ . This family contains also the Calabi-Yau manifold found by Yau and Tian, whose factor space was proposed as the first candidate for a compactification consistent with three fermion families.
7. One might hope that an infinite non-obvious solution family could be obtained from the ansatz expressible as products of exponential functions of  $Z$  and  $W$ . Exponentials are not consistent with the assumption that the functions  $f_i$  are homogenous polynomials of finite degree in projective coordinates so that the following argument is only for the purpose for learning something about the basic character of the equations.

$$\begin{aligned}
 f^1 &= E_{a_1, a_2, a_3}(Z) E_{\hat{a}_1, \hat{a}_2, \hat{a}_3}(W) \ , & f^2 &= E_{b_1, b_2, b_3}(Z) E_{\hat{b}_1, \hat{b}_2, \hat{b}_3}(W) \ , \\
 f^3 &= E_{c_1, c_2, c_3}(Z) E_{\hat{c}_1, \hat{c}_2, \hat{c}_3}(W) \ , & & (2.6.6) \\
 E_{a, b, c}(Z) &= \exp(az_1) \exp(bz_2) \exp(cz_3) \ .
 \end{aligned}$$

The parameters  $a, b, c$ , and  $\hat{a}, \hat{b}, \hat{c}$  can be arbitrary real numbers in real context. By the basic properties of exponential functions the field equations are algebraic. The conditions reduce to the vanishing of the products of determinants  $\det(a, b, c)$  and  $\det(\hat{a}, \hat{b}, \hat{c})$  so that the vanishing of either determinant is enough. Therefore the dependence can be arbitrary either in  $Z$  coordinates or in  $W$  coordinates. Linear superposition holds for the modes for which determinant vanishes which means that the vectors  $(a, b, c)$  or  $(\hat{a}, \hat{b}, \hat{c})$  are in the same plane.

Unfortunately, the vanishing conditions reduce to the conditions  $f^i(W) = 0$  for case a) and to  $f^i(Z) = 0$  for case b) so that the conditions are equivalent with those obtained by putting the "wave vector" to zero and the solutions reduce to obvious ones. The lesson is that the equations do not commute with the multiplication of the functions  $f^i$  with nowhere vanishing functions of  $W$  and  $Z$ . The equation selects a particular representation of the surfaces and one might argue that this should not be the case unless the hyper-surfaces defined by  $f^i$  contain some physically relevant information. One could consider the possibility that the vanishing conditions are replaced with conditions  $f^i = c_i$  with  $f^i(0) = 0$  in which case the information would be coded by a family of space-time surfaces obtained by varying  $c_i$ .

One might criticize the above equations since they are formulated directly in the product  $CP_3 \times CP_3$  of projective twistor by choosing a specific projective gauge by putting  $z^4 = 1, w^4 = 1$ . The manifestly projectively invariant formulation for the equations is in full twistor space so that 12-D space would be replaced with 16-D space. In this case one would have 4-D complex permutation symbol giving for these spaces Calabi-Yau structure with flat metric. The product of functions  $f = z^4 = \text{constant}$  and  $g = w^4 = \text{constant}$  would define the fourth function  $f_4 = fg$  fixing the projective gauge

$$\epsilon^{i_1 j_1 k_1 l_1} \epsilon^{i_2 j_2 k_2 l_2} \partial_{i_1 i_2} f^1 \partial_{j_1 j_2} f^2 \partial_{k_1 k_2} f^3 \partial_{l_1 l_2} f^4 = 0 \ , \ \partial_{ij} \equiv \partial_i \partial_j \ . \quad (2.6.7)$$

The functions  $f^i$  are homogenous polynomials of their twistor arguments to guarantee projective invariance. These equations are projectively invariant and reduce to the above form which means also loss of homogenous polynomial property. The undesirable feature is the loss of manifest projective invariance by the fixing of the projective gauge.

A more attractive ansatz is based on the idea that one must have one equation for each  $f^i$  to minimize the non-determinism of the equations obvious from the fact that there is single equation in 3-D lattice for three dynamical variables. The quartets  $(f^1, f^2, f^3, f^i)$ ,  $i = 1, 2, 3$  would define a possible minimally non-linear generalization of the equation

$$\epsilon^{i_1 j_1 k_1 l_1} \epsilon^{i_2 j_2 k_2 l_2} \partial_{i_1 i_2} f^1 \partial_{j_1 j_2} f^2 \partial_{k_1 k_2} f^m \partial_{l_1 l_2} f^4 = 0 \ , \ \partial_{ij} \equiv \partial_i \partial_j \ , \ m = 1, 2, 3 \ . \quad (2.6.8)$$

Note that the functions are homogenous polynomials of their arguments and analogous to spherical harmonics suggesting that they can allow a nice interpretation in terms of quantum classical correspondence.

The minimal non-linearity of the equations also conforms with the non-linearity of the field equations associated with Kähler action. Note that also in this case one can solve the equations by diagonalizing the dynamical coefficient matrix associated with the quadratic term and by identifying the eigen-vectors of zero eigen values. One could consider also more complicated strongly non-linear ansätze such as  $(f^i, f^i, f^i, f^i)$ ,  $i = 1, 2, 3$ , but these do not seem plausible.

1. *The explicit form of the equations using Taylor series expansion for multi-linear case*

In this section the equations associated with  $(f_1, f_2, f_3)$  ansatz are discussed in order to obtain a perspective about the general structure of the equations by using simpler (multilinearity) albeit probably non-realistic case as starting point. This experience can be applied directly to the  $(f^1, f^2, f^3, f^i)$  ansatz, which is quadratic in  $f^i$ .

The explicit form of the equations is obtained as infinite number of conditions relating the coefficients of the Taylor series of  $f^1$  and  $f^2$ . The treatment of the two variants for the equations is essentially identical and in the following only the manifestly projectively invariant form will be considered.

1. One can express the Taylor series as

$$\begin{aligned} f^1(Z, W) &= \sum_{m,n} C_{m,n} M_m(Z) M_n(W) , \\ f^2(Z, W) &= \sum_{m,n} D_{m,n} M_m(Z) M_n(W) , \\ f^3(Z, W) &= \sum_{m,n} E_{m,n} M_m(Z) M_n(W) , \\ M_{m \equiv (m_1, m_2, m_3)}(Z) &= z_1^{m_1} z_2^{m_2} z_3^{m_3} . \end{aligned} \quad (2.6.9)$$

2. The application of derivatives to the functions reduces to a simple algebraic operation

$$\partial_{ij}(M_m(Z)M_n(W)) = m_i n_j M_{m_1 - e_i}(Z) M_{n - e_j}(W) . \quad (2.6.10)$$

Here  $e_i$  denotes  $i$ :th unit vector.

3. Using the product rule  $M_m M_n = M_{m+n}$  one obtains

$$\begin{aligned} &\partial_{ij}(M_m(Z)M_n(W))\partial_{rs}(M_k(Z)M_l(W)) \\ &= m_i n_j k_r l_s \times M_{m - e_i}(Z) M_{n - e_j}(W) \times M_{k - e_r}(Z) M_{l - e_s}(W) \\ &= m_i n_j k_r l_s \times M_{m+k - e_i - e_r}(Z) \times M_{n+l - e_j - e_l}(W) . \end{aligned} \quad (2.6.11)$$

4. The equations reduce to the trilinear form

$$\begin{aligned} &\sum_{m,n,k,l,r,s} C_{m,n} D_{k,l} E_{r,s}(m, k, r)(n, l, s) M_{m+k+r-E}(Z) M_{n+l+s-E}(W) = 0 , \\ E &= e_1 + e_2 + e_3 , \quad (a, b, c) = \epsilon^{ijk} a_i b_j c_c . \end{aligned} \quad (2.6.12)$$

Here  $(a, b, c)$  denotes the determinant defined by the three index vectors involved. By introducing the summation indices

$$(M = m + k + r - E, k, r) , \quad (N = n + l + s - E, l, s)$$

one obtains an infinite number of conditions, one for each pair  $(M, N)$ . The condition for a given pair  $(M, N)$  reads as

$$\sum_{k,l,r,s} C_{M-k-r+E, N-l-s+E} D_{k,l} E_{r,s} \times (M - k - r + E, k, r)(N - l - s + E, l, s) = 0 . \quad (2.6.13)$$

These equations can be regarded as linear equations by regarding any matrix selected from  $\{C, D, E\}$  as a vector of linear space. The existence solutions requires that the determinant associated with the tensor product of other two matrices vanishes. This matrix is dynamical. Same applies to the tensor product of any of the matrices.

5. Hyper-determinant [?] is the generalization of the notion of determinant whose vanishing tells that multilinear equations have solutions. Now the vanishing of the hyper-determinant defined for the tensor product of the three-fold tensor power of the vector space defined by the coefficients of the Taylor expansion should provide the appropriate manner to characterize the conditions for the existence of the solutions. As already seen, solutions indeed exist so that the hyper-determinant must vanish. The elements of the hyper matrix are now products of determinants for the exponents of the monomials involved. The non-locality of the Kähler function as a functional of the partonic surface leads to the argument that the field equations of TGD for vanishing  $n$ :th variations of Kähler action are multilinear and that a vanishing of a generalized hyper-determinant characterizes this [?] .
6. Since the differential operators are homogenous polynomials of partial derivatives, the total degrees of  $M_m(Z)$  and  $M_m(W)$  defined as a sum  $D = \sum m_i$  is reduced by one unit by the action of both operators  $\partial_{ij}$ . For given value of  $M$  and  $N$  only the products

$$M_m(Z)M_n(W)M_k(Z)M_r(W)M_s(Z)M_l(W)$$

for which the vector valued degrees  $D_1 = m + k + r$  and  $D_2 = n + l + s$  have the same value are coupled. Since the degree is reduced by the operators appearing in the equation, polynomial solutions for which  $f^i$  contain monomials labelled by vectors  $m_i, n_i, r_i$  for which the components vary in a finite range  $(0, n_{max})$  look like a natural solution ansatz. All the degrees  $D_i \leq D_{i,max}$  appear in the solution ansatz so that quite a large number of conditions is obtained.

What is nice is that the equation can be interpreted as a difference equation in 3-D lattice with "time direction" defined by the direction of the diagonal.

1. The counterparts of time=constant slices are the planes  $n_1 + n_2 + n_3 = n$  defining outer surfaces of simplices having  $E$  as a normal vector. The difference equation does not seem to say nothing about the behavior in the transversal directions.  $M$  and  $N$  vary in the simplex planes satisfying  $\sum M_i = T_1, \sum N_i = T_2$ . It seems natural to choose  $T_1 = T_2 = T$  so that  $Z$  and  $W$  dynamics corresponds to the same "time". The number of points in the  $T = constant$  simplex plane increases with  $T$  which is analogous to cosmic expansion.
2. The "time evolution" with respect to  $T$  can be solved iteratively by increasing the value of  $\sum M_i = N_i = T$  by one unit at each step. Suppose that the values of coefficients are known and satisfy the conditions for  $(m, k, r)$  and  $(n, l, s)$  up to the maximum value  $T$  for the sum of the components of each of these six vectors. The region of known coefficients -"past"- obviously corresponds to the interior of the simplex bounded by the plane  $\sum M_i = \sum N_i = T$  having  $E$  as a normal. Let  $(m_{min}, n_{min}), (k_{min}, l_{min})$  and  $(r_{min}, s_{min})$  correspond to the smallest values of 3-indices for which the coefficients are non-vanishing- this could be called the moment of "Big Bang". The simplest but not necessary assumption is that these indices correspond zero vectors  $(0, 0, 0)$  analogous to the tip of light-cone.

3. For given values of  $M$  and  $N$  corresponding to same value of "cosmic time"  $T$  one can separate from the formula the terms which correspond to the un-known coefficients as the sum  $C_{M+E,N+E}D_{0,0}E_{0,0} + D_{M+E,N+E}D_{0,0}C_{0,0} + E_{M+E,N+E}C_{0,0}D_{0,0}$ . The remaining terms are by assumption already known. One can fix the normalization by choosing  $C_{0,0} = D_{0,0} = E_{0,0} = 1$ . With these assumptions the equation reduces at each point of the outer boundary of the simplex to the form

$$C_{M+E,N+E} + D_{M+E,N+E} + E_{M+E,N+E} = X$$

where  $X$  is something already known and contain only data about points in the plane  $m+k+r = M$  and  $n+r+s = N$ . Note that these planes have one "time like direction" unlike the simplex plane so that one could speak about a discrete analog of string world sheet in 3+3+3-D lattice space defined by a 2-plane with one time-like direction.

4. For each point of the simplex plane one has equation of the above form. The equation is non-deterministic since only constrain only the sum  $C_{M+E,N+E} + D_{M+E,N+E} + E_{M+E,N+E}$  at each point of the simplex plane to a plane in the complex 3-D space defined by them. Hence the number of solutions is very large. The condition that the solutions reduce to polynomials poses conditions on the coefficients since the quantities  $X$  associated with the plane  $T = T_{max}$  must vanish for each point of the simplex plane in this case. In fact, projective invariance means that the functions involved are homogenous functions in projective coordinates and thus polynomials and therefore reduce to polynomials of finite degree in 3-D treatment. This obviously gives additional condition to the equations.

### 2. The minimally non-linear option

The simple equation just discussed should be taken with a caution since the non-determinism seems to be too large if one takes seriously the analogy with classical dynamics. By the vacuum degeneracy also the time evolution associated with Kähler action breaks determinism in the standard sense of the word. The non-determinism is however not so strong and removed completely in local sense for non-vacuum extremals. One could also try to see the non-determinism as the analog for non-deterministic time evolution by quantum jumps.

One can however consider the already mentioned possibility of increasing the number of equations so that one would have three equations corresponding to the three unknown functions  $f^i$  so that the determinism associated with each step would be reduced. The equations in question would be of the same general form but with  $(f^1, f^2, f^3)$  replaced with some other combination.

1. In the genuinely projective situation where one can consider the  $(f^1, f^2, f^3, f^i)$ ,  $i = 1, 2, 3$  as a unique generalization of the equation. This would make the equations quadratic in  $f_i$  and reduce the non-determinism at given step of the time evolution. The new element is that now only monomials  $M_m(z)$  associated with the  $f^i$  with same degree of homogeneity defined by  $d = \sum m_i$  are consistent with projective invariance. Therefore the solutions are characterized by six integers  $(d_{i,1}, d_{i,2})$  having interpretation as analogs of conformal weights since they correspond to eigenvalues of scaling operators. That homogenous polynomials are in question gives hopes that a generalization of Witten's approach might make sense. The indices  $m$  vary at the outer surfaces of the six 3-simplices defined by  $(d_{i,1}, d_{i,2})$  and looking like tetrahedrons in 3-D space. The functions  $f^i$  are highly analogous to the homogenous functions appearing in group representations and quantum classical correspondence could be realized through the representation of the space-time surfaces in this manner.
2. The 3-determinants  $(a, b, c)$  appearing in the equations would be replaced by 4-determinants and the equations would have the same general form. One has

$$\sum_{k,l,r,s,t,u} C_{M-k-r-t+E, N-l-s-u+E} D_{k,l} E_{r,s} C_{t,u} \times \\ \times (M-k-r-t+E, k, r, t)(N-l-s-u+E, l, s, u) = 0, \\ E = e_1 + e_2 + e_3 + e_4, \quad (a, b, c, d) = \epsilon^{ijkl} a_i b_j c_k d_l. \quad (2.6.14)$$

and its variants in which  $D$  and  $E$  appear quadratically. The values of  $M$  and  $N$  are restricted to the tetrahedrons  $\sum M_i = \sum d_{k,1} + d_{1,i}$  and  $\sum N_i = \sum d_{i,2} + d_{i,2}$ ,  $i = 1, 2, 3$ . Therefore the dynamics in the index space is 3-dimensional. Since the index space is in a well-defined sense dual to  $CP_3$  as is also the  $CP_3$  in which the solutions are represented as counterparts of 3-surfaces, one could say that the 3-dimensionality of the dynamics corresponds to the dynamics of Chern-Simons action at space-like at the ends of  $CD$  and at light-like 3-surfaces.

3. The view based on 4-D time evolution is not useful since the solutions are restricted to time=constant plane in 4-D sense. The elimination of one of the projective coordinates would lead however to the analog of the above describe time evolution. In four-D context a more appropriate form of the equations is

$$\sum_{m,n,k,l,r,s} C_{m,n} D_{k,l} E_{r,s} C_{t,u}(m, k, r, t)(n, l, s, u) M_{m+k+r-E}(Z) M_{n+l+s-E}(W) = 0 \quad (2.6.15)$$

with similar equations for  $f^2$  and  $f^3$ . If one assumes that the  $CP_2$  image of the holomorphic 3-surface is unique (it can correspond to either  $CP_3$ ) the homogenous polynomials  $f^i$  must be symmetric under the exchange of  $Z$  and  $W$  so that the matrices  $C, D$ , and  $E$  are symmetric. This is equivalent to a replacement of the product of determinants with a sum of 16 products of determinants obtained by permuting the indices of each index pair  $(m, n)$ ,  $(k, l)$ ,  $(r, s)$  and  $(t, u)$ .

4. The number  $N_{cond}$  of conditions is given by the product  $N_{cond} = N(d_M)N(d_N)$  of numbers of points in the two tetrahedrons defined by the total conformal weights

$$\sum M_r = d_M = \sum_k d_{k,1} + d_{1,i} \quad \text{and} \quad \sum N_r = d_N = \sum_k d_{k,2} + d_{i,2} \quad , \quad i = 1, 2, 3.$$

The number  $N_{coeff}$  of coefficients is

$$N_{coeff} = \sum_k n(d_{k,1}) + \sum_k n(d_{k,2}) \quad ,$$

where  $n(d_{k,i})$  is the number points associated with the tetrahedron with conformal weight  $d_{k,i}$ . Since one has  $n(d) \propto d^3$ ,  $N_{cond}$  scales as

$$N_{cond} \propto d_M^3 d_N^3 = \left( \sum_k d_{k,1} + d_{1,i} \right)^3 \times \left( \sum_k d_{k,2} + d_{i,2} \right)^3$$

whereas the number  $N_{coeff}$  of coefficients scales as

$$N_{coeff} \propto \sum_k (d_{k,1}^3 + d_{k,2}^3) \quad .$$

$N_{cond}$  is clearly much larger than  $N_{coeff}$  so the solutions are analogous to partial waves and that the reduction of the rank for the matrices involved is an essential aspect of being a solution. The reduction of the rank for the coefficient matrices should reduce the effective number of coefficients so that solutions can be found. An interesting question is whether the coefficients are rationals with a suitable normalization allowed by independent conformal scalings. An analogy for the dynamics is quantum entanglement for 3+3 systems respecting the conservation of conformal weights and quantum classical correspondence taken to extreme suggests something like this.

5. One can interpret these equations as linear equations for the coefficients of the either linear term or as quadratic equations for the non-linear term. Also in the case of quadratic term one can apply general linear methods to identify the vanishing eigen values of the matrix of the quadratic form involved and to find the zero modes as solutions. The rank of the dynamically determined multiplier matrix must be non-maximal for the solutions to exist. One can imagine that the

rank changes at critical surfaces in the space of Taylor coefficients meaning a multi-furcation in the space determined by the coefficients of the polynomials. Also the degree of the polynomial can change at the critical point.

Solutions for which either determinant vanishes for all terms present in the solution exist. This is achieved if either the index vectors  $(m, l, r, t)$  or  $(n, l, s, u)$  in their respective parallel 3-planes are also in a 3-plane going through the origin. These solutions might be seen as the analogs of vacuum extremals of Chern-Simons action for which the  $CP_2$  projection is at most 2-D Lagrangian manifold.

Quantum classical correspondence requires that the space-time surface carries also information about the momenta of partons. This information is quasi-continuous. Also information about zero modes should have representation in terms of the coefficients of the polynomials. Is this really possible if only products of polynomials of fixed conformal weights with strong restrictions on coefficients can be used? The counterpart for the vacuum degeneracy of Kähler action might resolve the problem. The analog for the construction of space-time surfaces as deformations of vacuum extremals would be starting from a trivial solution and adding to the building blocks of  $f^i$  some terms of same degree for which the wave vectors are not in the intersection of a 3-plane and simplex planes. The still existing "vacuum part" of the solution could carry the needed information.

6. One can take "obvious solutions" characterized by different common 3-planes for the "wave vectors" characterizing the 8 monomials  $M_a(Z)$  and  $M_b(W)$ ,  $a \in \{m, k, r, t\}$  and  $b \in \{n, l, s, u\}$ . The coefficient matrices  $C, D, E, F$  are completely free. For the sum of these solutions the equations contain interaction terms for which at least two "wave vectors" belong to different 3-planes so that the corresponding 4-determinants are non-vanishing. The coefficients are not anymore free. Could the "obvious solutions" have interpretation in terms of different space-time sheets interacting via wormhole contacts? Or can one equate "obvious" with "vacuum" so that interaction between different vacuum space-time sheets via wormhole contact with 3-D  $CP_2$  projection would deform vacuum extremals to non-vacuum extremals? Quantum classical correspondence inspires the question whether the products for functions  $f_i$  associated with an obvious solution associated with a particular plane correspond to a tensor products for quantum states associated with a particular partonic 2-surface or space-time sheet.
7. Effective 2-dimensionality realized in terms of the extremals of Chern-Simons actions with Lagrange multiplier term coming from the weak form of electric magnetic duality should also have a concrete counterpart if one takes the analogy with the extremals of Kähler action seriously. The equations can be transformed to 3-D ones by the elimination of the fourth coordinate but the interpretation in terms of discrete time evolution seems to be impossible since all points are coupled. The total conformal weights of the monomials vary in the range  $[0, d_{1,i}]$  and  $[0, d_{2,i}]$  so that the non-vanishing coefficients are in the interior of 3-simplex. The information about the fourth coordinate is preserved being visible via the four-determinants.
8. It should be possible to relate the hierarchy with respect to conformal weights would to the geometrization of loop integrals if a generalization of twistor strings is in question. One could hope that there exists a hierarchy of solutions with levels characterized by the rank of the matrices appearing in the linear representation. There is a temptation to associate this hierarchy with the hierarchy of deformations of vacuum extremals of Kähler action forming also a hierarchy. If this is the case the obvious solutions would correspond to vacuum extremals. At each step when the rank of the matrices involved decreases the solution becomes nearer to vacuum extremal and there should exist vanishing second variation of Kähler action. This structural similarity gives hopes that the proposed ansatz might work. Also the fact that a generalization of the Penrose's twistorial description for the solutions of Maxwell's equations to the situation when Maxwell field is induced from the Kähler form of  $CP_2$  raises hopes. One must however remember that the consistency with other proposed solution ansätze and with what is believed to be known about the preferred extremals is an enormously powerful constraint and a mathematical miracle would be required.

## 2.7 Finiteness of generalized Feynman diagrams zero energy ontology

By effective 2-dimensionality partonic 2-surfaces plus the 4-D tangent space data at them code for quantum physics. The light-like orbits of partonic 2-surfaces in turn have interpretation as analogs of Feynman diagrams which correspond to 3-surfaces defining the regions at which the signature of the induced metric changes and 4-metric becomes degenerate. One could also identify the space-like regions of the space-time surfaces (deformed  $CP_2$  type vacuum extremals, in particular wormhole throats) as the counterparts of generalized Feynman diagrams. The regions with Minkowskian signature of the induced metric would in turn correspond to the many-sheeted version of external space-time in which the particles move. A very concrete connection between particle and space-time geometry and topology is clearly in question.

Zero energy ontology has already led to the idea of interpreting the virtual particles as pairs of positive and negative energy wormhole throats. Hitherto I have taken it as granted that ordinary Feynman diagrammatics generalizes more or less as such. It is however far from clear what really happens in the vertices of the generalized Feynmann diagrams. The safest approach relies on the requirement that unitarity realized in terms of Cutkosky rules in ordinary Feynman diagrammatics allows a generalization. This requires loop diagrams. In particular, photon-photon scattering can take place only via a fermionic square loop so that it seems that loops must be present at least in the topological sense.

One must be however ready for the possibility that something unexpectedly simple might emerge. For instance, the vision about algebraic physics allows naturally only finite sums for diagrams and does not favor infinite perturbative expansions. Hence the true believer on algebraic physics might dream about finite number of diagrams for a given reaction type. For simplicity generalized Feynman diagrams without the complications brought by the magnetic confinement since by the previous arguments the generalization need not bring in anything essentially new.

The basic idea of duality in early hadronic models was that the lines of the dual diagram representing particles are only re-arranged in the vertices. This however does not allow to get rid of off mass shell momenta. Zero energy ontology encourages to consider a stronger form of this principle in the sense that the virtual momenta of particles could correspond to pairs of on mass shell momenta of particles. If also interacting fermions are pairs of positive and negative energy throats in the interaction region the idea about reducing the construction of Feynman diagrams to some kind of lego rules might work.

### 2.7.1 Virtual particles as pairs of on mass shell particles in ZEO

The first thing is to try to define more precisely what generalized Feynman diagrams are. The direct generalization of Feynman diagrams implies that both wormhole throats and wormhole contacts join at vertices.

1. A simple intuitive picture about what happens is provided by diagrams obtained by replacing the points of Feynman diagrams (wormhole contacts) with short lines and imagining that the throats correspond to the ends of the line. At vertices where the lines meet the incoming on mass shell quantum numbers would sum up to zero. This approach leads to a straightforward generalization of Feynman diagrams with virtual particles replaced with pairs of on mass shell throat states of type  $++$ ,  $--$ , and  $+-$ . Incoming lines correspond to  $++$  type lines and outgoing ones to  $--$  type lines. The first two line pairs allow only time like net momenta whereas  $+-$  line pairs allow also space-like virtual momenta. The sign assigned to a given throat is dictated by the the sign of the on mass shell momentum on the line. The condition that Cutkosky rules generalize as such requires  $++$  and  $--$  type virtual lines since the cut of the diagram in Cutkosky rules corresponds to on mass shell outgoing or incoming states and must therefore correspond to  $++$  or  $--$  type lines.
2. The basic difference as compared to the ordinary Feynman diagrammatics is that loop integrals are integrals over mass shell momenta and that all throats carry on mass shell momenta. In each vertex of the loop mass incoming on mass shell momenta must sum up to on mass shell momentum. These constraints improve the behavior of loop integrals dramatically and give

excellent hopes about finiteness. It does not however seem that only a finite number of diagrams contribute to the scattering amplitude besides tree diagrams. The point is that if a the reactions  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ , where  $N_i$  denote particle numbers, are possible in a common kinematical region for  $N_2$ -particle states then also the diagrams  $N_1 \rightarrow N_2 \rightarrow N_3$  are possible. The virtual states  $N_2$  include all states in the intersection of kinematically allow regions for  $N_1 \rightarrow N_2$  and  $N_2 \rightarrow N_3$ . Hence the dream about finite number possible diagrams is not fulfilled if one allows massless particles. If all particles are massive then the particle number  $N_2$  for given  $N_1$  is limited from above and the dream is realized.

3. For instance, loops are not possible in the massless case or are highly singular (bringing in mind twistor diagrams) since the conservation laws at vertices imply that the momenta are parallel. In the massive case and allowing mass spectrum the situation is not so simple. As a first example one can consider a loop with three vertices and thus three internal lines. Three on mass shell conditions are present so that the four-momentum can vary in 1-D subspace only. For a loop involving four vertices there are four internal lines and four mass shell conditions so that loop integrals would reduce to discrete sums. Loops involving more than four vertices are expected to be impossible.
4. The proposed replacement of the elementary fermions with bound states of elementary fermions and monopoles  $X_{\pm}$  brings in the analog of stringy diagrammatics. The 2-particle wave functions in the momentum degrees of freedom of fermions and  $X_{\pm}$  might allow more flexibility and allow more loops. Note however that there are excellent hopes about the finiteness of the theory also in this case.

### 2.7.2 Loop integrals are manifestly finite

One can make also more detailed observations about loops.

1. The simplest situation is obtained if only 3-vertices are allowed. In this case conservation of momentum however allows only collinear momenta although the signs of energy need not be the same. Particle creation and annihilation is possible and momentum exchange is possible but is always light-like in the massless case. The scattering matrices of supersymmetric YM theories would suggest something less trivial and this raises the question whether something is missing. Magnetic monopoles are an essential element of also these theories as also massivation and symmetry breaking and this encourages to think that the formation of massive states as fermion  $X_{\pm}$  pairs is needed. Of course, in TGD framework one has also high mass excitations of the massless states making the scattering matrix non-trivial.
2. In YM theories on mass shell lines would be singular. In TGD framework this is not the case since the propagator is defined as the inverse of the 3-D dimensional reduction of the modified Dirac operator  $D$  containing also coupling to four-momentum (this is required by quantum classical correspondence and guarantees stringy propagators),

$$\begin{aligned} D &= i\hat{\Gamma}^{\alpha} p_{\alpha} + \hat{\Gamma}^{\alpha} D_{\alpha} \ , \\ p_{\alpha} &= p_k \partial_{\alpha} h^k \ . \end{aligned} \tag{2.7.1}$$

The propagator does not diverge for on mass shell massless momenta and the propagator lines are well-defined. This is of course of essential importance also in general case. Only for the incoming lines one can consider the possibility that 3-D Dirac operator annihilates the induced spinor fields. All lines correspond to generalized eigenstates of the propagator in the sense that one has  $D_3 \Psi = \lambda \gamma \Psi$ , where  $\gamma$  is modified gamma matrix in the direction of the stringy coordinate emanating from light-like surface and  $D_3$  is the 3-dimensional dimensional reduction of the 4-D modified Dirac operator. The eigenvalue  $\lambda$  is analogous to energy. Note that the eigenvalue spectrum depends on 4-momentum as a parameter.

3. Massless incoming momenta can decay to massless momenta with both signs of energy. The integration measure  $d^2k/2E$  reduces to  $dx/x$  where  $x \geq 0$  is the scaling factor of massless momentum. Only light-like momentum exchanges are however possible and scattering matrix is essentially trivial. The loop integrals are finite apart from the possible delicacies related to poles since the loop integrands for given massless wormhole contact are proportional to  $dx/x^3$  for large values of  $x$ .
4. Irrespective of whether the particles are massless or not, the divergences are obtained only if one allows too high vertices as self energy loops for which the number of momentum degrees of freedom is  $3N - 4$  for  $N$ -vertex. The construction of SUSY limit of TGD in [?] led to the conclusion that the parallelly propagating  $N$  fermions for given wormhole throat correspond to a product of  $N$  fermion propagators with same four-momentum so that for fermions and ordinary bosons one has the standard behavior but for  $N > 2$  non-standard so that these excitations are not seen as ordinary particles. Higher vertices are finite only if the total number  $N_F$  of fermions propagating in the loop satisfies  $N_F > 3N - 4$ . For instance, a 4-vertex from which  $N = 2$  states emanate is finite.

### 2.7.3 Taking into account magnetic confinement

What has been said above is not quite enough. As shown in the accompanying article and in [?] the weak form of electric-magnetic duality [?] leads to the picture about elementary particles as pairs of magnetic monopoles inspiring the notions of weak confinement based on magnetic monopole force. Also color confinement would have magnetic counterpart. This means that elementary particles would behave like string like objects in weak boson length scale. Therefore one must also consider the stringy case with wormhole throats replaced with fermion- $X_{\pm}$  pairs ( $X_{\pm}$  is electromagnetically neutral and  $\pm$  refers to the sign of the weak isospin opposite to that of fermion) and their super partners.

1. The simplest assumption in the stringy case is that fermion- $X_{\pm}$  pairs behave as coherent objects, that is scatter elastically. In more general case only their higher excitations identifiable in terms of stringy degrees of freedom would be created in vertices. The massivation of these states makes possible non-collinear vertices. An open question is how the massivation fermion- $X_{\pm}$  pairs relates to the existing TGD based description of massivation in terms of Higgs mechanism and modified Dirac operator.
2. Mass renormalization could come from self energy loops with negative energy lines as also vertex normalization. By very general arguments supersymmetry implies the cancellation of the self energy loops but would allow non-trivial vertex renormalization [?] .
3. If only 3-vertices are allowed, the loops containing only positive energy lines are possible if on mass shell fermion- $X_{\pm}$  pair (or its superpartner) can decay to a pair of positive energy pair particles of same kind. Whether this is possible depends on the masses involved. For ordinary particles these decays are not kinematically possible below intermediate boson mass scale (the decays  $F_1 \rightarrow F_2 + \gamma$  are forbidden kinematically or by the absence of flavor changing neutral currents whereas intermediate gauge bosons can decay to on mass shell fermion-antifermion pair).
4. The introduction of IR cutoff for 3-momentum in the rest system associated with the largest  $CD$  (causal diamond) looks natural as scale parameter of coupling constant evolution and p-adic length scale hypothesis favors the inverse of the size scale of  $CD$  coming in powers of two. This parameter would define the momentum resolution as a discrete parameter of the p-adic coupling constant evolution. This scale does not have any counterpart in standard physics. For electron,  $d$  quark, and  $u$  quark the proper time distance between the tips of  $CD$  corresponds to frequency of 10 Hz, 1280 Hz, and 160 Hz: all these frequencies define fundamental bio-rhythms [K22] .

These considerations have left completely untouched one important aspect of generalized Feynman diagrams: the necessity to perform a functional integral over the deformations of the partonic 2-surfaces at the ends of the lines- that is integration over WCW. Number theoretical universality requires that WCW and these integrals make sense also p-adically and in the following these aspects of generalized Feynman diagrams are discussed.

## Chapter 3

# The Recent Vision about Preferred Extremals and Solutions of the Modified Dirac Equation

### 3.1 Introduction

During years several approaches to what preferred extremals of Kähler action and solutions of the modified Dirac equation could be have been proposed and the challenge is to see whether at least some of these approaches are consistent with each other. It is good to list various approaches first.

1. For preferred extremals generalization of conformal invariance to 4-D situation is very attractive approach and leads to concrete conditions formally similar to those encountered in string model [K9]. In particular, Einstein's equations with cosmological constant follow as consistency conditions and field equations reduce to a purely algebraic statements analogous to those appearing in equations for minimal surfaces if one assumes that space-time surface has Hermitian structure or its Minkowskian variant Hamilton-Jacobi structure (Appendix). The older approach based on basic heuristics for massless equations, on effective 3-dimensionality, and weak form of electric magnetic duality, and Beltrami flows is also promising. An alternative approach is inspired by number theoretical considerations and identifies space-time surfaces as associative or co-associative sub-manifolds of octonionic imbedding space [K72].

The basic step of progress was the realization that the known extremals of Kähler action - certainly limiting cases of more general extremals - can be deformed to more general extremals having interpretation as preferred extremals.

- (a) The generalization boils down to the condition that field equations reduce to the condition that the traces  $Tr(TH^k)$  for the product of energy momentum tensor and second fundamental form vanish. In string models energy momentum tensor corresponds to metric and one obtains minimal surface equations. The equations reduce to purely algebraic conditions stating that  $T$  and  $H^k$  have no common components. Complex structure of string world sheet makes this possible.

Stringy conditions for metric stating  $g_{zz} = g_{\bar{z}\bar{z}} = 0$  generalize. The condition that field equations reduce to  $Tr(TH^k) = 0$  requires that the terms involving Kähler gauge current in field equations vanish. This is achieved if Einstein's equations hold true. The conditions guaranteeing the vanishing of the trace in turn boil down to the existence of Hermitian structure in the case of Euclidian signature and to the existence of its analog - Hamilton-Jacobi structure - for Minkowskian signature (Appendix). These conditions state that certain components of the induced metric vanish in complex coordinates or Hamilton-Jacobi coordinates.

In string model the replacement of the imbedding space coordinate variables with quantized ones allows to interpret the conditions on metric as Virasoro conditions. In the recent case generalization of classical Virasoro conditions to four-dimensional ones would be in question.

An interesting question is whether quantization of these conditions could make sense also in TGD framework at least as a useful trick to deduce information about quantum states in WCW degrees of freedom.

The interpretation of the extended algebra as Yangian [?] [?] suggested previously [?] to act as a generalization of conformal algebra in TGD Universe is attractive. There is also the conjecture that preferred extremals could be interpreted as quaternionic or co-quaternionic 4-surface of the octonionic imbedding space with octonionic representation of the gamma matrices defining the notion of tangent space quaternionicity.

2. There are also several approaches for solving the modified Dirac equation. The most promising approach is assumes that the solutions are restricted on 2-D stringy world sheets and/or partonic 2-surfaces. This strange looking view is a rather natural consequence of both strong form of holography and of number theoretic vision, and also follows from the notion of finite measurement resolution having discretization at partonic 2-surfaces as a geometric correlate. The conditions stating that electric charge is conserved for preferred extremals is an alternative very promising approach. One expects that stringy approach based on 4-D generalization of conformal invariance or its 2-D variant at 2-D preferred surfaces should also allow to understand the modified Dirac equation. In accordance with the earlier conjecture, all modes of the modified Dirac operator generate badly broken super-symmetries. Right-handed neutrino allows also holomorphic modes delocalized at entire space-time surface and the delocalization inside Euclidian region defining the line of generalized Feynman diagram is a good candidate for the right-handed neutrino generating the least broken super-symmetry. This super-symmetry seems however to differ from the ordinary one in that  $\nu_R$  is expected to behave like a passive spectator in the scattering.

In the following the question whether these various approaches are mutually consistent is discussed. It indeed turns out that the approach based on the conservation of electric charge leads under rather general assumptions to the proposal that solutions of the modified Dirac equation are localized on 2-dimensional string world sheets and/or partonic 2-surfaces. Einstein's equations are satisfied for the preferred extremals and this implies that the earlier proposal for the realization of Equivalence Principle is not needed. This leads to a considerable progress in the understanding of super Virasoro representations for super-symplectic and super-Kac-Moody algebra. In particular, the proposal is that super-Kac-Moody currents assignable to string world sheets define duals of gauge potentials and their generalization for gravitons: in the approximation that gauge group is Abelian - motivated by the notion of finite measurement resolution - the exponents for the sum of KM charges would define non-integrable phase factors. One can also identify Yangian as the algebra generated by these charges. The approach allows also to understand the special role of the right handed neutrino in SUSY according to TGD.

## 3.2 About deformations of known extremals of Kähler action

I have done a considerable amount of speculative guesswork to identify what I have used to call preferred extremals of Kähler action. The problem is that the mathematical problem at hand is extremely non-linear and that there is no existing mathematical literature. One must proceed by trying to guess the general constraints on the preferred extremals which look physically and mathematically plausible. The hope is that this net of constraints could eventually crystallize to Eureka! Certainly the recent speculative picture involves also wrong guesses. The need to find explicit ansatz for the deformations of known extremals based on some common principles has become pressing. The following considerations represent an attempt to combine the existing information to achieve this.

### 3.2.1 What might be the common features of the deformations of known extremals

The dream is to discover the deformations of all known extremals by guessing what is common to all of them. One might hope that the following list summarizes at least some common features.

### Effective three-dimensionality at the level of action

1. Holography realized as effective 3-dimensionality also at the level of action requires that it reduces to 3-dimensional effective boundary terms. This is achieved if the contraction  $j^\alpha A_\alpha$  vanishes. This is true if  $j^\alpha$  vanishes or is light-like, or if it is proportional to instanton current in which case current conservation requires that  $CP_2$  projection of the space-time surface is 3-dimensional. The first two options for  $j$  have a realization for known extremals. The status of the third option - proportionality to instanton current - has remained unclear.
2. As I started to work again with the problem, I realized that instanton current could be replaced with a more general current  $j = *B \wedge J$  or concretely:  $j^\alpha = \epsilon^{\alpha\beta\gamma\delta} B_\beta J_{\gamma\delta}$ , where  $B$  is vector field and  $CP_2$  projection is 3-dimensional, which it must be in any case. The contractions of  $j$  appearing in field equations vanish automatically with this ansatz.
3. Almost topological QFT property in turn requires the reduction of effective boundary terms to Chern-Simons terms: this is achieved by boundary conditions expressing weak form of electric magnetic duality. If one generalizes the weak form of electric magnetic duality to  $J = \Phi * J$  one has  $B = d\Phi$  and  $j$  has a vanishing divergence for 3-D  $CP_2$  projection. This is clearly a more general solution ansatz than the one based on proportionality of  $j$  with instanton current and would reduce the field equations in concise notation to  $Tr(TH^k) = 0$ .
4. Any of the alternative properties of the Kähler current implies that the field equations reduce to  $Tr(TH^k) = 0$ , where  $T$  and  $H^k$  are shorthands for Maxwellian energy momentum tensor and second fundamental form and the product of tensors is obvious generalization of matrix product involving index contraction.

### Could Einstein's equations emerge dynamically?

For  $j^\alpha$  satisfying one of the three conditions, the field equations have the same form as the equations for minimal surfaces except that the metric  $g$  is replaced with Maxwell energy momentum tensor  $T$ .

1. This raises the question about dynamical generation of small cosmological constant  $\Lambda$ :  $T = \Lambda g$  would reduce equations to those for minimal surfaces. For  $T = \Lambda g$  modified gamma matrices would reduce to induced gamma matrices and the modified Dirac operator would be proportional to ordinary Dirac operator defined by the induced gamma matrices. One can also consider weak form for  $T = \Lambda g$  obtained by restricting the consideration to sub-space of tangent space so that space-time surface is only "partially" minimal surface but this option is not so elegant although necessary for other than  $CP_2$  type vacuum extremals.
2. What is remarkable is that  $T = \Lambda g$  implies that the divergence of  $T$  which in the general case equals to  $j^\beta J_\beta^\alpha$  vanishes. This is guaranteed by one of the conditions for the Kähler current. Since also Einstein tensor has a vanishing divergence, one can ask whether the condition to  $T = \kappa G + \Lambda g$  could be the general condition. This would give Einstein's equations with cosmological term besides the generalization of the minimal surface equations. GRT would emerge dynamically from the non-linear Maxwell's theory although in slightly different sense as conjectured [K77]! Note that the expression for  $G$  involves also second derivatives of the imbedding space coordinates so that actually a partial differential equation is in question. If field equations reduce to purely algebraic ones, as the basic conjecture states, it is possible to have  $Tr(GH^k) = 0$  and  $Tr(gH^k) = 0$  separately so that also minimal surface equations would hold true.

What is amusing that the first guess for the action of TGD was curvature scalar. It gave analogs of Einstein's equations as a definition of conserved four-momentum currents. The recent proposal would give the analog of ordinary Einstein equations as a dynamical constraint relating Maxwellian energy momentum tensor to Einstein tensor and metric.

3. Minimal surface property is physically extremely nice since field equations can be interpreted as a non-linear generalization of massless wave equation: something very natural for non-linear variant of Maxwell action. The theory would be also very "stringy" although the fundamental action would not be space-time volume. This can however hold true only for Euclidian signature. Note that for  $CP_2$  type vacuum extremals Einstein tensor is proportional to metric so that for

them the two options are equivalent. For their small deformations situation changes and it might happen that the presence of  $G$  is necessary. The GRT limit of TGD discussed in [K77] [?] indeed suggests that  $CP_2$  type solutions satisfy Einstein's equations with large cosmological constant and that the small observed value of the cosmological constant is due to averaging and small volume fraction of regions of Euclidian signature (lines of generalized Feynman diagrams).

4. For massless extremals and their deformations  $T = \Lambda g$  cannot hold true. The reason is that for massless extremals energy momentum tensor has component  $T^{vv}$  which actually quite essential for field equations since one has  $H_{vv}^k = 0$ . Hence for massless extremals and their deformations  $T = \Lambda g$  cannot hold true if the induced metric has Hamilton-Jacobi structure meaning that  $g^{uu}$  and  $g^{vv}$  vanish. A more general relationship of form  $T = \kappa G + \Lambda G$  can however be consistent with non-vanishing  $T^{vv}$  but require that deformation has at most 3-D  $CP_2$  projection ( $CP_2$  coordinates do not depend on  $v$ ).
5. The non-determinism of vacuum extremals suggest for their non-vacuum deformations a conflict with the conservation laws. In, also massless extremals are characterized by a non-determinism with respect to the light-like coordinate but like-likeness saves the situation. This suggests that the transformation of a properly chosen time coordinate of vacuum extremal to a light-like coordinate in the induced metric combined with Einstein's equations in the induced metric of the deformation could allow to handle the non-determinism.

**Are complex structure of  $CP_2$  and Hamilton-Jacobi structure of  $M^4$  respected by the deformations?**

The complex structure of  $CP_2$  and Hamilton-Jacobi structure of  $M^4$  could be central for the understanding of the preferred extremal property algebraically.

1. There are reasons to believe that the Hermitian structure of the induced metric ((1,1) structure in complex coordinates) for the deformations of  $CP_2$  type vacuum extremals could be crucial property of the preferred extremals. Also the presence of light-like direction is also an essential elements and 3-dimensionality of  $M^4$  projection could be essential. Hence a good guess is that allowed deformations of  $CP_2$  type vacuum extremals are such that (2,0) and (0,2) components the induced metric and/or of the energy momentum tensor vanish. This gives rise to the conditions implying Virasoro conditions in string models in quantization:

$$g_{\xi^i \xi^j} = 0 \quad , \quad g_{\bar{\xi}^i \bar{\xi}^j} = 0 \quad , \quad i, j = 1, 2 \quad . \tag{3.2.1}$$

Holomorphisms of  $CP_2$  preserve the complex structure and Virasoro conditions are expected to generalize to 4-dimensional conditions involving two complex coordinates. This means that the generators have two integer valued indices but otherwise obey an algebra very similar to the Virasoro algebra. Also the super-conformal variant of this algebra is expected to make sense.

These Virasoro conditions apply in the coordinate space for  $CP_2$  type vacuum extremals. One expects similar conditions hold true also in field space, that is for  $M^4$  coordinates.

2. The integrable decomposition  $M^4(m) = M^2(m) + E^2(m)$  of  $M^4$  tangent space to longitudinal and transversal parts (non-physical and physical polarizations) - Hamilton-Jacobi structure- could be a very general property of preferred extremals and very natural since non-linear Maxwellian electrodynamics is in question. This decomposition led rather early to the introduction of the analog of complex structure in terms of what I called Hamilton-Jacobi coordinates  $(u, v, w, \bar{w})$  for  $M^4$ .  $(u, v)$  defines a pair of light-like coordinates for the local longitudinal space  $M^2(m)$  and  $(w, \bar{w})$  complex coordinates for  $E^2(m)$ . The Hamilton-Jacobi conditions on induced metric would be obtained by replacing imaginary unit in the definition of Hermitian metric for some complex coordinates with  $e$ ,  $e^2 = 1$  and defining hyper-complex conjugation as  $u \rightarrow v$  for light-like-coordinate (Appendix).

A good guess is that the deformations of massless extremals respect this structure. This condition gives rise to the analog of the constraints leading to Virasoro conditions stating the vanishing

of the non-allowed components of the induced metric plus the analogs of hermiticity conditions. Again the generators of the algebra would involve two integers and the structure is that of Virasoro algebra and also generalization to super algebra is expected to make sense. The moduli space of Hamilton-Jacobi structures would be part of the moduli space of the preferred extremals and analogous to the space of all possible choices of complex coordinates. The analogs of infinitesimal holomorphic transformations would preserve the modular parameters and give rise to a 4-dimensional Minkowskian analog of Virasoro algebra. The conformal algebra acting on  $CP_2$  coordinates acts in field degrees of freedom for Minkowskian signature.

### Field equations as purely algebraic conditions

If the proposed picture is correct, field equations would reduce basically to purely algebraically conditions stating that the Maxwellian energy momentum tensor has no common index pairs with the second fundamental form. For the deformations of  $CP_2$  type vacuum extremals  $T$  is a complex tensor of type (1,1) and second fundamental form  $H^k$  a tensor of type (2,0) and (0,2) so that  $Tr(TH^k) =$  is true. This requires that second light-like coordinate of  $M^4$  is constant so that the  $M^4$  projection is 3-dimensional. For Minkowskian signature of the induced metric Hamilton-Jacobi structure replaces conformal structure. Here the dependence of  $CP_2$  coordinates on second light-like coordinate of  $M^2(m)$  only plays a fundamental role. Note that now  $T^{vv}$  is non-vanishing (and light-like). This picture generalizes to the deformations of cosmic strings and even to the case of vacuum extremals.

### 3.2.2 What small deformations of $CP_2$ type vacuum extremals could be?

I was led to these arguments when I tried find preferred extremals of Kähler action, which would have 4-D  $CP_2$  and  $M^4$  projections - the Maxwell phase analogous to the solutions of Maxwell's equations that I conjectured long time ago. It however turned out that the dimensions of the projections can be ( $D_{M^4} \leq 3, D_{CP_2} = 4$ ) or ( $D_{M^4} = 4, D_{CP_2} \leq 3$ ). What happens is essentially breakdown of linear superposition so that locally one can have superposition of modes which have 4-D wave vectors in the same direction. This is actually very much like quantization of radiation field to photons now represented as separate space-time sheets and one can say that Maxwellian superposition corresponds to union of separate photonic space-time sheets in TGD. In the following I shall restrict the consideration to the deformations of  $CP_2$  type vacuum extremals.

#### Solution ansatz

I proceed by the following arguments to the ansatz.

1. Effective 3-dimensionality for action (holography) requires that action decomposes to vanishing  $j^\alpha A_\alpha$  term + total divergence giving 3-D "boundary" terms. The first term certainly vanishes (giving effective 3-dimensionality) for

$$D_\beta J^{\alpha\beta} = j^\alpha = 0 \quad .$$

Empty space Maxwell equations, something extremely natural. Also for the proposed GRT limit these equations are true.

2. How to obtain empty space Maxwell equations  $j^\alpha = 0$ ? The answer is simple: assume self duality or its slight modification:

$$J = *J$$

holding for  $CP_2$  type vacuum extremals or a more general condition

$$J = k * J \quad ,$$

In the simplest situation  $k$  is some constant not far from unity.  $*$  is Hodge dual involving 4-D permutation symbol.  $k = \text{constant}$  requires that the determinant of the induced metric is apart from constant equal to that of  $CP_2$  metric. It does not require that the induced metric

is proportional to the  $CP_2$  metric, which is not possible since  $M^4$  contribution to metric has Minkowskian signature and cannot be therefore proportional to  $CP_2$  metric.

One can consider also a more general situation in which  $k$  is scalar function as a generalization of the weak electric-magnetic duality. In this case the Kähler current is non-vanishing but divergenceless. This also guarantees the reduction to  $Tr(TH^k) = 0$ . In this case however the proportionality of the metric determinant to that for  $CP_2$  metric is not needed. This solution ansatz becomes therefore more general.

3. Field equations reduce with these assumptions to equations differing from minimal surfaces equations only in that metric  $g$  is replaced by Maxwellian energy momentum tensor  $T$ . Schematically:

$$Tr(TH^k) = 0 \quad ,$$

where  $T$  is the Maxwellian energy momentum tensor and  $H^k$  is the second fundamental form - asymmetric 2-tensor defined by covariant derivative of gradients of imbedding space coordinates.

**How to satisfy the condition  $Tr(TH^k) = 0$ ?**

It would be nice to have minimal surface equations since they are the non-linear generalization of massless wave equations. It would be also nice to have the vanishing of the terms involving Kähler current in field equations as a consequence of this condition. Indeed,  $T = \kappa G + \Lambda g$  implies this. In the case of  $CP_2$  vacuum extremals one cannot distinguish between these options since  $CP_2$  itself is constant curvature space with  $G \propto g$ . Furthermore, if  $G$  and  $g$  have similar tensor structure the algebraic field equations for  $G$  and  $g$  are satisfied separately so that one obtains minimal surface property also now. In the following minimal surface option is considered.

1. The first option is achieved if one has

$$T = \Lambda g \quad .$$

Maxwell energy momentum tensor would be proportional to the metric! One would have dynamically generated cosmological constant! This begins to look really interesting since it appeared also at the proposed GRT limit of TGD [?]. Note that here also non-constant value of  $\Lambda$  can be considered and would correspond to a situation in which  $k$  is scalar function: in this case the the determinant condition can be dropped and one obtains just the minimal surface equations.

2. Very schematically and forgetting indices and being sloppy with signs, the expression for  $T$  reads as

$$T = JJ - g/4Tr(JJ) \quad .$$

Note that the product of tensors is obtained by generalizing matrix product. This should be proportional to metric.

Self duality implies that  $Tr(JJ)$  is just the instanton density and does not depend on metric and is constant.

For  $CP_2$  type vacuum extremals one obtains

$$T = -g + g = 0 \quad .$$

Cosmological constant would vanish in this case.

3. Could it happen that for deformations a small value of cosmological constant is generated?

The condition would reduce to

$$JJ = (\Lambda - 1)g \quad .$$

$\Lambda$  must relate to the value of parameter  $k$  appearing in the generalized self-duality condition. For the most general ansatz  $\Lambda$  would not be constant anymore.

This would generalize the defining condition for Kähler form

$$JJ = -g \quad (i^2 = -1 \text{ geometrically})$$

stating that the square of Kähler form is the negative of metric. The only modification would be that index raising is carried out by using the induced metric containing also  $M^4$  contribution rather than  $CP_2$  metric.

4. Explicitly:

$$J_{\alpha\mu}J^{\mu}_{\beta} = (\Lambda - 1)g_{\alpha\beta} \ .$$

Cosmological constant would measure the breaking of Kähler structure. By writing  $g = s+m$  and defining index raising of tensors using  $CP_2$  metric and their product accordingly, this condition can be also written as

$$Jm = (\Lambda - 1)mJ \ .$$

If the parameter  $k$  is constant, the determinant of the induced metric must be proportional to the  $CP_2$  metric. If  $k$  is scalar function, this condition can be dropped. Cosmological constant would not be constant anymore but the dependence on  $k$  would drop out from the field equations and one would hope of obtaining minimal surface equations also now. It however seems that the dimension of  $M^4$  projection cannot be four. For 4-D  $M^4$  projection the contribution of the  $M^2$  part of the  $M^4$  metric gives a non-holomorphic contribution to  $CP_2$  metric and this spoils the field equations.

For  $T = \kappa G + \Lambda g$  option the value of the cosmological constant is large - just as it is for the proposed GRT limit of TGD [K77] [?]. The interpretation in this case is that the average value of cosmological constant is small since the portion of space-time volume containing generalized Feynman diagrams is very small.

### More detailed ansatz for the deformations of $CP_2$ type vacuum extremals

One can develop the ansatz to a more detailed form. The most obvious guess is that the induced metric is apart from constant conformal factor the metric of  $CP_2$ . This would guarantee self-duality apart from constant factor and  $j^\alpha = 0$ . Metric would be in complex  $CP_2$  coordinates tensor of type (1,1) whereas  $CP_2$  Riemann connection would have only purely holomorphic or anti-holomorphic indices. Therefore  $CP_2$  contributions in  $Tr(TH^k)$  would vanish identically.  $M^4$  degrees of freedom however bring in difficulty. The  $M^4$  contribution to the induced metric should be proportional to  $CP_2$  metric and this is impossible due to the different signatures. The  $M^4$  contribution to the induced metric breaks its Kähler property but would preserve Hermitian structure.

A more realistic guess based on the attempt to construct deformations of  $CP_2$  type vacuum extremals is following.

1. Physical intuition suggests that  $M^4$  coordinates can be chosen so that one has integrable decomposition to longitudinal degrees of freedom parametrized by two light-like coordinates  $u$  and  $v$  and to transversal polarization degrees of freedom parametrized by complex coordinate  $w$  and its conjugate.  $M^4$  metric would reduce in these coordinates to a direct sum of longitudinal and transverse parts. I have called these coordinates Hamilton Jacobi coordinates.
2.  $w$  would be holomorphic function of  $CP_2$  coordinates and therefore satisfy massless wave equation. This would give hopes about rather general solution ansatz.  $u$  and  $v$  cannot be holomorphic functions of  $CP_2$  coordinates. Unless wither  $u$  or  $v$  is constant, the induced metric would receive contributions of type (2,0) and (0,2) coming from  $u$  and  $v$  which would break Kähler structure and complex structure. These contributions would give no-vanishing contribution to all minimal surface equations. Therefore either  $u$  or  $v$  is constant: the coordinate line for non-constant coordinate -say  $u$ - would be analogous to the  $M^4$  projection of  $CP_2$  type vacuum extremal.

3. With these assumptions the induced metric would remain (1,1) tensor and one might hope that  $Tr(TH^k)$  contractions vanishes for all variables except  $u$  because there are no common index pairs (this if non-vanishing Christoffel symbols for  $H$  involve only holomorphic or anti-holomorphic indices in  $CP_2$  coordinates). For  $u$  one would obtain massless wave equation expressing the minimal surface property.
4. If the value of  $k$  is constant the determinant of the induced metric must be proportional to the determinant of  $CP_2$  metric. The induced metric would contain only the contribution from the transversal degrees of freedom besides  $CP_2$  contribution. Minkowski contribution has however rank 2 as  $CP_2$  tensor and cannot be proportional to  $CP_2$  metric. It is however enough that its determinant is proportional to the determinant of  $CP_2$  metric with constant proportionality coefficient. This condition gives an additional non-linear condition to the solution. One would have wave equation for  $u$  (also  $w$  and its conjugate satisfy massless wave equation) and determinant condition as an additional condition.

The determinant condition reduces by the linearity of determinant with respect to its rows to sum of conditions involved 0,1,2 rows replaced by the transversal  $M^4$  contribution to metric given if  $M^4$  metric decomposes to direct sum of longitudinal and transversal parts. Derivatives with respect to derivative with respect to particular  $CP_2$  complex coordinate appear linearly in this expression they can depend on  $u$  via the dependence of transversal metric components on  $u$ . The challenge is to show that this equation has (or does not have) non-trivial solutions.

5. If the value of  $k$  is scalar function the situation changes and one has only the minimal surface equations and Virasoro conditions.

What makes the ansatz attractive is that special solutions of Maxwell empty space equations are in question, equations reduces to non-linear generalizations of Euclidian massless wave equations, and possibly space-time dependent cosmological constant pops up dynamically. These properties are true also for the GRT limit of TGD [?].

### 3.2.3 Hamilton-Jacobi conditions in Minkowskian signature

The maximally optimistic guess is that the basic properties of the deformations of  $CP_2$  type vacuum extremals generalize to the deformations of other known extremals such as massless extremals, vacuum extremals with 2-D  $CP_2$  projection which is Lagrangian manifold, and cosmic strings characterized by Minkowskian signature of the induced metric. These properties would be following.

1. The recomposition of  $M^4$  tangent space to longitudinal and transversal parts giving Hamilton-Jacobi structure. The longitudinal part has hypercomplex structure but the second light-like coordinate is constant: this plays a crucial role in guaranteeing the vanishing of contractions in  $Tr(TH^k)$ . It is the algebraic properties of  $g$  and  $T$  which are crucial.  $T$  can however have light-like component  $T^{vv}$ . For the deformations of  $CP_2$  type vacuum extremals (1,1) structure is enough and is guaranteed if second light-like coordinate of  $M^4$  is constant whereas  $w$  is holomorphic function of  $CP_2$  coordinates.
2. What could happen in the case of massless extremals? Now one has 2-D  $CP_2$  projection in the initial situation and  $CP_2$  coordinates depend on light-like coordinate  $u$  and single real transversal coordinate. The generalization would be obvious: dependence on single light-like coordinate  $u$  and holomorphic dependence on  $w$  for complex  $CP_2$  coordinates. The constraint is  $T = \Lambda g$  cannot hold true since  $T^{vv}$  is non-vanishing (and light-like). This property restricted to transversal degrees of freedom could reduce the field equations to minimal surface equations in transversal degrees of freedom. The transversal part of energy momentum tensor would be proportional to metric and hence covariantly constant. Gauge current would remain light-like but would not be given by  $j = *d\phi \wedge J$ .  $T = \kappa G + \Lambda g$  seems to define the attractive option.

It therefore seems that the essential ingredient could be the condition

$$T = \kappa G + \lambda g \ ,$$

which has structure (1,1) in both  $M^2(m)$  and  $E^2(m)$  degrees of freedom apart from the presence of  $T^{vv}$  component with deformations having no dependence on  $v$ . If the second fundamental form has (2,0)+(0,2) structure, the minimal surface equations are satisfied provided Kähler current satisfies on of the proposed three conditions and if  $G$  and  $g$  have similar tensor structure.

One can actually pose the conditions of metric as complete analogs of stringy constraints leading to Virasoro conditions in quantization to give

$$g_{uu} = 0 \quad , \quad g_{vv} = 0 \quad , \quad g_{uw} = 0 \quad , \quad g_{\bar{w}\bar{w}} = 0 \quad . \quad (3.2.2)$$

This brings in mind the generalization of Virasoro algebra to four-dimensional algebra for which an identification in terms of non-local Yangian symmetry has been proposed [?]. The number of conditions is four and the same as the number of independent field equations. One can consider similar conditions also for the energy momentum tensor  $T$  but allowing non-vanishing component  $T^{vv}$  if deformations has no  $v$ -dependence. This would solve the field equations if the gauge current vanishes or is light-like. On this case the number of equations is 8. First order differential equations are in question and they can be also interpreted as conditions fixing the coordinates used since there is infinite number of manners to choose the Hamilton-Jacobi coordinates.

One can try to apply the physical intuition about general solutions of field equations in the linear case by writing the solution as a superposition of left and right propagating solutions:

$$\xi^k = f_+^k(u, w) + f_-^k(v, w) \quad . \quad (3.2.3)$$

This could guarantee that second fundamental form is of form (2,0)+(0,2) in both  $M^2$  and  $E^2$  part of the tangent space and these terms if  $Tr(TH^k)$  vanish identically. The remaining terms involve contractions of  $T^{uw}$ ,  $T^{u\bar{w}}$  and  $T^{vw}$ ,  $T^{v\bar{w}}$  with second fundamental form. Also these terms should sum up to zero or vanish separately. Second fundamental form has components coming from  $f_+^k$  and  $f_-^k$

Second fundamental form  $H^k$  has as basic building bricks terms  $\hat{H}^k$  given by

$$\hat{H}_{\alpha\beta}^k = \partial_\alpha \partial_\beta h^k + \binom{k}{l \ m} \partial_\alpha h^l \partial_\beta h^m \quad . \quad (3.2.4)$$

For the proposed ansatz the first terms give vanishing contribution to  $H_{uv}^k$ . The terms containing Christoffel symbols however give a non-vanishing contribution and one can allow only  $f_+^k$  or  $f_-^k$  as in the case of massless extremals. This reduces the dimension of  $CP_2$  projection to  $D = 3$ .

What about the condition for Kähler current? Kähler form has components of type  $J_{w\bar{w}}$  whose contravariant counterpart gives rise to space-like current component.  $J_{uw}$  and  $J_{u\bar{w}}$  give rise to light-like currents components. The condition would state that the  $J^{w\bar{w}}$  is covariantly constant. Solutions would be characterized by a constant Kähler magnetic field. Also electric field is represent. The interpretation both radiation and magnetic flux tube makes sense.

### 3.2.4 Deformations of cosmic strings

In the physical applications it has been assumed that the thickening of cosmic strings to Kähler magnetic flux tubes takes place. One indeed expects that the proposed construction generalizes also to the case of cosmic strings having the decomposition  $X^4 = X^2 \times Y^2 \subset M^4 \times CP_2$ , where  $X^2$  is minimal surface and  $Y^2$  a complex homologically non-trivial sub-manifold of  $CP_2$ . Now the starting point structure is Hamilton-Jacobi structure for  $M_m^2 \times Y^2$  defining the coordinate space.

1. The deformation should increase the dimension of either  $CP_2$  or  $M^4$  projection or both. How this thickening could take place? What comes in mind that the string orbits  $X^2$  can be interpreted as a distribution of longitudinal spaces  $M^2(x)$  so that for the deformation  $w$  coordinate becomes a holomorphic function of the natural  $Y^2$  complex coordinate so that  $M^4$  projection becomes 4-D but  $CP_2$  projection remains 2-D. The new contribution to the  $X^2$  part of the induced metric is vanishing and the contribution to the  $Y^2$  part is of type (1, 1) and the the ansatz  $T = \kappa G + \Lambda g$  might be needed as a generalization of the minimal surface equations The ratio of  $\kappa$  and  $G$  would be determined from the form of the Maxwellian energy momentum tensor and be fixed at the

limit of undeformed cosmic strong to  $T = (ag(Y^2) - bg(Y^2))$ . The value of cosmological constant is now large, and overall consistency suggests that  $T = \kappa G + \Lambda g$  is the correct option also for the  $CP_2$  type vacuum extremals.

2. One could also imagine that remaining  $CP_2$  coordinates could depend on the complex coordinate of  $Y^2$  so that also  $CP_2$  projection would become 4-dimensional. The induced metric would receive holomorphic contributions in  $Y^2$  part. As a matter fact, this option is already implied by the assumption that  $Y^2$  is a complex surface of  $CP_2$ .

### 3.2.5 Deformations of vacuum extremals?

What about the deformations of vacuum extremals representable as maps from  $M^4$  to  $CP_2$ ?

1. The basic challenge is the non-determinism of the vacuum extremals. One should perform the deformation so that conservation laws are satisfied. For massless extremals there is also non-determinism but it is associated with the light-like coordinate so that there are no problems with the conservation laws. This would suggest that a properly chosen time coordinate consistent with Hamilton-Jacobi decomposition becomes light-like coordinate in the induced metric. This poses a conditions on the induced metric.
2. Physical intuition suggests that one cannot require  $T = \Lambda g$  since this would mean that the rank of  $T$  is maximal whereas the original situation corresponds to the vanishing of  $T$ . For small deformations rank two for  $T$  looks more natural and one could think that  $T$  is proportional to a projection of metric to a 2-D subspace. The vision about the long length scale limit of TGD is that Einstein's equations are satisfied and this would suggest  $T = kG$  or  $T = \kappa G + \Lambda g$ . The rank of  $T$  could be smaller than four for this ansatz and this conditions binds together the values of  $\kappa$  and  $G$ .
3. These extremals have  $CP_2$  projection which in the generic case is 2-D Lagrangian sub-manifold  $Y^2$ . Again one could assume Hamilton-Jacobi coordinates for  $X^4$ . For  $CP_2$  one could assume Darboux coordinates  $(P_i, Q_i)$ ,  $i = 1, 2$ , in which one has  $A = P_i dQ_i$ , and that  $Y^2 \subset CP_2$  corresponds to  $Q_i = \text{constant}$ . In principle  $P_i$  would depend on arbitrary manner on  $M^4$  coordinates. It might be more convenient to use as coordinates  $(u, v)$  for  $M^2$  and  $(P_1, P_2)$  for  $Y^2$ . This covers also the situation when  $M^4$  projection is not 4-D. By its 2-dimensionality  $Y^2$  allows always a complex structure defined by its induced metric: this complex structure is not consistent with the complex structure of  $CP_2$  ( $Y^2$  is not complex sub-manifold).

Using Hamilton-Jacobi coordinates the pre-image of a given point of  $Y^2$  is a 2-dimensional sub-manifold  $X^2$  of  $X^4$  and defines also 2-D sub-manifold of  $M^4$ . The following picture suggests itself. The projection of  $X^2$  to  $M^4$  can be seen for a suitable choice of Hamilton-Jacobi coordinates as an analog of Lagrangian sub-manifold in  $M^4$  that is as surface for which  $v$  and  $Im(w)$  vary and  $u$  and  $Re(w)$  are constant.  $X^2$  would be obtained by allowing  $u$  and  $Re(w)$  to vary: as a matter fact,  $(P_1, P_2)$  and  $(u, Re(w))$  would be related to each other. The induced metric should be consistent with this picture. This would requires  $g_{uRe(w)} = 0$ .

For the deformations  $Q_1$  and  $Q_2$  would become non-constant and they should depend on the second light-like coordinate  $v$  only so that only  $g_{uu}$  and  $g_{uw}$  and  $g_{u\bar{w}}$   $g_{w,w}$  and  $g_{\bar{w},\bar{w}}$  receive contributions which vanish. This would give rise to the analogs of Virasoro conditions guaranteeing that  $T$  is a tensor of form (1,1) in both  $M^2$  and  $E^2$  indices and that there are no cross components in the induced metric. A more general formulation states that energy momentum tensor satisfies these conditions. The conditions on  $T$  might be equivalent with the conditions for  $g$  and  $G$  separately.

4. Einstein's equations provide an attractive manner to achieve the vanishing of effective 3-dimensionality of the action. Einstein equations would be second order differential equations and the idea that a deformation of vacuum extremal is in question suggests that the dynamics associated with them is in directions transversal to  $Y^2$  so that only the deformation is dictated partially by Einstein's equations.

5. Lagrangian manifolds do not involve complex structure in any obvious manner. One could however ask whether the deformations could involve complex structure in a natural manner in  $CP_2$  degrees of freedom so that the vanishing of  $g_{w\bar{w}}$  would be guaranteed by holomorphy of  $CP_2$  complex coordinate as function of  $w$ .

One should get the complex structure in some natural manner: in other words, the complex structure should relate to the geometry of  $CP_2$  somehow. The complex coordinate defined by say  $z = P_1 + iQ^1$  for the deformation suggests itself. This would suggest that at the limit when one puts  $Q_1 = 0$  one obtains  $P_1 = P_1(Re(w))$  for the vacuum extremals and the deformation could be seen as an analytic continuation of real function to region of complex plane. This is in spirit with the algebraic approach. The vanishing of Kähler current requires that the Kähler magnetic field is covariantly constant:  $D_z J^{z\bar{z}} = 0$  and  $D_{\bar{z}} J^{z\bar{z}} = 0$ .

6. One could consider the possibility that the resulting 3-D sub-manifold of  $CP_2$  can be regarded as contact manifold with induced Kähler form non-vanishing in 2-D section with natural complex coordinates. The third coordinate variable- call it  $s$ - of the contact manifold and second coordinate of its transversal section would depend on time space-time coordinates for vacuum extremals. The coordinate associated with the transversal section would be continued to a complex coordinate which is holomorphic function of  $w$  and  $u$ .
7. The resulting thickened magnetic flux tubes could be seen as another representation of Kähler magnetic flux tubes: at this time as deformations of vacuum flux tubes rather than cosmic strings. For this ansatz it is however difficult to imagine deformations carrying Kähler electric field.

### 3.2.6 About the interpretation of the generalized conformal algebras

The long-standing challenge has been finding of the direct connection between the super-conformal symmetries assumed in the construction of the geometry of the "world of classical worlds" (WCW) and possible conformal symmetries of field equations. 4-dimensionality and Minkowskian signature have been the basic problems. The recent construction provides new insights to this problem.

1. In the case of string models the quantization of the Fourier coefficients of coordinate variables of the target space gives rise to Kac-Moody type algebra and Virasoro algebra generators are quadratic in these. Also now Kac-Moody type algebra is expected. If one were to perform a quantization of the coefficients in Laurents series for complex  $CP_2$  coordinates, one would obtain interpretation in terms of  $su(3) = u(2) + t$  decomposition, where  $t$  corresponds to  $CP_3$ : the oscillator operators would correspond to generators in  $t$  and their commutator would give generators in  $u(2)$ .  $SU(3)/SU(2)$  coset representation for Kac-Moody algebra would be in question. Kac-Moody algebra would be associated with the generators in both  $M^4$  and  $CP_2$  degrees of freedom. This kind of Kac-Moody algebra appears in quantum TGD.
2. The constraints on induced metric imply a very close resemblance with string models and a generalization of Virasoro algebra emerges. An interesting question is how the two algebras acting on coordinate and field degrees of freedom relate to the super-conformal algebras defined by the symplectic group of  $\delta M^4_+ \times CP_2$  acting on space-like 3-surfaces at boundaries of  $CD$  and to the Kac-Moody algebras acting on light-like 3-surfaces. It has been conjectured that these algebras allow a continuation to the interior of space-time surface made possible by its slicing by 2-surfaces parametrized by 2-surfaces. The proposed construction indeed provides this kind of slicings in both  $M^4$  and  $CP_2$  factor.
3. In the recent case, the algebras defined by the Fourier coefficients of field variables would be Kac-Moody algebras. Virasoro algebra acting on preferred coordinates would be expressed in terms of the Kac-Moody algebra in the standard Sugawara construction applied in string models. The algebra acting on field space would be analogous to the conformal algebra assignable to the symplectic algebra so that also symplectic algebra is present. Stringy pragmatist could imagine quantization of symplectic algebra by replacing  $CP_2$  coordinates in the expressions of Hamiltonians with oscillator operators. This description would be counterpart for the construction of spinor harmonics in WCW and might provide some useful insights.

4. For given type of space-time surface either  $CP_2$  or  $M^4$  corresponds to Kac-Moody algebra but not both. From the point of view of quantum TGD it looks as that something were missing. An analogous problem was encountered at GRT limit of TGD [?]. When Euclidian space-time regions are allowed Einstein-Maxwell action is able to mimic standard model with a surprising accuracy but there is a problem: one obtains either color charges or  $M^4$  charges but not both. Perhaps it is not enough to consider either  $CP_2$  type vacuum extremal or its exterior but both to describe particle: this would give the direct product of the Minkowskian and Euclidian algebras acting on tensor product. This does not however seem to be consistent with the idea that the two descriptions are duality related (the analog of T-duality).

### 3.3 Under what conditions electric charge is conserved for the modified Dirac equation?

One might think that talking about the conservation of electric charge at 21st century is a waste of time. In TGD framework this is certainly not the case and the following arguments suggests that the conservation of electric charge is the Golden Road to the understanding of the spinorial dynamics.

1. In quantum field theories there are two manners to define em charge: as electric flux over 2-D surface sufficiently far from the source region or in the case of spinor field quantum mechanically as combination of fermion number and vectorial isospin. The latter definition is quantum mechanically more appropriate.
2. There is however a problem. In standard approach to gauge theory Dirac equation in the presence of charged classical gauge fields does not conserve the electric charge: electron is transformed to neutrino and vice versa. Quantization solves the problem since the non-conservation can be interpreted in terms of emission of gauge bosons. In TGD framework this does not work since one does not have path integral quantization anymore. Preferred extremals carry classical gauge fields and the question whether em charge is conserved arises. Heuristic picture suggests that em charge must be conserved. This condition might be actually one of the conditions defining what it is to be a preferred extremal. It is not however trivial whether this kind of additional condition can be posed.

#### 3.3.1 Conditions guaranteing the conservation of em charge

What does the conservation of em charge imply in the case of the modified Dirac equation? The obvious guess that the em charged part of the modified Dirac operator must annihilate the solutions, turns out to be correct as the following argument demonstrates.

1. Em charge as coupling matrix can be defined as a linear combination  $Q = aI + bI_3$ ,  $I_3 = J_{kl}\Sigma^{kl}$ , where  $I$  is unit matrix and  $I_3$  vectorial isospin matrix,  $J_{kl}$  is the Kähler form of  $CP_2$ ,  $\Sigma^{kl}$  denotes sigma matrices, and  $a$  and  $b$  are numerical constants different for quarks and leptons.  $Q$  is covariantly constant in  $M^4 \times CP_2$  and its covariant derivatives at space-time surface are also well-defined and vanish.
2. The modes of the modified Dirac equation should be eigen modes of  $Q$ . This is the case if the modified Dirac operator  $D$  commutes with  $Q$ . The covariant constancy of  $Q$  can be used to derive the condition

$$\begin{aligned}
 [D, Q] \Psi &= D_1 \Psi = 0 \quad , \\
 D &= \hat{\Gamma}^\mu D_\mu \quad , \quad D_1 = [D, Q] = \hat{\Gamma}_1^\mu D_\mu \quad , \quad \hat{\Gamma}_1^\mu = [\hat{\Gamma}^\mu, Q] \quad .
 \end{aligned}
 \tag{3.3.1}$$

Covariant constancy of  $J$  is absolutely essential: without it the resulting conditions would not be so simple.

It is easy to find that also  $[D_1, Q]\Psi = 0$  and its higher iterates  $[D_n, Q]\Psi = 0$ ,  $D_n = [D_{n-1}, Q]$  must be true. The solutions of the modified Dirac equation would have an additional symmetry.

3. The commutator  $D_1 = [D, Q]$  reduces to a sum of terms involving the commutators of the vectorial isospin  $I_3 = J_{kl}\Sigma^{kl}$  with the  $CP_2$  part of the gamma matrices:

$$D_1 = [Q, D] = [I_3, \Gamma_r] \partial_\mu s^r T^{\alpha\mu} D_\alpha . \quad (3.3.2)$$

In standard complex coordinates in which  $U(2)$  acts linearly the complexified gamma matrices can be chosen to be eigenstates of vectorial isospin. Only the charged flat space complexified gamma matrices  $\Gamma^A$  denoted by  $\Gamma^+$  and  $\Gamma^-$  possessing charges +1 and -1 contribute to the right hand side. Therefore the additional Dirac equation  $D_1\Psi = 0$  states

$$\begin{aligned} D_1\Psi &= [Q, D]\Psi = I_3(A) e_{Ar} \Gamma^A \partial_\mu s^r T^{\alpha\mu} D_\alpha \Psi \\ &= (e_{+r} \Gamma^+ - e_{-r} \Gamma^-) \partial_\mu s^r T^{\alpha\mu} D_\alpha \Psi = 0 . \end{aligned} \quad (3.3.3)$$

The next condition is

$$D_2\Psi = [Q, D]\Psi = (e_{+r} \Gamma^+ + e_{-r} \Gamma^-) \partial_\mu s^r T^{\alpha\mu} D_\alpha \Psi = 0 . \quad (3.3.4)$$

Only the relative sign of the two terms has changed. The remaining conditions give nothing new.

4. These equations imply two separate equations for the two charged gamma matrices

$$\begin{aligned} D_+\Psi &= T_+^\alpha \Gamma^+ D_\alpha \Psi = 0 , \\ D_-\Psi &= T_-^\alpha \Gamma^- D_\alpha \Psi = 0 , \\ T_\pm^\alpha &= e_{\pm r} \partial_\mu s^r T^{\alpha\mu} . \end{aligned} \quad (3.3.5)$$

These conditions state what one might have expected: the charged part of the modified Dirac operator annihilates separately the solutions. The reason is that the classical W fields are proportional to  $e_{r\pm}$ .

The above equations can be generalized to define a decomposition of the energy momentum tensor to charged and neutral components in terms of vierbein projections. The equations state that the analogs of the modified Dirac equation defined by charged components of the energy momentum tensor are satisfied separately.

5. In complex coordinates one expects that the two equations are complex conjugates of each other for Euclidian signature. For the Minkowskian signature an analogous condition should hold true. The dynamics enters the game in an essential manner: whether the equations can be satisfied depends on the coefficients  $a$  and  $b$  in the expression  $T = aG + bg$  implied by Einstein's equations in turn guaranteeing that the solution ansatz generalizing minimal surface solutions holds true [K9].
6. As a result one obtains three separate Dirac equations corresponding to the the neutral part  $D_0\Psi = 0$  and charged parts  $D_\pm\Psi = 0$  of the modified Dirac equation. By acting on the equations with these Dirac operators one obtains also that the commutators  $[D_+, D_-]$ ,  $[D_0, D_\pm]$  and also higher commutators obtained from these annihilate the induced spinor field mode. Therefore possibly infinite-dimensional algebra would annihilate the induced spinor fields unless the charged parts of the energy momentum tensor vanish identically.

### 3.3.2 Dirac equation in $CP_2$ as a test bench

What could the conservation of electric charge mean from the point of view of the solutions of the modified Dirac equation? The field equations for the preferred extremals of Kähler action reduce to purely algebraic conditions in the same manner as the field equations for the minimal surfaces in string model. Could something similar happen also for the modified Dirac equation and could the condition on charged part of the Dirac operator help to achieve this?

1. For  $CP_2$  type vacuum extremals the modified Dirac operator vanishes identically for the Kähler action. For volume action it reduces to the ordinary Dirac operator in  $CP_2$  and one can ask whether ordinary Dirac operator could in this case allow solutions with a well-defined em charge. Since also spinor harmonics of the imbedding space are expected to be important and associated with the representations of conformal symmetries assignable to the boundary of light cone involving symplectic group of  $\delta M_{\pm}^4 \times CP_2$ , it would be nice if this construction would work for  $CP_2$ .
2. One can construct the solutions of the ordinary Dirac equation from covariantly constant right-handed neutrino spinor playing the role of fermionic vacuum annihilated by the second half of complexified gamma matrices. Dirac equation reduces to Laplace equation for a scalar function and solution can be constructed from this "vacuum" by multiplying with the spherical harmonics of  $CP_2$  and applying Dirac operator [K39]. Similar construction works quite generally thanks to the existence of covariantly constant right handed neutrino spinor. Spherical harmonics of  $CP_2$  are only replaced with those of space-time surface possessing either hermitian structure of Hamilton-Jacobi structure (corresponding to Euclidian and Minkowskian signatures of the induced metric (Appendix)).
3. A good guess is that holomorphy codes the statement that only spinor harmonics of form  $(n, 0)$  and  $(0, n)$  should be allowed. The first problem is that these modes are not actually holomorphic since color triplet partial waves are proportional to  $1/\sqrt{1 + |\xi^1|^2 + |\xi^2|^2}$ : The are good hopes that covariant derivative containing also a term proportional to Kähler gauge potential and coupling to leptons and quarks differently takes care of this.

Dirac equation in  $CP_2$  allows only modes with  $(m, m+3)$ ,  $(m+3, m)$  for leptons and anti-leptons and modes  $(m+1, m)$  and  $(m, m+1)$  for quarks. More general solutions could be possible but would not be global solutions. If this picture is correct, the dynamics in fermionic degrees of freedom would be extremely restricted and only only very few color partial waves would survive.

4. Most holomorphic and anti-holomorphic modes for leptons and quarks would represent gauge degrees of freedom. The remaining three modes for quarks could be interpreted in terms of color of ground state. At first this looks good since only color neutral leptons and color triplet quarks would be allowed. This result just what has been observed and the experimental absence has indeed a challenge for quantum TGD. The experimental absence of higher modes would be due to Kac-Moody gauge invariance.

Lepto-pion hypothesis in its original form and postulating color octet leptons would be however wrong. This might not be a catastrophe: a variant of this hypothesis identifies lepto-pion as quark antiquark pair associated with scaled down variant of hadron physics [?].

5. A further work described in the sequel however shows that the correct identification of partial waves of imbedding space spinors is in terms of cm degrees of freedom of the partonic 2-surface and can be assigned to the super-symplectic conformal invariance dictating the ground states of Super-Kac-Moody representations. There is therefore no need to modify the earlier well-tested picture.

### 3.3.3 How to satisfy the conditions guaranteeing the conservation of em charge?

There are two manners to satisfy the conditions guaranteeing the conservation of em charge leading to three separate Dirac equations. The first option is inspired by string model and solutions are annihilated either by second charged gamma matrix or holomorphic covariant derivative or by the conjugates of these. For the second option the charged modified gamma matrices vanish identically.

### Holomorphy of the solutions

In string model holomorphy/antiholomorphy for the modes of the induced spinor field is essential from the point of view of Super-Virasoro conditions. For preferred extremals the holomorphy seems to be in a key role and it would not be surprising if this were the case also in the fermionic sector. Could the additional Dirac equations associated with charged parts of the modified Dirac operator be solved by a generalization of holomorphy or anti-holomorphy? For the second charged Dirac operator - say  $D_+$  - complexified gamma matrices would annihilate spinor mode and for the second one - say  $D_-$  - holomorphic covariant derivative would annihilate the spinor. Note that the gamma matrices  $\Gamma_+$  and  $\Gamma_-$  are hermitian conjugates of each other.

The condition that either charged gamma matrix annihilates the spinor mode for the space-time sheet in question requires super-symmetry. For  $CP_2$  one has this kind of supersymmetry but covariant constancy allows only right handed neutrino spinor: in this case however both holomorphic gamma matrices annihilate the spinor. In super-string models in flat target space, one has maximal supersymmetry allowing maximal number of covariantly constant spinor modes. For modified gamma matrices this kind of situation might be realized. If one allows the restriction of the induced spinor fields to string world sheets or partonic 2-surfaces, the situation simplifies further, and it might be possible to assume holomorphy in the complex coordinate parametrizing the 2-surface.

Either  $\Gamma_+$  or  $\Gamma_-$  should annihilate the spinor mode. For right-handed neutrino second half of complexified gamma matrices annihilate it. This condition is analogous to the condition that fermionic annihilation operators annihilate the state. In the recent case the condition is weaker since only single complexified gamma matrix annihilates the state. For  $CP_2$  Dirac operator one obtains four basic solutions corresponding to  $\nu_R, \Gamma_+\nu_R, \Gamma_0\nu_R, \Gamma_0\Gamma_+\nu_R$ .  $\Gamma_0$  is the second holomorphic complexified gamma matrix. Therefore it seems that one might be able to obtain at least two charged states for both quarks and lepton as required by the standard model plus possible higher color partial waves.

A stronger condition is that both  $\Gamma_+$  and  $\Gamma_-$  vanish and Dirac operator reduces to neutral Dirac operator acting on complex coordinate and its conjugate. If the vanishing of  $\Gamma_+$  or  $\Gamma_-$  takes place everywhere the energy momentum tensor must be effectively 2-dimensional. This option has been proposed earlier as a solution ansatz. If the vanishing occurs only at 2-D surface, effective 2-dimensionality holds true only at this surface. This option looks more plausible one.

### Option for which charged parts of energy momentum tensor vanish

The vanishing of the charged parts of the modified Dirac operator  $D$  - or equivalently, those of the energy momentum tensor - would reduce  $D$  to its neutral part and the conditions would trivialize. There would be no need for the full holomorphy, which could be an un-physical condition for  $CP_2$  and not favored if one assumes that all color partial waves in  $CP_2$  correspond to physical states in the construction of representations of the symplectic conformal algebra. On the other hand, the reduction of allowed modes to just the observed one (singlet for leptons and triplet for quarks) is an attractive property. In string models one would speak about super-symmetry breaking. Note that holomorphy in the remaining neutral complex or hyper-complex coordinate could provide elegant solution of the modified Dirac equation exactly in the same manner as it does in string models.

It is however not at all clear whether the charged part of the energy momentum tensor can vanish everywhere. Note however that since imbedding space projections of the energy momentum tensor are in question, the conditions do not mean reduction of the rank of energy momentum tensor to at most two. The possibility that the vanishing occurs only at 2-D surfaces analogous to string world sheets and that induced spinor fields must be restricted to these, is consistent with the existent vision

One can study the option allowing non-vanishing charged Dirac operators and requiring holomorphy, covariant constancy, and extended supersymmetry in more detail. To get some perspective one can the situation in the case of  $CP_2$  type vacuum extremals. In this case the energy momentum tensor and therefore also modified gamma matrices vanish identically. Therefore the situation trivializes and one might hope that for the deformations of  $CP_2$  type vacuum extremals the charged parts of the modified Dirac operator vanish or that holomorphy makes sense.

### 3.3.4 Could the solutions of the modified Dirac equation be restricted to 2-D surfaces?

The condition that the charged Dirac operators (and also neutral one) annihilate physical states is rather strong. If the charged parts  $T_{\pm}^{\alpha}$  of the energy momentum tensor vanish, these conditions apply only to the space-time surface. These conditions are however quite strong and the question is whether one could require them for 2-D sub-manifolds of space-time surface- the analogs of string world sheets- only, and assume that the modes of Dirac equation are restricted on these.

There are several other manners to end up with this view.

1. The vision inspired by the finite measurement resolution is that the solutions of the modified Dirac equation are singular and restricted to 2-dimensional surfaces identifiable as string world sheets in Minkowskian signature and as partonic 2-surfaces in Euclidian signature. For 3-D light-like surfaces solutions would be restricted at world lines defining strands of braid defining discretization as space-time correlate for the finite measurement resolution. The interesting self-referential aspect would be that physical system itself would define the finite measurement resolution.
2. Another interpretation is in terms of the number theoretical vision [K72]. Space-time surfaces define associative or co-associative 4-surfaces with tangent space allowing quaternionic or co-quaternionic structure or its Minkowskian variant. This is a formulation for the idea that classical dynamics is determined by associativity condition. One can however go further and require also commutativity or co-commutativity and this leads to string world sheets or partonic 2-surfaces. The vanishing of the charged components of the energy momentum tensor could be indeed seen as a condition stating that the surface is complex or co-complex sub-manifold (or hyper-complex or co-hyper-complex one).
3. Also strong form of holography leads to the idea that 2-D partonic surfaces or string world sheets and the 4-D tangent space data at them should be enough for the formulation of quantum theory and 4-D space-time surfaces are necessary only for the realization of quantum classical correspondence. One could say that space-time surface is analogous to phase space and that in quantum theory only 2-D slice of it analogous to Lagrangian sub-manifold can be used.

The general vision about preferred extremals involves a non-trivial aspect not yet mentioned [K9] and this allows to developed an argument in favor of reduction of spinorial dynamics to that at 2-D surfaces.

1. Various conserved currents are suggested to define integrable flows meaning that one can identify a global coordinate varying along the flow lines. Could the charged parts of the energy momentum tensor defined as currents define Beltrami flow? If so, these currents have expression of form  $J_{\pm} = \Phi_{\pm} \nabla \Psi_{\pm}$ , where  $\Phi_{\pm}$  and  $\Psi_{\pm}$  are complex scalar functions such that the latter ones define the global coordinate. If this is the case, then the surface at which  $J_{\pm}$  vanishes corresponds to the surface  $\Phi_{+} = \bar{\Phi}_{-} = 0$  and by complex valuedness of  $\Phi_{\pm} = 0$  is 2-dimensional rather than 0-dimensional as for a generic vector field. The charged parts of energy momentum tensor vanish identically as do the corresponding modified gamma matrices.
2. Vanishing of  $\Phi_{\pm}$  would reduce the 4-D conformal algebra to 2-dimensional conformal algebra associated with the string world sheet or partonic 2-surface, and this is just what is expected on basis of physical intuition. One could say that locally space-time surface reduces to effectively 2-D surface. Charge conservation would select 2-dimensional string world sheets and/or partonic 2-surfaces and reproduce the earlier picture inspired by the notion of finite measurement resolution, by number theoretical considerations, and by strong form of holography.

A couple of further comments about are in order.

1. A natural consistency condition is that the modified gamma matrices in the modified Dirac operator are parallel to the 2-D surface. Otherwise one obtains covariant derivatives in transversal direction giving delta functions. This requires that modified gamma matrices generate a 2-D subspace tangential to  $X^2$  at  $X^2$ . This condition need not hold true elsewhere. This would mean

that with respect to the effective metric defined by the anticommutators of the modified gamma matrices space-time surface becomes effectively 2-dimensional locally. Effective 2-dimensionality of the effective metric was conjectured already earlier but now it is restricted to string world sheets and partonic 2-surfaces thus appearing as singularities of the preferred extremals. String world sheets and partonic 2-surfaces must obey some dynamics and minimal surface equation in the effective metric is a good guess since it automatically would reduce the situation to 2-D one.

2. Weak form of electric magnetic duality states that at partonic 2-surface  $X^2$  the Kähler electric field strength  $J^{n\beta}$  in 2-dimensional tangent plane of  $X^4$  transversal to  $X^2$  is proportional to the 4-D dual of the Kähler magnetic field strength  $J_{\alpha\beta}$  at  $X^2$  :  $J^{n\beta} = k\epsilon^{n\beta\gamma\delta}J_{\gamma\delta}$  ,  $k = \text{constant}$ . The transversal plane is not unique without some additional condition and the natural condition is that it defines tangent plane to the string world sheet.

### 3.3.5 The algebra spanned by the modified Dirac operators

The conservation of em charge for the modified Dirac equation implies that the electromagnetic charge determined defined as  $Q = aI + bI_3$  is conserved in the classical electro-weak gauge fields identified as induced gauge fields. This condition is highly non-trivial and as has been found could hold true only at 2-D surfaces implying a stringy localization of fermions.

For the modified Dirac equation additional consistency conditions analogous to Super-Virasoro conditions follow from the conditions that electromagnetic charge is constant for the modes of the modified Dirac equation. The conditions state that the possibly infinite-dimensional algebra or super-algebra generated by the neutral part and two charged parts with charges  $\pm 1$  of the modified Dirac operator annihilates the preferred solutions of the modified Dirac equation.

For super-algebra option one would start with anti-commutators of the Dirac operators and consider commutators when either generators has even value of em charge. For algebra option one would consider only commutators which are formally Lie commutators of gamma matrix valued vector fields  $\Gamma_i^\alpha D_\alpha$  which ordinary derivatives replaced with covariant derivatives and components of the vector fields replaced with the modified gamma matrices obtained by contracting the neutral or charged part of the energy momentum tensor with flat space gamma matrices.

The commutator is the more feasible option as following arguments show.

1. Ordinary modified Dirac equation gives rise to a conserved fermionic current and its conservation could be seen as a consequence of the modified Dirac equation. The statement that the modified Dirac operators annihilate the induced spinors could thus be equivalent with the statement that SU(2) triplet of fermionic currents is conserved. In old fashioned hadron physics this corresponds to conserved vector current hypothesis.
2. The algebra defined by the commutators has the structure of vectorial SU(2) algebra and the natural guess is that this algebra relates closely to  $\mathcal{N} = 2$  super-conformal algebra for which super-generators  $G$  form SU(2) triplets and which allows conserved U(1) currents besides energy momentum tensor.

In the recent case the U(1) charge would be em charge. As a matter fact,  $\mathcal{N} = 2$  algebra is accompanied also by SU(2) algebra of conserved currents and the attractive interpretation is that the Dirac operators generate this algebra.

3. The algebra of Dirac operators annihilating the induced spinor field would define algebra of divergences of fermionic currents of form  $J_i^\alpha = \bar{\Psi}\Gamma_i^\alpha\Psi$ . These currents are conserved if the modified Dirac equations are satisfied. The algebra generated by the commutators of these fermionic currents assuming anti-commutation relations for the induced spinor fields should be equivalent with the algebra of Dirac operators. This should fix the anti-commutation relations for the induced spinor fields.
4. The outcome is a bosonic algebra of vector currents. By replacing  $\bar{\Psi}$  or  $\Psi$  with a mode of the induced spinor field one would obtain super-algebra generators of extended super-algebra. The divergences of fermionic and bosonic generators would generate algebra which vanishes identically for the solutions of the modified Dirac equation. The currents themselves would be non-vanishing.

5. If the charged currents vanish at 2-surface then the commutator of charged Dirac operator vanishes identically. The commutators of neutral and charged Dirac operators need not vanish identically and it might be necessary to pose this as an additional conditions. The vanishing conditions reduce to the vanishing of the ordinary commutator  $[T_0, T_{\pm}]$  of vector fields  $T_0$  and  $T_{\pm}$ .

What about the super algebra part of the Super-Virasoro algebra. Is it also present?

1. One must notice that it is the "gamma matrix fields" defined by neutral and charged parts of the modified gamma matrices  $\Gamma_i^A$  forming an  $SU(2)$  triplet and these anti-commute classically to parts of the modified metric for which certain parts should vanish. These "certain parts" should vanish also for the induced metric resulting as anti-commutators of the induced gamma matrices. The conditions are not expected to be independent and should correspond to Virasoro conditions for the induced metric.
2. The  $SU(2)$  Super Virasoro algebra discussed above would naturally relate to  $\mathcal{N} = 2$  variant of the ordinary Super-Virasoro algebra and electromagnetic charge would take the role of conserved  $U(1)$  current accompanying  $\mathcal{N} = 2$  algebra. This algebra indeed involves  $SU(2)$  as an additional symmetry algebra. Modified Dirac equations would correspond to conservation of the  $SU(2)$  currents and the vanishing conditions on the induced metric and/or its analog defined by the anti-commutators of the modified gamma matrices would correspond to Virasoro conditions. It is however not clear whether the modified gamma matrices - or rather, their second quantized variants - should annihilate the physical states. This condition would correspond for the induced spinor fields a condition stating that second half of complexified modified gamma matrices annihilates the right handed neutrino spinor serving as the analog of fermionic Fock vacuum.

### 3.3.6 Connection with the number theoretical vision about field equations

The recent progress in the understanding of preferred extremals of Kähler action suggests also an interesting connection to the number theoretic vision about field equations [K72]. In particular, it might be possible to understand how one can have Hermitian/Hamilton-Jacobi structure simultaneously with quaternionic structure and how quaternionic structure is possible for the Minkowskian signature of the induced metric.

One can imagine two manners of introducing octonionic and quaternionic structures. The first one is based on the introduction of octonionic representation of gamma matrices and second on the notion of octonion real-analycity.

1. If quaternionic structure is defined in terms of the octonionic representation of the imbedding space gamma matrices, there seems to be no obvious problems since one considers automatically complexification of quaternions represented in terms of gamma matrices. For the approach based on the notion of quaternion real analyticity, one is forced to use Wick rotation to define the quaternionic structure in Minkowskian regions or to introduce what I have called hyper-quaternionic structure by imbedding the space-time surface to a sub-space  $M^8$  of complexified octonions. This is admittedly artificial.
2. The octonionic representation effectively replaces  $SO(7,1)$  as tangent space group with  $G_2$  and means selection of preferred  $M^2 \subset M^4$  having interpretation complex plane of octonionic space. A more general condition is that the tangent space of space-time surface at each point contains preferred sub-space  $M^2(x) \subset M^4$  forming an integrable distribution. The same condition is involved with the definition of Hamilton-Jacobi structure. What puts bells ringing is that the modified Dirac equation for the octonionic representation of gamma matrices allows the conservation of electromagnetic charge in the proposed sense a observed for years ago. One can ask whether the conditions on the charged part of energy momentum tensor could relate to the reduction of  $SO(7,1)$  to  $G_2$ .
3. Octonionic gamma matrices appear also in the proposal stating that space-time surfaces are quaternionic in the sense that tangent space of the space-time surface is quaternionic in the sense that induced octonionic gamma matrices generate a quaternionic sub-space at a given point of space-time time. Besides this the already mentioned additional condition stating that

the tangent space contains preferred sub-space  $M^2 \subset M^4$  or integrable distribution of this kind of sub-spaces is required. It must be emphasized that induced rather than modified gamma matrices are natural in these conditions.

**Definition of quaternionicity based on gamma matrices**

The definition of quaternionicity in terms of gamma matrices looks more promising. This however raises two questions.

1. Can the quaternionicity of the space-time surface together with a preferred distribution of tangent planes  $M^2(x) \subset M^4$  or  $E^2(x) \subset CP_2$  be equivalent with the reduction of the field equations to the analogs of minimal surface equations stating that certain components of the induced metric in complex/Hamilton-Jacobi coordinates vanish in turn guaranteeing that field equations reduce to algebraic identifies following from the fact that energy momentum tensor and second fundamental form have no common components? This should be the case if one requires that the two solution ansätze are equivalent.
2. Can the conditions for the modified Dirac equation select complex of co-complex 2-sub-manifold of space-time surface identified as quaternionic or co-quaternionic 4-surface? Could the conditions stating the vanishing of charged energy momentum currents state that the spinor fields are localized to complex or co-complex (hyper-complex or co-hypercomplex) 2-surfaces?

One should assign to the space-time sheets both quaternionic and Hermitian or Hamilton-Jacobi structure. There are two structures involved. Euclidian metric is an essential aspect of what it is to be quaternionic or octonions. It however seems that one can assign to the induced metric only Hermitian or Hamilton-Jacobi structure. This leads to a serious of innocent questions.

1. Could these two structures be associated with canonical momentum currents and metric respectively? Anti-commutators of the modified gamma matrices define an effective metric expressible in terms of canonical momentum currents as

$$G^{\alpha\beta} = \Pi_k^\alpha \Pi^{\beta k} .$$

Here  $\Pi_k^\alpha = \partial L / \partial_\alpha h^k$  is the canonical momentum current. This effective metric should have a deep physical and mathematical meaning but this meaning has remained a mystery.

2. Could  $G$  be assigned with the quaternionic structure and induced metric to the Hermitian/Hamilton-Jacobi structures? Or perhaps vice versa? Could the neutral and charged components of the energy momentum tensor somehow correspond to quaternionic units?

The basic potential problem with the assignment of quaternionic structure to the induced gamma matrices is the signature of the metric in Minkowskian regions.

1. If quaternionic structures is defined in terms of the octonionic representation of the imbedding space gamma matrices, there seems to be no obvious problems since one considers automatically complexification of quaternions.
2. For the approach based on the notion of quaternion real analyticity, one is forced to use Wick rotation to define the quaternionic structure or to introduce hyper-quaternionic structure by imbedding the space-time surface to a sub-space  $M|_{\text{sup}_i} \otimes S_i / \text{sup}_i$  of complexified octonions. This is admittedly artificial.

Could one pose the additional requirement that the signature of the effective metric  $G$  defined by the modified gamma marices (and to be distinguished from Einstein tensor) is Euclidian in the sense that all four eigenvalues of this tensor would have same sign.

1. For the induced metric the projections of gamma matrices are given by

$$\Gamma_\alpha = \Gamma^a e_{a\alpha} , \quad e_{a\alpha} = e_{ak} \partial_\alpha h^k .$$

For the modified gamma matrices their analogs would be given by

$$\Gamma^\alpha = \Gamma^a E_a^\alpha \quad , \quad E_a^\alpha = e_a^k \Pi_k^\alpha \quad .$$

One cannot induce  $G$  from any metric defined in the imbedding space but the notion of tangent space quaternionicity is well-defined.

2. What quaternionic structure for  $G$  could mean? One can imagine several options.

- (a) For the ordinary complex structure metric has vanishing diagonal components and the inner product for infinitesimal vectors is just  $g_{z\bar{z}}(dz_1 d\bar{z}_2 + dz_2 d\bar{z}_1)$ . Could this formula generalize to  $g_{Q\bar{Q}}(dQ_1 d\bar{Q}_2 + dQ_2 d\bar{Q}_1)$ ? The generalization would be a direct generalization of conformal invariance to 4-D context stating that 4-metric is quaternion-conformally equivalent to flat metric. This would give additional strong condition on energy momentum tensor:

$$G = \Pi_k^\alpha \Pi^{\beta k} = T^2 \delta_{\alpha\beta} \quad .$$

The proportionality to Euclidian metric means in Minkowskian realm that the  $G$  is of form  $G = T^2(2u_\alpha u_\beta - g_{\alpha\beta})$ . Here  $u$  is time-like vector field satisfying  $u^\alpha u_\alpha = 1$  and having interpretation as a local four-velocity (in Robertson-Walker cosmology similar situation is encountered). The eigen value problem in the form  $G_\beta^\alpha x^\beta = \lambda x^\alpha$  makes sense and eigenvectors would be  $u^\alpha$  with eigenvalue  $\lambda = T^2$  and three vectors orthogonal to it with eigenvalue  $-T^2$ . This requires integrable flow defined by  $u$  and defining a preferred time coordinate. In number theoretic vision this kind of time coordinate is introduced and corresponds to the direction assignable to the octonionic real unit. Note that the vanishing of charged projections of the energy momentum tensor does not imply a reduction of the rank of  $T$  so that this options might work.

- (b) Quaternionicity could mean also the structure of hyper-Kähler manifold. Metric and Kähler form for Kähler manifold are generalized to metric representing quaternion real unit and three covariantly constant Kähler forms  $I_i$  obeying the multiplication rules for quaternions. The necessary condition is that the holonomy group equals to  $SU(2)$  identifiable as automorphism group of quaternions. One can also define quaternionic structure: there would exist three antisymmetric tensors, whose squares give the negative of the metric.  $CP_2$  allows quaternionic structure in this sense and only one of these forms is covariantly constant.

Could space-time surface allow Hyper-Kähler or quaternionic structure somehow induced from that of  $CP_2$ ? This does not work for  $G$ .  $G$  is quadratic in energy momentum tensor and therefore involves four power of  $J$  rather than being square of projection of  $J$  or two other quaternionic imaginary units of  $CP_2$ . One can of course ask whether the induced quaternionic units could obey the multiplication of quaternionic units and have same square given by the projection of  $CP_2$  metric. In this case  $CP_2$  metric would define the effective metric and would be indeed Euclidian. For the ansatz for preferred extremals with Minkowskian signature  $CP_2$  projection is at most 3-dimensional but also in this case the imaginary units might allow a realization as projections.

### Definition of quaternionicity based on octonion real-analyticity

Second definition of quaternionicity is on more shaky basis and motivated by the solutions of 2-D Laplace equation: quaternionic space-time surfaces would be obtained as zero loci of octonion real-analytic functions. Unfortunately octonion real-analyticity does not make sense in Minkowskian signature.

One could understand octonion real-analyticity in Minkowskian signature if one could understand the deeper meaning of Wick rotation. Octonion real analyticity formulated as a condition for the vanishing of the imaginary part of octonion real-analytic function makes sense for in octonionic coordinates for  $E^4 \times CP_2$  with Euclidian signature of metric.  $M^4 \times CP_2$  is however only a subspace of complexified octonions and not closed with respect to multiplication so that octonion real-analytic functions do not make sense in  $M^4 \times CP_2$ . Wick rotation should transform the solution candidate

defined by an octonion real-analytic function to that defined in  $M^4 \times CP_2$ . A natural additional condition is that Wick rotation should reduce to that taking  $M^2 \subset M^4$  to  $E^2 \subset E^4$ .

The following trivial observation made in the construction of Hamilton-Jacobi structure in  $M^4$  with Minkowskian signature of the induced metric (see the Appendix) as a Wick rotation of Hermitian structure in  $E^4$  might help here.

1. The components of the metric of  $E^2$  in complex coordinates  $(z, \bar{z})$  for  $E^2$  are given by  $g_{w\bar{w}} = -1$  whereas the metric of  $M^2$  in light-like coordinates  $(u = x+t, v = x-t)$  is given by  $g_{uv} = -1$ . The metric is same and  $M^2$  and  $E^2$  correspond only to different interpretations for the coordinates! One could say that  $M^4 \times CP_2$  and  $E^4 \times CP_2$  have same metric tensor, Kähler structure, and spinor structure. Since only these appear in field equations, one could hope that the solutions of field equations in  $M^4 \times CP_2$  and  $E^4 \times CP_2$  are obtained by Wick rotation. This for preferred extremals at least and if the field equations reduce to purely algebraic ones.
2. If one accepts the proposed construction of preferred extremals of Kähler action discussed in [?], the field equations indeed reduce to purely algebraic conditions satisfied if space-time surface possesses Hermitian structure in the case of Euclidian signature of the induced metric and Hamilton-Jacobi structure in the case of Minkowskian signature. Just as in the case of minimal surfaces, energy momentum tensor and second fundamental form have no common non-vanishing components. The algebraization requires as a consistency condition Einstein's equations with a cosmological term. Gravitational constant and cosmological constant follow as predictions.
3. If Wick rotation in the replacement of  $E^2$  coordinates  $(z, \bar{z})$  with  $M^2$  coordinates  $(u, v)$  makes sense, one can hope that field equations for the preferred extremals hold true also for a Wick rotated surfaces obtained by mapping  $M^2 \subset M^4$  to  $E^2 \subset E^4$ . Also Einstein's equations should be satisfied by the Wick rotated metric with Euclidian signature.
4. Wick rotation makes sense also for the surfaces defined by the vanishing of the imaginary part (complementary to quaternionic part) of octonion real-analytic function. Therefore one can hope that this ansatz could work. Wick rotation is non-trivial geometrically. For instance, light-like lines  $v = 0$  of hyper-complex plane  $M^2$  are taken to  $\bar{z} = 0$  defining a point of complex plane  $E^2$ . Note that non-invertible hyper-complex numbers correspond to the two light-like lines  $u = 0$  and  $v = 0$  whereas non-invertible complex numbers correspond to the origin of  $E^2$ .
5. If the conjecture holds true, one can apply to both factors in  $E^4 = E^2 \times E^2$  and to get preferred extremals in  $M^{2,2} \times CP_2$ . Minkowski space  $M^{2,2}$  is essential in twistor approach and the possibility to carry out Wick rotation for preferred extremals could justify Wick rotation in quantum theory.

### 3.3.7 Modification of the measurement interaction term

By quantum classical correspondence the momenta and other quantum numbers should have correlates in the geometry of the space-time sheet. This suggests an inclusion to the modified Dirac action of a general coordinate invariant measurement interaction term invariant under appropriate subgroup of isometries characterizing the choice of the measurement axis. In the following only the measurement interaction term assignable to four-momentum is discussed. One could assign this term only to 3-D space-like ends of space-time surface and the light-like wormhole throats. Somewhat surprisingly the effective gauge character of this term allows also the assignment to space-time interior.

The first guess for the measurement interaction term for 4-momentum would be as  $\lambda \bar{\Psi} \Gamma^\alpha p_\alpha \Psi$  restricted to 3-D preferred surface in question. This term however vanishes at the light-like orbits of wormhole throats since the modified gamma matrices defined by the Chern-Simons term contain only  $CP_2$  gamma matrices. This forced to replace the term with  $\lambda \bar{\Psi} \gamma^k p_k \Psi$  in the original approach [?]. This term does not possess a formal gauge character and treats  $M^4$  and  $CP_2$  asymmetrically. Second problem is that measurement interaction term is proportional to a constant  $\lambda$  with dimensions of mass and unless one can relate it to gravitational constant, is un-natural.

As already noticed, the measurement interaction term formally corresponds to a gauge transform of Kähler gauge potential by the gradient  $p_\alpha = p_k \partial_\alpha m^k$  defining the momentum projection. The change of the gauge eliminating this term introduces plane wave factor to the induced spinor field. The gauge transformation eliminating the measurement interaction term does not become trivial asymptotically

and might therefore carry physical information. Therefore one can consider also the possibility that measurement interaction term is introduced at the entire 4-D space-time sheet. In this case the change of gauge by a phase transformation introducing a plane-wave factor would lead to the equation without measurement interaction term and one would obtain holomorphic solutions.

Consider now the 4-D option in more detail.

1. One can argue that the measurement interaction term in the interior can be transformed away by a gauge transformation  $A_\alpha \rightarrow A_\alpha - p_\alpha$  so that the holomorphic solutions are not lost. The global nature of the gauge transformation gives hopes that it indeed codes information via the plane wave phase multiplying the holomorphic solutions. The projection  $p_\alpha$  appearing in the contraction with the modified gamma matrices is automatically parallel to the tangent space of the string world sheet or partonic 2-surface.
2. The question whether there is a connection between gravitational and ordinary Planck constants led to the conjecture that the gravitational momentum squared defined by the modified gamma matrices would be equal to inertial momentum squared [K25] just as Equivalence Principle requires. In other words, the gravitational longitudinal 2-momentum squared  $p_{gr}^2 = g_{eff}^{\alpha\beta} p_\alpha p_\beta$  would be equal to the inertial 2-momentum squared  $p_I^2 = m_2^{kl} p_k p_l$  at respective tangent spaces  $M^2$  resp.  $E^2$  of string world sheet resp. partonic 2-surface. At the ends of braid strands defining the intersections of string world sheets and partonic 2-surfaces, one would have

$$p_{gr}^2 = g_{eff,s}^{\alpha\beta} p_\alpha p_\beta + g_{eff,p}^{\alpha\beta} p_\alpha p_\beta = p^2 .$$

Here the subscripts 's' and 'p' refer to string world sheet and partonic 2-surface respectively.

3. It would be nice if this condition would somehow follow from the proposed field equation for the induced spinors at the edges of string world sheet, where one should treat the gauge conditions carefully without doing the gauge transformation. At the intersection point it would seem necessary to assume that the ordinary derivatives - maybe even covariant derivatives - vanish. If covariant derivatives vanish, the modified Dirac equation in 4-D sense would reduce to the condition that the sum of the measurement interaction terms annihilates the spinor modes. This would give

$$\Gamma^\alpha p_\alpha \Psi = 0$$

at the ends of braid strands and this would give massless condition in 4-D sense stating  $p_{gr,||}^2 + p_{gr,\perp}^2 = 0$ .

4. The modified Dirac equation contains a boundary term  $\Gamma^n \Psi$  at the boundaries of the string world sheet. The vanishing of  $\Gamma^n$  proportional to the canonical momentum current in the normal direction at wormhole throats could be forced by the condition that classical charges do not leak between Minkowskian and Euclidian regions of the space-time sheet. This condition cannot be posed at space-like 3-surfaces since they represent initial data.

To sum up, this option is favored because no dimensional coupling is needed and because one obtains a connection between ordinary Planck constant and gravitational Planck constant as discussed in [K25]. Also a close connection with braid picture and generalized Feynman diagrams with lines identified as massless wormhole throats emerges.

### 3.4 Preferred extremals and solutions of the modified Dirac equation and super-conformal symmetries

The new vision about preferred extremals and modified Dirac equations is bound to check the existing vision about super-conformal symmetries. One important discovery is that Einstein's equations follow from the vanishing of terms proportional to Kähler current in field equations for preferred extremals and Equivalence Principle at the classical level is realized automatically in all scales in contrast to

the earlier belief. This obviously must have implications to the general vision about Super-Virasoro representations and one must be ready to modify the existing picture based on the assumption that quantum version of Equivalence Principle is realized in terms coset representations.

The very special role of right handed neutrino is also bound to have profound implications. A further important outcome is the identification of gauge potentials as duals of Kac-Moody currents at the boundaries of string world sheets: quantum gauge potentials are defined only where they are needed that is the curves defining the non-integrable phase factors. This gives also rise to the realization of the conjecture Yangian in terms of the Kac-Moody charges and commutators in accordance with the earlier conjecture.

### 3.4.1 Super-conformal symmetries

It is good to summarize first the basic ideas about Super-Virasoro representations. TGD allows two kinds of super-conformal symmetries.

1. The first super-conformal symmetry is associated with  $\delta M_{\pm}^4 \times CP_2$  and corresponds to symplectic symmetries of  $\delta M_{\pm}^4 \times CP_2$ . The reason for extension of conformal symmetries is metric 2-dimensionality of the light-like boundary  $\delta M_{\pm}^4$  defining upper/lower boundary of causal diamond ( $CD$ ). This super-conformal symmetry is something new and corresponds to replacing finite-dimensional Lie-group  $G$  for Kac-Moody symmetry with infinite-dimensional symplectic group. The light-like radial coordinate of  $\delta M_{\pm}^4$  takes the role of the real part of complex coordinate  $z$  for ordinary conformal symmetry. Together with complex coordinate of  $S^2$  it defines 3-D restriction of Hamilton-Jacobi variant of 4-D super-conformal symmetries. One can continue the conformal symmetries from light-cone boundary to  $CD$  by forming a slicing by parallel copies of  $\delta M_{\pm}^4$ . There are two possible slicings corresponding to the choices  $\delta M_+^4$  and  $\delta M_-^4$  assignable to the upper and lower boundaries of  $CD$ . These two choices correspond to two arrows of geometric time for the basis of zero energy states in ZEO.
2. Super-symplectic degrees of freedom determine the electroweak and color quantum numbers of elementary particles. Bosonic emergence implies that ground states assignable to partonic 2-surfaces correspond to partial waves in  $\delta M_{\pm}^4$  and one obtains color partial waves in particular. These partial waves correspond to the solutions for the Dirac equation in imbedding space and the correlation between color and electroweak quantum numbers is not quite correct. Super-Kac-Moody generators give the compensating color for massless states obtained from tachyonic ground states guaranteeing that standard correlation is obtained. Super-symplectic degrees are therefore directly visible in particle spectrum. One can say that at the pointlike limit the WCW spinors reduce to tensor products of imbedding space spinors assignable to the center of mass degrees of freedom for the partonic 2-surfaces defining wormhole throats.

I have proposed a physical interpretation of super-symplectic vibrational degrees of freedom in terms of degrees of freedom assignable to non-perturbative QCD. These degrees of freedom would be responsible for most of the baryon masses but their theoretical understanding is lacking in QCD framework.

3. The second super-conformal symmetry is assigned light-like 3-surfaces and to the isometries and holonomies of the imbedding space and is analogous to the super-Kac-Moody symmetry of string models. Kac-Moody symmetries could be assigned to the light-like deformations of light-like 3-surfaces. Isometries give tensor factor  $E^2 \times SU(3)$  and holonomies factor  $SU(2)_L \times U(1)$ . Altogether one has 5 tensor factors to super-conformal algebra. That the number is just five is essential for the success p-adic mass calculations [K45, K39].

The construction of solutions of the modified Dirac equation suggests strongly that the fermionic representation of the Super-Kac-Moody algebra can be assigned as conserved charges associated with the space-like braid strands at both the 3-D space-like ends of space-time surfaces and with the light-like (or space-like with a small deformation) associated with the light-like 3-surfaces. The extension to Yangian algebra involving higher multilinears of super-Kac Moody generators is also highly suggestive. These charges would be non-local and assignable to several wormhole contacts simultaneously. The ends of braids would correspond points of partonic 2-surfaces defining a discretization of the partonic 2-surface having interpretation in terms of finite measurement resolution.

These symmetries would correspond to electroweak and strong gauge fields and to gravitation. The duals of the currents giving rise to Kac-Moody charges would define the counterparts of gauge potentials and the conserved Kac-Moody charges would define the counterparts of non-integrable phase factors in gauge theories. The higher Yangian charges would define generalization of non-integrable phase factors. This would suggest a rather direct connection with the twistorial program for calculating the scattering amplitudes implies also by zero energy ontology.

Quantization recipes have worked in the case of super-string models and one can ask whether the application of quantization to the coefficients of powers of complex coordinates or Hamilton-Jacobi coordinates could lead to the understanding of the 4-D variants of the conformal symmetries and give detailed information about the representations of the Kac-Moody algebra too.

### 3.4.2 What is the role of the right-handed neutrino?

A highly interesting aspect of Super-Kac-Moody symmetry is the special role of right handed neutrino.

1. Only right handed neutrino allows besides the modes restricted to 2-D surfaces also the 4D modes delocalized to the entire space-time surface. The first ones are holomorphic functions of single coordinate and the latter ones holomorphic functions of two complex/Hamilton-Jacobi coordinates. Only  $\nu_R$  has the full  $D = 4$  counterpart of the conformal symmetry and the localization to 2-surfaces has interpretation as super-conformal symmetry breaking halving the number of super-conformal generators.
2. This forces to ask for the meaning of super-partners. Are super-partners obtained by adding  $\nu_R$  neutrino localized at partonic 2-surface or delocalized to entire space-time surface or its Euclidian or Minkowskian region accompanying particle identified as wormhole throat? Only the Euclidian option allows to assign right handed neutrino to a unique partonic 2-surface. For the Minkowskian regions the assignment is to many particle state defined by the partonic 2-surfaces associated with the 3-surface. Hence for spartners the 4-D right-handed neutrino must be associated with the 4-D Euclidian line of the generalized Feynman diagram.
3. The orthogonality of the localized and de-localized right handed neutrino modes requires that 2-D modes correspond to higher color partial waves at the level of imbedding space. If color octet is in question, the 2-D right handed neutrino as the candidate for the generator of standard SUSY would combine with the left handed neutrino to form a massive neutrino. If 2-D massive neutrino acts as a generator of super-symmetries, it is in the same role as badly broken supersymmetries generated by other 2-D modes of the induced spinor field (SUSY with rather large value of  $\mathcal{N}$ ) and one can argue that the counterpart of standard SUSY cannot correspond to this kind of super-symmetries. The right-handed neutrinos delocalized inside the lines of generalized Feynman diagrams, could generate  $\mathcal{N} = 2$  variant of the standard SUSY.

#### How particle and right handed neutrino are bound together?

Ordinary SUSY means that apart from kinematical spin factors sparticles and particles behave identically with respect to standard model interactions. These spin factors would allow to distinguish between particles and sparticles. But is this the case now?

1. One can argue that 2-D particle and 4-D right-handed neutrino behave like independent entities, and because  $\nu_R$  has no standard model couplings this entire structure behaves like a particle rather than sparticle with respect to standard model interactions: the kinematical spin dependent factors would be absent.
2. The question is also about the internal structure of the sparticle. How the four-momentum is divided between the  $\nu_R$  and 2-D fermion. If  $\nu_R$  carries a negligible portion of four-momentum, the four-momentum carried by the particle part of sparticle is same as that carried by particle for given four-momentum so that the distinctions are only kinematical for the ordinary view about sparticle and trivial for the view suggested by the 4-D character of  $\nu_R$ .

Could sparticle character become manifest in the ordinary scattering of sparticle?

1. If  $\nu_R$  behaves as an independent unit not bound to the particle, it would continue in the original direction as particle scatters: sparticle would decay to particle and right-handed neutrino. If  $\nu_R$  carries a non-negligible energy the scattering could be detected via a missing energy. If not, then the decay could be detected by the interactions revealing the presence of  $\nu_R$ .  $\nu_R$  can have only gravitational interactions. What these gravitational interactions are is not however quite clear since the proposed identification of gravitational gauge potentials is as duals of Kac-Moody currents analogous to gauge potentials located at the boundaries of string world sheets. Does this mean that 4-D right-handed neutrino has no quantal gravitational interactions? Does internal consistency require  $\nu_R$  to have a vanishing gravitational and inertial masses and does this mean that this particle carries only spin?
2. The cautious conclusion would be following: if delocalized  $\nu_R$  and parton are un-correlated particle and sparticle cannot be distinguished experimentally and one might perhaps understand the failure to detect standard SUSY at LHC. Note however that the 2-D fermionic oscillator algebra defines badly broken large  $\mathcal{N}$  SUSY containing also massive (longitudinal momentum square is non-vanishing) neutrino modes as generators.

### Taking a closer look on sparticles

It is good to take a closer look at the delocalized right handed neutrino modes.

1. At imbedding space level that is in cm mass degrees of freedom they correspond to covariantly constant  $CP_2$  spinors carrying light-like momentum which for causal diamond could be discretized. For non-vanishing momentum one can speak about helicity having opposite sign for  $\nu_R$  and  $\bar{\nu}_R$ . For vanishing four-momentum the situation is delicate since only spin remains and Majorana like behavior is suggestive. Unless one has momentum continuum, this mode might be important and generate additional SUSY resembling standard  $\mathcal{N} = 1$  SUSY.
2. At space-time level the solutions of modified Dirac equation are holomorphic or anti-holomorphic.
  - (a) For non-constant holomorphic modes these characteristics correlate naturally with fermion number and helicity of  $\nu_R$ . One can assign creation/annihilation operator to these two kinds of modes and the sign of fermion number correlates with the sign of helicity.
  - (b) The covariantly constant mode is naturally assignable to the covariantly constant neutrino spinor of imbedding space. To the two helicities one can assign also oscillator operators  $\{a_{\pm}, a_{\pm}^{\dagger}\}$ . The effective Majorana property is expressed in terms of non-orthogonality of  $\nu_R$  and  $\bar{\nu}_R$  translated to the non-vanishing of the anti-commutator  $\{a_{+}^{\dagger}, a_{-}\} = \{a_{-}^{\dagger}, a_{+}\} = 1$ . The reduction of the rank of the  $4 \times 4$  matrix defined by anti-commutators to two expresses the fact that the number of degrees of freedom has halved.  $a_{+}^{\dagger} = a_{-}$  realizes the conditions and implies that one has only  $\mathcal{N} = 1$  SUSY multiplet since the state containing both  $\nu_R$  and  $\bar{\nu}_R$  is same as that containing no right handed neutrinos.
  - (c) One can wonder whether this SUSY is masked totally by the fact that sparticles with all possible conformal weights  $n$  for induced spinor field are possible and the branching ratio to  $n = 0$  channel is small. If momentum continuum is present, the zero momentum mode might be equivalent to nothing.

What can happen in spin degrees of freedom in super-symmetric interaction vertices if one accepts this interpretation? As already noticed, this depends solely on what one assumes about the correlation of the four-momenta of particle and  $\nu_R$ .

1. For SUSY generated by covariantly constant  $\nu_R$  and  $\bar{\nu}_R$  there is no neutrino four-momentum involved so that only spin matters. One cannot speak about the change of direction for  $\nu_R$ . In the scattering of sparticle the direction of particle changes and introduces different spin quantization axes.  $\nu_R$  retains its spin and in new system it is superposition of two spin projections. The presence of both helicities requires that the transformation  $\nu_R \rightarrow \bar{\nu}_R$  happens with an amplitude determined purely kinematically by spin rotation matrices. This is consistent with fermion number conservation modulo 2.  $\mathcal{N} = 1$  SUSY based on Majorana spinors is highly suggestive.

2. For SUSY generated by non-constant holomorphic and anti-holomorphic modes carrying fermion number the behavior in the scattering is different. Suppose that the sparticle does not split to particle moving in the new direction and  $\nu_R$  moving in the original direction so that also  $\nu_R$  or  $\bar{\nu}_R$  carrying some massless fraction of four-momentum changes its direction of motion. One can form the spin projections with respect to the new spin axis but must drop the projection which does not conserve fermion number. Therefore the kinematics at the vertices is different. Hence  $\mathcal{N} = 2$  SUSY with fermion number conservation is suggestive when the momentum directions of particle and  $\nu_R$  are completely correlated.
3. Since right-handed neutrino has no standard model couplings, p-adic thermodynamics for 4-D right-handed neutrino must correspond to a very low p-adic temperature  $T = 1/n$ . This implies that the excitations with non-vanishing conformal weights are effectively absent and one would have  $\mathcal{N} = 1$  SUSY effectively.

The simplest assumption is that particle and sparticle correspond to the same p-adic mass scale and have degenerate masses: it is difficult to imagine any good reason for why the p-adic mass scales should differ. This should have been observed -say in decay widths of weak bosons - unless the spartners correspond to large  $\hbar$  phase and therefore to dark matter. Note that for the badly broken 2-D  $\mathcal{N}=2$  SUSY in fermionic sector this kind of almost degeneracy cannot be excluded and I have considered an explanation for the mysterious X and Y mesons in terms of this degeneracy [K43].

### Why space-time SUSY is not possible in TGD framework?

LHC suggests that one does not have  $\mathcal{N} = 1$  SUSY in standard sense. Why one cannot have standard space-time SUSY in TGD framework. Let us begin by listing all arguments popping in mind.

1. Could covariantly constant  $\nu_R$  represents a gauge degree of freedom? This is plausible since the corresponding fermion current is non-vanishing.
2. The original argument for absence of space-time SUSY years ago was indirect:  $M^4 \times CP_2$  does not allow Majorana spinors so that  $\mathcal{N} = 1$  SUSY is excluded.
3. One can however consider  $\mathcal{N} = 2$  SUSY by including both helicities possible for covariantly constant  $\nu_R$ . For  $\nu_R$  the four-momentum vanishes so that one cannot distinguish the modes assigned to the creation operator and its conjugate via complex conjugation of the spinor. Rather, one oscillator operator and its conjugate correspond to the two different helicities of right-handed neutrino with respect to the direction determined by the momentum of the particle. The spinors can be chosen to be real in this basis. This indeed gives rise to an irreducible representation of spin 1/2 SUSY algebra with right-handed neutrino creation operator acting as a ladder operator. This is however  $\mathcal{N} = 1$  algebra and right-handed neutrino in this particular basis behaves effectively like Majorana spinor. One can argue that the system is mathematically inconsistent. By choosing the spin projection axis differently the spinor basis becomes complex. In the new basis one would have  $\mathcal{N} = 2$ , which however reduces to  $\mathcal{N} = 1$  in the real basis.
4. Or could it be that fermion and sfermion do exist but cannot be related by SUSY? In standard SUSY fermions and sfermions forming irreducible representations of super Poincare algebra are combined to components of superfield very much like finite-dimensional representations of Lorentz group are combined to those of Poincare. In TGD framework  $\nu_R$  generates in space-time interior generalization of 2-D super-conformal symmetry but covariantly constant  $\nu_R$  cannot give rise to space-time SUSY.

This would be very natural since right-handed neutrinos do not have any electroweak interactions and are delocalized into the interior of the space-time surface unlike other particles localized at 2-surfaces. It is difficult to imagine how fermion and  $\nu_R$  could behave as a single coherent unit reflecting itself in the characteristic spin and momentum dependence of vertices implied by SUSY. Rather, it would seem that fermion and sfermion should behave identically with respect to electroweak interactions.

The third argument looks rather convincing and can be developed to a precise argument.

1. If sfermion is to represent elementary bosons, the products of fermionic oscillator operators with the oscillator operators assignable to the covariantly constant right handed neutrinos must define might-be bosonic oscillator operators as  $b_n = a_n a$  and  $b_n^\dagger = a_n^\dagger a^\dagger$ . One can calculate the commutator for the product of operators. If fermionic oscillator operators commute, so do the corresponding bosonic operators. The commutator  $[b_n, b_n^\dagger]$  is however proportional to occupation number for  $\nu_R$  in  $\mathcal{N} = 1$  SUSY representation and vanishes for the second state of the representation. Therefore  $\mathcal{N} = 1$  SUSY is a pure gauge symmetry.
2. One can however have both irreducible representations of SUSY: for them either fermion or sfermion has a non-vanishing norm. One would have both fermions and sfermions but they would not belong to the same SUSY multiplet, and one cannot expect SUSY symmetries of 3-particle vertices.
3. For instance,  $\gamma FF$  vertex is closely related to  $\gamma \tilde{F} \tilde{F}$  in standard SUSY. Now one expects this vertex to decompose to a product of  $\gamma F \tilde{F}$  vertex and amplitude for the creation of  $\nu_R \tilde{\nu}_R$  from vacuum so that the characteristic momentum and spin dependent factors distinguishing between the couplings of photon to scalar and fermion are absent. Both states behave like fermions. The amplitude for the creation of  $\nu_R \tilde{\nu}_R$  from vacuum is naturally equal to unity as an occupation number operator by crossing symmetry. The presence of right-handed neutrinos would be invisible if this picture is correct. Whether this invisible label can have some consequences is not quite clear: one could argue that the decay rates of weak bosons to fermion pairs are doubled unless one introduces  $1/\sqrt{2}$  factors to couplings.

Where the sfermions might make themselves visible are loops. What loops are? Consider boson line first. Boson line is replaced with a sum of two contributions corresponding to ordinary contribution with fermion and antifermion at opposite throats and second contribution with fermion and antifermion accompanied by right-handed neutrino  $\nu_R$  and its antiparticle which now has opposite helicity to  $\nu_R$ . The loop for  $\nu_R$  decomposes to four pieces since also the propagation from wormhole throat to the opposite wormhole throat must be taken into account. Each of the four propagators equals to  $a_{1/2}^\dagger a_{-1/2}^\dagger$  or its hermitian conjugate. The product of these is slashed between vacuum states and anti-commutations give imaginary unit per propagator giving  $i^4 = 1$ . The two contributions are therefore identical and the scaling  $g \rightarrow g/\sqrt{2}$  for coupling constants guarantees that sfermions do not affect the scattering amplitudes at all. The argument is identical for the internal fermion lines.

### 3.4.3 WCW geometry and super-conformal symmetries

The vision about the geometry of WCW has been roughly the following and the recent steps of progress induce to it only small modifications if any.

1. Kähler geometry is forced by the condition that hermitian conjugation allows geometrization. Kähler function is given by the Kähler action coming from space-time regions with Euclidian signature of the induced metric identifiable as lines of generalized Feynman diagrams. Minkowskian regions give imaginary contribution identifiable as the analog of Morse function and implying interference effects and stationary phase approximation. The vision about quantum TGD as almost topological QFT inspires the proposal that Kähler action reduces to 3-D terms reducing to Chern-Simons terms by the weak form of electric-magnetic duality. The recent proposal for preferred extremals is consistent with this property realizing also holography implied by general coordinate invariance. Strong form of general coordinate invariance implying effective 2-dimensionality in turn suggests that Kähler action is expressible in terms of areas of partonic 2-surfaces and string world sheets.
2. The complexified gamma matrices of WCW come as hermitian conjugate pairs and anti-commute to the Kähler metric of WCW. Also bosonic generators of symplectic transformations of  $\delta M_\pm^4 \times CP_2$  assumed to act as isometries of WCW geometry can be complexified and appear as similar pairs. The action of isometry generators co-incides with that of symplectic generators at partonic 2-surfaces and string world sheets but elsewhere inside the space-time surface it is expected to be deformed from the symplectic action. The super-conformal transformations of

$\delta M_{\pm}^4 \times CP_2$  acting on the light-like radial coordinate of  $\delta M_{\pm}^4$  act as gauge symmetries of the geometry meaning that the corresponding WCW vector fields have zero norm.

3. WCW geometry has also zero modes which by definition do not contribute to WCW metric expect possibly by the dependence of the elements of WCW metric on zero modes through a conformal factor. In particular, induced  $CP_2$  Kähler form and its analog for sphere  $r_M = \text{constant}$  of light cone boundary are symplectic invariants, and one can define an infinite number of zero modes as invariants defined by Kähler fluxes over partonic 2-surfaces and string world sheets. This requires however the slicing of  $CD$  parallel copies of  $\delta M_{\pm}^4$  or  $\delta M_{\pm}^4$ . The physical interpretation of these non-quantum fluctuating degrees of freedom is as classical variables necessary for the interpretation of quantum measurement theory. Classical variable would metaphorically correspond the position of the pointer of the measurement instrument.
4. The construction receives a strong philosophical inspiration from the geometry of loop spaces. Loop spaces allow a unique Kähler geometry with maximal isometry group identifiable as Kac-Moody group. The reason is that otherwise Riemann connection does not exist. The only problem is that curvature scalar diverges since the Riemann tensor is by constant curvature property proportional to the metric. In 3-D case one would have union of constant curvature spaces labelled by zero modes and the situation is expected to be even more restrictive. The conjecture indeed is that WCW geometry exists only for  $H = M^4 \times CP_2$ : infinite-D Kähler geometric existence and therefore physics would be unique. One can also hope that Ricci scalar is finite and therefore zero by the constant curvature property so that Einstein's equations are satisfied.
5. WCW Hamiltonians determined the isometry currents and WCW metric is given in terms of the anti-commutators of the Killing vector fields associated with symplectic isometry currents. The WCW Hamiltonians generating symplectic isometries correspond to the Hamiltonians spanning the symplectic group of  $\delta M_{\pm}^4 \times CP_2$ . One can say that the space of quantum fluctuating degrees of freedom is this symplectic group of  $\delta M_{\pm}^4 \times CP_2$  or its subgroup or coset space: this must have very deep implications for the structure of the quantum TGD.
6. Zero energy ontology brings in additional delicacies. Basic objects are now unions of partonic 2-surfaces at the ends of  $CD$ . Also string world sheets would naturally contribute. One can generalize the expressions for the isometry generators in a straightforward manner by requiring that given isometry restricts to a symplectic transformation at partonic 2-surfaces and string world sheets.
7. One could criticize the effective metric 2-dimensionality forced by general consistency arguments as something non-physical. The Hamiltonians are expressed using only the data at partonic 2-surfaces: this includes also 4-D tangent space data via the weak form of electric-magnetic duality so that one has only effective 2-dimensionality. Obviously WCW geometry must have large gauge symmetries besides zero modes. The super-conformal symmetries indeed represent gauge symmetries of this kind. Effective 2-dimensionality realizing strong form of holography in turn is induced by the strong form of general coordinate invariance. Light-like 3-surfaces at which the signature of the induced metric changes must be equivalent with the 3-D space-like ends of space-time surfaces at the light-boundaries of space-time surfaces as far as WCW geometry is considered. This requires that the data from their 2-D intersections defining partonic 2-surfaces should dictate the WCW geometry. Note however that Super-Kac-Moody charges giving information about the interiors of 3-surfaces appear in the construction of the physical states.

What is the role of the right handed neutrino in this construction?

1. In the construction of components of WCW metric as anti-commutators of super-generators only the covariantly constant right-handed neutrino appears in the super-generators analogous to super-Kac-Moody generators. All holomorphic modes of right handed neutrino characterized by two integers could in principle contribute to the WCW gamma matrices identified as fermionic super-symplectic generators anti-commuting to the metric. At the space-like ends of space-time surface the holomorphic generators would restrict to symplectic generators since the radial

light-like coordinate  $r_M$  identified and complex coordinate of  $CP_2$  allowing identification as restrictions of two complex coordinates or Hamilton-Jacobi coordinates to light-like boundary.

2. The non-covariantly constant modes could also correspond to purely super-conformal gauge degrees of freedom. Originally the restriction to right-handed neutrino looked somewhat unsatisfactory but the recent view about Super-Kac-Moody symmetries makes its special role rather natural. One could say that WCW geometry possesses the maximal  $D = 4$  supersymmetry.
3. One can of course ask whether the Super-Kac-Moody generators assignable to the isometries of  $H$  and expressible as conserved charges associated with the boundaries of string world sheets could contribute to the WCW geometry via the anti-commutators. This option cannot be excluded but in this case the interpretation in terms of Hamiltonians is not obvious.

### 3.4.4 Equivalence Principle

An important physical input has been the condition that a generalization of Equivalence Principle is obtained.

1. The proposal has been that inertial and gravitational masses can be assigned with the super-symplectic and super-Kac-Moody representations via the condition that the scaling generator  $L_0$  defined as a difference of the corresponding generators for the two representations annihilates physical states. This requires that super-Kac-Moody algebra can be regarded in some sense as a sub-algebra of super-symplectic algebra. For isometries this would be natural but in the case of holonomies the situation is problematic. The idea has been that the ordinary realization of Equivalence Principle follows as Einstein's equations for fluctuations around vacuum extremals expressing the average energy momentum tensor for the fluctuations.
2. The emergence of Einstein's equations for preferred extremals as additional conditions [K9, K77] allowing the algebraization of the equations to analogs of minimal surface equations changes the situation completely. Is there anymore need to realize Equivalence Principle at quantum level? If one drops this condition one can imagine very simple option obtained as tensor product of the super-symplectic and super-Kac-Moody representations. Of course, coset representations for the symplectic group and its suitable subgroup - say subgroup defining measurement resolution - can be present but would not nothing to do with Equivalence Principle.
3. One can of course argue that one has very naturally to different mass squared operators and therefore inertial and gravitational masses. Inertial mass squared would be naturally assignable to the representations of the super-symplectic algebra imbedding space d'Alembertian and gravitational mass squared with the spinor d'Alembertian at string world sheets at space-time surfaces. Quantum level realization for Equivalence Principle could mean that these two mass squared operators are identical or something analogous to this. One can however criticize this idea as un-necessary and also because the signature of the effective metric defined by the modified Dirac gamma matrices is speculated to be Euclidian.

### 3.4.5 Constraints from p-adic mass calculations and ZEO

A further important physical input comes from p-adic thermodynamics forming a core element of p-adic mass calculations.

1. The first thing that one can get worried about relates to the extension of conformal symmetries. If the conformal symmetries generalize to  $D = 4$ , how can one take seriously the results of p-adic mass calculations based on 2-D conformal invariance? There is no reason to worry. The reduction of the conformal invariance to 2-D one for the preferred extremals takes care of this problem. This however requires that the fermionic contributions assignable to string world sheets and/or partonic 2-surfaces - Super- Kac-Moody contributions - should dictate the elementary particle masses. For hadrons also symplectic contributions should be present. This is a valuable hint in attempts to identify the mathematical structure in more detail.

2. ZEO suggests that all particles, even virtual ones correspond to massless wormhole throats carrying fermions. As a consequence, twistor approach would work and the kinematical constraints to vertices would allow the cancellation of divergences. This would suggest that the p-adic thermal expectation value is for the longitudinal  $M^2$  momentum squared (the definition of  $CD$  selects  $M^1 \subset M^2 \subset M^4$  as also does number theoretic vision). Also propagator would be determined by  $M^2$  momentum. Lorentz invariance would be obtained by integration of the moduli for  $CD$  including also Lorentz boosts of  $CD$ .
3. In the original approach one allows states with arbitrary large values of  $L_0$  as physical states. Usually one would require that  $L_0$  annihilates the states. In the calculations however mass squared was assumed to be proportional  $L_0$  apart from vacuum contribution. This is a questionable assumption. ZEO suggests that total mass squared vanishes and that one can decompose mass squared to a sum of longitudinal and transversal parts. If one can do the same decomposition to longitudinal and transverse parts also for the Super Virasoro algebra then one can calculate longitudinal mass squared as a p-adic thermal expectation in the transversal super-Virasoro algebra and only states with  $L_0 = 0$  would contribute and one would have conformal invariance in the standard sense.
4. In the original approach the assumption motivated by Lorentz invariance has been that mass squared is replaced with conformal weight in thermodynamics, and that one first calculates the thermal average of the conformal weight and then equates it with mass squared. This assumption is somewhat ad hoc. ZEO however suggests an alternative interpretation in which one has zero energy states for which longitudinal mass squared of positive energy state derive from p-adic thermodynamics. Thermodynamics - or rather, its square root - would become part of quantum theory in ZEO.  $M$ -matrix is indeed product of hermitian square root of density matrix multiplied by unitary  $S$ -matrix and defines the entanglement coefficients between positive and negative energy parts of zero energy state.
5. The crucial constraint is that the number of super-conformal tensor factors is  $N = 5$ : this suggests that thermodynamics applied in Super-Kac-Moody degrees of freedom assignable to string world sheets is enough, when one is interested in the masses of fermions and gauge bosons. Super-symplectic degrees of freedom can also contribute and determine the dominant contribution to baryon masses. Should also this contribution obey p-adic thermodynamics in the case when it is present? Or does the very fact that this contribution need not be present mean that it is not thermal? The symplectic contribution should correspond to hadronic p-adic length prime rather than the one assignable to (say)  $u$  quark. Hadronic p-adic mass squared and partonic p-adic mass squared cannot be summed since primes are different. If one accepts the basic rules [K46], longitudinal energy and momentum are additive as indeed assumed in perturbative QCD.
6. Calculations work if the vacuum expectation value of the mass squared must be assumed to be tachyonic. There are two options depending on whether one whether p-adic thermodynamics gives total mass squared or longitudinal mass squared.
  - (a) One could argue that the total mass squared has naturally tachyonic ground state expectation since for massless extremals longitudinal momentum is light-like and transversal momentum squared is necessarily present and non-vanishing by the localization to topological light ray of finite thickness of order p-adic length scale. Transversal degrees of freedom would be modeled with a particle in a box.
  - (b) If longitudinal mass squared is what is calculated, the condition would require that transversal momentum squared is negative so that instead of plane wave like behavior exponential damping would be required. This would conform with the localization in transversal degrees of freedom.
7. What about Equivalence Principle in this framework? A possible quantum counterpart of Equivalence Principle could be that the longitudinal parts of the imbedding space mass squared operator for a given massless state equals to that for d'Alembert operator assignable to the modified Dirac action. The attempts to formulate this in more precise manner however seem to produce only additional troubles.

### 3.4.6 The emergence of Yangian symmetry and gauge potentials as duals of Kac-Moody currents

Yangian symmetry plays a key role in  $\mathcal{N} = 4$  super-symmetric gauge theories. What is special in Yangian symmetry is that the algebra contains also multi-local generators. In TGD framework multi-locality would naturally correspond to that with respect to partonic 2-surfaces and string world sheets and the proposal has been that the Super-Kac-Moody algebras assignable to string worlds sheets could generalize to Yangian.

Witten has written a beautiful exposition of Yangian algebras [?]. Yangian is generated by two kinds of generators  $J^A$  and  $Q^A$  by a repeated formation of commutators. The number of commutations tells the integer characterizing the multi-locality and provides the Yangian algebra with grading by natural numbers. Witten describes a 2-dimensional QFT like situation in which one has 2-D situation and Kac-Moody currents assignable to real axis define the Kac-Moody charges as integrals in the usual manner. It is also assumed that the gauge potentials defined by the 1-form associated with the Kac-Moody current define a flat connection:

$$\partial_\mu j_\nu^A - \partial_\nu j_\mu^A + [j_\mu^A, j_\nu^A] = 0 . \quad (3.4.1)$$

This condition guarantees that the generators of Yangian are conserved charges. One can however consider alternative manners to obtain the conservation.

1. The generators of first kind - call them  $J^A$  - are just the conserved Kac-Moody charges. The formula is given by

$$J_A = \int_{-\infty}^{\infty} dx j^{A0}(x, t) . \quad (3.4.2)$$

2. The generators of second kind contain bi-local part. They are convolutions of generators of first kind associated with different points of string described as real axis. In the basic formula one has integration over the point of real axis.

$$Q^A = f_{BC}^A \int_{-\infty}^{\infty} dx \int_x^{\infty} dy j^{B0}(x, t) j^{C0}(y, t) - 2 \int_{-\infty}^{\infty} j_x^A dx . \quad (3.4.3)$$

These charges are indeed conserved if the curvature form is vanishing as a little calculation shows.

How to generalize this to the recent context?

1. The Kac-Moody charges would be associated with the braid strands connecting two partonic 2-surfaces - Strands would be located either at the space-like 3-surfaces at the ends of the space-time surface or at light-like 3-surfaces connecting the ends. Modified Dirac equation would define Super-Kac-Moody charges as standard Noether charges. Super charges would be obtained by replacing the second quantized spinor field or its conjugate in the fermionic bilinear by particular mode of the spinor field. By replacing both spinor field and its conjugate by its mode one would obtain a conserved c-number charge corresponding to an anti-commutator of two fermionic super-charges. The convolution involving double integral is however not number theoretically attractive whereas single 1-D integrals might make sense.
2. An encouraging observation is that the Hodge dual of the Kac-Moody current defines the analog of gauge potential and exponents of the conserved Kac-Moody charges could be identified as analogs for the non-integrable phase factors for the components of this gauge potential. This identification is precise only in the approximation that generators commute since only in this case the ordered integral  $P(\exp(i \int Adx))$  reduces to  $P(\exp(i \int Adx))$ . Partonic 2-surfaces connected

by braid strand would be analogous to nearby points of space-time in its discretization implying that Abelian approximation works. This conforms with the vision about finite measurement resolution as discretization in terms partonic 2-surfaces and braids.

This would make possible a direct identification of Kac-Moody symmetries in terms of gauge symmetries. For isometries one would obtain color gauge potentials and the analogs of gauge potentials for graviton field (in TGD framework the contraction with  $M^4$  vierbein would transform tensor field to 4 vector fields). For Kac-Moody generators corresponding to holonomies one would obtain electroweak gauge potentials. Note that super-charges would give rise to a collection of spartners of gauge potentials automatically. One would obtain a badly broken SUSY with very large value of  $\mathcal{N}$  defined by the number of spinor modes as indeed speculated earlier [?].

3. The condition that the gauge field defined by 1-forms associated with the Kac-Moody currents are trivial looks unphysical since it would give rise to the analog of topological QFT with gauge potentials defined by the Kac-Moody charges. For the duals of Kac-Moody currents defining gauge potentials only covariant divergence vanishes implying that curvature form is

$$F_{\alpha\beta} = \epsilon_{\alpha\beta} [j_\mu, j^\mu] , \quad (3.4.4)$$

so that the situation does not reduce to topological QFT unless the induced metric is diagonal. This is not the case in general for string world sheets.

4. It seems however that there is no need to assume that  $j_\mu$  defines a flat connection. Witten mentions that although the discretization in the definition of  $J^A$  does not seem to be possible, it makes sense for  $Q^A$  in the case of  $G = SU(N)$  for any representation of  $G$ . For general  $G$  and its general representation there exists no satisfactory definition of  $Q$ . For certain representations, such as the fundamental representation of  $SU(N)$ , the definition of  $Q^A$  is especially simple. One just takes the bi-local part of the previous formula:

$$Q^A = f_{BC}^A \sum_{i < j} J_i^B J_j^C . \quad (3.4.5)$$

What is remarkable that in this formula the summation need not refer to a discretized point of braid but to braid strands ordered by the label  $i$  by requiring that they form a connected polygon. Therefore the definition of  $J^A$  could be just as above.

5. This brings strongly in mind the interpretation in terms of twistor diagrams. Yangian would be identified as the algebra generated by the logarithms of non-integrable phase factors in Abelian approximation assigned with pairs of partonic 2-surfaces defined in terms of Kac-Moody currents assigned with the modified Dirac action. Partonic 2-surfaces connected by braid strand would be analogous to nearby points of space-time in its discretization. This would fit nicely with the vision about finite measurement resolution as discretization in terms partonic 2-surfaces and braids.

The resulting algebra satisfies the basic commutation relations

$$[J^A, J^B] = f_C^{AB} J^C , \quad [J^A, Q^B] = f_C^{AB} Q^C . \quad (3.4.6)$$

plus the rather complex Serre relations described in [?].

### 3.4.7 Quantum criticality and electro-weak gauge symmetries

Quantum criticality is one of the basic guiding principles of Quantum TGD. What it means mathematically is however far from clear.

1. What is obvious is that quantum criticality implies quantization of Kähler coupling strength as a mathematical analog of critical temperature so that the theory becomes mathematically unique if only single critical temperature is possible. Physically this means the presence of long range fluctuations characteristic for criticality and perhaps assignable to the effective hierarchy of Planck constants having explanation in terms of effective covering spaces of the imbedding space. This hierarchy follows from the vacuum degeneracy of Kähler action, which in turn implies 4-D spin-glass degeneracy. It is easy to interpret the degeneracy in terms of criticality.
2. At more technical level one would expect criticality to correspond deformations of a given preferred extremal defining a vanishing second variation of Kähler action. This is analogous to the vanishing of also second derivatives of potential function at extremum in certain directions so that the matrix defined by second derivatives does not have maximum rank. Entire hierarchy of criticalities is expected and a good finite-dimensional model is provided by the catastrophe theory of Thom [A16]. Cusp catastrophe [?] is the simplest catastrophe one can think of, and here the folds of cusp where discontinuous jump occurs correspond to criticality with respect to one control variable and the tip to criticality with respect to both control variables.
3. I have discussed what criticality could mean for modified Dirac action [?] and claimed that it leads to the existence of additional conserved currents defined by the variations which do not affect the value of Kähler action. These arguments are far from being mathematically rigorous and the recent view about the solutions of the modified Dirac equation predicting that the spinor modes are restricted to 2-D string world sheets requires a modification of these arguments.

In the following these arguments are updated. The unexpected result is that critical deformations induce conformal scalings of the modified metric and electro-weak gauge transformations of the induced spinor connection at  $X^2$ . Therefore holomorphy brings in the Kac-Moody symmetries associated with isometries of  $H$  (gravitation and color gauge group) and quantum criticality those associated with the holonomies of  $H$  (electro-weak-gauge group) as additional symmetries.

#### The variation of modes of the induced spinor field in a variation of space-time surface respecting the preferred extremal property

Consider first the variation of the induced spinor field in a variation of space-time surface respecting the preferred extremal property. The deformation must be such that the deformed modified Dirac operator  $D$  annihilates the modified mode. By writing explicitly the variation of the modified Dirac action (the action vanishes by modified Dirac equation) one obtains deformations and requiring its vanishing one obtains

$$\delta\Psi = D^{-1}(\delta D)\Psi . \tag{3.4.7}$$

$D^{-1}$  is the inverse of the modified Dirac operator defining the analog of Dirac propagator and  $\delta D$  defines vertex completely analogous to  $\gamma^k \delta A_k$  in gauge theory context. The functional integral over preferred extremals can be carried out perturbatively by expressing  $\delta D$  in terms of  $\delta h^k$  and one obtains stringy perturbation theory around  $X^2$  associated with the preferred extremal defining maximum of Kähler function in Euclidian region and extremum of Kähler action in Minkowskian region (stationary phase approximation).

What one obtains is stringy perturbation theory for calculating n-points functions for fermions at the ends of braid strands located at partonic 2-surfaces and representing intersections of string world sheets and partonic 2-surfaces at the light-like boundaries of  $CD$ s.  $\delta D$ - or more precisely, its partial derivatives with respect to functional integration variables - appear at the vertices located anywhere in the interior of  $X^2$  with outgoing fermions at braid ends. Bosonic propagators are replaced with correlation functions for  $\delta h^k$ . Fermionic propagator is defined by  $D^{-1}$ .

After 35 years or hard work this provides for the first time a reasonably explicit formula for the N-point functions of fermions. This is enough since by bosonic emergence [?] these N-point functions

define the basic building blocks of the scattering amplitudes. Note that bosonic emergence states that bosons corresponds to wormhole contacts with fermion and antifermion at the opposite wormhole throats.

### What critical modes could mean for the induced spinor fields?

What critical modes could mean for the induced spinor fields at string world sheets and partonic 2-surfaces. The problematic part seems to be the variation of the modified Dirac operator since it involves gradient. One cannot require that covariant derivative remains invariant since this would require that the components of the induced spinor connection remain invariant and this is quite too restrictive condition. Right handed neutrino solutions delocalized into entire  $X^2$  are however an exception since they have no electro-weak gauge couplings and in this case the condition is obvious: modified gamma matrices suffer a local scaling for critical deformations:

$$\delta\Gamma^\mu = \Lambda(x)\Gamma^\mu . \quad (3.4.8)$$

This guarantees that the modified Dirac operator  $D$  is mapped to  $\Lambda D$  and still annihilates the modes of  $\nu_R$  labelled by conformal weight, which thus remain unchanged.

What is the situation for the 2-D modes located at string world sheets? The condition is obvious.  $\Psi$  suffers an electro-weak gauge transformation as does also the induced spinor connection so that  $D_\mu$  is not affected at all. Criticality condition states that the deformation of the space-time surfaces induces a conformal scaling of  $\Gamma^\mu$  at  $X^2$ . It might be possible to continue this conformal scaling of the entire space-time sheet but this might be not necessary and this would mean that all critical deformations induced conformal transformations of the effective metric of the space-time surface defined by  $\{\Gamma^\mu, \Gamma^\nu\} = 2G^{\mu\nu}$ . Thus it seems that effective metric is indeed central concept (recall that if the conjectured quaternionic structure is associated with the effective metric, it might be possible to avoid problem related to the Minkowskian signature in an elegant manner).

In fact, one can consider even more general action of critical deformation: the modes of the induced spinor field would be mixed together in the infinitesimal deformation besides infinitesimal electroweak gauge transformation, which is same for all modes. This would extend electroweak gauge symmetry. Modified Dirac equation holds true also for these deformations. One might wonder whether the conjectured dynamically generated gauge symmetries assignable to finite measurement resolution could be generated in this manner.

The infinitesimal generator of a critical deformation  $J_M$  can be expressed as tensor product of matrix  $A_M$  acting in the space of zero modes and of a generator of infinitesimal electro-weak gauge transformation  $T_M(x)$  acting in the same manner on all modes:  $J_M = A_M \otimes T_M(x)$ .  $A_M$  is a spatially constant matrix and  $T_M(x)$  decomposes to a direct sum of left- and right-handed  $SU(2) \times U(1)$  Lie-algebra generators. Left-handed Lie-algebra generator can be regarded as a quaternion and right handed as a complex number. One can speak of a direct sum of left-handed local quaternion  $q_{M,L}$  and right-handed local complex number  $c_{M,R}$ . The commutator  $[J_M, J_N]$  is given by  $[J_M, J_N] = [A_M, A_N] \otimes \{T_M(x), T_N(x)\} + \{A_M, A_N\} \otimes [T_M(x), T_N(x)]$ . One has  $\{T_M(x), T_N(x)\} = \{q_{M,L}(x), q_{N,L}(x)\} \oplus \{c_{M,R}(x), c_{N,R}(x)\}$  and  $[T_M(x), T_N(x)] = [q_{M,L}(x), q_{N,L}(x)]$ . The commutators make sense also for more general gauge group but quaternion/complex number property might have some deeper role.

Thus the critical deformations would induce conformal scalings of the effective metric and dynamical electro-weak gauge transformations. Electro-weak gauge symmetry would be a dynamical symmetry restricted to string world sheets and partonic 2-surfaces rather than acting at the entire space-time surface. For 4-D delocalized right-handed neutrino modes the conformal scalings of the effective metric are analogous to the conformal transformations of  $M^4$  for  $\mathcal{N} = 4$  SYMs. Also ordinary conformal symmetries of  $M^4$  could be present for string world sheets and could act as symmetries of generalized Feynman graphs since even virtual wormhole throats are massless. An interesting question is whether the conformal invariance associated with the effective metric is the analog of dual conformal invariance in  $\mathcal{N} = 4$  theories.

Critical deformations of space-time surface are accompanied by conserved fermionic currents. By using standard Noetherian formulas one can write

$$J_i^\mu = \bar{\Psi}\Gamma^\mu\delta_i\Psi + \delta_i\bar{\Psi}\Gamma^\mu\Psi . \quad (3.4.9)$$

Here  $\delta\Psi_i$  denotes derivative of the variation with respect to a group parameter labeled by  $i$ . Since  $\delta\Psi_i$  reduces to an infinitesimal gauge transformation of  $\Psi$  induced by deformation, these currents are the analogs of gauge currents. The integrals of these currents along the braid strands at the ends of string world sheets define the analogs of gauge charges. The interpretation as Kac-Moody charges is also very attractive and I have proposed that the 2-D Hodge duals of gauge potentials could be identified as Kac-Moody currents. If so, the 2-D Hodge duals of  $J$  would define the quantum analogs of dynamical electro-weak gauge fields and Kac-Moody charge could be also seen as non-integral phase factor associated with the braid strand in Abelian approximation (the interpretation in terms of finite measurement resolution is discussed earlier).

One can also define super currents by replacing  $\bar{\Psi}$  or  $\Psi$  by a particular mode of the induced spinor field as well as c-number valued currents by performing the replacement for both  $\bar{\Psi}$  or  $\Psi$ . As expected, one obtains a super-conformal algebra with all modes of induced spinor fields acting as generators of super-symmetries restricted to 2-D surfaces. The number of the charges which do not annihilate physical states as also the effective number of fermionic modes could be finite and this would suggest that the integer  $\mathcal{N}$  for the supersymmetry in question is finite. This would conform with the earlier proposal inspired by the notion of finite measurement resolution implying the replacement of the partonic 2-surfaces with collections of braid ends.

Note that Kac-Moody charges might be associated with "long" braid strands connecting different wormhole throats as well as short braid strands connecting opposite throats of wormhole contacts. Both kinds of charges would appear in the theory.

#### What is the interpretation of the critical deformations?

Critical deformations bring in an additional gauge symmetry. Certainly not all possible gauge transformations are induced by the deformations of preferred extremals and a good guess is that they correspond to holomorphic gauge group elements as in theories with Kac-Moody symmetry. What is the physical character of this dynamical gauge symmetry?

1. Do the gauge charges vanish? Do they annihilate the physical states? Do only their positive energy parts annihilate the states so that one has a situation characteristic for the representation of Kac-Moody algebras. Or could some of these charges be analogous to the gauge charges associated with the constant gauge transformations in gauge theories and be therefore non-vanishing in the absence of confinement. Now one has electro-weak gauge charges and these should be non-vanishing. Can one assign them to deformations with a vanishing conformal weight and the remaining deformations to those with non-vanishing conformal weight and acting like Kac-Moody generators on the physical states?
2. The simplest option is that the critical Kac-Moody charges/gauge charges with non-vanishing positive conformal weight annihilate the physical states. Critical degrees of freedom would not disappear but make their presence known via the states labelled by different gauge charges assignable to critical deformations with vanishing conformal weight. Note that constant gauge transformations can be said to break the gauge symmetry also in the ordinary gauge theories unless one has confinement.
3. The hierarchy of quantum criticalities suggests however entire hierarchy of electro-weak Kac-Moody algebras. Does this mean a hierarchy of electro-weak symmetries breakings in which the number of Kac-Moody generators not annihilating the physical states gradually increases as also modes with a higher value of positive conformal weight fail to annihilate the physical state?

The only manner to have a hierarchy of algebras is by assuming that only the generators satisfying  $n \bmod N = 0$  define the sub-Kac-Moody algebra annihilating the physical states so that the generators with  $n \bmod N \neq 0$  would define the analogs of gauge charges. I have suggested for long time ago the relevance of kind of fractal hierarchy of Kac-Moody and Super-Virasoro algebras for TGD but failed to imagine any concrete realization.

A stronger condition would be that the algebra reduces to a finite dimensional algebra in the sense that the actions of generators  $Q_n$  and  $Q_{n+kN}$  are identical. This would correspond to periodic boundary conditions in the space of conformal weights. The notion of finite measurement resolution suggests that the number of independent fermionic oscillator operators is proportional to the number of braid ends so that an effective reduction to a finite algebra is expected.

Whatever the correct interpretation is, this would obviously refine the usual view about electro-weak symmetry breaking.

These arguments suggests the following overall view. The holomorphy of spinor modes gives rise to Kac-Moody algebra defined by isometries and includes besides Minkowskian generators associated with gravitation also  $SU(3)$  generators associated with color symmetries. Vanishing second variations in turn define electro-weak Kac-Moody type algebra.

Note that criticality suggests that one must perform functional integral over WCW by decomposing it to an integral over zero modes for which deformations of  $X^4$  induce only an electro-weak gauge transformation of the induced spinor field and to an integral over moduli corresponding to the remaining degrees of freedom.

### 3.4.8 The importance of being light-like

The singular geometric objects associated with the space-time surface have become increasingly important in TGD framework. In particular, the recent progress has made clear that these objects might be crucial for the understanding of quantum TGD. The singular objects are associated not only with the induced metric but also with the effective metric defined by the anti-commutators of the modified gamma matrices appearing in the modified Dirac equation and determined by the Kähler action.

#### The singular objects associated with the induced metric

Consider first the singular objects associated with the induced metric.

1. At light-like 3-surfaces defined by wormhole throats the signature of the induced metric changes from Euclidian to Minkowskian so that 4-metric is degenerate. These surfaces are carriers of elementary particle quantum numbers and the 4-D induced metric degenerates locally to 3-D one at these surfaces.
2. Braid strands at light-like 3-surfaces are most naturally light-like curves: this correspond to the boundary condition for open strings. One can assign fermion number to the braid strands. Braid strands allow an identification as curves along which the Euclidian signature of the string world sheet in Euclidian region transforms to Minkowskian one. Number theoretic interpretation would be as a transformation of complex regions to hyper-complex regions meaning that imaginary unit  $i$  satisfying  $i^2 = -1$  becomes hyper-complex unit  $e$  satisfying  $e^2 = 1$ . The complex coordinates  $(z, \bar{z})$  become hyper-complex coordinates  $(u = t + ex, v = t - ex)$  giving the standard light-like coordinates when one puts  $e = 1$ .

#### The singular objects associated with the effective metric

There are also singular objects assignable to the effective metric. According to the simple arguments already developed, string world sheets and possibly also partonic 2-surfaces are singular objects with respect to the effective metric defined by the anti-commutators of the modified gamma matrices rather than induced gamma matrices. Therefore the effective metric seems to be much more than a mere formal structure.

1. For instance, quaternionicity of the space-time surface could allow an elegant formulation in terms of the effective metric avoiding the problems due to the Minkowski signature. This is achieved if the effective metric has Euclidian signature  $\epsilon \times (1, 1, 1, 1)$ ,  $\epsilon = \pm 1$  or a complex counterpart of the Minkowskian signature  $\epsilon(1, 1, -1, -1)$ .
2. String world sheets and perhaps also partonic 2-surfaces could be understood as singularities of the effective metric. What happens that the effective metric with Euclidian signature  $\epsilon \times (1, 1, 1, 1)$  transforms to the signature  $\epsilon(1, 1, -1, -1)$  (say) at string world sheet so that one would have the degenerate signature  $\epsilon \times (1, 1, 0, 0)$  at the string world sheet.

What is amazing is that this works also number theoretically. It came as a total surprise to me that the notion of hyper-quaternions as a closed algebraic structure indeed exists. The hyper-quaternionic units would be given by  $(1, I, iJ, iK)$ , where  $i$  is a commuting imaginary unit

satisfying  $i^2 = -1$ . Hyper-quaternionic numbers defined as combinations of these units with real coefficients do form a closed algebraic structure which however fails to be a number field just like hyper-complex numbers do. Note that the hyper-quaternions obtained with real coefficients from the basis  $(1, iI, iJ, iK)$  fail to form an algebra since the product is not hyper-quaternion in this sense but belongs to the algebra of complexified quaternions. The same problem is encountered in the case of hyper-octonions defined in this manner. This has been a stone in my shoe since I feel strong disrelish towards Wick rotation as a trick for moving between different signatures.

3. Could also partonic 2-surfaces correspond to this kind of singular 2-surfaces? In principle, 2-D surfaces of 4-D space intersect at discrete points just as string world sheets and partonic 2-surfaces do so that this might make sense. By complex structure the situation is algebraically equivalent to the analog of plane with non-flat metric allowing all possible signatures  $(\epsilon_1, \epsilon_2)$  in various regions. At light-like curve either  $\epsilon_1$  or  $\epsilon_2$  changes sign and light-like curves for these two kinds of changes can intersect as one can easily verify by drawing what happens. At the intersection point the metric is completely degenerate and simply vanishes.
4. Replacing real 2-dimensionality with complex 2-dimensionality, one obtains by the universality of algebraic dimension the same result for partonic 2-surfaces and string world sheets. The braid ends at partonic 2-surfaces representing the intersection points of 2-surfaces of this kind would have completely degenerate effective metric so that the modified gamma matrices would vanish implying that energy momentum tensor vanishes as does also the induced Kähler field.
5. The effective metric suffers a local conformal scaling in the critical deformations identified in the proposed manner. Since ordinary conformal group acts on Minkowski space and leaves the boundary of light-cone invariant, one has two conformal groups. It is not however clear whether the  $M^4$  conformal transformations can act as symmetries in TGD, where the presence of the induced metric in Kähler action breaks  $M^4$  conformal symmetry. As found, also in TGD framework the Kac-Moody currents assigned to the braid strands generate Yangian: this is expected to be true also for the Kac-Moody counterparts of the conformal algebra associated with quantum criticality. On the other hand, in twistor program one encounters also two conformal groups and the space in which the second conformal group acts remains somewhat mysterious object. The Lie algebras for the two conformal groups generate the conformal Yangian and the integrands of the scattering amplitudes are Yangian invariants. Twistor approach should apply in TGD if zero energy ontology is right. Does this mean a deep connection?

What is also intriguing that twistor approach in principle works in strict mathematical sense only at signatures  $\epsilon \times (1, 1, -1 - 1)$  and the scattering amplitudes in Minkowski signature are obtained by analytic continuation. Could the effective metric give rise to the desired signature? Note that the notion of massless particle does not make sense in the signature  $\epsilon \times (1, 1, 1, 1)$ .

These arguments provide genuine a support for the notion of quaternionicity and suggest a connection with the twistor approach.

### 3.4.9 Realization of large $\mathcal{N}$ SUSY in TGD

The generators large  $\mathcal{N}$  SUSY algebras are obtained by taking fermionic currents for second quantized fermions and replacing either fermion field or its conjugate with its particular mode. The resulting super currents are conserved and define super charges. By replacing both fermion and its conjugate with modes one obtains c number valued currents. Therefore  $\mathcal{N} = \infty$  SUSY - presumably equivalent with super-conformal invariance - or its finite  $\mathcal{N}$  cutoff is realized in TGD framework and the challenge is to understand the realization in more detail.

#### Super-space viz. Grassmann algebra valued fields

Standard SUSY induces super-space extending space-time by adding anti-commuting coordinates as a formal tool. Many mathematicians are not enthusiastic about this approach because of the purely formal nature of anti-commuting coordinates. Also I regard them as a non-sense geometrically and there is actually no need to introduce them as the following little argument shows.

Grassmann parameters (anti-commuting theta parameters) are generators of Grassmann algebra and the natural object replacing super-space is this Grassmann algebra with coefficients of Grassmann algebra basis appearing as ordinary real or complex coordinates. This is just an ordinary space with additional algebraic structure: the mysterious anti-commuting coordinates are not needed. To me this notion is one of the conceptual monsters created by the over-pragmatic thinking of theoreticians.

This allows to replace field space with super field space, which is completely well-defined object mathematically, and leave space-time untouched. Linear field space is simply replaced with its Grassmann algebra. For non-linear field space this replacement does not work. This allows to formulate the notion of linear super-field just in the same manner as it is done usually.

The generators of super-symmetries in super-space formulation reduce to super translations, which anti-commute to translations. The super generators  $Q_\alpha$  and  $\bar{Q}_{\dot{\beta}}$  of super Poincare algebra are Weyl spinors commuting with momenta and anti-commuting to momenta:

$$\{Q_\alpha, \bar{Q}_{\dot{\beta}}\} = 2\sigma_{\alpha\dot{\beta}}^\mu P_\mu . \quad (3.4.10)$$

One particular representation of super generators acting on super fields is given by

$$\begin{aligned} D_\alpha &= i \frac{\partial}{\partial \theta_\alpha} , \\ D_{\dot{\alpha}} &= i \frac{\partial}{\partial \bar{\theta}_{\dot{\alpha}}} + \theta^\beta \sigma_{\beta\dot{\alpha}}^\mu \partial_\mu \end{aligned} \quad (3.4.11)$$

Here the index raising for 2-spinors is carried out using antisymmetric 2-tensor  $\epsilon^{\alpha\beta}$ . Super-space interpretation is not necessary since one can interpret this action as an action on Grassmann algebra valued field mixing components with different fermion numbers.

Chiral superfields are defined as fields annihilated by  $D_{\dot{\alpha}}$ . Chiral fields are of form  $\Psi(x^\mu + i\bar{\theta}\sigma^\mu\theta, \theta)$ . The dependence on  $\bar{\theta}_{\dot{\alpha}}$  comes only from its presence in the translated Minkowski coordinate annihilated by  $D_{\dot{\alpha}}$ . Super-space enthusiast would say that by a translation of  $M^4$  coordinates chiral fields reduce to fields, which depend on  $\theta$  only.

### The space of fermionic Fock states at partonic 2-surface as TGD counterpart of chiral super field

As already noticed, another manner to realize SUSY in terms of representations the super algebra of conserved super-charges. In TGD framework these super charges are naturally associated with the modified Dirac equation, and anti-commuting coordinates and super-fields do not appear anywhere. One can however ask whether one could identify a mathematical structure replacing the notion of chiral super field.

In [?] it was proposed that generalized chiral super-fields could effectively replace induced spinor fields and that second quantized fermionic oscillator operators define the analog of SUSY algebra. One would have  $\mathcal{N} = \infty$  if all the conformal excitations of the induced spinor field restricted on 2-surface are present. For right-handed neutrino the modes are labeled by two integers and delocalized to the interior of Euclidian or Minkowskian regions of space-time sheet.

The obvious guess is that chiral super-field generalizes to the field having as its components many-fermions states at partonic 2-surfaces with theta parameters and their conjugates in one-one correspondence with fermionic creation operators and their hermitian conjugates.

1. Fermionic creation operators - in classical theory corresponding anti-commuting Grassmann parameters - replace theta parameters. Theta parameters and their conjugates are not in one-one correspondence with spinor components but with the fermionic creation operators and their hermitian conjugates. One can say that the super-field in question is defined in the "world of classical worlds" (WCW) rather than in space-time. Fermionic Fock state at the partonic 2-surface is the value of the chiral super field at particular point of WCW.
2. The matrix defined by the  $\sigma^\mu \partial_\mu$  is replaced with a matrix defined by the modified Dirac operator  $D$  between spinor modes acting in the solution space of the modified Dirac equation. Since modified Dirac operator annihilates the modes of the induced spinor field, super covariant derivatives

reduce to ordinary derivatives with respect the theta parameters labeling the modes. Hence the chiral super field is a field that depends on  $\theta_m$  or conjugates  $\bar{\theta}_m$  only. In second quantization the modes of the chiral super-field are many-fermion states assigned to partonic 2-surfaces and string world sheets. Note that this is the only possibility since the notion of super-coordinate does not make sense now.

3. It would seem that the notion of super-field does not bring anything new. This is not the case. First of all, the spinor fields are restricted to 2-surfaces. Second point is that one cannot assign to the fermions of the many-fermion states separate non-parallel or even parallel four-momenta. The many-fermion state behaves like elementary particle. This has non-trivial implications for propagators and a simple argument [?] leads to the proposal that propagator for N-fermion partonic state is proportional to  $1/p^N$ . This would mean that only the states with fermion number equal to 1 or 2 behave like ordinary elementary particles.

#### How the fermionic anti-commutation relations are determined?

Understanding the fermionic anti-commutation relations is not trivial since all fermion fields except right-handed neutrino are assumed to be localized at 2-surfaces. Since fermionic conserved currents must give rise to well-defined charges as 3-D integrals the spinor modes must be proportional to a square root of delta function in normal directions. Furthermore, the modified Dirac operator must act only in the directions tangential to the 2-surface in order that the modified Dirac equation can be satisfied.

The square root of delta function can be formally defined by starting from the expansion of delta function in discrete basis for a particle in 1-D box. The product of two functions in x-space is convolution of Fourier transforms and the coefficients of Fourier transform of delta function are apart from a constant multiplier equal to 1:  $\delta(x) = K \sum_n \exp(inx/2\pi L)$ . Therefore the Fourier transform of square root of delta function is obtained by normalizing the Fourier transform of delta function by  $1/\sqrt{N}$ , where  $N \rightarrow \infty$  is the number of plane waves. In other words:  $\sqrt{\delta(x)} = \sqrt{\frac{K}{N}} \sum_n \exp(inx/2\pi L)$ .

Canonical quantization defines the standard approach to the second quantization of the Dirac equation.

1. One restricts the consideration to time=constant slices of space-time surface. Now the 3-surfaces at the ends of  $CD$  are natural slices. The intersection of string world sheet with these surfaces is 1-D whereas partonic 2-surfaces have 2-D Euclidian intersection with them.
2. The canonical momentum density is defined by

$$\begin{aligned} \Pi_\alpha &= \frac{\partial L}{\partial_t \bar{\Psi}_\alpha(x)} = \Gamma^t \Psi \quad , \\ \Gamma^t &= \frac{\partial L_K}{\partial(\partial_t h^k)} \quad . \end{aligned} \tag{3.4.12}$$

$L_K$  denotes Kähler action density: consistency requires  $D_\mu \Gamma^\mu = 0$ , and this is guaranteed only by using the modified gamma matrices defined by Kähler action. Note that  $\Gamma^t$  contains also the  $\sqrt{g_4}$  factor. Induced gamma matrices would require action defined by four-volume.  $t$  is time coordinate varying in direction tangential to 2-surface.

3. The standard equal time canonical anti-commutation relations state

$$\{\Pi_\alpha, \bar{\Psi}_\beta\} = \delta^3(x, y) \delta_{\alpha\beta} \quad . \tag{3.4.13}$$

Can these conditions be applied both at string world sheets and partonic 2-surfaces.

1. String world sheets do not pose problems. The restriction of the modes to string world sheets means that the square root of delta function in the normal direction of string world sheet takes care of the normal dimensions and the dynamical part of anti-commutation relations is 1-dimensional just as in the case of strings.
2. Partonic 2-surfaces are problematic. The  $\sqrt{g_4}$  factor in  $\Gamma^t$  implies that  $\Gamma^t$  approaches zero at partonic 2-surfaces since they belong to light-like wormhole throats at which the signature of the induced metric changes. Energy momentum tensor appearing in  $\Gamma^t$  involves to index raisins by induced metric so that it can grow without limit as one approaches partonic two-surface. Therefore it is quite possible that the limit is finite and the boundary conditions defined by the weak form of electric magnetic duality might imply that the limit is finite. The open question is whether one can apply canonical quantization at partonic 2-surfaces. One can also ask whether one can define induced spinor fields at wormhole throats only at the ends of string world sheets so that partonic 2-surface would be effectively discretized. This cautious conclusion emerged in the earlier study of the modified Dirac equation [?].
3. Suppose that one can assume spinor modes at partonic 2-surfaces. 2-D conformal invariance suggests that the situation reduces to effectively one-dimensional also at the partonic two-surfaces. If so, one should pose the anti-commutation relations at some 1-D curves of the partonic 2-surface only. This is the only sensible option. The point is that the action of the modified Dirac operator is tangential so that also the canonical momentum current must be tangential and one can fix anti-commutations only at some set of curves of the partonic 2-surface.

One can of course worry what happens at the limit of vacuum extremals. The problem is that  $\Gamma^t$  vanishes for space-time surfaces reducing to vacuum extremals at the 2-surfaces carrying fermions so that the anti-commutations are inconsistent. Should one require - as done earlier- that the anti-commutation relations make sense at this limit and cannot therefore have the standard form but involve the scalar magnetic flux formed from the induced Kähler form by permuting it with the 2-D permutations symbol? The restriction to preferred extremals, which are always non-vacuum extremals, might allow to avoid this kind of problems automatically.

In the case of right-handed neutrino the situation is genuinely 3-dimensional and in this case non-vacuum extremal property must hold true in the regions where the modes of  $\nu_R$  are non-vanishing. The same mechanism would save from problems also at the partonic 2-surfaces. The dynamics of induced spinor fields must avoid classical vacuum. Could this relate to color confinement? Could hadrons be surrounded by an insulating layer of Kähler vacuum?

## 3.5 Twistor revolution and TGD

Lubos Motl wrote a nice summary about the talk of Nima Arkani Hamed about twistor revolution in Strings 2012 and gave also a link to the talk [?]. It seems that Nima and collaborators are ending to a picture about scattering amplitudes which strongly resembles that provided by generalized Feynman diagrammatics in TGD framework

TGD framework is much more general than  $\mathcal{N} = 4$  SYM and is to it same as general relativity for special relativity whereas the latter is completely explicit. Of course, I cannot hope that TGD view could be taken seriously - at least publicly. One might hope that these approaches could be combined some day: both have a lot to give for each other. Below I compare these approaches.

### 3.5.1 The origin of twistor diagrammatics

In TGD framework zero energy ontology forces to replace the idea about continuous unitary evolution in Minkowski space with something more general assignable to causal diamonds (CDs), and S-matrix is replaced with a square root of density matrix equal to a hermitian l square root of density matrix multiplied by unitary S-matrix. Also in twistor approach unitarity has ceased to be a star actor. In p-Adic context continuous unitary time evolution fails to make sense also mathematically.

Twistor diagrammatics involves only massless on mass shell particles on both external and internal lines. Zero energy ontology (ZEO) requires same in TGD: wormhole lines carry parallelly moving

massless fermions and antifermions. The mass shell conditions at vertices are enormously powerful and imply UV finiteness. Also IR finiteness follows if external particles are massive.

What one means with mass is however a delicate matter. What does one mean with mass? I have pondered 35 years this question and the recent view is inspired by p-adic mass calculations and ZEO, and states that observed mass is in a well-defined sense expectation value of longitudinal mass squared for all possible choices of  $M^2 \subset M^4$  characterizing the choices of quantization axis for energy and spin at the level of "world of classical worlds" (WCW) assignable with given causal diamond  $CD$ .

The choice of quantization axis thus becomes part of the geometry of WCW. All wormhole throats are massless but develop non-vanishing longitudinal mass squared. Gauge bosons correspond to wormhole contacts and thus consist of pairs of massless wormhole throats. Gauge bosons could develop 4-D mass squared but also remain massless in 4-D sense if the throats have parallel massless momenta. Longitudinal mass squared is however non-vanishing and p-adic thermodynamics predicts it.

### 3.5.2 The emergence of 2-D sub-dynamics at space-time level

Nima et al introduce ordering of the vertices in 4-D case. Ordering and related braiding are however essentially 2-D notions. Somehow 2-D theory must be a part of the 4-D theory also at space-time level, and I understood that understanding this is the challenge of the twistor approach at this moment.

The twistor amplitude can be represented as sum over the permutations of  $n$  external gluons and all diagrams corresponding to the same permutation are equivalent. Permutations are more like braidings since they carry information about how the permutation proceeded as a homotopy. Yang-Baxter equation emerges and states associativity of the braid group. The allowed braidings are minimal braidings in the sense that the repetitions of permutations of two adjacent vertices are not considered to be separate. Minimal braidings reduce to ordinary permutations. Nima also talks about affine braidings which I interpret as analogs of Kac-Moody algebras meaning that one uses projective representations which for Kac-Moody algebra mean non-trivial central extension. Perhaps the condition is that the square of a permutation permuting only two vertices which each other gives only a non-trivial phase factor. Lubos suggests an alternative interpretation which would select only special permutations and cannot be therefore correct.

There are rules of identifying the permutation associated with a given diagram involving only basic 3-gluon vertex with white circle and its conjugate. Lubos explains this "Mickey Mouse in maze" rule in his posting in detail: to determine the image  $p(n)$  of vertex  $n$  in the permutation put a mouse in the maze defined by the diagram and let it run around obeying single rule: if the vertex is black turn to the right and if the vertex is white turn to the left. The mouse cannot remain in a loop: if it would do so, the rule would force it to run back to  $n$  after single full loop and one would have a fixed point:  $p(n) = n$ . The reduction in the number of diagrams is enormous: the infinity of different diagrams reduces to  $n!$  diagrams!

What happens in TGD framework?

1. In TGD framework string world sheets and partonic 2-surfaces (or either or these if they are dual notions as conjectured) at space-time surface would define the sought for 2-D theory, and one obtains indeed perturbative expansion with fermionic propagator defined by the inverse of the modified Dirac operator and bosonic propagator defined by the correlation function for small deformations of the string world sheet. The vertices of twistor diagrams emerge as braid ends defining the intersections of string world sheets and partonic 2-surfaces.

String model like description becomes part of TGD and the role of string world sheets in  $X^4$  is highly analogous to that of string world sheets connecting branes in  $AdS^5 \times S^5$  of  $\mathcal{N} = 4$  SYM. In TGD framework 10-D  $AdS^5 \times S^5$  is replaced with 4-D space-time surface in  $M^4 \times CP_2$ . The meaning of the analog of  $AdS^5$  duality in TGD framework should be understood. In particular, it could be that the descriptions involving string world sheets on one hand and partonic 2-surfaces - or 3-D orbits of wormhole throats defining the generalized Feynman diagram- on the other hand are dual to each other. I have conjectured something like this earlier but it takes some time for this kind of issues to find their natural answer.

2. As described in the article, string world sheets and partonic 2-surfaces emerge directly from the construction of the solutions of the modified Dirac equation by requiring conservation of em charge. This result has been conjectured already earlier but using other less direct arguments.

2-D "string world sheets" as sub-manifolds of the space-time surface make the ordering possible, and guarantee the finiteness of the perturbation theory involving n-point functions of a conformal QFT for fermions at wormhole throats and n-point functions for the deformations of the space-time surface. Conformal invariance should dictate these n-point functions to a high degree. In TGD framework the fundamental 3-vertex corresponds to joining of light-like orbits of three wormhole contacts along their 2-D ends (partonic 2-surfaces).

### 3.5.3 The emergence of Yangian symmetry

Yangian symmetry associated with the conformal transformations of  $M^4$  is a key symmetry of Grassmannian approach. Is it possible to derive it in TGD framework?

1. TGD indeed leads to a concrete representation of Yangian algebra as generalization of color and electroweak gauge Kac-Moody algebra using general formula discussed in Witten's article about Yangian algebras (see the article).
2. Article discusses also a conjecture about 2-D Hodge duality of quantized YM gauge potentials assignable to string world sheets with Kac-Moody currents. Quantum gauge potentials are defined only where they are needed - at string world sheets rather than entire 4-D space-time.
3. Conformal scalings of the effective metric defined by the anticommutators of the modified gamma matrices emerges as realization of quantum criticality. They are induced by critical deformations (second variations not changing Kähler action) of the space-time surface. This algebra can be generalized to Yangian using the formulas in Witten's article (see the article).
4. Critical deformations induce also electroweak gauge transformations and even more general symmetries for which infinitesimal generators are products of  $U(n)$  generators permuting  $n$  modes of the modified Dirac operator and infinitesimal generators of local electro-weak gauge transformations. These symmetries would relate in a natural manner to finite measurement resolution realized in terms of inclusions of hyperfinite factors with included algebra taking the role of gauge group transforming to each other states not distinguishable from each other.
5. How to end up with Grassmannian picture in TGD framework? This has inspired some speculations in the past. From Nima's lecture one however learns that Grassmannian picture emerges as a convenient parametrization. One starts from the basic 3-gluon vertex or its conjugate expressed in terms of twistors. Momentum conservation implies that with the three twistors  $\lambda_i$  or their conjugates are proportional to each other (depending on which is the case one assigns white or black dot with the vertex). This constraint can be expressed as a delta function constraint by introducing additional integration variables and these integration variables lead to the emergence of the Grassmannian  $G_{n,k}$  where  $n$  is the number of gluons, and  $k$  the number of positive helicity gluons.

Since only momentum conservation is involved, and since twistorial description works because only massless on mass shell virtual particles are involved, one is bound to end up with the Grassmannian description also in TGD.

### 3.5.4 The analog of $AdS^5$ duality in TGD framework

The generalization of  $AdS^5$  duality of  $\mathcal{N} = 4$  SYMs to TGD framework is highly suggestive and states that string world sheets and partonic 2-surfaces play a dual role in the construction of M-matrices. Some terminology first.

1. Let us agree that string world sheets and partonic 2-surfaces refer to 2-surfaces in the slicing of space-time region defined by Hermitian structure or Hamilton-Jacobi structure.
2. Let us also agree that *singular* string world sheets and partonic 2-surfaces are surfaces at which the *effective* metric defined by the anticommutators of the modified gamma matrices degenerates to effectively 2-D one.

3. Braid strands at wormhole throats in turn would be loci at which the *induced* metric of the string world sheet transforms from Euclidian to Minkowskian as the signature of induced metric changes from Euclidian to Minkowskian.

AdS<sup>5</sup> duality suggest that string world sheets are in the same role as string world sheets of 10-D space connecting branes in AdS<sup>5</sup> duality for  $\mathcal{N} = 4$  SYM. What is important is that there should exist a duality meaning two manners to calculate the amplitudes. What the duality could mean now?

1. Also in TGD framework the first manner would be string model like description using string world sheets. The second one would be a generalization of conformal QFT at light-like 3-surfaces (allowing generalized conformal symmetry) defining the lines of generalized Feynman diagram. The correlation functions to be calculated would have points at the intersections of partonic 2-surfaces and string world sheets and would represent braid ends.
2. General Coordinate Invariance (GCI) implies that physics should be codable by 3-surfaces. Light-like 3-surfaces define 3-surfaces of this kind and same applies to space-like 3-surfaces. There are also preferred 3-surfaces of this kind. The orbits of 2-D wormhole throats at which 4-metric degenerates to 3-dimensional one define preferred light-like 3-surfaces. Also the space-like 3-surfaces at the ends of space-time surface at light-like boundaries of causal diamonds (CDs) define preferred space-like 3-surfaces. Both light-like and space-like 3-surfaces should code for the same physics and therefore their intersections defining partonic 2-surfaces plus the 4-D tangent space data at them should be enough to code for physics. This is strong form of GCI implying effective 2-dimensionality. As a special case one obtains singular string world sheets at which the effective metric reduces to 2-dimensional and singular partonic 2-surfaces defining the wormhole throats. For these 2-surfaces situation could be especially simple mathematically.
3. The guess inspired by strong GCI is that string world sheet -partonic 2-surface duality holds true. The functional integrals over the deformations of 2 kinds of 2-surfaces should give the same result so that functional integration over either kinds of 2-surfaces should be enough. Note that the members of a given pair in the slicing intersect at discrete set of points and these points define braid ends carrying fermion number. Discretization and braid picture follow automatically.
4. Scattering amplitudes in the twistorial approach could be thus calculated by using *any* pair in the slicing - or only either member of the pair if the analog of AdS<sup>5</sup> duality holds true as argued. The possibility to choose any pair in the slicing means general coordinate invariance as a symmetry of the Kähler metric of WCW and of the entire theory suggested already early: Kähler functions for difference choices in the slicing would differ by a real part of holomorphic function and give rise to same Kähler metric of "world of classical worlds" (WCW). For a general pair one obtains functional integral over deformations of space-time surface inducing deformations of 2-surfaces with only other kind 2-surface contributing to amplitude. This means the analog of stringy QFT: Minkowskian or Euclidian string theory depending on choice.
5. For singular string world sheets and partonic 2-surfaces an enormous simplification results. The propagators for fermions and correlation functions for deformations reduce to 1-D instead of being 2-D: the propagation takes place only along the light-like lines at which the string world sheets with Euclidian signature (inside  $CP_2$  like regions) change to those with Minkowskian signature of induced metric. The local reduction of space-time dimension would be very real for particles moving along sub-manifolds at which higher dimensional space-time has reduced metric dimension: they cannot get out from lower-D sub-manifold. This is like ending down to 1-D black hole interior and one would obtain the analog of ordinary Feynman diagrammatics. This kind of Feynman diagrammatics involving only braid strands is what I have indeed ended up earlier so that it seems that I can trust good intuition combined with a sloppy mathematics sometimes works;-).

These singular lines represent orbits of point like particles carrying fermion number at the orbits of wormhole throats. Furthermore, in this representation the expansions coming from string world sheets and partonic 2-surfaces are identical automatically. This follows from the fact that only the light-like lines connecting points common to singular string world sheets and singular partonic 2-surfaces appear as propagator lines!

6. The TGD analog of AdS<sup>5</sup> duality of  $\mathcal{N} = 4$  SUSYs would be trivially true as an identity in this special case, and the good guess is that it is true also generally. One could indeed use integral over either string world sheets or partonic 2-sheets to deduce the amplitudes.

What is important to notice that singularities of Feynman diagrams crucial for the Grassmannian approach of Nima and others would correspond at space-time level 2-D singularities of the effective metric defined by the modified gamma matrices defined as contractions of canonical momentum currents for Kähler action with ordinary gamma matrices of the imbedding space and therefore directly reflecting classical dynamics.

### 3.5.5 Problems of the twistor approach from TGD point of view

Twistor approach has also its problems and here TGD suggests how to proceed. Signature problem is the first problem.

1. Twistor diagrammatics works in a strict mathematical sense only for  $M^{2,2}$  with metric signature (1,1,-1,-1) rather than  $M^4$  with metric signature (1,-1,-1,-1). Metric signature is wrong in the physical case. This is a real problem which must be solved eventually.
2. Effective metric defined by anticommutators of the modified gamma matrices (to be distinguished from the induced gamma matrices) could solve that problem since it would have the correct signature in TGD framework (see the article). String world sheets and partonic 2-surfaces would correspond to the 2-D singularities of this effective metric at which the even-even signature (1,1,1,1) changes to even-even signature (1,1,-1,-1). Space-time at string world sheet would become locally 2-D with respect to effective metric just as space-time becomes locally 3-D with respect to the induced metric at the light-like orbits of wormhole throats. String world sheets become also locally 1-D at light-like curves at which Euclidian signature of world sheet in induced metric transforms to Minkowskian.
3. Twistor amplitudes are indeed singularities and string world sheets implied in TGD framework by conservation of em charge would represent these singularities at space-time level. At the end of the talk Nima conjectured about lower-dimensional manifolds of space-time as representation of space-time singularities. Note that string world sheets and partonic 2-surfaces have been part of TGD for years. TGD is of course to  $\mathcal{N} = 4$  SYM what general relativity is for the special relativity. Space-time surface is dynamical and possesses induced and effective metrics rather than being flat.

Second limitation is that twistor diagrammatics works only for planar diagrams. This is a problem which must be also fixed sooner or later.

1. This perhaps dangerous and blasphemous statement that I will regret it some day but I will make it;-). Nima and others have not yet discovered that  $M^2 \subset M^4$  must be there but will discover it when they begin to generalize the results to non-planar diagrams and realize that Feynman diagrams are analogous to knot diagrams in 2-D plane (with crossings allowed) and that this 2-D plane must correspond to  $M^2 \subset M^4$ . The different choices of causal diamond  $CD$  correspond to different choices of  $M^2$  representing choice of quantization axes 4-momentum and spin. The integral over these choices guarantees Lorentz invariance. Gauge conditions are modified: longitudinal  $M^2$  projection of massless four-momentum is orthogonal to polarization so that three polarizations are possible: states are massive in longitudinal sense.
2. In TGD framework one replaces the lines of Feynman diagrams with the light-like 3-surfaces defining orbits of wormhole throats. These lines carry many fermion states defining braid strands at light-like 3-surfaces. There is internal braiding associated with these braid strands. String world sheets connect fermions at different wormhole throats with space-like braid strands. The  $M^2$  projections of generalized Feynman diagrams with 4-D "lines" replaced with genuine lines define the ordinary Feynman diagram as the analog of braid diagram. The conjecture is that one can reduce non-planar diagrams to planar diagrams using a procedure analogous to the construction of knot invariants by un-knotting the knot in Alexandrian manner by allowing it to be cut temporarily.

3. The permutations of string vertices emerge naturally as one constructs diagrams by adding to the interior of polygon sub-polygons connected to the external vertices. This corresponds to the addition of internal partonic two-surfaces. There are very many equivalent diagrams of this kind. Only permutations matter and the permutation associated with a given diagram of this kind can be deduced by the Mickey-Mouse rule described explicitly by Lubos. A connection with planar operads is highly suggestive and also conjecture already earlier in TGD framework.

### 3.5.6 Could $\mathcal{N} = 2$ or $\mathcal{N} = 4$ SUSY be a part of TGD after all?

Whether right-handed neutrinos generate a supersymmetry in TGD has been a long standing open question.  $\mathcal{N} = 1$  SUSY is certainly excluded by fermion number conservation but already  $\mathcal{N} = 2$  defining a "complexification" of  $\mathcal{N} = 1$  SUSY is possible and could generate right-handed neutrino and its antiparticle. These states should however possess a non-vanishing light-like momentum since the fully covariantly constant right-handed neutrino generates zero norm states. So called massless extremals (MEs) allow massless solutions of the modified Dirac equation for right-handed neutrino in the interior of space-time surface, and this seems to be case quite generally in Minkowskian signature for preferred extremals. This suggests that particle represented as magnetic flux tube structure with two wormhole contacts sliced between two MEs could serve as a starting point in attempts to understand the role of right handed neutrinos and how  $\mathcal{N} = 2$  or  $\mathcal{N} = 4$  SYM emerges at the level of space-time geometry. The following arguments inspired by the article of Nima Arkani-Hamed et al [?] about twistorial scattering amplitudes suggest a more detailed physical interpretation of the possible SUSY associated with the right-handed neutrinos.

The fact that right handed neutrinos have only gravitational interaction suggests a radical re-interpretation of SUSY: no SUSY breaking is needed since it is very difficult to distinguish between mass degenerate partners of ordinary particles. In order to distinguish between different partners one must be able to compare the gravitomagnetic energies of partners in slowly varying external gravimagnetic field: this effect is extremely small.

### Scattering amplitudes and the positive Grassmannian

The work of Nima Arkani-Hamed and others represents something which makes me very optimistic and I would be happy if I could understand the horrible technicalities of their work. The article Scattering Amplitudes and the Positive Grassmannian by Arkani-Hamed, Bourjaily, Cachazo, Goncharov, Postnikov, and Trnka [?] summarizes the recent situation in a form, which should be accessible to ordinary physicist. Lubos has already discussed the article. The following considerations do not relate much to the main message of the article (positive Grassmannians) but more to the question how this approach could be applied in TGD framework.

#### 1. All scattering amplitudes have on shell amplitudes for massless particles as building bricks

The key idea is that all planar amplitudes can be constructed from on shell amplitudes: all virtual particles are actually real. In zero energy ontology I ended up with the representation of TGD analogs of Feynman diagrams using only mass shell massless states with both positive and negative energies. The enormous number of kinematic constraints eliminates UV and IR divergences and also the description of massive particles as bound states of massless ones becomes possible.

In TGD framework quantum classical correspondence requires a space-time correlate for the on mass shell property and it indeed exists. The mathematically ill-defined path integral over all 4-surfaces is replaced with a superposition of preferred extremals of Kähler action analogous to Bohr orbits, and one has only a functional integral over the 3-D ends at the light-like boundaries of causal diamond (Euclidian/Minkowskian space-time regions give real/imaginary Chern-Simons exponent to the vacuum functional). This would be obviously the deeper principle behind on mass shell representation of scattering amplitudes that Nima and others are certainly trying to identify. This principle in turn reduces to general coordinate invariance at the level of the world of classical worlds.

Quantum classical correspondence and quantum ergodicity would imply even stronger condition: the quantal correlation functions should be identical with classical correlation functions for any preferred extremal in the superposition: all preferred extremals in the superposition would be statistically equivalent [?]. 4-D spin glass degeneracy of Kähler action however suggests that this is probably too strong a condition applying only to building bricks of the superposition.

Minimal surface property is the geometric counterpart for masslessness and the preferred extremals are also minimal surfaces: this property reduces to the generalization of complex structure at space-time surfaces, which I call Hamilton-Jacobi structure for the Minkowskian signature of the induced metric. Einstein Maxwell equations with cosmological term are also satisfied.

*2. Massless extremals and twistor approach*

The decomposition  $M^4 = M^2 \times E^2$  is fundamental in the formulation of quantum TGD, in the number theoretical vision about TGD, in the construction of preferred extremals, and for the vision about generalized Feynman diagrams. It is also fundamental in the decomposition of the degrees of string to longitudinal and transversal ones. An additional item to the list is that also the states appearing in thermodynamical ensemble in p-adic thermodynamics correspond to four-momenta in  $M^2$  fixed by the direction of the Lorentz boost. In twistor approach to TGD the possibility to decompose also internal lines to massless states at parallel space-time sheets is crucial.

Can one find a concrete identification for  $M^2 \times E^2$  decomposition at the level of preferred extremals? Could these preferred extremals be interpreted as the internal lines of generalized Feynman diagrams carrying massless momenta? Could one identify the mass of particle predicted by p-adic thermodynamics with the sum of massless classical momenta assignable to two preferred extremals of this kind connected by wormhole contacts defining the elementary particle?

Candidates for this kind of preferred extremals indeed exist. Local  $M^2 \times E^2$  decomposition and light-like longitudinal massless momentum assignable to  $M^2$  characterizes "massless extremals" (MEs, "topological light rays"). The simplest MEs correspond to single space-time sheet carrying a conserved light-like  $M^2$  momentum. For several MEs connected by wormhole contacts the longitudinal massless momenta are not conserved anymore but their sum defines a time-like conserved four-momentum: one has a bound states of massless MEs. The stable wormhole contacts binding MEs together possess Kähler magnetic charge and serve as building bricks of elementary particles. Particles are necessary closed magnetic flux tubes having two wormhole contacts at their ends and connecting the two MEs.

The sum of the classical massless momenta assignable to the pair of MEs is conserved even when they exchange momentum. Quantum classical correspondence requires that the conserved classical rest energy of the particle equals to the prediction of p-adic mass calculations. The massless momenta assignable to MEs would naturally correspond to the massless momenta propagating along the internal lines of generalized Feynman diagrams assumed in zero energy ontology. Masslessness of virtual particles makes also possible twistor approach. This supports the view that MEs are fundamental for the twistor approach in TGD framework.

*3. Scattering amplitudes as representations for braids whose threads can fuse at 3-vertices*

Just a little comment about the content of the article. The main message of the article is that non-equivalent contributions to a given scattering amplitude in  $\mathcal{N} = 4$  SYM represent elements of the group of permutations of external lines - or to be more precise - decorated permutations which replace permutation group  $S_n$  with  $n!$  elements with its decorated version containing  $2^n n!$  elements. Besides 3-vertex the basic dynamical process is permutation having the exchange of neighboring lines as a generating permutation completely analogous to fundamental braiding. BFCW bridge has interpretation as a representations for the basic braiding operation.

This supports the TGD inspired proposal (TGD as almost topological QFT) that generalized Feynman diagrams are in some sense also knot or braid diagrams allowing besides braiding operation also two 3-vertices [?]. The first 3-vertex generalizes the standard stringy 3-vertex but with totally different interpretation having nothing to do with particle decay: rather particle travels along two paths simultaneously after  $1 \rightarrow 2$  decay. Second 3-vertex generalizes the 3-vertex of ordinary Feynman diagram (three 4-D lines of generalized Feynman diagram identified as Euclidian space-time regions meet at this vertex). The main idea is that in TGD framework knotting and braiding emerges at two levels.

1. At the level of space-time surface string world sheets at which the induced spinor fields (except right-handed neutrino [?]) are localized due to the conservation of electric charge can form 2-knots and can intersect at discrete points in the generic case. The boundaries of strings world sheets at light-like wormhole throat orbits and at space-like 3-surfaces defining the ends of the space-time at light-like boundaries of causal diamonds can form ordinary 1-knots, and get linked and braided. Elementary particles themselves correspond to closed loops at the ends of

space-time surface and can also get knotted (possible effects are discussed in [?]).

2. One can assign to the lines of generalized Feynman diagrams lines in  $M^2$  characterizing given causal diamond. Therefore the 2-D representation of Feynman diagrams has concrete physical interpretation in TGD. These lines can intersect and what suggests itself is a description of non-planar diagrams (having this kind of intersections) in terms of an algebraic knot theory. A natural guess is that it is this knot theoretic operation which allows to describe also non-planar diagrams by reducing them to planar ones as one does when one constructs knot invariant by reducing the knot to a trivial one. Scattering amplitudes would be basically knot invariants.

"Almost topological" has also a meaning usually not assigned with it. Thurston's geometrization conjecture stating that geometric invariants of canonical representation of manifold as Riemann geometry, defined topological invariants, could generalize somehow. For instance, the geometric invariants of preferred extremals could be seen as topological or more refined invariants (symplectic, conformal in the sense of 4-D generalization of conformal structure). If quantum ergodicity holds true, the statistical geometric invariants defined by the classical correlation functions of various induced classical gauge fields for preferred extremals could be regarded as this kind of invariants for sub-manifolds. What would distinguish TGD from standard topological QFT would be that the invariants in question would involve length scale and thus have a physical content in the usual sense of the word!

### Could $\mathcal{N} = 2$ or $\mathcal{N} = 4$ SUSY have something to do with TGD?

$\mathcal{N} = 4$  SYM has been the theoretical laboratory of Nima and others.  $\mathcal{N} = 4$  SYM is definitely a completely exceptional theory, and one cannot avoid the question whether it could in some sense be part of fundamental physics. In TGD framework right handed neutrinos have remained a mystery: whether one should assign space-time SUSY to them or not. Could they give rise to something resembling  $\mathcal{N} = 2$  or  $\mathcal{N} = 4$  SUSY with fermion number conservation?

#### 1. Earlier results

My latest view is that *fully* covariantly constant right-handed neutrinos decouple from the dynamics completely. I will repeat first the earlier arguments which consider only fully covariantly constant right-handed neutrinos.

1.  $\mathcal{N} = 1$  SUSY is certainly excluded since it would require Majorana property not possible in TGD framework since it would require superposition of left and right handed neutrinos and lead to a breaking of lepton number conservation. Could one imagine SUSY in which both MEs between which particle wormhole contacts reside have  $\mathcal{N} = 2$  SUSY which combine to form an  $\mathcal{N} = 4$  SUSY?
2. Right-handed neutrinos which are covariantly constant right-handed neutrinos in both  $M^4$  degrees of freedom cannot define a non-trivial theory as shown already earlier. They have no electroweak nor gravitational couplings and carry no momentum, only spin.

The fully covariantly constant right-handed neutrinos with two possible helicities at given ME would define representation of SUSY at the limit of vanishing light-like momentum. At this limit the creation and annihilation operators creating the states would have vanishing anticommutator so that the oscillator operators would generate Grassmann algebra. Since creation and annihilation operators are hermitian conjugates, the states would have zero norm and the states generated by oscillator operators would be pure gauge and decouple from physics. This is the core of the earlier argument demonstrating that  $\mathcal{N} = 1$  SUSY is not possible in TGD framework: LHC has given convincing experimental support for this belief.

#### 2. Could massless right-handed neutrinos covariantly constant in $CP_2$ degrees of freedom define $\mathcal{N} = 2$ or $\mathcal{N} = 4$ SUSY?

Consider next right-handed neutrinos, which are covariantly constant in  $CP_2$  degrees of freedom but have a light-like four-momentum. In this case fermion number is conserved but this is consistent with  $\mathcal{N} = 2$  SUSY at both MEs with fermion number conservation.  $\mathcal{N} = 2$  SUSYs could emerge from  $\mathcal{N} = 4$  SUSY when one half of SUSY generators annihilate the states, which is a basic phenomenon in supersymmetric theories.

1. At space-time level right-handed neutrinos couple to the space-time geometry - gravitation - although weak and color interactions are absent. One can say that this coupling forces them to move with light-like momentum parallel to that of ME. At the level of space-time surface right-handed neutrinos have a spectrum of excitations of four-dimensional analogs of conformal spinors at string world sheet (Hamilton-Jacobi structure).

For MEs one indeed obtains massless solutions depending on longitudinal  $M^2$  coordinates only since the induced metric in  $M^2$  differs from the light-like metric only by a contribution which is light-like and contracts to zero with light-like momentum in the same direction. These solutions are analogs of (say) left movers of string theory. The dependence on  $E^2$  degrees of freedom is holomorphic. That left movers are only possible would suggest that one has only single helicity and conservation of fermion number at given space-time sheet rather than 2 helicities and non-conserved fermion number: two real Majorana spinors combine to single complex Weyl spinor.

2. At imbedding space level one obtains a tensor product of ordinary representations of  $\mathcal{N} = 2$  SUSY consisting of Weyl spinors with opposite helicities assigned with the ME. The state content is same as for a reduced  $\mathcal{N} = 4$  SUSY with four  $\mathcal{N} = 1$  Majorana spinors replaced by two complex  $\mathcal{N} = 2$  spinors with fermion number conservation. This gives 4 states at both space-time sheets constructed from  $\nu_R$  and its antiparticle. Altogether the two MEs give 8 states, which is one half of the 16 states of  $\mathcal{N} = 4$  SUSY so that a degeneration of this symmetry forced by non-Majorana property is in question.

3. *Is the dynamics of  $\mathcal{N} = 2$  or  $\mathcal{N} = 4$  SYM possible in right-handed neutrino sector?*

Could  $\mathcal{N} = 2$  or  $\mathcal{N} = 4$  SYM be a part of quantum TGD? Could TGD be seen a fusion of a degenerate  $\mathcal{N} = 4$  SYM describing the right-handed neutrino sector and string theory like theory describing the contribution of string world sheets carrying other leptonic and quark spinors? Or could one imagine even something simpler?

What is interesting that the net momenta assigned to the right handed neutrinos associated with a pair of MEs would correspond to the momenta assignable to the particles and obtained by p-adic mass calculations. It would seem that right-handed neutrinos provide a representation of the momenta of the elementary particles represented by wormhole contact structures. Does this mimicry generalize to a full duality so that all quantum numbers and even microscopic dynamics of defined by generalized Feynman diagrams (Euclidian space-time regions) would be represented by right-handed neutrinos and MEs? Could a generalization of  $\mathcal{N} = 4$  SYM with non-trivial gauge group with proper choices of the ground states helicities allow to represent the entire microscopic dynamics?

Irrespective of the answer to this question one can compare the TGD based view about supersymmetric dynamics with what I have understood about  $\mathcal{N} = 4$  SYM.

1. In the scattering of MEs induced by the dynamics of Kähler action the right-handed neutrinos play a passive role. Modified Dirac equation forces them to adopt the same direction of four-momentum as the MEs so that the scattering reduces to the geometric scattering for MEs as one indeed expects on basis of quantum classical correspondence. In  $\nu_R$  sector the basic scattering vertex involves four MEs and could be a re-sharing of the right-handed neutrino content of the incoming two MEs between outgoing two MEs respecting fermion number conservation. Therefore  $\mathcal{N} = 4$  SYM with fermion number conservation would represent the scattering of MEs at quantum level.
2.  $\mathcal{N} = 4$  SUSY would suggest that also in the degenerate case one obtains the full scattering amplitude as a sum of permutations of external particles followed by projections to the directions of light-like momenta and that BCFW bridge represents the analog of fundamental braiding operation. The decoration of permutations means that each external line is effectively doubled. Could the scattering of MEs can be interpreted in terms of these decorated permutations? Could the doubling of permutations by decoration relate to the occurrence of pairs of MEs?

One can also revert these questions. Could one construct massive states in  $\mathcal{N} = 4$  SYM using pairs of momenta associated with particle with integer label  $k$  and its decorated copy with label  $k+n$ ? Massive external particles obtained in this manner as bound states of massless ones could solve the IR divergence problem of  $\mathcal{N} = 4$  SYM.

3. The description of amplitudes in terms of leading singularities means picking up of the singular contribution by putting the fermionic propagators on mass shell. In the recent case it would give the inverse of massless Dirac propagator acting on the spinor at the end of the internal line annihilating it if it is a solution of Dirac equation.

The only way out is a kind of cohomology theory in which solutions of Dirac equation represent exact forms. Dirac operator defines the exterior derivative  $d$  and virtual lines correspond to non-physical helicities with  $d\Psi \neq 0$ . Virtual fermions would be on mass-shell fermions with non-physical polarization satisfying  $d^2\Psi = 0$ . External particles would be those with physical polarization satisfying  $d\Psi = 0$ , and one can say that the Feynman diagrams containing physical helicities split into products of Feynman diagrams containing only non-physical helicities in internal lines.

4. The fermionic states at wormhole contacts should define the ground states of SUSY representation with helicity  $+1/2$  and  $-1/2$  rather than spin 1 or  $-1$  as in standard realization of  $\mathcal{N} = 4$  SYM used in the article. This would modify the theory but the twistorial and Grassmannian description would remain more or less as such since it depends on light-likeness and momentum conservation only.

#### 4. 3-vertices for sparticles are replaced with 4-vertices for MEs

In  $\mathcal{N} = 4$  SYM the basic vertex is on mass-shell 3-vertex which requires that for real light-like momenta all 3 states are parallel. One must allow complex momenta in order to satisfy energy conservation and light-likeness conditions. This is strange from the point of view of physics although number theoretically oriented person might argue that the extensions of rationals involving also imaginary unit are rather natural.

The complex momenta can be expressed in terms of two light-like momenta in 3-vertex with one real momentum. For instance, the three light-like momenta can be taken to be  $p, k$ , and  $p - ka$  with  $k = ap_R$ . Here  $p$  (incoming momentum) and  $p_R$  are real light-like momenta satisfying  $p \cdot p_R = 0$  but with opposite sign of energy, and  $a$  is complex number. What is remarkable that also the negative sign of energy is necessary also now.

In zero energy ontology the situation is different due to the presence of a pair of MEs, the allowance of negative energies in internal lines, and the fact that scattering is of sparticles is induced by that of MEs. In the simplest vertex a massive external particle with non-parallel MEs carrying non-parallel light-like momenta can decay to a pair of MEs with light-like momenta. This can be interpreted as 4-ME-vertex rather than 3-vertex (say) BFF so that complex momenta are not needed. For an incoming boson identified as wormhole contact the vertex can be seen as BFF vertex.

To obtain space-like momentum exchanges one must allow negative sign of energy and one has strong conditions coming from momentum conservation and light-likeness which allow non-trivial solutions since the basically 4-vertices are in question. This reduces dramatically the number of graphs. Note that one can also consider vertices in which three pairs of MEs join along their ends so that 6 MEs (analog of 3-bson vertex) would be involved.

#### 5. Is SUSY breaking possible or needed?

It is difficult to imagine the breaking of the proposed kind of SUSY in TGD framework, and the first guess is that all these 4 super-partners of particle have identical masses. p-Adic thermodynamics does not distinguish between these states and the only possibility is that the p-adic primes differ for the spartners. But is the breaking of SUSY really necessary? Can one really distinguish between the 8 different states of a given elementary particle using the recent day experimental methods?

1. In electroweak and color interactions the spartners behave in an identical manner classically. The coupling of right-handed neutrinos to space-time geometry however forces the right-handed neutrinos to adopt the same direction of four-momentum as MEs has. Could some gravitational effect allow to distinguish between spartners? This would be trivially the case if the p-adic mass scales of spartners would be different. Why this should be the case remains however an open question.
2. In the case of unbroken SUSY only spin distinguishes between spartners. Spin determines statistics and the first naive guess would be that bosonic spartners obey totally different atomic

physics allowing condensation of selectrons to the ground state. Very probably this is not true: the right-handed neutrinos are delocalized to 4-D MEs and other fermions correspond to wormhole contact structures and 2-D string world sheets.

The coupling of the spin to the space-time geometry seems to provide the only possible manner to distinguish between spartners. Could one imagine a gravimagnetic effect with energy splitting proportional to the product of gravimagnetic moment and external gravimagnetic field  $B$ ? If gravimagnetic moment is proportional to spin projection in the direction of  $B$ , a non-trivial effect would be possible. Needless to say this kind of effect is extremely small so that the unbroken SUSY might remain undetected.

3. If the spin of sparticle be seen in the classical angular momentum of ME as quantum classical correspondence would suggest then the value of the angular momentum might allow to distinguish between spartners. Also now the effect is extremely small.

### 3.6 $M^8 - H$ duality, preferred extremals, criticality, and Mandelbrot fractals

$M^8 - H$  duality [K72] represents an intriguing connection between number theory and TGD but the mathematics involved is extremely abstract and difficult so that I can only represent conjectures. In the following the basic duality is used to formulate a general conjecture for the construction of preferred extremals by iterative procedure. What is remarkable and extremely surprising is that the iteration gives rise to the analogs of Mandelbrot fractals and space-time surfaces can be seen as fractals defined as fixed sets of iteration. The analogy with Mandelbrot set can be also seen as a geometric correlate for quantum criticality.

#### 3.6.1 $M^8 - H$ duality briefly

$M^8 - M^4 \times CP_2$  duality [?] states that certain 4-surfaces of  $M^8$  regarded as a sub-space of complexified octonions can be mapped in a natural manner to 4-surfaces in  $M^4 \times CP_2$ : this would mean that  $M^4 \times CP_2$  and therefore also the symmetries of standard model would have purely number theoretical meaning.

Consider a distribution of two planes  $M^2(x)$  integrating to a 2-surface  $\tilde{M}^2$  with the property that a fixed 1-plane  $M^1$  defining time axis globally is contained in each  $M^2(x)$  and therefore in  $\tilde{M}^2$ .  $M^1$  defines real axis of octonionic plane  $M^8$  and  $M^2(x)$  a local hyper-complex plane. Quaternionic subspaces with this property can be parameterized by points of  $CP_2$ : this leads to  $M^8 - H$  duality as can be shown by a simple argument.

1. Hyper-octonionic subspace of complexified octonions is obtained by multiplying octonionic imaginary units by commuting imaginary unit. This does not bring anything new as far as automorphisms are considered so that it is enough to consider octonions (so that  $M^2$  is replaced with  $C$ ). Octonionic frame consists of orthogonal octonionic units. The space of octonionic frames containing sub-frame spanning fixed  $C$  is parameterized by  $SU(3)$ . The reason is that complexified octonionic units can be decomposed to the representations of  $SU(3) \subset G_2$  as  $1 + 1 + 3 + \bar{3}$  and the sub-frame 1+1 spans the preferred  $C$ .
2. The quaternionic planes  $H$  are represented by frames defined by four unit octonions spanning a quaternionic plane. Fixing  $C \subset H$  means fixing the 1+1 part in the above decomposition. The sub-group of  $SU(3)$  leaving the plane  $H$  invariant can perform only a rotation in the plane defined by two quaternionic units in 3. This sub-group is  $U(2)$  so that the space of quaternionic planes  $H \supset C$  is parameterized by  $SU(3)/U(2) = CP_2$ .
3. Therefore quaternionic tangent plane  $H \supset C$  can be mapped to a point of  $CP_2$ . In particular, any quaternionic surface in  $E^8$ , whose tangent plane at each point is quaternionic and contains  $C$ , can be mapped to  $E^4 \times CP_2$  by mapping the point  $(e_1, e_2) \in E^4 \times E^4$  to  $(e_1, s) \in E^4 \times CP_2$ . The generalization from  $E^8$  to  $M^8$  is trivial. This is essentially what  $M^8 - H$  duality says.

This can be made more explicit. Define quaternionic surfaces in  $M^8$  as 4-surfaces, whose tangent plane is quaternionic at each point  $x$  and contains the local hyper-complex plane  $M^2(x)$  and is therefore labelled by a point  $s(x) \in CP_2$ . One can write these surfaces as union over 2-D surfaces associated with points of  $\tilde{M}^2$ :

$$X^4 = \cup_{x \in \tilde{M}^2} X^2(x) \subset E^6 .$$

These surfaces can be mapped to surfaces of  $M^4 \times CP_2$  via the correspondence  $(m(x), e(x)) \rightarrow (m, s(T(X^4(x))))$ . Also the image surface contains at given point  $x$  the preferred plane  $M^2(x) \supset M^1$ . One can also write these surfaces as union over 2-D surfaces associated with points of  $\tilde{M}^2$ :

$$X^4 = \cup_{x \in \tilde{M}^2} X^2(x) \subset E^2 \times CP_2 .$$

One can also ask what are the conditions under which one can map surfaces  $X^4 = \cup_{x \in \tilde{M}^2} X^2 \subset E^2 \times CP_2$  to 4-surfaces in  $M^8$ . The map would be given by  $(m, s) \rightarrow (m, T^4(s))$  and the surface would be of the form as already described. The surface  $X^4$  must be such that the distribution of 4-D tangent planes defined in  $M^8$  is integrable and this gives complicated integrability conditions. One might hope that the conditions might hold true for preferred extremals satisfying some additional conditions.

One must make clear that the conditions discussed above do not allow most general possible surface.

1. The point is that for preferred extremals with Euclidian signature of metric the  $M^4$  projection is 3-dimensional and involves light like projection. Here the fact that light-like line  $L \subset M^2$  spans  $M^2$  in the sense that the complement of its orthogonal complement in  $M^8$  is  $M^2$ . Therefore one could consider also more general solution ansatz for which one has

$$X^4 = \cup_{x \in L(x) \subset \tilde{M}^2} X^3(x) \subset E^2 \times CP_2 .$$

2. One can also consider co-quaternionic surfaces as surfaces for which tangent space is in the dual of a quaternionic subspace. This says that the normal bundle rather than tangent bundle is quaternionic. The space-time regions with Euclidian signature of induced metric correspond naturally to co-quaternionic surfaces. Quaternionic surfaces are maximal associative sub-manifolds of octonionic space and one of the key ideas of the number theoretic vision about TGD is that associativity (co-associativity) defines the dynamics of space-time surfaces. That this dynamics gives preferred extremals of Kähler action remains to be proven.

### 3.6.2 The integrability conditions

The integrability conditions are associated with the expression of tangent vectors of  $T(X^4)$  as a linear combination of coordinate gradients  $\nabla m^k$ , where  $m^k$  denote the coordinates of  $M^8$ . Consider the 4 tangent vectors  $e_i$  for the quaternionic tangent plane (containing  $M^2(x)$ ) regarded as vectors of  $M^8$ .  $e_i$  have components  $e_i^k$ ,  $i = 1, \dots, 4$ ,  $k = 1, \dots, 8$ . One must be able to express  $e_i$  as linear combinations of coordinate gradients  $\nabla m^k$ :

$$e_i^k = e_i^\alpha \partial_\alpha m^k .$$

Here  $x^\alpha$  and  $e^k$  denote coordinates for  $X^4$  and  $M^8$ . By forming inner products of  $e_i$  one finds that matrix  $e_i^\alpha$  represents the components of vierbein at  $X^4$ . One can invert this matrix to get  $e_\alpha^i$  satisfying  $e_\alpha^i e_i^\beta = \delta_\alpha^\beta$  and  $e_\alpha^i e_j^\alpha = \delta_j^i$ . One can solve the coordinate gradients  $\nabla m^k$  from above equation to get

$$\partial_\alpha m^k = e_\alpha^i e_i^k \equiv E_\alpha^k .$$

The integrability conditions follow from the gradient property and state

$$D_\alpha E_\beta^k = D_\beta E_\alpha^k .$$

One obtains  $8 \times 6 = 48$  conditions in the general case. The slicing to a union of two-surfaces labeled by  $M^2(x)$  reduces the number of conditions since the number of coordinates  $m^k$  reduces from 8 to 6

and one has 36 integrability conditions but still them is much larger than the number of free variables—essentially the six transversal coordinates  $m^k$ .

For co-quaternionic surfaces one can formulate integrability conditions now as conditions for the existence of integrable distribution of orthogonal complements for tangent planes and it seems that the conditions are formally similar.

### 3.6.3 How to solve the integrability conditions and field equations for preferred extremals?

The basic idea has been that the integrability condition characterize preferred extremals so that they can be said to be quaternionic in a well-defined sense. Could one imagine solving the integrability conditions by some simple ansatz utilizing the core idea of  $M^8 - H$  duality? What comes in mind is that  $M^8$  represents tangent space of  $M^4 \times CP_2$  so that one can assign to any point  $(m, s)$  of 4-surface  $X^4 \subset M^4 \times CP_2$  a tangent plane  $T^4(x)$  in its tangent space  $M^8$  identifiable as subspace of complexified octonions in the proposed manner. Assume that  $s \in CP_2$  corresponds to a fixed tangent plane containing  $M^2(x)$ , and that all planes  $M^2(x)$  are mapped to the same standard fixed hyper-octonionic plane  $M^2 \subset M^8$ , which does not depend on  $x$ . This guarantees that  $s$  corresponds to a unique quaternionic tangent plane for given  $M^2(x)$ .

Consider the map  $T \circ s$ . The map takes the tangent plane  $T^4$  at point  $(m, e) \in M^4 \times E^4$  and maps it to  $(m, s_1 = s(T^4)) \in M^4 \times CP_2$ . The obvious identification of quaternionic tangent plane at  $(m, s_1)$  would be as  $T^4$ . One would have  $T \circ s = Id$ . One could do this for all points of the quaternion surface  $X^4 \subset E^4$  and hope of getting smooth 4-surface  $X^4 \subset H$  as a result. This is the case if the integrability conditions at various points  $(m, s(T^4)(x)) \in H$  are satisfied. One could equally well start from a quaternionic surface of  $H$  and end up with integrability conditions in  $M^8$  discussed above. The geometric meaning would be that the quaternionic surface in  $H$  is image of quaternionic surface in  $M^8$  under this map.

Could one somehow generalize this construction so that one could iterate the map  $T \circ s$  to get  $T \circ s = Id$  at the limit? If so, quaternionic space-time surfaces would be obtained as limits of iteration for rather arbitrary space-time surface in either  $M^8$  or  $H$ . One can also consider limit cycles, even limiting manifolds with finite-dimension which would give quaternionic surfaces. This would give a connection with chaos theory.

1. One could try to proceed by discretizing the situation in  $M^8$  and  $H$ . One does not fix quaternionic surface at either side but just considers for a fixed  $m_2 \in M^2(x)$  a discrete collection  $X \{(T_i^4) \supset M^2(x)$  of quaternionic planes in  $M^8$ . The points  $e_{2,i} \in E^2 \subset M^2 \times E^2 = M^4$  are not fixed. One can also assume that the points  $s_i = s(T_i^4)$  of  $CP_2$  defined by the collection of planes form in a good approximation a cubic lattice in  $CP_2$  but this is not absolutely essential. Complex Eguchi-Hanson coordinates  $\xi^i$  are natural choice for the coordinates of  $CP_2$ . Assume also that the distances between the nearest  $CP_2$  points are below some upper limit.
2. Consider now the iteration. One can map the collection  $X$  to  $H$  by mapping it to the set  $s(X)$  of pairs  $((m_2, s_i)$ . Next one must select some candidates for the points  $e_{2,i} \in E^2 \subset M^4$  somehow. One can define a piece-wise linear surface in  $M^4 \times CP_2$  consisting of 4-planes defined by the nearest neighbors of given point  $(m_2, e_{2,i}, s_i)$ . The coordinates  $e_{2,i}$  for  $E^2 \subset M^4$  can be chosen rather freely. The collection  $(e_{2,i}, s_i)$  defines a piece-wise linear surface in  $H$  consisting of four-cubes in the simplest case. One can hope that for certain choices of  $e_{2,i}$  the four-cubes are quaternionic and that there is some further criterion allowing to choose the points  $e_{2,i}$  uniquely. The tangent planes contain by construction  $M^2(x)$  so that the product of remaining two spanning tangent space vectors  $(e_3, e_4)$  must give an element of  $M^2$  in order to achieve quaternionicity. Another natural condition would be that the resulting tangent planes are not only quaternionic but also as near as possible to the planes  $T_i^4$ . These conditions allow to find  $e_{2,i}$  giving rise to geometrically determined quaternionic tangent planes as near as possible to those determined by  $s^i$ .
3. What to do next? Should one replace the quaternionic planes  $T_i^4$  with geometrically determined quaternionic planes as near as possible to them and map them to points  $s_i$  slightly different from the original one and repeat the procedure? This would not add new points to the approximation, and this is an unsatisfactory feature.

4. Second possibility is based on the addition of the quaternionic tangent planes obtained in this manner to the original collection of quaternionic planes. Therefore the number of points in discretization increases and the added points of  $CP_2$  are as near as possible to existing ones. One can again determine the points  $e_{2,i}$  in such a manner that the resulting geometrically determined quaternionic tangent planes are as near as possible to the original ones. This guarantees that the algorithm converges.
5. The iteration can be stopped when desired accuracy is achieved: in other words the geometrically determined quaternionic tangent planes are near enough to those determined by the points  $s_i$ . Also limit cycles are possible and would be assignable to the transversal coordinates  $e_{2i}$  varying periodically during iteration. One can quite well allow this kind of cycles, and they would mean that  $e_2$  coordinate as a function of  $CP_2$  coordinates characterizing the tangent plane is many-valued. This is certainly very probable for solutions representable locally as graphs  $M^4 \rightarrow CP_2$ . In this case the tangent planes associated with distant points in  $E^2$  would be strongly correlated which must have non-trivial physical implications. The iteration makes sense also p-adically and it might be that in some cases only p-adic iteration converges for some value of  $p$ .

It is not obvious whether the proposed procedure gives rise to a smooth or even continuous 4-surface. The conditions for this are geometric analogs of the above described algebraic integrability conditions for the map assigning to the surface in  $M^4 \times CP_2$  a surface in  $M^8$ . Therefore  $M^8 - H$  duality could express the integrability conditions and preferred extremals would be 4-surfaces having counterparts also in the tangent space  $M^8$  of  $H$ .

One might hope that the self-referentiality condition  $s \circ T = Id$  for the  $CP_2$  projection of  $(m, s)$  or its fractal generalization could solve the complicated integrability conditions for the map  $T$ . The image of the space-time surface in tangent space  $M^8$  in turn could be interpreted as a description of space-time surface using coordinates defined by the local tangent space  $M^8$ . Also the analogy for the duality between position and momentum suggests itself.

Is there any hope that this kind of construction could make sense? Or could one demonstrate that it fails? If  $s$  would fix completely the tangent plane it would be probably easy to kill the conjecture but this is not the case. Same  $s$  corresponds for different planes  $M^2(x)$  to different point tangent plane. Presumably they are related by a local  $G_2$  or  $SO(7)$  rotation. Note that the construction can be formulated without any reference to the representation of the imbedding space gamma matrices in terms of octonions. Complexified octonions are enough in the tangent space of  $M^8$ .

### 3.6.4 Connection with Mandelbrot fractal and fractals as fixed sets for iteration

The occurrence of iteration in the construction of preferred extremals suggests a deep connection with the standard construction of 2-D fractals by iteration - about which Mandelbrot fractal [?, ?] is the canonical example.  $X^2(x)$  (or  $X^3(x)$  in the case of light-like  $L(x) \subset M^2(x)$ ) could be identified as a union of orbits for the iteration of  $s \circ T$ . The appearance of the iteration map in the construction of solutions of field equation would answer positively to a long standing question whether the extremely beautiful mathematics of 2-D fractals could have some application at the level of fundamental physics according to TGD.

$X^2$  (or  $X^3$ ) would be completely analogous to Mandelbrot set in the sense that it would be boundary separating points in two different basis of attraction. In the case of Mandelbrot set iteration would take points at the other side of boundary to origin on the other side and to infinity. The points of Mandelbrot set are permuted by the iteration. In the recent case  $s \circ T$  maps  $X^2$  (or  $X^3$ ) to itself. This map need not be diffeomorphism or even continuous map. The criticality of  $X^2$  (or  $X^3$ ) could be seen as a geometric correlate for quantum criticality.

In fact, iteration plays a very general role in the construction of fractals. Very general fractals can be defined as fixed sets of iteration and simple rules for iteration produce impressive representations for fractals appearing in Nature. The book of Michael Barnsley [?] gives fascinating pictures about fractals appearing in Nature using this method. Therefore it would be highly satisfactory if space-time surfaces would be in a well-defined sense fixed sets of iteration. This would be also numerically beautiful aspect since fixed sets of iteration can be obtained as infinite limit of iteration for almost arbitrary initial set. This construction recipe would also give a concrete content for the notion measurement resolution at the level of construction of preferred extremals.

What is intriguing is that there are several very attractive approaches to the construction of preferred extremals. The challenge of unifying them still remains to be met.

### 3.7 Do geometric invariants of preferred extremals define topological invariants of space-time surface and code for quantum physics?

The recent progress in the understanding of preferred extremals [K9] led to a reduction of the field equations to conditions stating for Euclidian signature the existence of Kähler metric. The resulting conditions are a direct generalization of corresponding conditions emerging for the string world sheet and stating that the 2-metric has only non-diagonal components in complex/hypercomplex coordinates. Also energy momentum of Kähler action and has this characteristic (1,1) tensor structure. In Minkowskian signature one obtains the analog of 4-D complex structure combining hyper-complex structure and 2-D complex structure.

The construction lead also to the understanding of how Einstein's equations with cosmological term follow as a consistency condition guaranteeing that the covariant divergence of the Maxwell's energy momentum tensor assignable to Kähler action vanishes. This gives  $T = kG + \Lambda g$ . By taking trace a further condition follows from the vanishing trace of  $T$ :

$$R = \frac{4\Lambda}{k} . \tag{3.7.1}$$

That any preferred extremal should have a constant Ricci scalar proportional to cosmological constant is very strong prediction. Note however that both  $\Lambda$  and  $k \propto 1/G$  are both parameters characterizing one particular preferred extremal. One could of course argue that the dynamics allowing only constant curvature space-times is too simple. The point is however that particle can topologically condense on several space-time sheets meaning effective superposition of various classical fields defined by induced metric and spinor connection.

The following considerations demonstrate that preferred extremals can be seen as canonical representatives for the constant curvature manifolds playing central role in Thurston's geometrization theorem [?] known also as hyperbolization theorem implying that geometric invariants of space-time surfaces transform to topological invariants. The generalization of the notion of Ricci flow to Maxwell flow in the space of metrics and further to Kähler flow for preferred extremals in turn gives a rather detailed vision about how preferred extremals organize to one-parameter orbits. It is quite possible that Kähler flow is actually discrete. The natural interpretation is in terms of dissipation and self organization. Somewhat surprisingly, hyperbolization theorem stating that very many 4-manifolds allow a metric with negative constant curvature gives a first principle explanation for the small negative value of cosmological constant implying accelerated cosmic expansion!

Quantum classical correspondence suggests that this line of thought could be continued even further: could the geometric invariants of the preferred extremals could code not only for space-time topology but also for quantum physics? How to calculate the correlation functions and coupling constant evolution has remained a basic unresolved challenge of quantum TGD. Could the correlation functions be reduced to statistical geometric invariants of preferred extremals? The latest (means the end of 2012) and perhaps the most powerful idea hitherto about coupling constant evolution is quantum classical correspondence in statistical sense stating that the statistical properties of a preferred extremal in quantum superposition of them are same as those of the zero energy state in question. This principle would be quantum generalization of ergodic theorem stating that the time evolution of a single member of ensemble represents the ensemble statistically. This principle would allow to deduce correlation functions and S-matrix from the statistical properties of single preferred extremal alone using classical intuition. Also coupling constant evolution would be coded by the statistical properties of the representative preferred extremal.

### 3.7.1 Preferred extremals of Kähler action as manifolds with constant Ricci scalar whose geometric invariants are topological invariants

An old conjecture inspired by the preferred extremal property is that the geometric invariants of space-time surface serve as topological invariants. The reduction of Kähler action to 3-D Chern-Simons terms [K9] gives support for this conjecture as a classical counterpart for the view about TGD as almost topological QFT. The following arguments give a more precise content to this conjecture in terms of existing mathematics.

1. It is not possible to represent the scaling of the induced metric as a deformation of the space-time surface preserving the preferred extremal property since the scale of  $CP_2$  breaks scale invariance. Therefore the curvature scalar cannot be chosen to be equal to one numerically. Therefore also the parameter  $R = 4\Lambda/k$  and also  $\Lambda$  and  $k$  separately characterize the equivalence class of preferred extremals as is also physically clear.

Also the volume of the space-time sheet closed inside causal diamond  $CD$  remains constant along the orbits of the flow and thus characterizes the space-time surface.  $\Lambda$  and even  $k \propto 1/G$  can indeed depend on space-time sheet and p-adic length scale hypothesis suggests a discrete spectrum for  $\Lambda/k$  expressible in terms of p-adic length scales:  $\Lambda/k \propto 1/L_p^2$  with  $p \simeq 2^k$  favored by p-adic length scale hypothesis. During cosmic evolution the p-adic length scale would increase gradually. This would resolve the problem posed by cosmological constant in GRT based theories.

2. One could also see the preferred extremals as 4-D counterparts of constant curvature 3-manifolds in the topology of 3-manifolds. An interesting possibility raised by the observed negative value of  $\Lambda$  is that most 4-surfaces are constant negative curvature 4-manifolds. By a general theorem coset spaces  $H^4/\Gamma$ , where  $H^4 = SO(1,4)/SO(4)$  is hyperboloid of  $M^5$  and  $\Gamma$  a torsion free discrete subgroup of  $SO(1,4)$  [?]. It is not clear to me, whether the constant value of Ricci scalar implies constant sectional curvatures and therefore hyperbolic space property. It could happen that the space of spaces with constant Ricci curvature contain a hyperbolic manifold as an especially symmetric representative. In any case, the geometric invariants of hyperbolic metric are topological invariants.

By Mostow rigidity theorem [?] finite-volume hyperbolic manifold is unique for  $D > 2$  and determined by the fundamental group of the manifold. Since the orbits under the Kähler flow preserve the curvature scalar the manifolds at the orbit must represent different imbeddings of one and hyperbolic 4-manifold. In 2-D case the moduli space for hyperbolic metric for a given genus  $g > 0$  is defined by Teichmueller parameters and has dimension  $6(g - 1)$ . Obviously the exceptional character of  $D = 2$  case relates to conformal invariance. Note that the moduli space in question plays a key role in p-adic mass calculations [K16].

In the recent case Mostow rigidity theorem could hold true for the Euclidian regions and maybe generalize also to Minkowskian regions. If so then both "topological" and "geometro" in "Topological GeometroDynamics" would be fully justified. The fact that geometric invariants become topological invariants also conforms with "TGD as almost topological QFT" and allows the notion of scale to find its place in topology. Also the dream about exact solvability of the theory would be realized in rather convincing manner.

These conjectures are the main result independent of whether the generalization of the Ricci flow discussed in the sequel exists as a continuous flow or possibly discrete sequence of iterates in the space of preferred extremals of Kähler action. My sincere hope is that the reader could grasp how far reaching these result really are.

### 3.7.2 Is there a connection between preferred extremals and AdS<sub>4</sub>/CFT correspondence?

The preferred extremals satisfy Einstein Maxwell equations with a cosmological constant and have negative curvature for negative value of  $\Lambda$ . 4-D space-times with hyperbolic metric provide canonical representation for a large class of four-manifolds and an interesting question is whether these spaces are obtained as preferred extremals and/or vacuum extremals.

4-D hyperbolic space with Minkowski signature is locally isometric with  $\text{AdS}_4$ . This suggests at connection with  $\text{AdS}_4/\text{CFT}$  correspondence of M-theory. The boundary of AdS would be now replaced with 3-D light-like orbit of partonic 2-surface at which the signature of the induced metric changes. The metric 2-dimensionality of the light-like surface makes possible generalization of 2-D conformal invariance with the light-like coordinate taking the role of complex coordinate at light-like boundary. AdS would presumably represent a special case of a more general family of space-time surfaces with constant Ricci scalar satisfying Einstein-Maxwell equations and generalizing the  $\text{AdS}_4/\text{CFT}$  correspondence.

This gives motivations for finding whether  $\text{AdS}_4$  allows an imbedding as a vacuum extremal to  $M^4 \times S^2 \subset M^4 \times CP_2$ , where  $S^2$  is a homologically trivial geodesic sphere of  $CP_2$ . It is easy to guess the general form of the imbedding by writing the line elements of,  $M^4$ ,  $S^2$ , and  $\text{AdS}_4$ .

1. The line element of  $M^4$  in spherical Minkowski coordinates  $(m, r_M, \theta, \phi)$  reads as

$$ds^2 = dm^2 - dr_M^2 - r_M^2 d\Omega^2 . \quad (3.7.2)$$

2. Also the line element of  $S^2$  is familiar:

$$ds^2 = -R^2(d\Theta^2 + \sin^2(\theta)d\Phi^2) . \quad (3.7.3)$$

3. By visiting in Wikipedia one learns that in spherical coordinate the line element of  $\text{AdS}_4$  is given by

$$\begin{aligned} ds^2 &= A(r)dt^2 - \frac{1}{A(r)}dr^2 - r^2d\Omega^2 , \\ A(r) &= 1 + y^2 , \quad y = \frac{r}{r_0} . \end{aligned} \quad (3.7.4)$$

4. From these formulas it is easy to see that the ansatz is of the same general form as for the imbedding of Schwarzschild-Nordstöm metric:

$$\begin{aligned} m &= \Lambda t + h(y) , \quad r_M = r , \\ \Theta &= s(y) , \quad \Phi = \omega(t + f(y)) . \end{aligned} \quad (3.7.5)$$

The non-trivial conditions on the components of the induced metric are given by

$$\begin{aligned} g_{tt} &= \Lambda^2 - x^2 \sin^2(\Theta) = A(r) , \\ g_{tr} &= \frac{1}{r_0} \left[ \Lambda \frac{dh}{dy} - x^2 \sin^2(\theta) \frac{df}{dr} \right] = 0 , \\ g_{rr} &= \frac{1}{r_0^2} \left[ \left( \frac{dh}{dy} \right)^2 - 1 - x^2 \sin^2(\theta) \left( \frac{df}{dy} \right)^2 - R^2 \left( \frac{d\Theta}{dy} \right)^2 \right] = -\frac{1}{A(r)} , \\ x &= R\omega . \end{aligned} \quad (3.7.6)$$

By some simple algebraic manipulations one can derive expressions for  $\sin(\Theta)$ ,  $df/dr$  and  $dh/dr$ .

1. For  $\Theta(r)$  the equation for  $g_{tt}$  gives the expression

$$\begin{aligned} \sin(\Theta) &= \pm \frac{P^{1/2}}{x} , \\ P &= \Lambda^2 - A = \Lambda^2 - 1 - y^2 . \end{aligned} \quad (3.7.7)$$

The condition  $0 \leq \sin^2(\Theta) \leq 1$  gives the conditions

$$(\Lambda^2 - x^2 - 1)^{1/2} \leq y \leq (\Lambda^2 - 1)^{1/2} . \quad (3.7.8)$$

Clearly only a spherical shell is possible.

2. From the vanishing of  $g_{tr}$  one obtains

$$\frac{dh}{dy} = \frac{P}{\Lambda} \frac{df}{dy} , \quad (3.7.9)$$

3. The condition for  $g_{rr}$  gives

$$\left(\frac{df}{dy}\right)^2 = \text{frac} r_0^2 AP [A^{-1} - R^2 \left(\frac{d\Theta}{dy}\right)^2] . \quad (3.7.10)$$

Clearly, the right-hand side is positive if  $P \geq 0$  holds true and  $Rd\Theta/dy$  is small. From this condition one can solve by expressing  $d\Theta/dy$  using chain rule as

$$\left(\frac{d\Theta}{dy}\right)^2 = \frac{x^2 y^2}{P(P-x^2)} . \quad (3.7.11)$$

One obtains

$$\left(\frac{df}{dy}\right)^2 = \Lambda r_0^2 \frac{y^2}{AP} \left[ \frac{1}{1+y^2} - x^2 \left(\frac{R}{r_0}\right)^2 \frac{1}{P(P-x^2)} \right] . \quad (3.7.12)$$

The right hand side of this equation is non-negative for certain range of parameters and variable  $y$ . Note that for  $r_0 \gg R$  the second term on the right hand side can be neglected. In this case it is easy to integrate  $f(y)$ .

The conclusion is that  $\text{AdS}_4$  allows a local imbedding as a vacuum extremal. Whether also an imbedding as a non-vacuum preferred extremal to homologically non-trivial geodesic sphere is possible, is an interesting question.

### 3.7.3 Generalizing Ricci flow to Maxwell flow for 4-geometries and Kähler flow for space-time surfaces

The notion of Ricci flow has played a key part in the geometrization of topological invariants of Riemann manifolds. I certainly did not have this in mind when I choose to call my unification attempt "Topological Geometro-dynamics" but this title strongly suggests that a suitable generalization of Ricci flow could play a key role in the understanding of also TGD.

**Ricci flow and Maxwell flow for 4-geometries**

The observation about constancy of 4-D curvature scalar for preferred extremals inspires a generalization of the well-known volume preserving Ricci flow [?] introduced by Richard Hamilton. Ricci flow is defined in the space of Riemann metrics as

$$\frac{dg_{\alpha\beta}}{dt} = -2R_{\alpha\beta} + 2\frac{R_{avg}}{D}g_{\alpha\beta} . \tag{3.7.13}$$

Here  $R_{avg}$  denotes the average of the scalar curvature, and  $D$  is the dimension of the Riemann manifold. The flow is volume preserving in average sense as one easily checks ( $\langle g^{\alpha\beta} dg_{\alpha\beta}/dt \rangle = 0$ ). The volume preserving property of this flow allows to intuitively understand that the volume of a 3-manifold in the asymptotic metric defined by the Ricci flow is topological invariant. The fixed points of the flow serve as canonical representatives for the topological equivalence classes of 3-manifolds. These 3-manifolds (for instance hyperbolic 3-manifolds with constant sectional curvatures) are highly symmetric. This is easy to understand since the flow is dissipative and destroys all details from the metric.

What happens in the recent case? The first thing to do is to consider what might be called Maxwell flow in the space of all 4-D Riemann manifolds allowing Maxwell field.

1. First of all, the vanishing of the trace of Maxwell's energy momentum tensor codes for the volume preserving character of the flow defined as

$$\frac{dg_{\alpha\beta}}{dt} = T_{\alpha\beta} . \tag{3.7.14}$$

Taking covariant divergence on both sides and assuming that  $d/dt$  and  $D_\alpha$  commute, one obtains that  $T^{\alpha\beta}$  is divergenceless.

This is true if one assumes Einstein's equations with cosmological term. This gives

$$\frac{dg_{\alpha\beta}}{dt} = kG_{\alpha\beta} + \Lambda g_{\alpha\beta} = kR_{\alpha\beta} + \left(-\frac{kR}{2} + \Lambda\right)g_{\alpha\beta} . \tag{3.7.15}$$

The trace of this equation gives that the curvature scalar is constant. Note that the value of the Kähler coupling strength plays a highly non-trivial role in these equations and it is quite possible that solutions exist only for some critical values of  $\alpha_K$ . Quantum criticality should fix the allow value triplets  $(G, \Lambda, \alpha_K)$  apart from overall scaling

$$(G, \Lambda, \alpha_K) \rightarrow (xG, \Lambda/x, x\alpha_K) .$$

Fixing the value of  $G$  fixes the values remaining parameters at critical points. The rescaling of the parameter  $t$  induces a scaling by  $x$ .

2. By taking trace one obtains the already mentioned condition fixing the curvature to be constant, and one can write

$$\frac{dg_{\alpha\beta}}{dt} = kR_{\alpha\beta} - \Lambda g_{\alpha\beta} . \tag{3.7.16}$$

Note that in the recent case  $R_{avg} = R$  holds true since curvature scalar is constant. The fixed points of the flow would be Einstein manifolds [?, ?] satisfying

$$R_{\alpha\beta} = \frac{\Lambda}{k}g_{\alpha\beta} \tag{3.7.17}$$

3. It is by no means obvious that continuous flow is possible. The condition that Einstein-Maxwell equations are satisfied might pick up from a completely general Maxwell flow a discrete subset as solutions of Einstein-Maxwell equations with a cosmological term. If so, one could assign to this subset a sequence of values  $t_n$  of the flow parameter  $t$ .
4. I do not know whether 3-dimensionality is somehow absolutely essential for getting the topological classification of closed 3-manifolds using Ricci flow. This ignorance allows me to pose some innocent questions. Could one have a canonical representation of 4-geometries as spaces with constant Ricci scalar? Could one select one particular Einstein space in the class four-metrics and could the ratio  $\Lambda/k$  represent topological invariant if one normalizes metric or curvature scalar suitably. In the 3-dimensional case curvature scalar is normalized to unity. In the recent case this normalization would give  $k = 4\Lambda$  in turn giving  $R_{\alpha\beta} = g_{\alpha\beta}/4$ . Does this mean that there is only single fixed point in local sense, analogous to black hole toward which all geometries are driven by the Maxwell flow? Does this imply that only the 4-volume of the original space would serve as a topological invariant?

### Maxwell flow for space-time surfaces

One can consider Maxwell flow for space-time surfaces too. In this case Kähler flow would be the appropriate term and provides families of preferred extremals. Since space-time surfaces inside CD are the basic physical objects are in TGD framework, a possible interpretation of these families would be as flows describing physical dissipation as a four-dimensional phenomenon polishing details from the space-time surface interpreted as an analog of Bohr orbit.

1. The flow is now induced by a vector field  $j^k(x, t)$  of the space-time surface having values in the tangent bundle of imbedding space  $M^4 \times CP_2$ . In the most general case one has Kähler flow without the Einstein equations. This flow would be defined in the space of all space-time surfaces or possibly in the space of all extremals. The flow equations reduce to

$$h_{kl}D_\alpha j^k(x, t)D_\beta h^l = \frac{1}{2}T_{\alpha\beta} . \quad (3.7.18)$$

The left hand side is the projection of the covariant gradient  $D_\alpha j^k(x, t)$  of the flow vector field  $j^k(x, t)$  to the tangent space of the space-time surface.  $D_{alpha}$  is covariant derivative taking into account that  $j^k$  is imbedding space vector field. For a fixed point space-time surface this projection must vanish assuming that this space-time surface reachable. A good guess for the asymptotia is that the divergence of Maxwell energy momentum tensor vanishes and that Einstein's equations with cosmological constant are well-defined.

Asymptotes corresponds to vacuum extremals. In Euclidian regions  $CP_2$  type vacuum extremals and in Minkowskian regions to any space-time surface in any 6-D sub-manifold  $M^4 \times Y^2$ , where  $Y^2$  is Lagrangian sub-manifold of  $CP_2$  having therefore vanishing induced Kähler form. Symplectic transformations of  $CP_2$  combined with diffeomorphisms of  $M^4$  give new Lagrangian manifolds. One would expect that vacuum extremals are approached but never reached at second extreme for the flow.

If one assumes Einstein's equations with a cosmological term, allowed vacuum extremals must be Einstein manifolds. For  $CP_2$  type vacuum extremals this is the case. It is quite possible that these fixed points do not actually exist in Minkowskian sector, and could be replaced with more complex asymptotic behavior such as limit, chaos, or strange attractor.

2. The flow could be also restricted to the space of preferred extremals. Assuming that Einstein Maxwell equations indeed hold true, the flow equations reduce to

$$h_{kl}D_\alpha j^k(x, t)\partial_\beta h^l = \frac{1}{2}(kR_{\alpha\beta} - \Lambda g_{\alpha\beta}) . \quad (3.7.19)$$

Preferred extremals would correspond to a fixed sub-manifold of the general flow in the space of all 4-surfaces.

3. One can also consider a situation in which  $j^k(x, t)$  is replaced with  $j^k(h, t)$  defining a flow in the entire imbedding space. This assumption is probably too restrictive. In this case the equations reduce to

$$(D_r j_l(x, t) + D_l j_r) \partial_\alpha h^r \partial_\beta h^l = k R_{\alpha\beta} - \Lambda g_{\alpha\beta} . \quad (3.7.20)$$

Here  $D_r$  denotes covariant derivative. Asymptotia is achieved if the tensor  $D_k j_l + D_l j_k$  becomes orthogonal to the space-time surface. Note for that Killing vector fields of  $H$  the left hand side vanishes identically. Killing vector fields are indeed symmetries of also asymptotic states.

It must be made clear that the existence of a continuous flow in the space of preferred extremals might be too strong a condition. Already the restriction of the general Maxwell flow in the space of metrics to solutions of Einstein-Maxwell equations with cosmological term might lead to discretization, and the assumption about repretability as 4-surface in  $M^4 \times CP_2$  would give a further condition reducing the number of solutions. On the other hand, one might consider a possibility of a continuous flow in the space of constant Ricci scalar metrics with a fixed 4-volume and having hyperbolic spaces as the most symmetric representative.

### Dissipation, self organization, transition to chaos, and coupling constant evolution

A beautiful connection with concepts like dissipation, self-organization, transition to chaos, and coupling constant evolution suggests itself.

1. It is not at all clear whether the vacuum extremal limits of the preferred extremals can correspond to Einstein spaces except in special cases such as  $CP_2$  type vacuum extremals isometric with  $CP_2$ . The imbeddability condition however defines a constraint force which might well force asymptotically more complex situations such as limit cycles and strange attractors. In ordinary dissipative dynamics an external energy feed is essential prerequisite for this kind of non-trivial self-organization patterns.

In the recent case the external energy feed could be replaced by the constraint forces due to the imbeddability condition. It is not too difficult to imagine that the flow (if it exists!) could define something analogous to a transition to chaos taking place in a stepwise manner for critical values of the parameter  $t$ . Alternatively, these discrete values could correspond to those values of  $t$  for which the preferred extremal property holds true for a general Maxwell flow in the space of 4-metrics. Therefore the preferred extremals of Kähler action could emerge as one-parameter (possibly discrete) families describing dissipation and self-organization at the level of space-time dynamics.

2. For instance, one can consider the possibility that in some situations Einstein's equations split into two mutually consistent equations of which only the first one is independent

$$\begin{aligned} x J^\alpha{}_\nu J^{\nu\beta} &= R^{\alpha\beta} , \\ L_K &= x J^\alpha{}_\nu J^{\nu\beta} = 4\Lambda , \\ x &= \frac{1}{16\pi\alpha_K} . \end{aligned} \quad (3.7.21)$$

Note that the first equation indeed gives the second one by tracing. This happens for  $CP_2$  type vacuum extremals.

Kähler action density would reduce to cosmological constant which should have a continuous spectrum if this happens always. A more plausible alternative is that this holds true only asymptotically. In this case the flow equation could not lead arbitrary near to vacuum extremal, and one can think of situation in which  $L_K = 4\Lambda$  defines an analog of limiting cycle or perhaps even strange attractor. In any case, the assumption would allow to deduce the asymptotic value

of the action density which is of utmost importance from calculational point of view: action would be simply  $S_K = 4\Lambda V_4$  and one could also say that one has minimal surface with  $\Lambda$  taking the role of string tension.

3. One of the key ideas of TGD is quantum criticality implying that Kähler coupling strength is analogous to critical temperature. Second key idea is that p-adic coupling constant evolution represents discretized version of continuous coupling constant evolution so that each p-adic prime would correspond a fixed point of ordinary coupling constant evolution in the sense that the 4-volume characterized by the p-adic length scale remains constant. The invariance of the geometric and thus geometric parameters of hyperbolic 4-manifold under the Kähler flow would conform with the interpretation as a flow preserving scale assignable to a given p-adic prime. The continuous evolution in question (if possible at all!) might correspond to a fixed p-adic prime. Also the hierarchy of Planck constants relates to this picture naturally. Planck constant  $\hbar_{eff} = n\hbar$  corresponds to a multi-furcation generating n-sheeted structure and certainly affecting the fundamental group.
4. One can of course question the assumption that a continuous flow exists. The property of being a solution of Einstein-Maxwell equations, imbeddability property, and preferred extremal property might allow only discrete sequences of space-time surfaces perhaps interpretable as orbit of an iterated map leading gradually to a fractal limit. This kind of discrete sequence might be also be selected as preferred extremals from the orbit of Maxwell flow without assuming Einstein-Maxwell equations. Perhaps the discrete p-adic coupling constant evolution could be seen in this manner and be regarded as an iteration so that the connection with fractality would become obvious too.

#### Does a 4-D counterpart of thermodynamics make sense?

The interpretation of the Kähler flow in terms of dissipation, the constancy of  $R$ , and almost constancy of  $L_K$  suggest an interpretation in terms of 4-D variant of thermodynamics natural in zero energy ontology (ZEO), where physical states are analogs for pairs of initial and final states of quantum event are quantum superpositions of classical time evolutions. Quantum theory becomes a "square root" of thermodynamics so that 4-D analog of thermodynamics might even replace ordinary thermodynamics as a fundamental description. If so this 4-D thermodynamics should be qualitatively consistent with the ordinary 3-D thermodynamics.

1. The first naive guess would be the interpretation of the action density  $L_K$  as an analog of energy density  $e = E/V_3$  and that of  $R$  as the analog to entropy density  $s = S/V_3$ . The asymptotic states would be analogs of thermodynamical equilibria having constant values of  $L_K$  and  $R$ .
2. Apart from an overall sign factor  $\epsilon$  to be discussed, the analog of the first law  $de = Tds - pdV/V$  would be

$$dL_K = kdR + \Lambda \frac{dV_4}{V_4} .$$

One would have the correspondences  $S \rightarrow \epsilon RV_4$ ,  $e \rightarrow \epsilon L_K$  and  $k \rightarrow T$ ,  $p \rightarrow -\Lambda$ .  $k \propto 1/G$  indeed appears formally in the role of temperature in Einstein's action defining a formal partition function via its exponent. The analog of second law would state the increase of the magnitude of  $\epsilon RV_4$  during the Kähler flow.

3. One must be very careful with the signs and discuss Euclidian and Minkowskian regions separately. Concerning purely thermodynamic aspects at the level of vacuum functional Euclidian regions are those which matter.
  - (a) For  $CP_2$  type vacuum extremals  $L_K \propto E^2 + B^2$ ,  $R = \Lambda/k$ , and  $\Lambda$  are positive. In thermodynamical analogy for  $\epsilon = 1$  this would mean that pressure is negative.
  - (b) In Minkowskian regions the value of  $R = \Lambda/k$  is negative for  $\Lambda < 0$  suggested by the large abundance of 4-manifolds allowing hyperbolic metric and also by cosmological considerations. The asymptotic formula  $L_K = 4\Lambda$  considered above suggests that also Kähler action

is negative in Minkowskian regions for magnetic flux tubes dominating in TGD inspired cosmology: the reason is that the magnetic contribution to the action density  $L_K \propto E^2 - B^2$  dominates.

Consider now in more detail the 4-D thermodynamics interpretation in Euclidian and Minkowskian regions assuming that the evolution by quantum jumps has Kähler flow as a space-time correlate.

1. In Euclidian regions the choice  $\epsilon = 1$  seems to be more reasonable one. In Euclidian regions  $-\Lambda$  as the analog of pressure would be negative, and asymptotically (that is for  $CP_2$  type vacuum extremals) its value would be proportional to  $\Lambda \propto 1/GR^2$ , where  $R$  denotes  $CP_2$  radius defined by the length of its geodesic circle.

A possible interpretation for negative pressure is in terms of string tension effectively inducing negative pressure (note that the solutions of the modified Dirac equation indeed assign a string to the wormhole contact). The analog of the second law would require the increase of  $RV_4$  in quantum jumps. The magnitudes of  $L_K$ ,  $R$ ,  $V_4$  and  $\Lambda$  would be reduced and approach their asymptotic values. In particular,  $V_4$  would approach asymptotically the volume of  $CP_2$ .

2. In Minkowskian regions Kähler action contributes to the vacuum functional a phase factor analogous to an imaginary exponent of action serving in the role of Morse function so that thermodynamics interpretation can be questioned. Despite this one can check whether thermodynamic interpretation can be considered. The choice  $\epsilon = -1$  seems to be the correct choice now.  $-\Lambda$  would be analogous to a negative pressure whose gradually decreases. In 3-D thermodynamics it is natural to assign negative pressure to the magnetic flux tube like structures as their effective string tension defined by the density of magnetic energy per unit length.  $-R \geq 0$  would entropy and  $-L_K \geq 0$  would be the analog of energy density.

$R = \Lambda/k$  and the reduction of  $\Lambda$  during cosmic evolution by quantum jumps suggests that the larger the volume of CD and thus of (at least) Minkowskian space-time sheet the smaller the negative value of  $\Lambda$ .

Assume the recent view about state function reduction explaining how the arrow of geometric time is induced by the quantum jump sequence defining experienced time [?]. According to this view zero energy states are quantum superpositions over  $CD$ s of various size scales but with common tip, which can correspond to either the upper or lower light-like boundary of  $CD$ . The sequence of quantum jumps the gradual increase of the average size of  $CD$  in the quantum superposition and therefore that of average value of  $V_4$ . On the other hand, a gradual decrease of both  $-L_K$  and  $-R$  looks physically very natural. If Kähler flow describes the effect of dissipation by quantum jumps in ZEO then the space-time surfaces would gradually approach nearly vacuum extremals with constant value of entropy density  $-R$  but gradually increasing 4-volume so that the analog of second law stating the increase of  $-RV_4$  would hold true.

3. The interpretation of  $-R > 0$  as negentropy density assignable to entanglement is also possible and is consistent with the interpretation in terms of second law. This interpretation would only change the sign factor  $\epsilon$  in the proposed formula. Otherwise the above arguments would remain as such.

### 3.7.4 Could correlation functions, S-matrix, and coupling constant evolution be coded the statistical properties of preferred extremals?

Quantum classical correspondence states that all aspects of quantum states should have correlates in the geometry of preferred extremals. In particular, various elementary particle propagators should have a representation as properties of preferred extremals. This would allow to realize the old dream about being able to say something interesting about coupling constant evolution although it is not yet possible to calculate the M-matrices and U-matrix. Hitherto everything that has been said about coupling constant evolution has been rather speculative arguments except for the general vision that it reduces to a discrete evolution defined by p-adic length scales. General first principle definitions are however much more valuable than ad hoc guesses even if the latter give rise to explicit formulas.

In quantum TGD and also at its QFT limit various correlation functions in given quantum state should code for its properties. By quantum classical correspondence these correlation functions should

have counterparts in the geometry of preferred extremals. Even more: these classical counterparts for a given preferred extremal ought to be identical with the quantum correlation functions for the superposition of preferred extremals. This correspondence could be called quantum ergodicity by its analogy with ordinary ergodicity stating that the member of ensemble becomes representative of ensemble.

1. The marvelous implication of quantum ergodicity would be that one could calculate everything solely classically using the classical intuition - the only intuition that we have. Quantum ergodicity would also solve the paradox raised by the quantum classical correspondence for momentum eigenstates. Any preferred extremal in their superposition defining momentum eigenstate should code for the momentum characterizing the superposition itself. This is indeed possible if every extremal in the superposition codes the momentum to the properties of classical correlation functions which are identical for all of them.
2. The only manner to possibly achieve quantum ergodicity is in terms of the statistical properties of the preferred extremals. It should be possible to generalize the ergodic theorem stating that the properties of statistical ensemble are represented by single space-time evolution in the ensemble of time evolutions. Quantum superposition of classical worlds would effectively reduce to single classical world as far as classical correlation functions are considered. The notion of finite measurement resolution suggests that one must state this more precisely by adding that classical correlation functions are calculated in a given UV and IR resolutions meaning UV cutoff defined by the smallest CD and IR cutoff defined by the largest CD present.
3. The skeptic inside me immediately argues that TGD Universe is 4-D spin glass so that this quantum ergodic theorem must be broken. In the case of the ordinary spin classes one has not only statistical average for a fixed Hamiltonian but a statistical average over Hamiltonians. There is a probability distribution over the coupling parameters appearing in the Hamiltonian. Maybe the quantum counterpart of this is needed to predict the physically measurable correlation functions.

Could this average be an ordinary classical statistical average over quantum states with different classical correlation functions? This kind of average is indeed taken in density matrix formalism. Or could it be that the square root of thermodynamics defined by ZEO actually gives automatically rise to this average? The eigenvalues of the "hermitian square root" of the density matrix would code for components of the state characterized by different classical correlation functions. One could assign these contributions to different "phases".

4. Quantum classical correspondence in statistical sense would be very much like holography (now individual classical state represents the entire quantum state). Quantum ergodicity would pose a rather strong constraint on quantum states. This symmetry principle could actually fix the spectrum of zero energy states to a high degree and fix therefore the M-matrices given by the product of hermitian square root of density matrix and unitary S-matrix and unitary U-matrix having M-matrices as its orthonormal rows.
5. In TGD inspired theory of consciousness the counterpart of quantum ergodicity is the postulate that the space-time geometry provides a symbolic representation for the quantum states and also for the contents of consciousness assignable to quantum jumps between quantum states. Quantum ergodicity would realize this strongly self-referential looking condition. The positive and negative energy parts of zero energy state would be analogous to the initial and final states of quantum jump and the classical correlation functions would code for the contents of consciousness like written formulas code for the thoughts of mathematician and provide a sensory feedback.

How classical correlation functions should be defined?

1. General Coordinate Invariance and Lorentz invariance are the basic constraints on the definition. These are achieved for the space-time regions with Minkowskian signature and 4-D  $M^4$  projection if linear Minkowski coordinates are used. This is equivalent with the contraction of the indices of tensor fields with the space-time projections of  $M^4$  Killing vector fields representing translations.

Accepting this generalization, there is no need to restrict oneself to 4-D  $M^4$  projection and one can also consider also Euclidian regions identifiable as lines of generalized Feynman diagrams.

Quantum ergodicity very probably however forces to restrict the consideration to Minkowskian and Euclidian space-time regions and various phases associated with them. Also  $CP_2$  Killing vector fields can be projected to space-time surface and give a representation for classical gluon fields. These in turn can be contracted with  $M^4$  Killing vectors giving rise to gluon fields as analogs of graviton fields but with second polarization index replaced with color index.

2. The standard definition for the correlation functions associated with classical time evolution is the appropriate starting point. The correlation function  $G_{XY}(\tau)$  for two dynamical variables  $X(t)$  and  $Y(t)$  is defined as the average  $G_{XY}(\tau) = \int_T X(t)Y(t+\tau)dt/T$  over an interval of length  $T$ , and one can also consider the limit  $T \rightarrow \infty$ . In the recent case one would replace  $\tau$  with the difference  $m_1 - m_2 = m$  of  $M^4$  coordinates of two points at the preferred extremal and integrate over the points of the extremal to get the average. The finite time interval  $T$  is replaced with the volume of causal diamond in a given length scale. Zero energy state with given quantum numbers for positive and negative energy parts of the state defines the initial and final states between which the fields appearing in the correlation functions are defined.
3. What correlation functions should be considered? Certainly one could calculate correlation functions for the induced spinor connection given electro-weak propagators and correlation functions for  $CP_2$  Killing vector fields giving correlation functions for gluon fields using the description in terms of Killing vector fields. If one can uniquely separate from the Fourier transform uniquely a term of form  $Z/(p^2 - m^2)$  by its momentum dependence, the coefficient  $Z$  can be identified as coupling constant squared for the corresponding gauge potential component and one can in principle deduce coupling constant evolution purely classically. One can imagine of calculating spinorial propagators for string world sheets in the same manner. Note that also the dependence on color quantum numbers would be present so that in principle all that is needed could be calculated for a single preferred extremal without the need to construct QFT limit and to introduce color quantum numbers of fermions as spin like quantum numbers (color quantum numbers corresponds to  $CP_2$  partial wave for the tip of the CD assigned with the particle).
4. What about Higgs field? TGD in principle allows scalar and pseudo-scalars which could be called Higgs like states. These states are however not necessary for particle massivation although they can represent particle massivation and must do so if one assumes that QFT limit exist. p-Adic thermodynamics however describes particle massivation microscopically.

The problem is that Higgs like field does not seem to have any obvious space-time correlate. The trace of the second fundamental form is the obvious candidate but vanishes for preferred extremals which are both minimal surfaces and solutions of Einstein Maxwell equations with cosmological constant. If the string world sheets at which all spinor components except right handed neutrino are localized for the general solution ansatz of the modified Dirac equation, the corresponding second fundamental form at the level of imbedding space defines a candidate for classical Higgs field. A natural expectation is that string world sheets are minimal surfaces of space-time surface. In general they are however not minimal surfaces of the imbedding space so that one might achieve a microscopic definition of classical Higgs field and its vacuum expectation value as an average of one point correlation function over the string world sheet.

Many detailed speculations about coupling constant evolution to be discussed in the sections below must be taken as innovative guesses doomed to have the eventual fate of guesses. The notion of quantum ergodicity could however be one of the really deep ideas about coupling constant evolution comparable to the notion of p-adic coupling constant evolution. Quantum Ergodicity (briefly QE) would also state something extremely non-trivial also about the construction of correlation functions and S-matrix. Because this principle is so new, the rest of the chapter does not yet contain any applications of QE. This should not lead the reader to under-estimate the potential power of QE.

### 3.8 Appendix: Hamilton-Jacobi structure

In the following the definition of Hamilton-Jacobi structure is discussed in detail.

### 3.8.1 Hermitian and hyper-Hermitian structures

The starting point is the observation that besides the complex numbers forming a number field there are hyper-complex numbers. Imaginary unit  $i$  is replaced with  $e$  satisfying  $e^2 = 1$ . One obtains an algebra but not a number field since the norm is Minkowskian norm  $x^2 - y^2$ , which vanishes at light-cone  $x = y$  so that light-like hypercomplex numbers  $x \pm e$  do not have inverse. One has "almost" number field.

Hyper-complex numbers appear naturally in 2-D Minkowski space since the solutions of a massless field equation can be written as  $f = g(u = t - ex) + h(v = t + ex)$  which  $e^2 = 1$  realized by putting  $e = 1$ . Therefore Wick rotation relates sums of holomorphic and antiholomorphic functions to sums of hyper-holomorphic and anti-hyper-holomorphic functions. Note that  $u$  and  $v$  are hyper-complex conjugates of each other.

Complex  $n$ -dimensional spaces allow Hermitian structure. This means that the metric has in complex coordinates  $(z_1, \dots, z_n)$  the form in which the matrix elements of metric are nonvanishing only between  $z_i$  and complex conjugate of  $z_j$ . In 2-D case one obtains just  $ds^2 = g_{z\bar{z}} dz d\bar{z}$ . Note that in this case metric is conformally flat since line element is proportional to the line element  $ds^2 = dz d\bar{z}$  of plane. This form is always possible locally. For complex  $n$ -D case one obtains  $ds^2 = g_{i\bar{j}} dz^i d\bar{z}^j$ .  $g_{i\bar{j}} = \overline{g_{j\bar{i}}}$  guaranteeing the reality of  $ds^2$ . In 2-D case this condition gives  $g_{z\bar{z}} = \overline{g_{z\bar{z}}}$ .

How could one generalize this line element to hyper-complex  $n$ -dimensional case. In 2-D case Minkowski space  $M^2$  one has  $ds^2 = g_{uv} du dv$ ,  $g_{uv} = 1$ . The obvious generalization would be the replacement  $ds^2 = g_{u_i v_j} du^i dv^j$ . Also now the analogs of reality conditions must hold with respect to  $u_i \leftrightarrow v_i$ .

### 3.8.2 Hamilton-Jacobi structure

Consider next the path leading to Hamilton-Jacobi structure.

4-D Minkowski space  $M^4 = M^2 \times E^2$  is Cartesian product of hyper-complex  $M^2$  with complex plane  $E^2$ , and one has  $ds^2 = dudv + dzd\bar{z}$  in standard Minkowski coordinates. One can also consider more general integrable decompositions of  $M^4$  for which the tangent space  $TM^4 = M^4$  at each point is decomposed to  $M^2(x) \times E^2(x)$ . The physical analogy would be a position dependent decomposition of the degrees of freedom of massless particle to longitudinal ones ( $M^2(x)$ : light-like momentum is in this plane) and transversal ones ( $E^2(x)$ : polarization vector is in this plane). Cylindrical and spherical variants of Minkowski coordinates define two examples of this kind of coordinates (it is perhaps a good exercise to think what kind of decomposition of tangent space is in question in these examples). An interesting mathematical problem highly relevant for TGD is to identify all possible decompositions of this kind for empty Minkowski space.

The integrability of the decomposition means that the planes  $M^2(x)$  are tangent planes for 2-D surfaces of  $M^4$  analogous to Euclidian string world sheet. This gives slicing of  $M^4$  to Minkowskian string world sheets parametrized by euclidian string world sheets. The question is whether the sheets are stringy in a strong sense: that is minimal surfaces. This is not the case: for spherical coordinates the Euclidian string world sheets would be spheres which are not minimal surfaces. For cylindrical and spherical coordinates however  $M^2(x)$  integrate to plane  $M^2$  which is minimal surface.

Integrability means in the case of  $M^2(x)$  the existence of light-like vector field  $J$  whose flow lines define a global coordinate. Its existence implies also the existence of its conjugate and together these vector fields give rise to  $M^2(x)$  at each point. This means that one has  $J = \Psi \nabla \Phi$ :  $\Phi$  indeed defines the global coordinate along flow lines. In the case of  $M^2$  either the coordinate  $u$  or  $v$  would be the coordinate in question. This kind of flows are called Beltrami flows. Obviously the same holds for the transversal planes  $E^2$ .

One can generalize this metric to the case of general 4-D space with Minkowski signature of metric. At least the elements  $g_{uv}$  and  $g_{z\bar{z}}$  are non-vanishing and can depend on both  $u, v$  and  $z, \bar{z}$ . They must satisfy the reality conditions  $g_{z\bar{z}} = \overline{g_{z\bar{z}}}$  and  $g_{uv} = \overline{g_{vu}}$  where complex conjugation in the argument involves also  $u \leftrightarrow v$  besides  $z \leftrightarrow \bar{z}$ .

The question is whether the components  $g_{uz}, g_{vz}$ , and their complex conjugates are non-vanishing if they satisfy some conditions. They can. The direct generalization from complex 2-D space would be that one treats  $u$  and  $v$  as complex conjugates and therefore requires a direct generalization of the hermiticity condition

$$g_{uz} = \overline{g_{v\bar{z}}} \ , \ g_{vz} = \overline{g_{u\bar{z}}} \ .$$

This would give complete symmetry with the complex 2-D (4-D in real sense) spaces. This would allow the algebraic continuation of hermitian structures to Hamilton-Jacobi structures by just replacing  $i$  with  $e$  for some complex coordinates.

## Chapter 4

# Elementary Particle Vacuum Functionals

### 4.1 Introduction

One of the basic ideas of TGD approach has been genus-generation correspondence: boundary components of the 3-surface should be carriers of elementary particle numbers and the observed fermion families should correspond to various boundary topologies. The details of the assumed correspondence have evolved during years.

1. The first proposal indeed indeed that both fermions and bosons correspond to boundary components so that the genus of the boundary component would classify the particles topologically. At this time I still believed that stringy diagrams would have a direct generalization in TGD framework implying that  $g$  would define additive quantum number effectively. Later it became clear that it is Feynman diagrams which must be generalized and the partons at primary vertices must have same genus. Stringy diagrams are still there but have totally different interpretation.
2. Boundary component was later replaced with the light-like surface at which the signature of the induced metric changes and it was natural to identify bosons as wormhole contacts carrying fermion and antifermion quantum numbers at opposite light-like worm-hole throats. Hence bosons would be labeled by pairs  $(g_1, g_2)$  of genera. For gravitons one had to assume pairs of wormhole contacts in order to obtain spin 2. Already at this stage it became clear that  $SU(3)$  should act as a dynamical symmetry with fermions in triplet representation and bosons in octet and singlet representations. The light bosons would correspond to singlets which would guarantee universality of the couplings to fermion families.
3. For long time fermions were identified as single throats but twistorial program and the properties of Chern-Simons Dirac operator suggesting strongly that the fundamental entities must be massless, forced to replace physical fermion with a wormhole contact characterized by  $(g, g)$  and transforming like triplet with respect to  $SU(3)$  as far as vertices are considered. The hypothesis that  $SU(3)$  acts as dynamical symmetry for the reaction vertices has very powerful implications and allows only BFF type vertices required also by bosonic emergence and SUSY symmetry.
4. A further step in the evolution of ideas was the realization that electric-magnetic duality forces to identify all elementary particles as "weak" string like objects consisting of Kähler magnetic flux tubes with opposite magnetic charges at ends. This meant that all elementary particles - not only gravitons- are described by "weak" strings. Note that this stringy character should not be confused with that for wormhole contacts for which throats effectively play the role of string ends. One can say that fundamental objects are massless states at wormhole throats and that all elementary particles as well as string like objects emerge from them.

One might hope that this picture is not too far from the final one as far elementary particles are considered. If one accepts this picture the remaining question is why the number of genera is just three. Could this relate to the fact that  $g \leq 2$  Riemann surfaces are always hyper-elliptic (have global

$Z_2$  conformal symmetry) unlike  $g > 2$  surfaces? Why the complete bosonic de-localization of the light families should be restricted inside the hyper-elliptic sector? Does the  $Z_2$  conformal symmetry make these states light and make possible delocalization and dynamical  $SU(3)$  symmetry? Could it be that for  $g > 2$  elementary particle vacuum functionals vanish for hyper-elliptic surfaces? If this the case and if the time evolution for partonic 2-surfaces changing  $g$  commutes with  $Z_2$  symmetry then the vacuum functionals localized to  $g \leq 2$  surfaces do not disperse to  $g > 2$  sectors.

In order to provide answers to either series of questions one must know something about the dependence of the elementary particle state functionals on the geometric properties of the boundary component and in the sequel an attempt to construct what might be called elementary particle vacuum functionals, is made. Irrespective of what identification of interaction vertices is adopted, the arguments involved with the construction involve only the string model type vertices so that the previous discussion seems to apply more or less as such.

The basic assumptions underlying the construction are the following ones:

1. Elementary particle vacuum functionals depend on the geometric properties of the two-surface  $X^2$  representing elementary particle.
2. Vacuum functionals possess extended Diff invariance: all 2-surfaces on the orbit of the 2-surface  $X^2$  correspond to the same value of the vacuum functional. This condition is satisfied if vacuum functionals have as their argument, not  $X^2$  as such, but some 2- surface  $Y^2$  belonging to the unique orbit of  $X^2$  (determined by the principle selecting preferred extremal of the Kähler action as a generalized Bohr orbit [? ] ) and determined in  $Dif f^3$  invariant manner.
3. Zero energy ontology allows to select uniquely the partonic two surface as the intersection of the wormhole throat at which the signature of the induced 4-metric changes with either the upper or lower boundary of  $CD \times CP_2$ . This is essential since otherwise one one could not specify the vacuum functional uniquely.
4. Vacuum functionals possess conformal invariance and therefore for a given genus depend on a finite number of variables specifying the conformal equivalence class of  $Y^2$ .
5. Vacuum functionals satisfy the cluster decomposition property: when the surface  $Y^2$  degenerates to a union of two disjoint surfaces (particle decay in string model inspired picture), vacuum functional decomposes into a product of the vacuum functionals associated with disjoint surfaces.
6. Elementary particle vacuum functionals are stable against the two-particle decay  $g \rightarrow g_1 + g_2$  and one particle decay  $g \rightarrow g - 1$ .

In the following the construction will be described in more detail.

1. Some basic concepts related to the description of the space of the conformal equivalence classes of Riemann surfaces are introduced and the concept of hyper-ellipticity is introduced. Since theta functions will play a central role in the construction of the vacuum functionals, also their basic properties are discussed.
2. After these preliminaries the construction of elementary particle vacuum functionals is carried out.
3. Possible explanations for the experimental absence of the higher fermion families are considered.

## 4.2 Identification of elementary particles

The developments in the formulation of quantum TGD which have taken place during the period 2005-2007 [?, K17] suggest dramatic simplifications of the general picture discussed in the earlier version of this chapter. p-Adic mass calculations [?, K46, K43] leave a lot of freedom concerning the detailed identification of elementary particles.

### 4.2.1 The evolution of the topological ideas about elementary particles

One of the basic ideas of TGD approach has been genus-generation correspondence: boundary components of the 3-surface should be carriers of elementary particle numbers and the observed fermion families should correspond to various boundary topologies.

With the advent of zero energy ontology this picture changed somewhat. It is the wormhole throats identified as light-like 3-surfaces at which with the induced metric of the space-time surface changes its signature from Minkowskian to Euclidian, which correspond to the light-like orbits of partonic 2-surfaces. One cannot of course exclude the possibility that also boundary components could allow to satisfy boundary conditions without assuming vacuum extremal property of nearby space-time surface. The intersections of the wormhole throats with the light-like boundaries of causal diamonds ( $CD$ s) identified as intersections of future and past directed light cones ( $CD \times CP_2$  is actually in question but I will speak about  $CD$ s) define special partonic 2-surfaces and it is the moduli of these partonic 2-surfaces which appear in the elementary particle vacuum functionals naturally.

The first modification of the original simple picture comes from the identification of physical particles as bound states of pairs of wormhole contacts and from the assumption that for generalized Feynman diagrams stringy trouser vertices are replaced with vertices at which the ends of light-like wormhole throats meet. In this picture the interpretation of the analog of trouser vertex is in terms of propagation of same particle along two different paths. This interpretation is mathematically natural since vertices correspond to 2-manifolds rather than singular 2-manifolds which are just splitting to two disjoint components. Second complication comes from the weak form of electric-magnetic duality forcing to identify physical particles as weak strings with magnetic monopoles at their ends and one should understand also the possible complications caused by this generalization.

These modifications force to consider several options concerning the identification of light fermions and bosons and one can end up with a unique identification only by making some assumptions. Masslessness of all wormhole throats- also those appearing in internal lines- and dynamical  $SU(3)$  symmetry for particle generations are attractive general enough assumptions of this kind. This means that bosons and their super-partners correspond to wormhole contacts with fermion and antifermion at the throats of the contact. Free fermions and their superpartners could correspond to  $CP_2$  type vacuum extremals with single wormhole throat. It turns however that dynamical  $SU(3)$  symmetry forces to identify massive (and possibly topologically condensed) fermions as  $(g, g)$  type wormhole contacts.

#### Do free fermions correspond to single wormhole throat or $(g, g)$ wormhole?

The original interpretation of genus-generation correspondence was that free fermions correspond to wormhole throats characterized by genus. The idea of  $SU(3)$  as a dynamical symmetry suggested that gauge bosons correspond to octet and singlet representations of  $SU(3)$ . The further idea that all lines of generalized Feynman diagrams are massless poses a strong additional constraint and it is not clear whether this proposal as such survives.

1. Twistorial program assumes that fundamental objects are massless wormhole throats carrying collinearly moving many-fermion states and also bosonic excitations generated by super-symplectic algebra. In the following consideration only purely bosonic and single fermion throats are considered since they are the basic building blocks of physical particles. The reason is that propagators for high excitations behave like  $p^{-n}$ ,  $n$  the number of fermions associated with the wormhole throat. Therefore single throat allows only spins 0, 1/2, 1 as elementary particles in the usual sense of the word.
2. The identification of massive fermions (as opposed to free massless fermions) as wormhole contacts follows if one requires that fundamental building blocks are massless since at least two massless throats are required to have a massive state. Therefore the conformal excitations with  $CP_2$  mass scale should be assignable to wormhole contacts also in the case of fermions. As already noticed this is not the end of the story: weak strings are required by the weak form of electric-magnetic duality.
3. If free fermions corresponding to single wormhole throat, topological condensation is an essential element of the formation of stringy states. The topological condensation of fermions by topological sum (fermionic  $CP_2$  type vacuum extremal touches another space-time sheet) suggest  $(g, 0)$

wormhole contact. Note however that the identification of wormhole throat is as 3-surface at which the signature of the induced metric changes so that this conclusion might be wrong. One can indeed consider also the possibility of  $(g, g)$  pairs as an outcome of topological condensation. This is suggested also by the idea that wormhole throats are analogous to string like objects and only this option turns out to be consistent with the  $BFF$  vertex based on the requirement of dynamical  $SU(3)$  symmetry to be discussed later. The structure of reaction vertices makes it possible to interpret  $(g, g)$  pairs as  $SU(3)$  triplet. If bosons are obtained as fusion of fermionic and antifermionic throats (touching of corresponding  $CP_2$  type vacuum extremals) they correspond naturally to  $(g_1, g_2)$  pairs.

4. p-Adic mass calculations distinguish between fermions and bosons and the identification of fermions and bosons should be consistent with this difference. The maximal p-adic temperature  $T = 1$  for fermions could relate to the weakness of the interaction of the fermionic wormhole throat with the wormhole throat resulting in topological condensation. This wormhole throat would however carry momentum and 3-momentum would in general be non-parallel to that of the fermion, most naturally in the opposite direction.

p-Adic mass calculations suggest strongly that for bosons p-adic temperature  $T = 1/n$ ,  $n > 1$ , so that thermodynamical contribution to the mass squared is negligible. The low p-adic temperature could be due to the strong interaction between fermionic and antifermionic wormhole throat leading to the "freezing" of the conformal degrees of freedom related to the relative motion of wormhole throats.

5. The weak form of electric-magnetic duality forces second wormhole throat with opposite magnetic charge and the light-like momenta could sum up to massive momentum. In this case string tension corresponds to electroweak length scale. Therefore p-adic thermodynamics must be assigned to wormhole contacts and these appear as basic units connected by Kähler magnetic flux tube pairs at the two space-time sheets involved. Weak stringy degrees of freedom are however expected to give additional contribution to the mass, perhaps by modifying the ground state conformal weight.

#### Dynamical $SU(3)$ fixes the identification of fermions and bosons and fundamental interaction vertices

For 3 light fermion families  $SU(3)$  suggests itself as a dynamical symmetry with fermions in fundamental  $N = 3$ -dimensional representation and  $N \times N = 9$  bosons in the adjoint representation and singlet representation. The known gauge bosons have same couplings to fermionic families so that they must correspond to the singlet representation. The first challenge is to understand whether it is possible to have dynamical  $SU(3)$  at the level of fundamental reaction vertices.

This is a highly non-trivial constraint. For instance, the vertices in which  $n$  wormhole throats with same  $(g_1, g_2)$  glued along the ends of lines are not consistent with this symmetry. The splitting of the fermionic worm-hole contacts before the proper vertices for throats might however allow the realization of dynamical  $SU(3)$ . The condition of  $SU(3)$  symmetry combined with the requirement that virtual lines resulting also in the splitting of wormhole contacts are always massless, leads to the conclusion that massive fermions correspond to  $(g, g)$  type wormhole contacts transforming naturally like  $SU(3)$  triplet. This picture conforms with the identification of free fermions as throats but not with the naive expectation that their topological condensation gives rise to  $(g, 0)$  wormhole contact.

The argument leading to these conclusions runs as follows.

1. The question is what basic reaction vertices are allowed by dynamical  $SU(3)$  symmetry.  $FFB$  vertices are in principle all that is needed and they should obey the dynamical symmetry. The meeting of entire wormhole contacts along their ends is certainly not possible. The splitting of fermionic wormhole contacts before the vertices might be however consistent with  $SU(3)$  symmetry. This would give two a pair of 3-vertices at which three wormhole lines meet along partonic 2-surfaces (rather than along 3-D wormhole contacts).
2. Note first that crossing gives all possible reaction vertices of this kind from  $F(g_1)\bar{F}(g_2) \rightarrow B(g_1, g_2)$  annihilation vertex, which is relatively easy to visualize. In this reaction  $F(g_1)$  and  $\bar{F}(g_2)$  wormhole contacts split first. If one requires that all wormhole throats involved are

massless, the two wormhole throats resulting in splitting and carrying no fermion number must carry light-like momentum so that they cannot just disappear. The ends of the wormhole throats of the boson must be glued together with the end of the fermionic wormhole throat and its companion generated in the splitting of the wormhole. This means that fermionic wormhole first splits and the resulting throats meet at the partonic 2-surface.

This requires that topologically condensed fermions correspond to  $(g, g)$  pairs rather than  $(g, 0)$  pairs. The reaction mechanism allows the interpretation of  $(g, g)$  pairs as a triplet of dynamical  $SU(3)$ . The fundamental vertices would be just the splitting of wormhole contact and 3-vertices for throats since  $SU(3)$  symmetry would exclude more complex reaction vertices such as  $n$ -boson vertices corresponding to the gluing of  $n$  wormhole contact lines along their 3-dimensional ends. The couplings of singlet representation for bosons would have the same coupling to all fermion families so that the basic experimental constraint would be satisfied.

3. Both fermions and bosons cannot correspond to octet and singlet of  $SU(3)$ . In this case reaction vertices should correspond algebraically to the multiplication of matrix elements  $e_{ij}$ :  $e_{ij}e_{kl} = \delta_{jk}e_{il}$  allowing for instance  $F(g_1, g_2) + \bar{F}(g_2, g_3) \rightarrow B(g_1, g_3)$ . Neither the fusion of entire wormhole contacts along their ends nor the splitting of wormhole throats before the fusion of partonic 2-surfaces allows this kind of vertices so that  $BFF$  vertex is the only possible one. Also the construction of QFT limit starting from bosonic emergence led to the formulation of perturbation theory in terms of Dirac action allowing only  $BFF$  vertex as fundamental vertex [?].
4. Weak electric-magnetic duality brings in an additional complication.  $SU(3)$  symmetry poses also now strong constraints and it would seem that the reactions must involve copies of basic  $BFF$  vertices for the pairs of ends of weak strings. The string ends with the same Kähler magnetic charge should meet at the vertex and give rise to  $BFF$  vertices. For instance,  $F\bar{F}B$  annihilation vertex would in this manner give rise to the analog of stringy diagram in which strings join along ends since two string ends disappear in the process.
5. This picture means that all elementary particles - not only gravitons- are described by "weak" strings involving four wormhole throats. Fundamental objects would be partonic 2-surfaces, which in principle can carry arbitrary high fermion numbers  $N$  but only  $N = 1, 2$  correspond to particles with fermionic and bosonic propagators and the remaining ones correspond to propagators behaving like  $p^{-n}$ ,  $n > 2$ , and having interpretation in terms of broken SUSY with a large value of  $\mathcal{N}$  identified as the number of fermionic modes. This compositeness of elementary particles should become manifest below weak length scale. Note that this stringy character should not be confused with that for the wormhole contacts for which conformal invariance implies that throats effectively play the role of string ends. One can say that fundamental objects are massless wormhole throats and that all elementary particles as well as string like objects emerge from them.

### 4.2.2 Graviton and other stringy states

Fermion and anti-fermion can give rise to only single unit of spin since it is impossible to assign angular momentum with the relative motion of wormhole throats. Hence the identification of graviton as single wormhole contact is not possible. The only conclusion is that graviton must be a superposition of fermion-anti-fermion pairs and boson-anti-boson pairs with coefficients determined by the coupling of the parton to graviton. Graviton-graviton pairs might emerge in higher orders. Fermion and anti-fermion would reside at the same space-time sheet and would have a non-vanishing relative angular momentum. Also bosons could have non-vanishing relative angular momentum and Higgs bosons must indeed possess it.

Gravitons are stable if the throats of wormhole contacts carry non-vanishing gauge fluxes so that the throats of wormhole contacts are connected by flux tubes carrying the gauge flux. The mechanism producing gravitons would be the splitting of partonic 2-surfaces via the basic vertex. A connection with string picture emerges with the counterpart of string identified as the flux tube connecting the wormhole throats. Gravitational constant would relate directly to the value of the string tension.

The development of the understanding of gravitational coupling has had many twists and it is perhaps to summarize the basic misunderstandings.

1.  $CP_2$  length scale  $R$ , which is roughly  $10^{3.5}$  times larger than Planck length  $l_P = \sqrt{\hbar G}$ , defines a fundamental length scale in TGD. The challenge is to predict the value of Planck length  $\sqrt{\hbar G}$ . The outcome was an identification of a formula for  $R^2/\hbar G$  predicting that the magnitude of Kähler coupling strength  $\alpha_K$  is near to fine structure constant in electron length scale (for ordinary value of Planck constant should be added here).
2. The emergence of the parton level formulation of TGD finally demonstrated that  $G$  actually appears in the fundamental parton level formulation of TGD as a fundamental constant characterizing the  $M^4$  part of  $CP_2$  Kähler gauge potential [K15, ?]. This part is pure gauge in the sense of standard gauge theory but necessary to guarantee that the theory does not reduce to topological QFT. Quantum criticality requires that  $G$  remains invariant under p-adic coupling constant evolution and is therefore predictable in principle at least.
3. The TGD view about coupling constant evolution [K2] predicts the proportionality  $G \propto L_p^2$ , where  $L_p$  is p-adic length scale. Together with input from p-adic mass calculations one ends up to two conclusions. The correct conclusion was that Kähler coupling strength is equal to the fine structure constant in the p-adic length scale associated with Mersenne prime  $p = M_{127} = 2^{127} - 1$  assignable to electron [K2]. I have considered also the possibility that  $\alpha_K$  would be equal to electro-weak  $U(1)$  coupling in this scale.
4. The additional - wrong- conclusion was that gravitons must always correspond to the p-adic prime  $M_{127}$  since  $G$  would otherwise vary as function of p-adic length scale. As a matter fact, the question was for years whether it is  $G$  or  $g_K^2$  which remains invariant under p-adic coupling constant evolution. I found both options unsatisfactory until I realized that RG invariance is possible for both  $g_K^2$  and  $G$ ! The point is that the exponent of the Kähler action associated with the piece of  $CP_2$  type vacuum extremal assignable with the elementary particle is exponentially sensitive to the volume of this piece and logarithmic dependence on the volume fraction is enough to compensate the  $L_p^2 \propto p$  proportionality of  $G$  and thus guarantee the constancy of  $G$ .

The explanation for the small value of the gravitational coupling strength serves as a test for the proposed picture. The exchange of ordinary gauge boson involves the exchange of single  $CP_2$  type extremal giving the exponent of Kähler action compensated by state normalization. In the case of graviton exchange two wormhole contacts are exchanged and this gives second power for the exponent of Kähler action which is not compensated. It would be this additional exponent that would give rise to the huge reduction of gravitational coupling strength from the naive estimate  $G \sim L_p^2$ .

### 4.2.3 Spectrum of non-stringy states

The 1-throat character of fermions is consistent with the generation-genus correspondence. The 2-throat character of bosons predicts that bosons are characterized by the genera  $(g_1, g_2)$  of the wormhole throats. Note that the interpretation of fundamental fermions as wormhole contacts with second throat identified as a Fock vacuum is excluded.

The general bosonic wave-function would be expressible as a matrix  $M_{g_1, g_2}$  and ordinary gauge bosons would correspond to a diagonal matrix  $M_{g_1, g_2} = \delta_{g_1, g_2}$  as required by the absence of neutral flavor changing currents (say gluons transforming quark genera to each other). 8 new gauge bosons are predicted if one allows all  $3 \times 3$  matrices with complex entries orthonormalized with respect to trace meaning additional dynamical  $SU(3)$  symmetry. Ordinary gauge bosons would be  $SU(3)$  singlets in this sense. The existing bounds on flavor changing neutral currents give bounds on the masses of the boson octet. The 2-throat character of bosons should relate to the low value  $T = 1/n \ll 1$  for the p-adic temperature of gauge bosons as contrasted to  $T = 1$  for fermions.

If one forgets the complications due to the stringy states (including graviton), the spectrum of elementary fermions and bosons is amazingly simple and almost reduces to the spectrum of standard model. In the fermionic sector one would have fermions of standard model. By simple counting leptonic wormhole throat could carry  $2^3 = 8$  states corresponding to 2 polarization states, 2 charge states, and sign of lepton number giving  $8+8=16$  states altogether. Taking into account phase conjugates gives  $16+16=32$  states.

In the non-stringy boson sector one would have bound states of fermions and phase conjugate fermions. Since only two polarization states are allowed for massless states, one obtains  $(2 + 1) \times$

Figure 4.1: Definition of the canonical homology basis

$(3 + 1) = 12$  states plus phase conjugates giving  $12+12=24$  states. The addition of color singlet states for quarks gives 48 gauge bosons with vanishing fermion number and color quantum numbers. Besides 12 electro-weak bosons and their 12 phase conjugates there are 12 exotic bosons and their 12 phase conjugates. For the exotic bosons the couplings to quarks and leptons are determined by the orthogonality of the coupling matrices of ordinary and boson states. For exotic counterparts of  $W$  bosons and Higgs the sign of the coupling to quarks is opposite. For photon and  $Z^0$  also the relative magnitudes of the couplings to quarks must change. Altogether this makes  $48+16+16=80$  states. Gluons would result as color octet states. Family replication would extend each elementary boson state into  $SU(3)$  octet and singlet and elementary fermion states into  $SU(3)$  triplets.

## 4.3 Basic facts about Riemann surfaces

In the following some basic aspects about Riemann surfaces will be summarized. The basic topological concepts, in particular the concept of the mapping class group, are introduced, and the Teichmueller parameters are defined as conformal invariants of the Riemann surface, which in fact specify the conformal equivalence class of the Riemann surface completely.

### 4.3.1 Mapping class group

The first homology group  $H_1(X^2)$  of a Riemann surface of genus  $g$  contains  $2g$  generators  $[?, ?, ?]$ : this is easy to understand geometrically since each handle contributes two homology generators. The so called canonical homology basis can be identified as in Fig. 4.3.1.

One can define the so called intersection number  $J(a, b)$  for two elements  $a$  and  $b$  of the homology group as the number of intersection points for the curves  $a$  and  $b$  counting the orientation. Since  $J(a, b)$  depends on the homology classes of  $a$  and  $b$  only, it defines an antisymmetric quadratic form in  $H_1(X^2)$ . In the canonical homology basis the non-vanishing elements of the intersection matrix are:

$$J(a_i, b_j) = -J(b_j, a_i) = \delta_{i,j} . \quad (4.3.1)$$

$J$  clearly defines symplectic structure in the homology group.

The dual to the canonical homology basis consists of the harmonic one-forms  $\alpha_i, \beta_i, i = 1, \dots, g$  on  $X^2$ . These 1-forms satisfy the defining conditions

$$\begin{aligned} \int_{a_i} \alpha_j &= \delta_{i,j} & \int_{b_i} \alpha_j &= 0 \\ \int_{a_i} \beta_j &= 0 & \int_{b_i} \beta_j &= \delta_{i,j} \end{aligned} \quad (4.3.2)$$

The following identity helps to understand the basic properties of the Teichmueller parameters

$$\int_{X^2} \theta \wedge \eta = \sum_{i=1, \dots, g} \left[ \int_{a_i} \theta \int_{b_i} \eta - \int_{b_i} \theta \int_{a_i} \eta \right] . \quad (4.3.3)$$

The existence of topologically nontrivial diffeomorphisms, when  $X^2$  has genus  $g > 0$ , plays an important role in the sequel. Denoting by  $Diff$  the group of the diffeomorphisms of  $X^2$  and by  $Diff_0$  the normal subgroup of the diffeomorphisms homotopic to identity, one can define the mapping class group  $M$  as the coset group

$$M = Diff/Diff_0 . \quad (4.3.4)$$

The generators of  $M$  are so called Dehn twists along closed curves  $a$  of  $X^2$ . Dehn twist is defined by excising a small tubular neighborhood of  $a$ , twisting one boundary of the resulting tube by  $2\pi$  and gluing the tube back into the surface: see Fig. 13.6.2.

Figure 4.2: Definition of the Dehn twist

It can be shown that a minimal set of generators is defined by the following curves

$$a_1, b_1, a_1^{-1} a_2^{-1}, a_2, b_2, a_2^{-1} a_3^{-1}, \dots, a_g, b_g . \quad (4.3.5)$$

The action of these transformations in the homology group can be regarded as a symplectic linear transformation preserving the symplectic form defined by the intersection matrix. Therefore the matrix representing the action of  $Diff$  on  $H_1(X^2)$  is  $2g \times 2g$  matrix  $M$  with integer entries leaving  $J$  invariant:  $MJM^T = J$ . Mapping class group is often referred also as a symplectic modular group and denoted by  $Sp(2g, Z)$ . The matrix representing the action of  $M$  in the canonical homology basis decomposes into four  $g \times g$  blocks  $A, B, C$  and  $D$

$$M = \begin{pmatrix} A & B \\ C & D \end{pmatrix} , \quad (4.3.6)$$

where  $A$  and  $D$  operate in the subspaces spanned by the homology generators  $a_i$  and  $b_i$  respectively and  $C$  and  $D$  map these spaces to each other. The notation  $D = [A, B; C, D]$  will be used in the sequel: in this notation the representation of the symplectic form  $J$  is  $J = [0, 1; -1, 0]$ .

### 4.3.2 Teichmueller parameters

The induced metric on the two-surface  $X^2$  defines a unique complex structure. Locally the metric can always be written in the form

$$ds^2 = e^{2\phi} dz d\bar{z} . \quad (4.3.7)$$

where  $z$  is local complex coordinate. When one covers  $X^2$  by coordinate patches, where the line element has the above described form, the transition functions between coordinate patches are holomorphic and therefore define a complex structure.

The conformal transformations  $\xi$  of  $X^2$  are defined as the transformations leaving invariant the angles between the vectors of  $X^2$  tangent space invariant: the angle between the vectors  $X$  and  $Y$  at point  $x$  is same as the angle between the images of the vectors under Jacobian map at the image point  $\xi(x)$ . These transformations need not be globally defined and in each coordinate patch they correspond to holomorphic (anti-holomorphic) mappings as is clear from the diagonal form of the metric in the local complex coordinates. A distinction should be made between local conformal transformations and globally defined conformal transformations, which will be referred to as conformal symmetries: for instance, for hyper-elliptic surfaces the group of the conformal symmetries contains two-element group  $Z_2$ .

Using the complex structure one can decompose one-forms to linear combinations of one-forms of type  $(1,0)$  ( $f(z, \bar{z})dz$ ) and  $(0,1)$  ( $f(z, \bar{z})d\bar{z}$ ).  $(1,0)$  form  $\omega$  is holomorphic if the function  $f$  is holomorphic:  $\omega = f(z)dz$  on each coordinate patch.

There are  $g$  independent holomorphic one forms  $\omega_i$  known also as Abelian differentials of the first kind [?, ?, ?] and one can fix their normalization by the condition

$$\int_{a_i} \omega_j = \delta_{ij} . \quad (4.3.8)$$

This condition completely specifies  $\omega_i$ .

Teichmueller parameters  $\Omega_{ij}$  are defined as the values of the forms  $\omega_i$  for the homology generators  $b_j$

$$\Omega_{ij} = \int_{b_j} \omega_i . \quad (4.3.9)$$

The basic properties of Teichmueller parameters are the following:

- i) The  $g \times g$  matrix  $\Omega$  is symmetric: this is seen by applying the formula (4.3.3) for  $\theta = \omega_i$  and  $\eta = \omega_j$ .
- ii) The imaginary part of  $\Omega$  is positive:  $Im(\Omega) > 0$ . This is seen by the application of the same formula for  $\theta = \eta$ . The space of the matrices satisfying these conditions is known as Siegel upper half plane.
- iii) The space of Teichmueller parameters can be regarded as a coset space  $Sp(2g, R)/U(g)$  [?]: the action of  $Sp(2g, R)$  is of the same form as the action of  $Sp(2g, Z)$  and  $U(g) \subset Sp(2g, R)$  is the isotropy group of a given point of Teichmueller space.
- iv) Teichmueller parameters are conformal invariants as is clear from the holomorphy of the defining one-forms.
- v) Teichmueller parameters specify completely the conformal structure of Riemann surface [?].

Although Teichmueller parameters fix the conformal structure of the 2-surface completely, they are not in one-to-one correspondence with the conformal equivalence classes of the two-surfaces:

- i) The dimension for the space of the conformal equivalence classes is  $D = 3g - 3$ , when  $g > 1$  and smaller than the dimension of Teichmueller space given by  $d = (g \times g + g)/2$  for  $g > 3$ : all Teichmueller matrices do not correspond to a Riemann surface. In TGD approach this does not produce any problems as will be found later.
- ii) The action of the topologically nontrivial diffeomorphisms on Teichmueller parameters is nontrivial and can be deduced from the action of the diffeomorphisms on the homology ( $Sp(2g, Z)$  transformation) and from the defining condition  $\int_{a_i} \omega_j = \delta_{i,j}$ : diffeomorphisms correspond to elements  $[A, B; C, D]$  of  $Sp(2g, Z)$  and act as generalized Möbius transformations

$$\Omega \rightarrow (A\Omega + B)(C\Omega + D)^{-1} . \quad (4.3.10)$$

All Teichmueller parameters related by  $Sp(2g, Z)$  transformations correspond to the same Riemann surface.

iii) The definition of the Teichmueller parameters is not unique since the definition of the canonical homology basis involves an arbitrary numbering of the homology basis. The permutation  $S$  of the handles is represented by same  $g \times g$  orthogonal matrix both in the basis  $\{a_i\}$  and  $\{b_i\}$  and induces a similarity transformation in the space of the Teichmueller parameters

$$\Omega \rightarrow S\Omega S^{-1} . \quad (4.3.11)$$

Clearly, the Teichmueller matrices related by a similarity transformations correspond to the same conformal equivalence class. It is easy to show that handle permutations in fact correspond to  $Sp(2g, Z)$  transformations.

### 4.3.3 Hyper-ellipticity

The motivation for considering hyper-elliptic surfaces comes from the fact, that  $g > 2$  elementary particle vacuum functionals turn out to be vanishing for hyper-elliptic surfaces and this in turn will be later used to provide a possible explanation the non-observability of  $g > 2$  particles.

Hyper-elliptic surface  $X$  can be defined abstractly as two-fold branched cover of the sphere having the group  $Z_2$  as the group of conformal symmetries (see [?, ?, ?] . Thus there exists a map  $\pi : X \rightarrow S^2$  so that the inverse image  $\pi^{-1}(z)$  for a given point  $z$  of  $S^2$  contains two points except at a finite number (say  $p$ ) of points  $z_i$  (branch points) for which the inverse image contains only one point.  $Z_2$  acts as conformal symmetries permuting the two points in  $\pi^{-1}(z)$  and branch points are fixed points of the involution.

The concept can be generalized [?] : g-hyper-elliptic surface can be defined as a 2-fold covering of genus  $g$  surface with a finite number of branch points. One can consider also p-fold coverings instead of 2-fold coverings: a common feature of these Riemann surfaces is the existence of a discrete group of conformal symmetries.

A concrete representation for the hyper-elliptic surfaces [?] is obtained by studying the surface of  $C^2$  determined by the algebraic equation

$$w^2 - P_n(z) = 0 , \quad (4.3.12)$$

where  $w$  and  $z$  are complex variables and  $P_n(z)$  is a complex polynomial. One can solve  $w$  from the above equation

$$w_{\pm} = \pm \sqrt{P_n(z)} , \quad (4.3.13)$$

where the square root is determined so that it has a cut along the positive real axis. What happens that  $w$  has in general two roots (two-fold covering property), which coincide at the roots  $z_i$  of  $P_n(z)$  and if  $n$  is odd, also at  $z = \infty$ : these points correspond to branch points of the hyper-elliptic surface and their number  $r$  is always even:  $r = 2k$ .  $w$  is discontinuous at the cuts associated with the square root in general joining two roots of  $P_n(z)$  or if  $n$  is odd, also some root of  $P_n$  and the point  $z = \infty$ . The representation of the hyper-elliptic surface is obtained by identifying the two branches of  $w$  along the cuts. From the construction it is clear that the surface obtained in this manner has genus  $k - 1$ . Also it is clear that  $Z_2$  permutes the different roots  $w_{\pm}$  with each other and that  $r = 2k$  branch points correspond to fixed points of the involution.

The following facts about the hyper-elliptic surfaces [?, ?] turn out to be important in the sequel:

- i) All  $g < 3$  surfaces are hyper-elliptic.
- ii)  $g \geq 3$  hyper-elliptic surfaces are not in general hyper-elliptic and form a set of codimension 2 in the space of the conformal equivalence classes [?] .

### 4.3.4 Theta functions

An extensive and detailed account of the theta functions and their applications can be found in the book of Mumford [?] . Theta functions appear also in the loop calculations of string [?] [?] . In the following the so called Riemann theta function and theta functions with half integer characteristics will be defined as sections (not strictly speaking functions) of the so called Jacobian variety.

For a given Teichmueller matrix  $\Omega$ , Jacobian variety is defined as the  $2g$ -dimensional torus obtained by identifying the points  $z$  of  $C^g$  ( vectors with  $g$  complex components) under the equivalence

$$z \sim z + \Omega m + n \quad , \quad (4.3.14)$$

where  $m$  and  $n$  are points of  $Z^g$  (vectors with  $g$  integer valued components) and  $\Omega$  acts in  $Z^g$  by matrix multiplication.

The definition of Riemann theta function reads as

$$\Theta(z|\Omega) = \sum_n \exp(i\pi n \cdot \Omega \cdot n + i2\pi n \cdot z) \quad . \quad (4.3.15)$$

Here  $\cdot$  denotes standard inner product in  $C^g$ . Theta functions with half integer characteristics are defined in the following manner. Let  $a$  and  $b$  denote vectors of  $C^g$  with half integer components (component either vanishes or equals to  $1/2$ ). Theta function with characteristics  $[a, b]$  is defined through the following formula

$$\Theta[a, b](z|\Omega) = \sum_n \exp[i\pi(n+a) \cdot \Omega \cdot (n+a) + i2\pi(n+a) \cdot (z+b)] \quad . \quad (4.3.16)$$

A brief calculation shows that the following identity is satisfied

$$\Theta[a, b](z|\Omega) = \exp(i\pi a \cdot \Omega \cdot a + i2\pi a \cdot b) \times \Theta(z + \Omega a + b|\Omega) \quad (4.3.17)$$

Theta functions are not strictly speaking functions in the Jacobian variety but rather sections in an appropriate bundle as can be seen from the identities

$$\begin{aligned} \Theta[a, b](z + m|\Omega) &= \exp(i2\pi a \cdot m) \Theta[a, b](z|\Omega) \quad , \\ \Theta[a, b](z + \Omega m|\Omega) &= \exp(\alpha) \Theta[a, b](z|\Omega) \quad , \\ \exp(\alpha) &= \exp(-i2\pi b \cdot m) \exp(-i\pi m \cdot \Omega \cdot m - 2\pi m \cdot z) \quad . \end{aligned} \quad (4.3.18)$$

The number of theta functions is  $2^{2g}$  and same as the number of nonequivalent spinor structures defined on two-surfaces. This is not an accident [?] : theta functions with given characteristics turn out to be in a close relation to the functional determinants associated with the Dirac operators defined on the two-surface. It is useful to divide the theta functions to even and odd theta functions according to whether the inner product  $4a \cdot b$  is even or odd integer. The numbers of even and odd theta functions are  $2^{g-1}(2^g + 1)$  and  $2^{g-1}(2^g - 1)$  respectively.

The values of the theta functions at the origin of the Jacobian variety understood as functions of Teichmueller parameters turn out to be of special interest in the following and the following notation will be used:

$$\Theta[a, b](\Omega) \equiv \Theta[a, b](0|\Omega) \quad , \quad (4.3.19)$$

$\Theta[a, b](\Omega)$  will be referred to as theta functions in the sequel. From the defining properties of odd theta functions it can be found that they are odd functions of  $z$  and therefore vanish at the origin of the Jacobian variety so that only even theta functions will be of interest in the sequel.

An important result is that also some *even* theta functions vanish for  $g > 2$  hyper-elliptic surfaces : in fact one can characterize  $g > 2$  hyper-elliptic surfaces by the vanishing properties of the theta functions [?, ?] . The vanishing property derives from conformal symmetry ( $Z_2$  in the case of hyper-elliptic surfaces) and the vanishing phenomenon is rather general [?] : theta functions tend to vanish for Riemann surfaces possessing discrete conformal symmetries. It is not clear (to the author) whether the presence of a conformal symmetry is in fact equivalent with the vanishing of some theta functions. As already noticed, spinor structures and the theta functions with half integer characteristics are in one-to-one correspondence and the vanishing of theta function with given half integer characteristics is equivalent with the vanishing of the Dirac determinant associated with the corresponding spinor structure or equivalently: with the existence of a zero mode for the Dirac operator [?] . For odd characteristics zero mode exists always: for even characteristics zero modes exist, when the surface is hyper-elliptic or possesses more general conformal symmetries.

## 4.4 Elementary particle vacuum functionals

The basic assumption is that elementary particle families correspond to various elementary particle vacuum functionals associated with the 2-dimensional boundary components of the 3-surface. These functionals need not be localized to a single boundary topology. Neither need their dependence on the boundary component be local. An important role in the following considerations is played by the fact that the minimization requirement of the Kähler action associates a unique 3-surface to each boundary component, the "Bohr orbit" of the boundary and this surface provides a considerable (and necessarily needed) flexibility in the definition of the elementary particle vacuum functionals. There are several natural constraints to be satisfied by elementary particle vacuum functionals.

### 4.4.1 Extended Diff invariance and Lorentz invariance

Extended Diff invariance is completely analogous to the extension of 3-dimensional Diff invariance to four-dimensional Diff invariance in the interior of the 3-surface. Vacuum functional must be invariant not only under diffeomorphisms of the boundary component but also under the diffeomorphisms of the 3- dimensional "orbit"  $Y^3$  of the boundary component. In other words: the value of the vacuum functional must be same for any time slice on the orbit boundary component. This is guaranteed if vacuum functional is functional of some two-surface  $Y^2$  belonging to the orbit and defined in  $Diff^3$  invariant manner.

An additional natural requirement is Poincare invariance. In the original formulation of the theory only Lorentz transformations of the light cone were exact symmetries of the theory. In this framework the definition of  $Y^2$  as the intersection of the orbit with the hyperboloid  $\sqrt{m_{kl}m^k m^l} = a$  is  $Diff^3$  and Lorentz invariant.

#### 1. Interaction vertices as generalization of stringy vertices

For stringy diagrams Poincare invariance of conformal equivalence class and general coordinate invariance are far from being a trivial issues. Vertices are now not completely unique since there is an infinite number of singular 3-manifolds which can be identified as vertices even if one assumes space-likeness. One should be able to select a unique singular 3-manifold to fix the conformal equivalence class.

One might hope that Lorentz invariant invariant and general coordinate invariant definition of  $Y^2$  results by introducing light cone proper time  $a$  as a height function specifying uniquely the point at which 3-surface is singular (stringy diagrams help to visualize what is involved), and by restricting the singular 3-surface to be the intersection of  $a = \text{constant}$  hyperboloid of  $M^4$  containing the singular point with the space-time surface. There would be non-uniqueness of the conformal equivalence class due to the choice of the origin of the light cone but the decomposition of the configuration space of 3-surfaces to a union of configuration spaces characterized by unions of future and past light cones could resolve this difficulty.

#### 2. Interaction vertices as generalization of ordinary ones

If the interaction vertices are identified as intersections for the ends of space-time sheets representing particles, the conformal equivalence class is naturally identified as the one associated with the intersection of the boundary component or light like causal determinant with the vertex. Poincare invariance of the conformal equivalence class and generalized general coordinate invariance follow trivially in this case.

#### 4.4.2 Conformal invariance

Conformal invariance implies that vacuum functionals depend on the conformal equivalence class of the surface  $Y^2$  only. What makes this idea so attractive is that for a given genus  $g$  configuration space becomes effectively finite-dimensional. A second nice feature is that instead of trying to find coordinates for the space of the conformal equivalence classes one can construct vacuum functionals as functions of the Teichmueller parameters.

That one can construct this kind of functions as suitable functions of the Teichmueller parameters is not trivial. The essential point is that the boundary components can be regarded as submanifolds of  $M_+^4 \times CP_2$ : as a consequence vacuum functional can be regarded as a composite function:

$$2\text{-surface} \rightarrow \text{Teichmueller matrix } \Omega \text{ determined by the induced metric} \rightarrow \Omega_{vac}(\Omega)$$

Therefore the fact that there are Teichmueller parameters which do not correspond to any Riemann surface, doesn't produce any trouble. It should be noticed that the situation differs from that in the Polyakov formulation of string models, where one doesn't assume that the metric of the two-surface is induced metric (although classical equations of motion imply this).

#### 4.4.3 Diff invariance

Since several values of the Teichmueller parameters correspond to the same conformal equivalence class, one must pose additional conditions on the functions of the Teichmueller parameters in order to obtain single valued functions of the conformal equivalence class.

The first requirement of this kind is the invariance under topologically nontrivial Diff transformations inducing  $Sp(2g, Z)$  transformation  $(A, B; C, D)$  in the homology basis. The action of these transformations on Teichmueller parameters is deduced by requiring that holomorphic one-forms satisfy the defining conditions in the transformed homology basis. It turns out that the action of the topologically nontrivial diffeomorphism on Teichmueller parameters can be regarded as a generalized Möbius transformation:

$$\Omega \rightarrow (A\Omega + B)(C\Omega + D)^{-1} . \quad (4.4.1)$$

Vacuum functional must be invariant under these transformations. It should be noticed that the situation differs from that encountered in the string models. In TGD the integration measure over the configuration space is Diff invariant: in string models the integration measure is the integration measure of the Teichmueller space and this is not invariant under  $Sp(2g, Z)$  but transforms like a density: as a consequence the counterpart of the vacuum functional must be also modular covariant since it is the product of vacuum functional and integration measure, which must be modular invariant.

It is possible to show that the quantities

$$(\Theta[a, b]/\Theta[c, d])^4 . \quad (4.4.2)$$

and their complex conjugates are  $Sp(2g, Z)$  invariants [?] and therefore can be regarded as basic building blocks of the vacuum functionals.

Teichmueller parameters are not uniquely determined since one can always perform a permutation of the  $g$  handles of the Riemann surface inducing a redefinition of the canonical homology basis (permutation of  $g$  generators). These transformations act as similarities of the Teichmueller matrix:

$$\Omega \rightarrow S\Omega S^{-1} , \quad (4.4.3)$$

where  $S$  is the  $g \times g$  matrix representing the permutation of the homology generators understood as orthonormal vectors in the  $g$ -dimensional vector space. Therefore the Teichmueller parameters related by these similarity transformations correspond to the same conformal equivalence class of the Riemann surfaces and vacuum functionals must be invariant under these similarities.

It is easy to find out that these similarities permute the components of the theta characteristics:  $[a, b] \rightarrow [S(a), S(b)]$ . Therefore the invariance requirement states that the handles of the Riemann surface behave like bosons: the vacuum functional constructed from the theta functions is invariant under the permutations of the theta characteristics. In fact, this requirement brings in nothing new. Handle permutations can be regarded as  $Sp(2g, Z)$  transformations so that the modular invariance alone guarantees invariance under handle permutations.

#### 4.4.4 Cluster decomposition property

Consider next the behavior of the vacuum functional in the limit, when boundary component with genus  $g$  splits to two separate boundary components of genera  $g_1$  and  $g_2$  respectively. The splitting into two separate boundary components corresponds to the reduction of the Teichmueller matrix  $\Omega^g$  to a direct sum of  $g_1 \times g_1$  and  $g_2 \times g_2$  matrices ( $g_1 + g_2 = g$ ):

$$\Omega^g = \Omega^{g_1} \oplus \Omega^{g_2} \quad , \quad (4.4.4)$$

when a suitable definition of the Teichmueller parameters is adopted. The splitting can also take place without a reduction to a direct sum: the Teichmueller parameters obtained via  $Sp(2g, Z)$  transformation from  $\Omega^g = \Omega^{g_1} \oplus \Omega^{g_2}$  do not possess direct sum property in general.

The physical interpretation is obvious: the non-diagonal elements of the Teichmueller matrix describe the geometric interaction between handles and at this limit the interaction between the handles belonging to the separate surfaces vanishes. On the physical grounds it is natural to require that vacuum functionals satisfy cluster decomposition property at this limit: that is they reduce to the product of appropriate vacuum functionals associated with the composite surfaces.

Theta functions satisfy cluster decomposition property [?, ?]. Theta characteristics reduce to the direct sums of the theta characteristics associated with  $g_1$  and  $g_2$  ( $a = a_1 \oplus a_2$ ,  $b = b_1 \oplus b_2$ ) and the dependence on the Teichmueller parameters is essentially exponential so that the cluster decomposition property indeed results:

$$\Theta[a, b](\Omega^g) = \Theta[a_1, b_1](\Omega^{g_1})\Theta[a_2, b_2](\Omega^{g_2}) \quad . \quad (4.4.5)$$

Cluster decomposition property holds also true for the products of theta functions. This property is also satisfied by suitable homogenous polynomials of thetas. In particular, the following quantity playing central role in the construction of the vacuum functional obeys this property

$$Q_0 = \sum_{[a, b]} \Theta[a, b]^4 \bar{\Theta}[a, b]^4 \quad , \quad (4.4.6)$$

where the summation is over all even theta characteristics (recall that odd theta functions vanish at the origin of  $C^g$ ).

Together with the  $Sp(2g, Z)$  invariance the requirement of cluster decomposition property implies that the vacuum functional must be representable in the form

$$\Omega_{vac} = P_{M, N}(\Theta^4, \bar{\Theta}^4) / Q_{M, N}(\Theta^4, \bar{\Theta}^4) \quad (4.4.7)$$

where the homogenous polynomials  $P_{M, N}$  and  $Q_{M, N}$  have same degrees ( $M$  and  $N$  as polynomials of  $\Theta[a, b]^4$  and  $\bar{\Theta}[a, b]^4$ ).

#### 4.4.5 Finiteness requirement

Vacuum functional should be finite. Finiteness requirement is satisfied provided the numerator  $Q_{M,N}$  of the vacuum functional is real and positive definite. The simplest quantity of this type is the quantity  $Q_0$  defined previously and its various powers.  $Sp(2g, Z)$  invariance and finiteness requirement are satisfied provided vacuum functionals are of the following general form

$$\Omega_{vac} = \frac{P_{N,N}(\Theta^4, \bar{\Theta}^4)}{Q_0^N}, \quad (4.4.8)$$

where  $P_{N,N}$  is homogenous polynomial of degree  $N$  with respect to  $\Theta[a, b]^4$  and  $\bar{\Theta}[a, b]^4$ . In addition  $P_{N,N}$  is invariant under the permutations of the theta characteristics and satisfies cluster decomposition property.

#### 4.4.6 Stability against the decay $g \rightarrow g_1 + g_2$

Elementary particle vacuum functionals must be stable against the genus conserving decays  $g \rightarrow g_1 + g_2$ . This decay corresponds to the limit at which Teichmueller matrix reduces to a direct sum of the matrices associated with  $g_1$  and  $g_2$  (note however the presence of  $Sp(2g, Z)$  degeneracy). In accordance with the topological description of the particle reactions one expects that this decay doesn't occur if the vacuum functional in question vanishes at this limit.

In general the theta functions are non-vanishing at this limit and vanish provided the theta characteristics reduce to a direct sum of the odd theta characteristics. For  $g < 2$  surfaces this condition is trivial and gives no constraints on the form of the vacuum functional. For  $g = 2$  surfaces the theta function  $\Theta(a, b)$ , with  $a = b = (1/2, 1/2)$  satisfies the stability criterion identically (odd theta functions vanish identically), when Teichmueller parameters separate into a direct sum. One can however perform  $Sp(2g, Z)$  transformations giving new points of Teichmueller space describing the decay. Since these transformations transform theta characteristics in a nontrivial manner to each other and since all even theta characteristics belong to same  $Sp(2g, Z)$  orbit [?, ?], the conclusion is that stability condition is satisfied provided  $g = 2$  vacuum functional is proportional to the product of fourth powers of all even theta functions multiplied by its complex conjugate.

If  $g > 2$  there always exists some theta functions, which vanish at this limit and the minimal vacuum functional satisfying this stability condition is of the same form as in  $g = 2$  case, that is proportional to the product of the fourth powers of all even Theta functions multiplied by its complex conjugate:

$$\Omega_{vac} = \prod_{[a,b]} \Theta[a, b]^4 \bar{\Theta}[a, b]^4 / Q_0^N, \quad (4.4.9)$$

where  $N$  is the number of even theta functions. The results obtained imply that genus-generation correspondence is one to one for  $g > 1$  for the minimal vacuum functionals. Of course, the multiplication of the minimal vacuum functionals with functionals satisfying all criteria except stability criterion gives new elementary particle vacuum functionals: a possible physical identification of these vacuum functionals is most naturally as some kind of excited states.

One of the questions posed in the beginning was related to the experimental absence of  $g > 0$ , possibly massless, elementary bosons. The proposed stability criterion suggests a nice explanation. The point is that elementary particles are stable against decays  $g \rightarrow g_1 + g_2$  but not with respect to the decay  $g \rightarrow g + sphere$ . As a consequence the direct emission of  $g > 0$  gauge bosons is impossible unlike the emission of  $g = 0$  bosons: for instance the decay muon  $\rightarrow$  electron  $+(g = 1)$  photon is forbidden.

#### 4.4.7 Stability against the decay $g \rightarrow g - 1$

This stability criterion states that the vacuum functional is stable against single particle decay  $g \rightarrow g - 1$  and, if satisfied, implies that vacuum functional vanishes, when the genus of the surface is smaller than  $g$ . In stringy framework this criterion is equivalent to a separate conservation of various lepton numbers: for instance, the spontaneous transformation of muon to electron is forbidden. Notice that

this condition doesn't imply that the vacuum functional is localized to a single genus: rather the vacuum functional of genus  $g$  vanishes for all surfaces with genus smaller than  $g$ . This hierarchical structure should have a close relationship to Cabibbo-Kobayashi-Maskawa mixing of the quarks.

The stability criterion implies that the vacuum functional must vanish at the limit, when one of the handles of the Riemann surface suffers a pinch. To deduce the behavior of the theta functions at this limit, one must find the behavior of Teichmueller parameters, when  $i$ :th handle suffers a pinch. Pinch implies that a suitable representative of the homology generator  $a_i$  or  $b_i$  contracts to a point.

Consider first the case, when  $a_i$  contracts to a point. The normalization of the holomorphic one-form  $\omega_i$  must be preserved so that  $\omega_i$  must behave as  $1/z$ , where  $z$  is the complex coordinate vanishing at pinch. Since the homology generator  $b_i$  goes through the pinch it seems obvious that the imaginary part of the Teichmueller parameter  $\Omega_{ii} = \int_{b_i} \omega_i$  diverges at this limit (this conclusion is made also in [?]):  $Im(\Omega_{ii}) \rightarrow \infty$ .

Of course, this criterion doesn't cover all possible manners the pinch can occur: pinch might take place also, when the components of the Teichmueller matrix remain finite. In the case of torus topology one finds that  $Sp(2g, Z)$  element  $(A, B; C, D)$  takes  $Im(\Omega) = \infty$  to the point  $C/D$  of real axis. This suggests that pinch occurs always at the boundary of the Teichmueller space: the imaginary part of  $\Omega_{ij}$  either vanishes or some matrix element of  $Im(\Omega)$  diverges.

Consider next the situation, when  $b_i$  contracts to a point. From the definition of the Teichmueller parameters it is clear that the matrix elements  $\Omega_{kl}$ , with  $k, l \neq i$  suffer no change. The matrix element  $\Omega_{ki}$  obviously vanishes at this limit. The conclusion is that  $i$ :th row of Teichmueller matrix vanishes at this limit. This result is obtained also by deriving the  $Sp(2g, Z)$  transformation permuting  $a_i$  and  $b_i$  with each other: in case of torus this transformation reads  $\Omega \rightarrow -1/\Omega$ .

Consider now the behavior of the theta functions, when pinch occurs. Consider first the limit, when  $Im(\Omega_{ii})$  diverges. Using the general definition of  $\Theta[a, b]$  it is easy to find out that all theta functions for which the  $i$ :th component  $a_i$  of the theta characteristic is non-vanishing (that is  $a_i = 1/2$ ) are proportional to the exponent  $exp(-\pi\Omega_{ii}/4)$  and therefore vanish at the limit. The theta functions with  $a_i = 0$  reduce to  $g-1$  dimensional theta functions with theta characteristic obtained by dropping  $i$ :th components of  $a_i$  and  $b_i$  and replacing Teichmueller matrix with Teichmueller matrix obtained by dropping  $i$ :th row and column. The conclusion is that all theta functions of type  $\Theta(a, b)$  with  $a = (1/2, 1/2, \dots, 1/2)$  satisfy the stability criterion in this case.

What happens for the  $Sp(2g, Z)$  transformed points on the real axis? The transformation formula for theta function is given by [?, ?]

$$\Theta[a, b]((A\Omega + B)(C\Omega + D)^{-1}) = exp(i\phi)det(C\Omega + D)^{1/2}\Theta[c, d](\Omega) , \quad (4.4.10)$$

where

$$\begin{pmatrix} c \\ d \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \left( \begin{pmatrix} a \\ b \end{pmatrix} - \begin{pmatrix} (CD^T)_d/2 \\ (AB^T)_d/2 \end{pmatrix} \right) . \quad (4.4.11)$$

Here  $\phi$  is a phase factor irrelevant for the recent purposes and the index  $d$  refers to the diagonal part of the matrix in question.

The first thing to notice is the appearance of the diverging square root factor, which however disappears from the vacuum functionals ( $P$  and  $Q$  have same degree with respect to thetas). The essential point is that theta characteristics transform to each other: as already noticed all even theta characteristics belong to the same  $Sp(2g, Z)$  orbit. Therefore the theta functions vanishing at  $Im(\Omega_{ii}) = \infty$  do not vanish at the transformed points. It is however clear that for a given Teichmueller parametrization of pinch some theta functions vanish always.

Similar considerations in the case  $\Omega_{ik} = 0$ ,  $i$  fixed, show that all theta functions with  $b = (1/2, \dots, 1/2)$  vanish identically at the pinch. Also it is clear that for  $Sp(2g, Z)$  transformed points one can always find some vanishing theta functions. The overall conclusion is that the elementary particle vacuum functionals obtained by using  $g \rightarrow g_1 + g_2$  stability criterion satisfy also  $g \rightarrow g - 1$  stability criterion since they are proportional to the product of all even theta functions. Therefore

the only nontrivial consequence of  $g \rightarrow g - 1$  criterion is that also  $g = 1$  vacuum functionals are of the same general form as  $g > 1$  vacuum functionals.

A second manner to deduce the same result is by restricting the consideration to the hyper-elliptic surfaces and using the representation of the theta functions in terms of the roots of the polynomial appearing in the definition of the hyper-elliptic surface [?]. When the genus of the surface is smaller than three (the interesting case), this representation is all what is needed since all surfaces of genus  $g < 3$  are hyper-elliptic.

Since hyper-elliptic surfaces can be regarded as surfaces obtained by gluing two compactified complex planes along the cuts connecting various roots of the defining polynomial it is obvious that the process  $g \rightarrow g - 1$  corresponds to the limit, when two roots of the defining polynomial coincide. This limit corresponds either to disappearance of a cut or the fusion of two cuts to a single cut. Theta functions are expressible as the products of differences of various roots (Thomae's formula [?])

$$\Theta[a, b]^4 \propto \prod_{i < j \in T} (z_i - z_j) \prod_{k < l \in CT} (z_k - z_l) , \quad (4.4.12)$$

where  $T$  denotes some subset of  $\{1, 2, \dots, 2g\}$  containing  $g + 1$  elements and  $CT$  its complement. Hence the product of all even theta functions vanishes, when two roots coincide. Furthermore, stability criterion is satisfied only by the product of the theta functions.

Lowest dimensional vacuum functionals are worth of more detailed consideration.

- i)  $g = 0$  particle family corresponds to a constant vacuum functional: by continuity this vacuum functional is constant for all topologies.
- ii) For  $g = 1$  the degree of  $P$  and  $Q$  as polynomials of the theta functions is 24: the critical number of transversal degrees of freedom in bosonic string model! Probably this result is not an accident.
- ii) For  $g = 2$  the corresponding degree is 80 since there are 10 even genus 2 theta functions.

There are large numbers of vacuum functionals satisfying the relevant criteria, which do not satisfy the proposed stability criteria. These vacuum functionals correspond either to many particle states or to unstable single particle states.

#### 4.4.8 Continuation of the vacuum functionals to higher genus topologies

From continuity it follows that vacuum functionals cannot be localized to single boundary topology. Besides continuity and the requirements listed above, a natural requirement is that the continuation of the vacuum functional from the sector  $g$  to the sector  $g + k$  reduces to the product of the original vacuum functional associated with genus  $g$  and  $g = 0$  vacuum functional at the limit when the surface with genus  $g + k$  decays to surfaces with genus  $g$  and  $k$ : this requirement should guarantee the conservation of separate lepton numbers although different boundary topologies suffer mixing in the vacuum functional. These requirements are satisfied provided the continuation is constructed using the following rule:

Perform the replacement

$$\Theta[a, b]^4 \rightarrow \sum_{c, d} \Theta[a \oplus c, b \oplus d]^4 \quad (4.4.13)$$

for each fourth power of the theta function. Here  $c$  and  $d$  are Theta characteristics associated with a surface with genus  $k$ . The same replacement is performed for the complex conjugates of the theta function. It is straightforward to check that the continuations of elementary particle vacuum functionals indeed satisfy the cluster decomposition property and are continuous.

To summarize, the construction has provided hoped for answers to some questions stated in the beginning: stability requirements explain the separate conservation of lepton numbers and the experimental absence of  $g > 0$  elementary bosons. What has not been explained is the experimental absence of  $g > 2$  fermion families. The vanishing of the  $g > 2$  elementary particle vacuum functionals for the hyper-elliptic surfaces however suggest a possible explanation: under some conditions on the surface  $X^2$  the surfaces  $Y^2$  are hyper-elliptic or possess some conformal symmetry so that elementary particle vacuum functionals vanish for them. This conjecture indeed might make sense since the surfaces  $Y^2$  are determined by the asymptotic dynamics and one might hope that the surfaces  $Y^2$  are analogous to the final states of a dissipative system.

## 4.5 Explanations for the absence of the $g > 2$ elementary particles from spectrum

The decay properties of the intermediate gauge bosons [?] are consistent with the assumption that the number of the light neutrinos is  $N = 3$ . Also cosmological considerations pose upper bounds on the number of the light neutrino families and  $N = 3$  seems to be favored [?]. It must be however emphasized that p-adic considerations [K43] encourage the consideration the existence of higher genera with neutrino masses such that they are not produced in the laboratory at present energies. In any case, for TGD approach the finite number of light fermion families is a potential difficulty since genus-generation correspondence suggests that the number of the fermion (and possibly also boson) families is infinite. Therefore one had better to find a good argument showing that the number of the observed neutrino families, or more generally, of the observed elementary particle families, is small also in the world described by TGD.

It will be later found that also TGD inspired cosmology requires that the number of the effectively massless fermion families must be small after Planck time. This suggests that boundary topologies with handle number  $g > 2$  are unstable and/or very massive so that they, if present in the spectrum, disappear from it after Planck time, which correspond to the value of the light cone proper time  $a \simeq 10^{-11}$  seconds.

In accordance with the spirit of TGD approach it is natural to wonder whether some geometric property differentiating between  $g > 2$  and  $g < 3$  boundary topologies might explain why only  $g < 3$  boundary components are observable. One can indeed find a good candidate for this kind of property: namely hyper-ellipticity, which states that Riemann surface is a two-fold branched covering of sphere possessing two-element group  $Z_2$  as conformal automorphisms. All  $g < 3$  Riemann surfaces are hyper-elliptic unlike  $g > 2$  Riemann surfaces, which in general do not possess this property. Thus it is natural to consider the possibility that hyper-ellipticity or more general conformal symmetries might explain why only  $g < 2$  topologies correspond to the observed elementary particles.

As regards to the present problem the crucial observation is that some even theta functions vanish for the hyper-elliptic surfaces with genus  $g > 2$  [?]. What is essential is that these surfaces have the group  $Z_2$  as conformal symmetries. Indeed, the vanishing phenomenon is more general. Theta functions tend to vanish for  $g > 2$  two-surfaces possessing discrete group of conformal symmetries [?]: for instance, instead of sphere one can consider branched coverings of higher genus surfaces.

From the general expression of the elementary particle vacuum functional it is clear that elementary particle vacuum functionals vanish, when  $Y^2$  is hyper-elliptic surface with genus  $g > 2$  and one might hope that this is enough to explain why the number of elementary particle families is three.

### 4.5.1 Hyper-ellipticity implies the separation of $g \leq 2$ and $g > 2$ sectors to separate worlds

If the vertices are defined as intersections of space-time sheets of elementary particles and if elementary particle vacuum functionals are required to have  $Z_2$  symmetry, the localization of elementary particle vacuum functionals to  $g \leq 2$  topologies occurs automatically. Even if one allows as limiting case vertices for which 2-manifolds are pinched to topologies intermediate between  $g > 2$  and  $g \leq 2$  topologies,  $Z_2$  symmetry present for both topological interpretations implies the vanishing of this kind of vertices. This applies also in the case of stringy vertices so that also particle propagation would respect the effective number of particle families.  $g > 2$  and  $g \leq 2$  topologies would behave much like their own worlds in this approach. This is enough to explain the experimental findings if one can understand why the  $g > 2$  particle families are absent as incoming and outgoing states or are very heavy.

### 4.5.2 What about $g > 2$ vacuum functionals which do not vanish for hyper-elliptic surfaces?

The vanishing of all  $g \geq 2$  vacuum functionals for hyper-elliptic surfaces cannot hold true generally. There must exist vacuum functionals which do satisfy this condition. This suggest that elementary particle vacuum functionals for  $g > 2$  states have interpretation as bound states of  $g$  handles and that the more general states which do not vanish for hyper-elliptic surfaces correspond to many-particle

states composed of bound states  $g \leq 2$  handles and cannot thus appear as incoming and outgoing states. Thus  $g > 2$  elementary particles would decouple from  $g \leq 2$  states.

### 4.5.3 Should higher elementary particle families be heavy?

TGD predicts an entire hierarchy of scaled up variants of standard model physics for which particles do not appear in the vertices containing the known elementary particles and thus behave like dark matter [K82]. Also  $g > 2$  elementary particles would behave like dark matter and in principle there is no absolute need for them to be heavy.

The safest option would be that  $g > 2$  elementary particles are heavy and the breaking of  $Z_2$  symmetry for  $g \geq 2$  states could guarantee this. p-Adic considerations lead to a general mass formula for elementary particles such that the mass of the particle is proportional to  $\frac{1}{\sqrt{p}}$  [K45]. Also the dependence of the mass on particle genus is completely fixed by this formula. What remains however open is what determines the p-adic prime associated with a particle with given quantum numbers. Of course, it could quite well occur that  $p$  is much smaller for  $g > 2$  genera than for  $g \leq 2$  genera.

### 4.5.4 Could higher genera have interpretation as many-particle states?

The topological explanation of family replication phenomenon of fermions in terms of the genus  $g$  defined as the number of handles added to sphere to obtain the quantum number carrying partonic 2-surface distinguishes TGD from GUTs and string models. The orbit of the partonic 2-surface defines 3-D light-like orbit identified as wormhole throat at which the induced metric changes its signature. The original model of elementary particle involved only single boundary component replaced later by a wormhole throat. The generalization to the recent situation in which elementary particles correspond to wormhole flux tubes of length of order weak length scales with pairs of wormhole throats at its ends is straight-forward.

The basic objection against the proposal is that it predicts infinite number of particle families unless the  $g \leq 3$  topologies are preferred for some reason. Conformal and modular symmetries are basic symmetries of the theory and global conformal symmetries provide an excellent candidate for the sought for reason why.

1. For  $g \leq 3$  the 2-surfaces are always hyper-elliptic which means that they have always  $Z_2$  as global conformal symmetries. For  $g \geq 2$  these symmetries are absent in the generic case. Moreover, the modular invariant elementary particle vacuum functionals  $|a_i\rangle$  vanish for hyper-elliptic surfaces for  $g \geq 2$ . This leaves several options to consider. The basic idea is however that ground states are usually highly symmetric and that elementary particles correspond to ground states.
2. The simplest guess is that  $g \geq 2$  surfaces correspond to very massive states decaying rapidly to states with smaller genus. Due to the conformal symmetry  $g \leq 3$  surfaces would be analogous to ground states and would have small masses.
3. The possibility to have partonic 2-surfaces of macroscopic and even astrophysical size identifiable as seats of anyonic macroscopic quantum phases [?] suggests an alternative interpretation consistent with global conformal symmetries. For partonic 2-surfaces of macroscopic size it seems natural to consider handles as particles glued to a much larger partonic 2-surface by topological sum operation (topological condensation).

All orientable manifolds can be obtained by topological sum operation from what can be called prime manifolds. In 2-D orientable case prime manifolds are sphere and torus representing in well-defined sense 0 and 1 so that topological sum corresponds to addition of positive integers arithmetically. This would suggest that only sphere and torus appear as single particle states. Particle interpretation however requires that also  $g = 0$  and  $g = 2$  surfaces topologically condensed to a larger anyonic 2-surface have similar interpretation, at least if they have small enough size. What kind of argument could justify this kind of interpretation?

4. An argument based on symmetries suggests itself. The reduction of degrees of freedom is the generic signature of bound state. Bound state property implies also the reduction of approximate single particle symmetries to an exact overall symmetry. Rotational symmetries of hydrogen

atom represent a good example of this. For free many particle states each particle transforms according to a representation of rotation group having total angular momentum defined as sum of its spin and angular momentum. For bound states rotational degrees of freedom are strongly correlated and only overall rotations of the state define rotational symmetries.

In this spirit one could interpret sphere as vacuum, torus as single handle state, and torus with handle as a bound state of 2 handles in conformal degrees of freedom meaning that the  $Z_2$  symmetries of vacuum and handles are frozen in topological condensation (topological sum) to single overall  $Z_2$ . If this interpretation is correct,  $g \geq 2$  2-surfaces would always have a decomposition to many-particle states consisting of spheres, tori and tori with single handle glued to a larger sphere by topological sum. Each of these topologically condensed composites would possess  $Z_2$  as approximate single particle symmetry.

## 4.6 Elementary particle vacuum functionals for dark matter

One of the open questions is how dark matter hierarchy reflects itself in the properties of the elementary particles. The basic questions are how the quantum phase  $q = ep(2i\pi/n)$  makes itself visible in the solution spectrum of the modified Dirac operator  $D$  and how elementary particle vacuum functionals depend on  $q$ . Considerable understanding of these questions emerged recently. One can generalize modular invariance to fractional modular invariance for Riemann surfaces possessing  $Z_n$  symmetry and perform a similar generalization for theta functions and elementary particle vacuum functionals. In particular, without any further assumptions  $n = 2$  dark fermions have only three families. The existence of space-time correlate for fermionic 2-valuedness suggests that fermions indeed correspond to  $n = 2$ , or more generally to even values of  $n$ , so that this result would hold quite generally. Elementary bosons (actually exotic particles) would correspond to  $n = 1$ , and more generally odd values of  $n$ , and could have also higher families.

### 4.6.1 Connection between Hurwitz zetas, quantum groups, and hierarchy of Planck constants?

The action of modular group  $SL(2, Z)$  on Riemann zeta [?] is induced by its action on theta function [?] . The action of the generator  $\tau \rightarrow -1/\tau$  on theta function is essential in providing the functional equation for Riemann Zeta. Usually the action of the generator  $\tau \rightarrow \tau + 1$  on Zeta is not considered explicitly. The surprise was that the action of the generator  $\tau \rightarrow \tau + 1$  on Riemann Zeta does not give back Riemann zeta but a more general function known as Hurwitz zeta  $\zeta(s, z)$  for  $z = 1/2$ . One finds that Hurwitz zetas for certain rational values of argument define in a well defined sense representations of fractional modular group to which quantum group can be assigned naturally. This could allow to code the value of the quantum phase  $q = exp(i2\pi/n)$  to the solution spectrum of the modified Dirac operator  $D$ .

#### Hurwitz zetas

Hurwitz zeta is obtained by replacing integers  $m$  with  $m + z$  in the defining sum formula for Riemann Zeta:

$$\zeta(s, z) = \sum_m (m + z)^{-s} . \quad (4.6.1)$$

Riemann zeta results for  $z = n$ .

Hurwitz zeta obeys the following functional equation for rational  $z = m/n$  of the second argument [?] :

$$\zeta(1 - s, \frac{m}{n}) = \frac{2\Gamma(s)}{2\pi n} \sum_{k=1}^n \cos(\frac{\pi s}{2} - \frac{2\pi km}{n}) \zeta(s, \frac{k}{n}) . \quad (4.6.2)$$

The representation of Hurwitz zeta in terms of  $\theta$  [?] is given by the equation

$$\int_0^\infty [\theta(z, it) - 1] t^{s/2} \frac{dt}{t} = \pi^{(1-s)/2} \Gamma\left(\frac{1-s}{2}\right) [\zeta(1-s, z) + \zeta(1-s, 1-z)] . \quad (4.6.3)$$

By the periodicity of the theta function this gives for  $z = n$  Riemann zeta.

### The action of $\tau \rightarrow \tau + 1$ transforms $\zeta(s, 0)$ to $\zeta(s, 1/2)$

The action of the transformations  $\tau \rightarrow \tau + 1$  on the integral representation of Riemann Zeta [?] in terms of  $\theta$  function [?]

$$\theta(z; \tau) - 1 = 2 \sum_{n=1}^{\infty} [\exp(i\pi\tau)]^{n^2} \cos(2\pi n z) \quad (4.6.4)$$

is given by

$$\pi^{-s/2} \Gamma\left(\frac{s}{2}\right) \zeta(s) = \int_0^\infty [\theta(0; it) - 1] t^{s/2} \frac{dt}{t} . \quad (4.6.5)$$

Using the first formula one finds that the shift  $\tau = it \rightarrow \tau + 1$  in the argument  $\theta$  induces the shift  $\theta(0; \tau) \rightarrow \theta(1/2; \tau)$ . Hence the result is Hurwitz zeta  $\zeta(s, 1/2)$ . For  $\tau \rightarrow \tau + 2$  one obtains Riemann Zeta.

Thus  $\zeta(s, 0)$  and  $\zeta(s, 1/2)$  behave like a doublet under modular transformations. Under the subgroup of modular group obtained by replacing  $\tau \rightarrow \tau + 1$  with  $\tau \rightarrow \tau + 2$  Riemann Zeta forms a singlet. The functional equation for Hurwitz zeta relates  $\zeta(1-s, 1/2)$  to  $\zeta(s, 1/2)$  and  $\zeta(s, 1) = \zeta(s, 0)$  so that also now one obtains a doublet, which is not surprising since the functional equations directly reflects the modular transformation properties of theta functions. This doublet might be the proper object to study instead of singlet if one considers full modular invariance.

### Hurwitz zetas form $n$ -plets closed under the action of fractional modular group

The inspection of the functional equation for Hurwitz zeta given above demonstrates that  $\zeta(s, m/n)$ ,  $m = 0, 1, \dots, n$ , form in a well-defined sense an  $n$ -plet under fractional modular transformations obtained by using generators  $\tau \rightarrow -1/\tau$  and  $\tau \rightarrow \tau + 2/n$ . The latter corresponds to the unimodular matrix  $(a, b; c, d) = (1, 2/n; 0, 1)$ . These matrices obviously form a group. Note that Riemann zeta is always one member of the multiplet containing  $n$  Hurwitz zetas.

These observations bring in mind fractionization of quantum numbers, quantum groups corresponding to the quantum phase  $q = \exp(i2\pi/n)$ , and the inclusions for hyper-finite factors of type  $II_1$  partially characterized by these quantum phases. Fractional modular group obtained using generator  $\tau \rightarrow \tau + 2/n$  and Hurwitz zetas  $\zeta(s, k/n)$  could very naturally relate to these and related structures.

#### 4.6.2 Could Hurwitz zetas relate to dark matter?

These observations suggest a speculative application to quantum TGD.

#### Basic vision about dark matter

1. In TGD framework inclusions of HFFs of type  $II_1$  are directly related to the hierarchy of Planck constants involving a generalization of the notion of imbedding space obtained by gluing together copies of 8-D  $H = M^4 \times CP_2$  with a discrete bundle structure  $H \rightarrow H/Z_{n_a} \times Z_{n_b}$  together along the 4-D intersections of the associated base spaces [K25]. A book like structure results and various levels of dark matter correspond to the pages of this book. One can say that elementary particles proper are maximally quantum critical and live in the 4-D intersection of these imbedding spaces whereas their "field bodies" reside at the pages of the Big Book. Note that analogous book like structures results when real and various p-adic variants of the imbedding space are glued together along common algebraic points.

2. The integers  $n_a$  and  $n_b$  give Planck constant as  $\hbar/\hbar_0 = n_a/n_b$ , whose most general value is a rational number. In Platonic spirit one can argue that number theoretically simple integers involving only powers of 2 and Fermat primes are favored physically. Phase transitions between different matters occur at the intersection.
3. The inclusions  $\mathcal{N} \subset \mathcal{M}$  of HFFs relate also to quantum measurement theory with finite measurement resolution with  $\mathcal{N}$  defining the measurement resolution so that N-rays replace complex rays in the projection postulate and quantum space  $\mathcal{M}/\mathcal{N}$  having fractional dimension effectively replaces  $\mathcal{M}$ .
4. Geometrically the fractional modular invariance would naturally relate to the fact that Riemann surface (partonic 2-surface) can be seen as an  $n_a \times n_b$ -fold covering of its projection to the base space of  $H$ : fractional modular transformations corresponding to  $n_a$  and  $n_b$  would relate points at different sheets of the covering of  $M^4$  and  $CP_2$ . This means  $Z_{n_a n_b} = Z_{n_a} \times Z_{n_b}$  conformal symmetry. This suggests that the fractionization could be a completely general phenomenon happening also for more general zeta functions.

### What about exceptional cases $n = 1$ and $n = 2$ ?

Also  $n = 1$  and  $n = 2$  are present in the hierarchy of Hurwitz zetas (singlet and doublet). They do not correspond to allowed Jones inclusion since one has  $n > 2$  for them. What could this mean?

1. It would seem that the fractionization of modular group relates to Jones inclusions ( $n > 2$ ) giving rise to fractional statistics.  $n = 2$  corresponding to the full modular group  $Sl(2, \mathbb{Z})$  could relate to the very special role of 2-valued logic, to the degeneracy of  $n = 2$  polygon in plane, to the very special role played by 2-component spinors playing exceptional role in Riemann geometry with spinor structure, and to the canonical representation of HFFs of type  $II_1$  as fermionic Fock space (spinors in the world of classical worlds). Note also that  $SU(2)$  defines the building block of compact non-commutative Lie groups and one can obtain Lie-algebra generators of Lie groups from  $n$  copies of  $SU(2)$  triplets and posing relations which distinguish the resulting algebra from a direct sum of  $SU(2)$  algebras.
2. Also  $n = 2$ -fold coverings  $M^4 \rightarrow M^4/Z_2$  and  $CP_2 \rightarrow CP_2/Z_2$  seem to make sense. One can argue that by quantum classical correspondence the spin half property of imbedding space spinors should have space-time correlate. Could  $n = 2$  coverings allow to define the space-time correlates for particles having half odd integer spin or weak isospin? If so, bosons would correspond to  $n = 1$  and fermions to  $n = 2$ . One could of course counter argue that induced spinor fields already represent fermions at space-time level and there is no need for the doubling of the representation.

The trivial group  $Z_1$  and  $Z_2$  are exceptional since  $Z_1$  does not define any quantization axis and  $Z_2$  allows any quantization axis orthogonal to the line connecting two points. For  $n \geq 3$   $Z_n$  fixes the direction of quantization axis uniquely. This obviously correlates with  $n \geq 3$  for Jones inclusions.

### Dark elementary particle functionals

One might wonder what might be the dark counterparts of elementary particle vacuum functionals. Theta functions  $\theta_{[a,b]}(z, \Omega)$  with characteristic  $[a, b]$  for Riemann surface of genus  $g$  as functions of  $z$  and Teichmueller parameters  $\Omega$  are the basic building blocks of modular invariant vacuum functionals defined in the finite-dimensional moduli space whose points characterize the conformal equivalence class of the induced metric of the partonic 2-surface. Obviously, kind of spinorial variants of theta functions are in question with  $g + g$  spinor indices for genus  $g$ .

The recent case corresponds to  $g = 1$  Riemann surface (torus) so that  $a$  and  $b$  are  $g = 1$ -component vectors having values 0 or  $1/2$  and Hurwitz zeta corresponds to  $\theta_{[0,1/2]}$ . The four Jacobi theta functions listed in Wikipedia [?] correspond to these thetas for torus. The values for  $a$  and  $b$  are 0 and 1 for them but this is a mere convention.

The extensions of modular group to fractional modular groups obtained by replacing integers with integers shifted by multiples of  $1/n$  suggest the existence of new kind of q-theta functions with

characteristics  $[a, b]$  with  $a$  and  $b$  being  $g$ -component vectors having fractional values  $k/n$ ,  $k = 0, 1 \dots n-1$ . There exists also a definition of  $q$ -theta functions working for  $0 \leq |q| < 1$  but not for roots of unity [?] . The  $q$ -theta functions assigned to roots of unity would be associated with Riemann surfaces with additional  $Z_n$  conformal symmetry but not with generic Riemann surfaces and obtained by simply replacing the value range of characteristics  $[a, b]$  with the new value range in the defining formula

$$\Theta[a, b](z|\Omega) = \sum_n \exp[i\pi(n+a) \cdot \Omega \cdot (n+a) + i2\pi(n+a) \cdot (z+b)] \quad . \quad (4.6.6)$$

for theta functions. If  $Z_n$  conformal symmetry is relevant for the definition of fractional thetas it is probably so because it would make the generalized theta functions sections in a bundle with a finite fiber having  $Z_n$  action.

This hierarchy would correspond to the hierarchy of quantum groups for roots of unity and Jones inclusions and one could probably define also corresponding zeta function multiplets. These theta functions would be building blocks of the elementary particle vacuum functionals for dark variants of elementary particles invariant under fractional modular group. They would also define a hierarchy of fractal variants of number theoretic functions: it would be interesting to see what this means from the point of view of Langlands program [?] discussed also in TGD framework [?] involving ordinary modular invariance in an essential manner.

This hierarchy would correspond to the hierarchy of quantum groups for roots of unity and Jones inclusions and one could probably define also corresponding zeta function multiplets. These theta functions would be building blocks of the elementary particle vacuum functionals for dark variants of elementary particles invariant under fractional modular group.

### Hierarchy of Planck constants defines a hierarchy of quantum critical systems

Dark matter hierarchy corresponds to a hierarchy of conformal symmetries  $Z_n$  of partonic 2-surfaces with genus  $g \geq 1$  such that factors of  $n$  define subgroups of conformal symmetries of  $Z_n$ . By the decomposition  $Z_n = \prod_{p|n} Z_p$ , where  $p|n$  tells that  $p$  divides  $n$ , this hierarchy corresponds to an hierarchy of increasingly quantum critical systems in modular degrees of freedom. For a given prime  $p$  one has a sub-hierarchy  $Z_p, Z_{p^2} = Z_p \times Z_p$ , etc... such that the moduli at  $n+1$ :th level are contained by  $n$ :th level. In the similar manner the moduli of  $Z_n$  are sub-moduli for each prime factor of  $n$ . This mapping of integers to quantum critical systems conforms nicely with the general vision that biological evolution corresponds to the increase of quantum criticality as Planck constant increases.

The group of conformal symmetries could be also non-commutative discrete group having  $Z_n$  as a subgroup. This inspires a very short-lived conjecture that only the discrete subgroups of  $SU(2)$  allowed by Jones inclusions are possible as conformal symmetries of Riemann surfaces having  $g \geq 1$ . Besides  $Z_n$  one could have tetrahedral and icosahedral groups plus cyclic group  $Z_{2n}$  with reflection added but not  $Z_{2n+1}$  nor the symmetry group of cube. The conjecture is wrong. Consider the orbit of the subgroup of rotational group on standard sphere of  $E^3$ , put a handle at one of the orbits such that it is invariant under rotations around the axis going through the point, and apply the elements of subgroup. You obtain a Riemann surface having the subgroup as its isometries. Hence all discrete subgroups of  $SU(2)$  can act even as isometries for some value of  $g$ .

The number theoretically simple ruler-and-compass integers having as factors only first powers of Fermat primes and power of 2 would define a physically preferred sub-hierarchy of quantum criticality for which subsequent levels would correspond to powers of 2: a connection with  $p$ -adic length scale hypothesis suggests itself.

Spherical topology is exceptional since in this case the space of conformal moduli is trivial and conformal symmetries correspond to the entire  $SL(2, C)$ . This would suggest that only the fermions of lowest generation corresponding to the spherical topology are maximally quantum critical. This brings in mind Jones inclusions for which the defining subgroup equals to  $SU(2)$  and Jones index equals to  $M/N = 4$ . In this case all discrete subgroups of  $SU(2)$  label the inclusions. These inclusions would correspond to fiber space  $CP_2 \rightarrow CP_2/U(2)$  consisting of geodesic spheres of  $CP_2$ . In this case the discrete subgroup might correspond to a selection of a subgroup of  $SU(2) \subset SU(3)$  acting non-trivially on the geodesic sphere. Cosmic strings  $X^2 \times Y^2 \subset M^4 \times CP_2$  having geodesic spheres of  $CP_2$  as their ends could correspond to this phase dominating the very early cosmology.

### Fermions in TGD Universe allow only three families

What is nice that if fermions correspond to  $n = 2$  dark matter with  $Z_2$  conformal symmetry as strong quantum classical correspondence suggests, the number of ordinary fermion families is three without any further assumptions. To see this suppose that also the sectors corresponding to  $M^4 \rightarrow M^4/Z_2$  and  $CP_2 \rightarrow CP_2/Z_2$  coverings are possible.  $Z_2$  conformal symmetry implies that partonic Riemann surfaces are hyper-elliptic. For genera  $g > 2$  this means that some theta functions of  $\theta_{[a,b]}$  appearing in the product of theta functions defining the vacuum functional vanish. Hence fermionic elementary particle vacuum functionals would vanish for  $g > 2$  and only 3 fermion families would be possible for  $n = 2$  dark matter.

This results can be strengthened. The existence of space-time correlate for the fermionic 2-valuedness suggests that fermions quite generally to even values of  $n$ , so that this result would hold for all fermions. Elementary bosons (actually exotic particles belonging to Kac-Moody type representations) would correspond to odd values of  $n$ , and could possess also higher families. There is a nice argument supporting this hypothesis.  $n$ -fold discretization provided by covering associated with  $H$  corresponds to discretization for angular momentum eigenstates. Minimal discretization for  $2j + 1$  states corresponds to  $n = 2j + 1$ .  $j = 1/2$  requires  $n = 2$  at least,  $j = 1$  requires  $n = 3$  at least, and so on.  $n = 2j + 1$  allows spins  $j \leq n - 1/2$ . This spin-quantum phase connection at the level of space-time correlates has counterpart for the representations of quantum  $SU(2)$ .

These rules would hold only for genuinely elementary particles corresponding to single partonic component and all bosonic particles of this kind are exotics (excitations in only "vibrational" degrees of freedom of partonic 2-surface with modular invariance eliminating quite a number of them.

## Chapter 5

# Massless States and Particle Massivation

### 5.1 Introduction

This article represents the most recent view about particle massivation in TGD framework. This topic is necessarily quite extended since many several notions and new mathematics is involved. Therefore the calculation of particle masses involves five chapters ( [K16, K39, K46, K43] of [K45] ). In the following my goal is to provide an up-to-date summary whereas the chapters are unavoidably a story about evolution of ideas.

The identification of the spectrum of light particles reduces to two tasks: the construction of massless states and the identification of the states which remain light in p-adic thermodynamics. The latter task is relatively straightforward. The thorough understanding of the massless spectrum requires however a real understanding of quantum TGD. It would be also highly desirable to understand why p-adic thermodynamics combined with p-adic length scale hypothesis works. A lot of progress has taken place in these respects during last years.

Zero energy ontology providing a detailed geometric view about bosons and fermions, the generalization of  $S$ -matrix to what I call  $M$ -matrix, the notion of finite measurement resolution characterized in terms of inclusions of von Neumann algebras, the derivation of p-adic coupling constant evolution and p-adic length scale hypothesis from the first principles, the realization that the counterpart of Higgs mechanism involves generalized eigenvalues of the modified Dirac operator: these are represent important steps of progress during last years with a direct relevance for the understanding of particle spectrum and massivation although the predictions of p-adic thermodynamics are not affected.

During 2010 a further progress took place as I wrote articles about TGD to Prespacetime journal [?, ?, ?, ?, ?, ?, ?, ?]. These steps of progress relate closely to zero energy ontology, bosonic emergence, the realization of the importance of twistors in TGD, and to the discovery of the weak form of electric-magnetic duality. Twistor approach and the understanding of the Chern-Simons Dirac operator served as a midwife in the process giving rise to the birth of the idea that all particles at fundamental level are massless and that both ordinary elementary particles and string like objects emerge from them. Even more, one can interpret virtual particles as being composed of these massless on mass shell particles assignable to wormhole throats so that four-momentum conservation poses extremely powerful constraints on loop integrals and makes them manifestly finite.

The weak form of electric-magnetic duality led to the realization that elementary particles correspond to bound states of two wormhole throats with opposite Kähler magnetic charges with second throat carrying weak isospin compensating that of the fermion state at second wormhole throat. Both fermions and bosons correspond to wormhole contacts: in the case of fermions topological condensation generates the second wormhole throat. This means that altogether four wormhole throats are involved with both fermions, gauge bosons, and gravitons (for gravitons this is unavoidable in any case). For p-adic thermodynamics the mathematical counterpart of string corresponds to a wormhole contact with size of order  $CP_2$  size with the role of its ends played by wormhole throats at which the signature of the induced 4-metric changes. The key observation is that for massless states the throats of spin 1 particle must have opposite three-momenta so that gauge bosons are necessarily

massive, even photon and other particles usually regarded as massless must have small mass which in turn cancels infrared divergences and give hopes about exact Yangian symmetry generalizing that of  $\mathcal{N} = 4$  SYM. Besides this there is weak "stringy" contribution to the mass assignable to the magnetic flux tubes connecting the two wormhole throats at the two space-time sheets.

### 5.1.1 Physical states as representations of super-symplectic and Super Kac-Moody algebras

Physical states belong to the representation of super-symplectic algebra and Super Kac-Moody algebra assignable  $SO(2) \times SU(3) \times SU(2)_{rot} \times U(2)_{ew}$  associated with the 2-D surfaces  $X^2$  defined by the intersections of 3-D light like causal determinants with  $\delta M_{\pm}^4 \times CP_2$ . These 2-surfaces have interpretation as partons.

It has taken considerable effort to understand the relationship between super-symplectic and super Kac-Moody algebras and there are still many uncertainties involved. What looks like the most plausible option relies on the generalization of a coset construction proposed already for years ago but given up because of the lacking understanding of how SKM and SC algebras could be lifted to the level of imbedding space. The progress in the *Physics as generalized number theory* program provided finally a justification for the coset construction.

1. Assume a generalization of the coset construction in the sense that the differences of super Kac-Moody Virasoro generators (SKMV) and super-symplectic Virasoro generators (SSV) annihilate the physical states. The interpretation is in terms of TGD counterpart for Einstein's equations realizing Equivalence Principle. Mass squared is identified as the p-adic thermal expectation value of either  $SKMV$  or  $SSV$  conformal weight (gravitational or inertial mass) in a superposition of states with  $SKMV$  ( $SSV$ ) conformal weight  $n \geq 0$  annihilated by  $SKMV - SSV$ .
2. Construct first ground states with negative conformal weight annihilated by  $SKMV$  and  $SSV$  generators  $G_n, L_n, n < 0$ . Apply to these states generators of tensor factors of Super Viraroso algebras to obtain states with vanishing  $SSV$  and  $SKMV$  conformal weights. After this construct thermal states as superpositions of states obtained by applying  $SKMV$  generators and corresponding  $SSV$  generators  $G_n, L_n, n > 0$ . Assume that these states are annihilated by  $SSV$  and  $SKMV$  generators  $G_n, L_n, n > 0$  and by the differences of all  $SSV$  and  $SKMV$  generators.
3. Super-symplectic algebra represents a completely new element and in the case of hadrons the non-perturbative contribution to the mass spectrum is easiest to understand in terms of super-symplectic thermal excitations contributing roughly 70 per cent to the p-adic thermal mass of the hadron. It must be however emphasized that by SKMV-SSV duality one can regard these contributions equivalently as SKM or SC contributions.

Yangian algebras associated with the super-conformal algebras and motivated by twistorial approach generalize the super-conformal symmetry and make it multi-local in the sense that generators can act on several partonic 2-surfaces simultaneously. These partonic 2-surfaces generalize the vertices for the external massless particles in twistor Grassmann diagrams [?]. The implications of this symmetry are yet to be deduced but one thing is clear: Yangians are tailor made for the description of massive bound states formed from several partons identified as partonic 2-surfaces. The preliminary discussion of what is involved can be found in [?].

### 5.1.2 Particle massivation

Particle massivation can be regarded as a generation of thermal conformal weight identified as mass squared and due to a thermal mixing of a state with vanishing conformal weight with those having higher conformal weights. The observed mass squared is not p-adic thermal expectation of mass squared but that of conformal weight so that there are no problems with Lorentz invariance.

One can imagine several microscopic mechanisms of massivation. The following proposal is the winner in the fight for survival between several competing scenarios.

1. The original observation was that the pieces of  $CP_2$  type vacuum extremals representing elementary particles have random light-like curve as an  $M^4$  projection so that the average motion

correspond to that of massive particle. Light-like randomness gives rise to classical Virasoro conditions. This picture generalizes since the basic dynamical objects are light-like but otherwise random 3-surfaces. The identification of elementary particles developed in three steps.

- (a) Fermions are identified as light-like 3-surfaces at which the signature of induced metric of deformed  $CP_2$  type extremals changes from Euclidian to the Minkowskian signature of the background space-time sheet. Gauge bosons and Higgs correspond to wormhole contacts with light-like throats carrying fermion and antifermion quantum numbers. Gravitons correspond to pairs of wormhole contacts bound to string like object by the fluxes connecting the wormhole contacts. The randomness of the light-like 3-surfaces and associated super-conformal symmetries justify the use of thermodynamics and the question remains why this thermodynamics can be taken to be p-adic. The proposed identification of bosons means enormous simplification in thermodynamical description since all calculations reduced to the calculations to fermion level. This picture generalizes to include super-symmetry. The fermionic oscillator operators associated with the partonic 2-surfaces act as generators of badly broken SUSY and right-handed neutrino gives to the not so badly broken  $\mathcal{N} = 1$  SUSY consistent with empirical facts.
  - (b) The next step was to realize that the topological condensation of fermion generates second wormhole throat which carries momentum but no fermionic quantum numbers. This is also needed to the massivation by p-adic thermodynamics applied to the analogs of string like objects defined by wormhole throats with throats taking the role of string ends. p-Adic thermodynamics did not however allow a satisfactory understanding of the gauge bosons masses and it was clear that Higgsy contribution should be present and dominate for gauge bosons. Gauge bosons should also somehow obtain their longitudinal polarizations and here Higgs like particles indeed predicted by the basic picture suggests itself strongly.
  - (c) A further step was the discovery of the weak form of electric-magnetic duality, which led to the realization that wormhole throats possess Kähler magnetic charge so that a wormhole throat with opposite magnetic charge is needed to compensate this charge. This wormhole throat can also compensate the weak isospin of the second wormhole throat so that weak confinement and massivation results. In the case of quarks magnetic confinement might take place in hadronic rather than weak length scale. Second crucial observation was that gauge bosons are necessarily massive since the light-like momenta at two throats must correspond to opposite three-momenta so that no Higgs potential is needed. This leads to a picture in which gauge bosons eat the Higgs scalars and also photon, gluons, and gravitons develop small mass.
2. The fundamental parton level description of TGD is based on almost topological QFT for light-like 3-surfaces. Dynamics is constrained by the requirement that  $CP_2$  projection is for extremals of Chern-Simons action 2-dimensional and for off-shell states light-likeness is the only constraint. As a matter fact, the basic theory relies on the modified Dirac action associated with Chern-Simons action and Kähler action in the sense that the generalizes eigenmodes of Chern-Simons Dirac operator correspond to the zero modes of Kähler action localized to the light-like 3-surfaces representing partons. In this manner the data about the dynamics of Kähler action is feeded to the eigenvalue spectrum. Eigenvalues are interpreted as square roots of ground state conformal weights.
  3. The symmetries respecting light-likeness property give rise to Kac-Moody type algebra and super-symplectic symmetries emerge also naturally as well as  $\mathcal{N} = 4$  character of super-conformal invariance. The coset construction for super-symplectic Virasoro algebra and Super Kac-Moody algebra identified in physical sense as sub-algebra of former implies that the four-momenta assignable to the two algebras are identical. The interpretation is in terms of the identity of gravitational inertial masses and generalization of Equivalence Principle.
  4. Instead of energy, the Super Kac-Moody Virasoro (or equivalently super-symplectic) generator  $L_0$  (essentially mass squared) is thermalized in p-adic thermodynamics (and also in its real version assuming it exists). The fact that mass squared is thermal expectation of conformal weight guarantees Lorentz invariance. That mass squared, rather than energy, is a fundamental quantity at  $CP_2$  length scale is also suggested by a simple dimensional argument (Planck mass

squared is proportional to  $\hbar$  so that it should correspond to a generator of some Lie-algebra (Virasoro generator  $L_0!$ ).

5. By Equivalence Principle the thermal average of mass squared can be calculated either in terms of thermodynamics for either super-symplectic of Super Kac-Moody Virasoro algebra and p-adic thermodynamics is consistent with conformal invariance.
6. There is also a modular contribution to the mass squared, which can be estimated using elementary particle vacuum functionals in the conformal modular degrees of freedom of the partonic 2-surface. It dominates for higher genus partonic 2-surfaces. For bosons both Virasoro and modular contributions seem to be negligible and could be due to the smallness of the p-adic temperature.
7. A long standing problem has been whether coupling to Higgs boson is needed to explain gauge boson masses via a generation of Higgs vacuum expectation having possibly interpretation in terms of a coherent state. Before the detailed model for elementary particles in terms of pairs of wormhole contacts at the ends of flux tubes the picture about the situation was as follows. From the beginning it was clear that is that ground state conformal weight must be negative. Then it became clear that the ground state conformal weight need not be a negative integer. The deviation  $\Delta h$  of the total ground state conformal weight from negative integer gives rise to Higgs type contribution to the thermal mass squared and dominates in case of gauge bosons for which p-adic temperature is small. In the case of fermions this contribution to the mass squared is small. The possible Higgs vacuum expectation makes sense only at QFT limit and would be naturally proportional to  $\Delta h$  so that the coupling to Higgs would only apparently cause gauge boson massivation. It is natural to relate  $\Delta h$  to the generalized eigenvalues of Chern-Simons Dirac operator.
8. A natural identification of the non-integer contribution to the conformal weight is as Higgsy and stringy contributions to the vacuum conformal weight. In twistor approach the generalized eigenvalues of Chern-Simons Dirac operator for external particles indeed correspond to light-like momenta and when the three-momenta are opposite this gives rise to non-vanishing mass. Higgs is necessary to give longitudinal polarizations for gauge bosons and also gauge bosons usually regarded as exactly massless particles would naturally receive small mass in this manner so that Higgs would disappear completely from the spectrum. The theoretical motivation for small mass would be exact Yangian symmetry. Higgs vacuum expectation assignable to coherent state of Higgs bosons is not needed to explain the boson masses.

An important question concerns the justification of p-adic thermodynamics.

1. The underlying philosophy is that real number based TGD can be algebraically continued to various p-adic number fields. This gives justification for the use of p-adic thermodynamics although the mapping of p-adic thermal expectations to real counterparts is not completely unique. The physical justification for p-adic thermodynamics is effective p-adic topology characterizing the 3-surface: this is the case if real variant of light-like 3-surface has large number of common algebraic points with its p-adic counterpart obeying same algebraic equations but in different number field. In fact, there is a theorem stating that for rational surfaces the number of rational points is finite and rational (more generally algebraic points) would naturally define the notion of number theoretic braid essential for the realization of number theoretic universality.
2. The most natural option is that the descriptions in terms of both real and p-adic thermodynamics make sense and are consistent. This option indeed makes if the number of generalized eigen modes of modified Dirac operator is finite. This is indeed the case if one accepts periodic boundary conditions for the Chern-Simons Dirac operator. In fact, the solutions are localized at the strands of braids [?] . This makes sense because the theory has hydrodynamic interpretation [?] . This reduces  $\mathcal{N} = \infty$  to finite SUSY and realizes finite measurement resolution as an inherent property of dynamics.

The finite number of fermionic oscillator operators implies an effective cutoff in the number conformal weights so that conformal algebras reduce to finite-dimensional algebras. The first guess would be that integer label for oscillator operators becomes a number in finite field for

some prime. This means that one can calculate mass squared also by using real thermodynamics but the consistency with p-adic thermodynamics gives extremely strong number theoretical constraints on mass scale. This consistency condition allows also to solve the problem how to map a negative ground state conformal weight to its p-adic counterpart. Negative conformal weight is divided into a negative half odd integer part plus positive part  $\Delta h$ , and negative part corresponds as such to p-adic integer whereas positive part is mapped to p-adic number by canonical identification.

p-Adic thermodynamics is what gives to this approach its predictive power.

1. p-Adic temperature is quantized by purely number theoretical constraints (Boltzmann weight  $\exp(-E/kT)$  is replaced with  $p^{L_0/T_p}$ ,  $1/T_p$  integer) and fermions correspond to  $T_p = 1$  whereas  $T_p = 1/n$ ,  $n > 1$ , seems to be the only reasonable choice for gauge bosons.
2. p-Adic thermodynamics forces to conclude that  $CP_2$  radius is essentially the p-adic length scale  $R \sim L$  and thus of order  $R \simeq 10^{3.5} \sqrt{\hbar G}$  and therefore roughly  $10^{3.5}$  times larger than the naive guess. Hence p-adic thermodynamics describes the mixing of states with vanishing conformal weights with their Super Kac-Moody Virasoro excitations having masses of order  $10^{-3.5}$  Planck mass.

### 5.1.3 What next?

The successes of p-adic mass calculations are basically due to the power of super-conformal symmetries and of number theory. One cannot deny that the description of the Higgsey aspects of massivation and of hadrons involves phenomenological elements. There are however excellent hopes that it might be possible some day to calculate everything from first principles. The non-local Yangian symmetry generalizing the super-conformal algebras suggests itself strongly as a fundamental symmetry of quantum TGD. The generalized of the Yangian symmetry replaces points with partonic 2-surfaces being multi-local with respect to them, and leads to general formulas for multi-local operators representing four-momenta and other conserved charges of composite states. In TGD framework even elementary particles involve two wormhole contacts having each two wormhole throats identified as the fundamental partonic entities. Therefore Yangian approach would naturally define the first principle approach to the understanding of masses of elementary particles and their bound states (say hadrons). The power of this extended symmetry might be enough to deduce universal mass formulas. One of the future challenges would therefore be the mathematical and physical understanding of Yangian symmetry. This would however require the contributions of professional mathematicians.

## 5.2 Identification of elementary particles

### 5.2.1 Partons as wormhole throats and particles as bound states of wormhole contacts

The assumption that partonic 2-surfaces correspond to representations of Super Virasoro algebra has been an unchallenged assumption of the p-adic mass calculations for a long time although one might argue that these objects do not possess stringy characteristics, in particular they do not possess two ends. The progress in the understanding of the modified Dirac equation and the introduction of the weak form of electric magnetic duality [?] however forces to modify the picture about the origin of the string mass spectrum.

1. The weak form of electric-magnetic duality, the basic facts about modified Dirac equation and the proposed twistorialization of quantum TGD [?] force to conclude that both strings and bosons and their super-counterparts emerge from massless fermions moving collinearly at partonic two-surfaces. Stringy mass spectrum is consistent with this only if p-adic thermodynamics describes wormhole contacts as analogs of stringy objects having quantum numbers at the throats playing the role of string ends. For instance, the three-momenta of massless wormhole throats could be in opposite direction so that wormhole contact would become massive. The fundamental string like objects would therefore correspond to the wormhole contacts with size scale of order  $CP_2$  length.

Already these objects must have a correct correlation between color and electroweak quantum numbers. The colored super-generators taking care that anomalous color is compensated can be assigned with purely bosonic quanta associated with the wormhole throats which carry no fermion number.

2. Second modification comes from the necessity to assume weak confinement in the sense that each wormhole throat carrying fermionic numbers is accompanied by a second wormhole throat carrying neutrino pair cancelling the net weak isospin so that only electromagnetic charge remains unscreened. This screening must take place in weak length scale so that ordinary elementary particles are predicted to be string like objects. This string tension has however nothing to do with the fundamental string tension responsible for the mass spectrum. This picture is forced also by the fact that fermionic wormhole throats necessarily carry Kähler magnetic charge [?] so that in the case of leptons the second wormhole throat must carry a compensating Kähler magnetic charge. In the case of quarks one can consider the possibility that magnetic charges are not neutralized completely in weak scale and that the compensation occurs in QCD length scale so that Kähler magnetic confinement would accompany color confinement. This means color magnetic confinement since classical color gauge fields are proportional to induced Kähler field.

These modifications do not seem to appreciably affect the results of calculations, which depend only on the number of tensor factors in super Virasoro representation, they are not taken explicitly into account in the calculations. The predictions of the general theory are consistent with the earliest mass calculations, and the earlier ad hoc parameters disappear. In particular, optimal lowest order predictions for the charged lepton masses are obtained and photon, gluon and graviton appear as essentially massless particles. What is new is the possibility to describe the massivation of gauge bosons by including the contribution from the string tension of weak string like objects: weak boson masses have indeed been the trouble makers and have forced to conclude that Higgs expectation might be needed unless some other mechanism contributes to the conformal vacuum weight of the ground state.

### 5.2.2 Family replication phenomenon topologically

One of the basic ideas of TGD approach has been genus-generation correspondence: boundary components of the 3-surface should be carriers of elementary particle numbers and the observed particle families should correspond to various boundary topologies.

With the advent of zero energy ontology this picture changed somewhat. It is the wormhole throats identified as light-like 3-surfaces at which with the induced metric of the space-time surface changes its signature from Minkowskian to Euclidian, which correspond to the light-like orbits of partonic 2-surfaces. One cannot of course exclude the possibility that also boundary components could allow to satisfy boundary conditions without assuming vacuum extremal property of nearby space-time surface. The intersections of the wormhole throats with the light-like boundaries of causal diamonds ( $CD$ s) identified as intersections of future and past directed light cones ( $CD \times CP_2$  is actually in question but I will speak about  $CD$ s) define special partonic 2-surfaces and it is the moduli of these partonic 2-surfaces which appear in the elementary particle vacuum functionals naturally.

The first modification of the original simple picture comes from the identification of physical particles as bound states of pairs of wormhole contacts and from the assumption that for generalized Feynman diagrams stringy trouser vertices are replaced with vertices at which the ends of light-like wormhole throats meet. In this picture the interpretation of the analog of trouser vertex is in terms of propagation of same particle along two different paths. This interpretation is mathematically natural since vertices correspond to 2-manifolds rather than singular 2-manifolds which are just splitting to two disjoint components. Second complication comes from the weak form of electric-magnetic duality forcing to identify physical particles as weak strings with magnetic monopoles at their ends and one should understand also the possible complications caused by this generalization.

These modifications force to consider several options concerning the identification of light fermions and bosons and one can end up with a unique identification only by making some assumptions. Masslessness of all wormhole throats- also those appearing in internal lines- and dynamical  $SU(3)$  symmetry for particle generations are attractive general enough assumptions of this kind. This means that bosons and their super-partners correspond to wormhole contacts with fermion and antifermion

at the throats of the contact. Free fermions and their superpartners could correspond to  $CP_2$  type vacuum extremals with single wormhole throat. It turns however that dynamical  $SU(3)$  symmetry forces to identify massive (and possibly topologically condensed) fermions as  $(g, g)$  type wormhole contacts.

### Do free fermions correspond to single wormhole throat or $(g, g)$ wormhole?

The original interpretation of genus-generation correspondence was that free fermions correspond to wormhole throats characterized by genus. The idea of  $SU(3)$  as a dynamical symmetry suggested that gauge bosons correspond to octet and singlet representations of  $SU(3)$ . The further idea that all lines of generalized Feynman diagrams are massless poses a strong additional constraint and it is not clear whether this proposal as such survives.

1. Twistorial program assumes that fundamental objects are massless wormhole throats carrying collinearly moving many-fermion states and also bosonic excitations generated by supersymplectic algebra. In the following consideration only purely bosonic and single fermion throats are considered since they are the basic building blocks of physical particles. The reason is that propagators for high excitations behave like  $p^{-n}$ ,  $n$  the number of fermions associated with the wormhole throat. Therefore single throat allows only spins 0, 1/2, 1 as elementary particles in the usual sense of the word.
2. The identification of massive fermions (as opposed to free massless fermions) as wormhole contacts follows if one requires that fundamental building blocks are massless since at least two massless throats are required to have a massive state. Therefore the conformal excitations with  $CP_2$  mass scale should be assignable to wormhole contacts also in the case of fermions. As already noticed this is not the end of the story: weak strings are required by the weak form of electric-magnetic duality.
3. If free fermions corresponding to single wormhole throat, topological condensation is an essential element of the formation of stringy states. The topological condensation of fermions by topological sum (fermionic  $CP_2$  type vacuum extremal touches another space-time sheet) suggest  $(g, 0)$  wormhole contact. Note however that the identification of wormhole throat is as 3-surface at which the signature of the induced metric changes so that this conclusion might be wrong. One can indeed consider also the possibility of  $(g, g)$  pairs as an outcome of topological condensation. This is suggested also by the idea that wormhole throats are analogous to string like objects and only this option turns out to be consistent with the  $BFF$  vertex based on the requirement of dynamical  $SU(3)$  symmetry to be discussed later. The structure of reaction vertices makes it possible to interpret  $(g, g)$  pairs as  $SU(3)$  triplet. If bosons are obtained as fusion of fermionic and antifermionic throats (touching of corresponding  $CP_2$  type vacuum extremals) they correspond naturally to  $(g_1, g_2)$  pairs.
4. p-Adic mass calculations distinguish between fermions and bosons and the identification of fermions and bosons should be consistent with this difference. The maximal p-adic temperature  $T = 1$  for fermions could relate to the weakness of the interaction of the fermionic wormhole throat with the wormhole throat resulting in topological condensation. This wormhole throat would however carry momentum and 3-momentum would in general be non-parallel to that of the fermion, most naturally in the opposite direction.

p-Adic mass calculations suggest strongly that for bosons p-adic temperature  $T = 1/n$ ,  $n > 1$ , so that thermodynamical contribution to the mass squared is negligible. The low p-adic temperature could be due to the strong interaction between fermionic and antifermionic wormhole throat leading to the "freezing" of the conformal degrees of freedom related to the relative motion of wormhole throats.

5. The weak form of electric-magnetic duality forces second wormhole throat with opposite magnetic charge and the light-like momenta could sum up to massive momentum. In this case string tension corresponds to electroweak length scale. Therefore p-adic thermodynamics must be assigned to wormhole contacts and these appear as basic units connected by Kähler magnetic flux tube pairs at the two space-time sheets involved. Weak stringy degrees of freedom are however

expected to give additional contribution to the mass, perhaps by modifying the ground state conformal weight.

### Dynamical $SU(3)$ fixes the identification of fermions and bosons and fundamental interaction vertices

For 3 light fermion families  $SU(3)$  suggests itself as a dynamical symmetry with fermions in fundamental  $N = 3$ -dimensional representation and  $N \times N = 9$  bosons in the adjoint representation and singlet representation. The known gauge bosons have same couplings to fermionic families so that they must correspond to the singlet representation. The first challenge is to understand whether it is possible to have dynamical  $SU(3)$  at the level of fundamental reaction vertices.

This is a highly non-trivial constraint. For instance, the vertices in which  $n$  wormhole throats with same  $(g_1, g_2)$  glued along the ends of lines are not consistent with this symmetry. The splitting of the fermionic worm-hole contacts before the proper vertices for throats might however allow the realization of dynamical  $SU(3)$ . The condition of  $SU(3)$  symmetry combined with the requirement that virtual lines resulting also in the splitting of wormhole contacts are always massless, leads to the conclusion that massive fermions correspond to  $(g, g)$  type wormhole contacts transforming naturally like  $SU(3)$  triplet. This picture conforms with the identification of free fermions as throats but not with the naive expectation that their topological condensation gives rise to  $(g, 0)$  wormhole contact.

The argument leading to these conclusions runs as follows.

1. The question is what basic reaction vertices are allowed by dynamical  $SU(3)$  symmetry.  $FFB$  vertices are in principle all that is needed and they should obey the dynamical symmetry. The meeting of entire wormhole contacts along their ends is certainly not possible. The splitting of fermionic wormhole contacts before the vertices might be however consistent with  $SU(3)$  symmetry. This would give two a pair of 3-vertices at which three wormhole lines meet along partonic 2-surfaces (rather than along 3-D wormhole contacts).
2. Note first that crossing gives all possible reaction vertices of this kind from  $F(g_1)\bar{F}(g_2) \rightarrow B(g_1, g_2)$  annihilation vertex, which is relatively easy to visualize. In this reaction  $F(g_1)$  and  $\bar{F}(g_2)$  wormhole contacts split first. If one requires that all wormhole throats involved are massless, the two wormhole throats resulting in splitting and carrying no fermion number must carry light-like momentum so that they cannot just disappear. The ends of the wormhole throats of the boson must be glued together with the end of the fermionic wormhole throat and its companion generated in the splitting of the wormhole. This means that fermionic wormhole first splits and the resulting throats meet at the partonic 2-surface.

his requires that topologically condensed fermions correspond to  $(g, g)$  pairs rather than  $(g, 0)$  pairs. The reaction mechanism allows the interpretation of  $(g, g)$  pairs as a triplet of dynamical  $SU(3)$ . The fundamental vertices would be just the splitting of wormhole contact and 3-vertices for throats since  $SU(3)$  symmetry would exclude more complex reaction vertices such as  $n$ -boson vertices corresponding the gluing of  $n$  wormhole contact lines along their 3-dimensional ends. The couplings of singlet representation for bosons would have same coupling to all fermion families so that the basic experimental constraint would be satisfied.

3. Both fermions and bosons cannot correspond to octet and singlet of  $SU(3)$ . In this case reaction vertices should correspond algebraically to the multiplication of matrix elements  $e_{ij}$ :  $e_{ij}e_{kl} = \delta_{jk}e_{il}$  allowing for instance  $F(g_1, g_2) + \bar{F}(g_2, g_3) \rightarrow B(g_1, g_3)$ . Neither the fusion of entire wormhole contacts along their ends nor the splitting of wormhole throats before the fusion of partonic 2-surfaces allows this kind of vertices so that  $BFF$  vertex is the only possible one. Also the construction of QFT limit starting from bosonic emergence led to the formulation of perturbation theory in terms of Dirac action allowing only  $BFF$  vertex as fundamental vertex [?].
4. Weak electric-magnetic duality brings in an additional complication.  $SU(3)$  symmetry poses also now strong constraints and it would seem that the reactions must involve copies of basic  $BFF$  vertices for the pairs of ends of weak strings. The string ends with the same Kähler magnetic charge should meet at the vertex and give rise to  $BFF$  vertices. For instance,  $F\bar{F}B$  annihilation vertex would in this manner give rise to the analog of stringy diagram in which strings join along ends since two string ends disappear in the process.

If one accepts this picture the remaining question is why the number of genera is just three. Could this relate to the fact that  $g \leq 2$  Riemann surfaces are always hyper-elliptic (have global  $Z_2$  conformal symmetry) unlike  $g > 2$  surfaces? Why the complete bosonic de-localization of the light families should be restricted inside the hyper-elliptic sector? Does the  $Z_2$  conformal symmetry make these states light and make possible delocalization and dynamical  $SU(3)$  symmetry? Could it be that for  $g > 2$  elementary particle vacuum functionals vanish for hyper-elliptic surfaces? If this the case and if the time evolution for partonic 2-surfaces changing  $g$  commutes with  $Z_2$  symmetry then the vacuum functionals localized to  $g \leq 2$  surfaces do not disperse to  $g > 2$  sectors.

### The notion of elementary particle vacuum functional

Obviously one must know something about the dependence of the elementary particle state functionals on the geometric properties of the boundary component and in the sequel an attempt to construct what might be called elementary particle vacuum functionals, is made.

The basic assumptions underlying the construction are the following ones:

1. Elementary particle vacuum functionals depend on the geometric properties of the two-surface  $X^2$  representing elementary particle.
2. Vacuum functionals possess extended Diff invariance: all 2-surfaces on the orbit of the 2-surface  $X^2$  correspond to the same value of the vacuum functional. This condition is satisfied if vacuum functionals have as their argument, not  $X^2$  as such, but some 2-surface  $Y^2$  belonging to the unique orbit of  $X^2$  (determined by the principle selecting preferred extremal of the Kähler action as a generalized Bohr orbit [?]) and determined in  $Diff^3$  invariant manner.
3. Zero energy ontology allows to select uniquely the partonic two surface as the intersection of the wormhole throat at which the signature of the induced 4-metric changes with either the upper or lower boundary of  $CD \times CP_2$ . This is essential since otherwise one could not specify the vacuum functional uniquely.
4. Vacuum functionals possess conformal invariance and therefore for a given genus depend on a finite number of variables specifying the conformal equivalence class of  $Y^2$ .
5. Vacuum functionals satisfy the cluster decomposition property: when the surface  $Y^2$  degenerates to a union of two disjoint surfaces (particle decay in string model inspired picture), vacuum functional decomposes into a product of the vacuum functionals associated with disjoint surfaces.
6. Elementary particle vacuum functionals are stable against the decay  $g \rightarrow g_1 + g_2$  and one particle decay  $g \rightarrow g - 1$ . This process corresponds to genuine particle decay only for stringy diagrams. For generalized Feynman diagrams the interpretation is in terms of propagation along two different paths simultaneously.

In [K16] the construction of elementary particle vacuum functionals is described in more detail. This requires some basic concepts related to the description of the space of the conformal equivalence classes of Riemann surfaces and the concept of hyper-ellipticity. Since theta functions will play a central role in the construction of the vacuum functionals, also their basic properties are needed. Also possible explanations for the experimental absence of the higher fermion families are considered.

## 5.3 Non-topological contributions to particle masses from p-adic thermodynamics

In TGD framework p-adic thermodynamics provides a microscopic theory of particle massivation in the case of fermions. The idea is very simple. The mass of the particle results from a thermal mixing of the massless states with  $CP_2$  mass excitations of super-conformal algebra. In p-adic thermodynamics the Boltzmann weight  $\exp(-E/T)$  does not exist in general and must be replaced with  $p^{L_0/T_p}$  which exists for Virasoro generator  $L_0$  if the inverse of the p-adic temperature is integer valued  $T_p = 1/n$ . The expansion in powers of  $p$  converges extremely rapidly for physical values of  $p$ , which are rather large. Therefore the three lowest terms in expansion give practically exact results. Thermal massivation

does not not necessarily lead to light states and this drops a large number of exotic states from the spectrum of light particles. The partition functions of N-S and Ramond type representations are not changed in TGD framework despite the fact that fermionic super generators carry fermion numbers and are not Hermitian. Thus the practical calculations are relatively straightforward.

In free fermion picture the p-adic thermodynamics in the boson sector is for fermion-antifermion states associated with the two throats of the bosonic wormhole. The question is whether the thermodynamical mass squared is just the sum of the two independent fermionic contributions for Ramond representations or should one use N-S type representation resulting as a tensor product of Ramond representations.

The overall conclusion about p-adic mass calculations is that fermionic mass spectrum is predicted in an excellent accuracy but that the thermal masses of the intermediate gauge bosons come 20-30 per cent to large for  $T_p = 1$  and are completely negligible for  $T_p = 1/2$ . This forces to consider very seriously the possibility that thermal contribution to the bosonic mass is negligible and that TGD can, contrary to the original expectations, provide dynamical Higgs field as a fundamental field. The identification of Higgs as wormhole contact would provide this field. The bound state character of the boson states could be responsible for  $T_p < 1$ . For this option the Higgs contribution to fermion masses would be negligible.

A more plausible option is based on the identification of the Higgs like contribution in terms of the deviation of the ground state conformal weight from negative half integer. The negative ground state conformal weights in turn correspond to the squares of the generalized eigenvalues of the modified Dirac operator determined by the dynamics of Kähler action for preferred extremals.

A microscopic theory explaining the non-half integer contribution to the conformal weight follows from the identification of the physical elementary particles in terms of pairs of wormhole contacts with upper and lower throat pairs connected by Kähler magnetic flux tubes. This requires zero energy ontology, weak form of electric-magnetic duality, and twistor approach as theoretical ingredients. This gives also a nice connection with Higgs mechanism. TGD predicts scalar and pseudo scalar Higgs which correspond to SU(2) triplet and singlet and therefore same representations of SU(2) as electroweak gauge bosons. Higgs vacuum expectation is not needed and there are strong reasons to believe that also gauge bosons regarded usually as massless receive a small mass and scalar Higgs boson disappears completely from the spectrum. This could happen also for Higgsinos if they combine with gauginos to form massive fermions. Only pseudo scalar Higgs and its super partner would remain in the spectrum for this option unless they combine with possibly existing massless axial gauge bosons and their super partners to form massive states.

### 5.3.1 Partition functions are not changed

One must write Super Virasoro conditions for  $L_n$  and *both*  $G_n$  and  $G_n^\dagger$  rather than for  $L_n$  and  $G_n$  as in the case of the ordinary Super Virasoro algebra, and it is a priori not at all clear whether the partition functions for the Super Virasoro representations remain unchanged. This requirement is however crucial for the construction to work at all in the fermionic sector, since even the slightest changes for the degeneracies of the excited states can change light state to a state with mass of order  $m_0$  in the p-adic thermodynamics.

#### Super conformal algebra

Super Virasoro algebra is generated by the bosonic the generators  $L_n$  ( $n$  is an integer valued index) and by the fermionic generators  $G_r$ , where  $r$  can be either integer (Ramond) or half odd integer (NS).  $G_r$  creates quark/lepton for  $r > 0$  and antiquark/antilepton for  $r < 0$ . For  $r = 0$ ,  $G_0$  creates lepton and its Hermitian conjugate anti-lepton. The defining commutation and anti-commutation relations are the following:

$$\begin{aligned}
 [L_m, L_n] &= (m-n)L_{m+n} + \frac{c}{2}m(m^2-1)\delta_{m,-n} , \\
 [L_m, G_r] &= \left(\frac{m}{2} - r\right)G_{m+r} , \\
 [L_m, G_r^\dagger] &= \left(\frac{m}{2} - r\right)G_{m+r}^\dagger , \\
 \{G_r, G_s^\dagger\} &= 2L_{r+s} + \frac{c}{3}\left(r^2 - \frac{1}{4}\right)\delta_{m,-n} , \\
 \{G_r, G_s\} &= 0 , \\
 \{G_r^\dagger, G_s^\dagger\} &= 0 .
 \end{aligned} \tag{5.3.1}$$

By the inspection of these relations one finds some results of a great practical importance.

1. For the Ramond algebra  $G_0, G_1$  and their Hermitian conjugates generate the  $r \geq 0, n \geq 0$  part of the algebra via anti-commutations and commutations. Therefore all what is needed is to assume that Super Virasoro conditions are satisfied for these generators in case that  $G_0$  and  $G_0^\dagger$  annihilate the ground state. Situation changes if the states are *not* annihilated by  $G_0$  and  $G_0^\dagger$  since then one must assume the gauge conditions for both  $L_1, G_1$  and  $G_1^\dagger$  besides the mass shell conditions associated with  $G_0$  and  $G_0^\dagger$ , which however do not affect the number of the Super Virasoro excitations but give mass shell condition and constraints on the state in the cm spin degrees of freedom. This will be assumed in the following. Note that for the ordinary Super Virasoro only the gauge conditions for  $L_1$  and  $G_1$  are needed.
2. NS algebra is generated by  $G_{1/2}$  and  $G_{3/2}$  and their Hermitian conjugates (note that  $G_{3/2}$  cannot be expressed as the commutator of  $L_1$  and  $G_{1/2}$ ) so that only the gauge conditions associated with these generators are needed. For the ordinary Super Virasoro only the conditions for  $G_{1/2}$  and  $G_{3/2}$  are needed.

### Conditions guaranteing that partition functions are not changed

The conditions guaranteing the invariance of the partition functions in the transition to the modified algebra must be such that they reduce the number of the excitations and gauge conditions for a given conformal weight to the same number as in the case of the ordinary Super Virasoro.

1. The requirement that physical states are invariant under  $G \leftrightarrow G^\dagger$  corresponds to the charge conjugation symmetry and is very natural. As a consequence, the gauge conditions for  $G$  and  $G^\dagger$  are not independent and their number reduces by a factor of one half and is the same as in the case of the ordinary Super Virasoro.
2. As far as the number of the thermal excitations for a given conformal weight is considered, the only remaining problem are the operators  $G_n G_n^\dagger$ , which for the ordinary Super Virasoro reduce to  $G_n G_n = L_{2n}$  and do not therefore correspond to independent degrees of freedom. In present case this situation is achieved only if one requires

$$(G_n G_n^\dagger - G_n^\dagger G_n)|phys\rangle = 0 . \tag{5.3.2}$$

It is not clear whether this condition must be posed separately or whether it actually follows from the representation of the Super Virasoro algebra automatically.

### Partition function for Ramond algebra

Under the assumptions just stated, the partition function for the Ramond states not satisfying any gauge conditions

$$Z(t) = 1 + 2t + 4t^2 + 8t^3 + 14t^4 + \dots , \tag{5.3.3}$$

which is identical to that associated with the ordinary Ramond type Super Virasoro.

For a Super Virasoro representation with  $N = 5$  sectors, of main interest in TGD, one has

$$\begin{aligned} Z_N(t) &= Z^{N=5}(t) = \sum D(n)t^n \\ &= 1 + 10t + 60t^2 + 280t^3 + \dots \end{aligned} \quad (5.3.4)$$

The degeneracies for the states satisfying gauge conditions are given by

$$d(n) = D(n) - 2D(n-1) . \quad (5.3.5)$$

corresponding to the gauge conditions for  $L_1$  and  $G_1$ . Applying this formula one obtains for  $N = 5$  sectors

$$d(0) = 1 , \quad d(1) = 8 , \quad d(2) = 40 , \quad d(3) = 160 . \quad (5.3.6)$$

The lowest order contribution to the p-adic mass squared is determined by the ratio

$$r(n) = \frac{D(n+1)}{D(n)} ,$$

where the value of  $n$  depends on the effective vacuum weight of the ground state fermion. Light state is obtained only provided the ratio is integer. The remarkable result is that for lowest lying states the ratio is integer and given by

$$r(1) = 8 , \quad r(2) = 5 , \quad r(3) = 4 . \quad (5.3.7)$$

It turns out that  $r(2) = 5$  gives the best possible lowest order prediction for the charged lepton masses and in this manner one ends up with the condition  $h_{vac} = -3$  for the tachyonic vacuum weight of Super Virasoro.

### Partition function for NS algebra

For NS representations the calculation of the degeneracies of the physical states reduces to the calculation of the partition function for a single particle Super Virasoro

$$Z_{NS}(t) = \sum_n z(n/2)t^{n/2} . \quad (5.3.8)$$

Here  $z(n/2)$  gives the number of Super Virasoro generators having conformal weight  $n/2$ . For a state with  $N$  active sectors (the sectors with a non-vanishing weight for a given ground state) the degeneracies can be read from the N-particle partition function expressible as

$$Z_N(t) = Z^N(t) . \quad (5.3.9)$$

Single particle partition function is given by the expression

$$Z(t) = 1 + t^{1/2} + t + 2t^{3/2} + 3t^2 + 4t^{5/2} + 5t^3 + \dots \quad (5.3.10)$$

Using this representation it is an easy task to calculate the degeneracies for the operators of conformal weight  $\Delta$  acting on a state having  $N$  active sectors.

One can also derive explicit formulas for the degeneracies and calculation gives

$$\begin{aligned}
 D(0, N) &= 1 , & D(1/2, N) &= N , \\
 D(1, N) &= \frac{N(N+1)}{2} , & D(3/2, N) &= \frac{N}{6}(N^2 + 3N + 8) , \\
 D(2, N) &= \frac{N}{2}(N^2 + 2N + 3) , & D(5/2, N) &= 9N(N - 1) , \\
 D(3, N) &= 12N(N - 1) + 2N(N - 1) .
 \end{aligned} \tag{5.3.11}$$

as a function of the conformal weight  $\Delta = 0, 1/2, \dots, 3$ .

The number of states satisfying Super Virasoro gauge conditions created by the operators of a conformal weight  $\Delta$ , when the number of the active sectors is  $N$ , is given by

$$d(\Delta, N) = D(\Delta, N) - D(\Delta - 1/2, N) - D(\Delta - 3/2, N) . \tag{5.3.12}$$

The expression derives from the observation that the physical states satisfying gauge conditions for  $G^{1/2}$ ,  $G^{3/2}$  satisfy the conditions for all Super Virasoro generators. For  $T_p = 1$  light bosons correspond to the integer values of  $d(\Delta + 1, N)/d(\Delta, N)$  in case that massless states correspond to thermal excitations of conformal weight  $\Delta$ : they are obtained for  $\Delta = 0$  only (massless ground state). This is what is required since the thermal degeneracy of the light boson ground state would imply a corresponding factor in the energy density of the black body radiation at very high temperatures. For the physically most interesting nontrivial case with  $N = 2$  two active sectors the degeneracies are

$$d(0, 2) = 1 , \quad d(1, 2) = 1 , \quad d(2, 2) = 3 , \quad d(3, 2) = 4 . \tag{5.3.13}$$

$N, \Delta$	0	1/2	1	3/2	2	5/2	3
2	1	1	1	3	3	4	4
3	1	2	3	9	11		
4	1	3	5	19	26		
5	1	4	10	24	150		

Table 3. Degeneracies  $d(\Delta, N)$  of the operators satisfying NS type gauge conditions as a function of the number  $N$  of the active sectors and of the conformal weight  $\Delta$  of the operator. Only those degeneracies, which are needed in the mass calculation for bosons assuming that they correspond to N-S representations are listed.

### 5.3.2 Fundamental length and mass scales

The basic difference between quantum TGD and super-string models is that the size of  $CP_2$  is not of order Planck length but much larger: of order  $10^{3.5}$  Planck lengths. This conclusion is forced by several consistency arguments, the mass scale of electron, and by the cosmological data allowing to fix the string tension of the cosmic strings which are basic structures in TGD inspired cosmology.

#### The relationship between $CP_2$ radius and fundamental p-adic length scale

One can relate  $CP_2$  'cosmological constant' to the p-adic mass scale: for  $k_L = 1$  one has

$$m_0^2 = \frac{m_1^2}{k_L} = m_1^2 = 2\Lambda . \tag{5.3.14}$$

$k_L = 1$  results also by requiring that p-adic thermodynamics leaves charged leptons light and leads to optimal lowest order prediction for the charged lepton masses.  $\Lambda$  denotes the 'cosmological constant' of  $CP_2$  ( $CP_2$  satisfies Einstein equations  $G^{\alpha\beta} = \Lambda g^{\alpha\beta}$  with cosmological term).

The real counterpart of the p-adic thermal expectation for the mass squared is sensitive to the choice of the unit of p-adic mass squared which is by definition mapped as such to the real unit in canonical identification. Thus an important factor in the p-adic mass calculations is the correct identification of the p-adic mass squared scale, which corresponds to the mass squared unit and hence to the unit of the p-adic numbers. This choice does not affect the spectrum of massless states but can affect the spectrum of light states in case of intermediate gauge bosons.

1. For the choice

$$M^2 = m_0^2 \leftrightarrow 1 \tag{5.3.15}$$

the spectrum of  $L_0$  is integer valued.

2. The requirement that all sufficiently small mass squared values for the color partial waves are mapped to real integers, would fix the value of p-adic mass squared unit to

$$M^2 = \frac{m_0^2}{3} \leftrightarrow 1 . \tag{5.3.16}$$

For this choice the spectrum of  $L_0$  comes in multiples of 3 and it is possible to have a first order contribution to the mass which cannot be of thermal origin (say  $m^2 = p$ ). This indeed seems to happen for electro-weak gauge bosons.

p-Adic mass calculations allow to relate  $m_0$  to electron mass and to Planck mass by the formula

$$\begin{aligned} \frac{m_0}{m_{Pl}} &= \frac{1}{\sqrt{5 + Y_e}} \times 2^{127/2} \times \frac{m_e}{m_{Pl}} , \\ m_{Pl} &= \frac{1}{\sqrt{\hbar G}} . \end{aligned} \tag{5.3.17}$$

For  $Y_e = 0$  this gives  $m_0 = .2437 \times 10^{-3} m_{Pl}$ .

This means that  $CP_2$  radius  $R$  defined by the length  $L = 2\pi R$  of  $CP_2$  geodesic is roughly  $10^{3.5}$  times the Planck length. More precisely, using the relationship

$$\Lambda = \frac{3}{2R^2} = M^2 = m_0^2 ,$$

one obtains for

$$L = 2\pi R = 2\pi \sqrt{\frac{3}{2}} \frac{1}{m_0} \simeq 3.1167 \times 10^4 \sqrt{\hbar G} \text{ for } Y_e = 0 . \tag{5.3.18}$$

The result came as a surprise: the first belief was that  $CP_2$  radius is of order Planck length. It has however turned out that the new identification solved elegantly some long standing problems of TGD.

$Y_e$	0	.5	.7798
$(m_0/m_{Pl})10^3$	.2437	.2323	.2266
$K_R \times 10^{-7}$	2.5262	2.7788	2.9202
$(L_R/\sqrt{\hbar G}) \times 10^{-4}$	3.1580	3.3122	3.3954
$K \times 10^{-7}$	2.4606	2.4606	2.4606
$(L/\sqrt{\hbar G}) \times 10^{-4}$	3.1167	3.1167	3.1167
$K_R/K$	1.0267	1.1293	1.1868

Table 1. Table gives the values of the ratio  $K_R = R^2/G$  and  $CP_2$  geodesic length  $L = 2\pi R$  for  $Y_e \in \{0, 0.5, 0.7798\}$ . Also the ratio of  $K_R/K$ , where  $K = 2 \times 3 \times 5 \times 7 \times 11 \times 13 \times 17 \times 19 \times 23 \times 2^{-3} * (15/17)$  is rational number producing  $R^2/G$  approximately is given.

The value of top quark mass favors  $Y_e = 0$  and  $Y_e = .5$  is largest value of  $Y_e$  marginally consistent with the limits on the value of top quark mass.

### $CP_2$ radius as the fundamental p-adic length scale

The identification of  $CP_2$  radius as the fundamental p-adic length scale is forced by the Super Virasoro invariance. The pleasant surprise was that the identification of the  $CP_2$  size as the fundamental p-adic length scale rather than Planck length solved many long standing problems of older TGD.

1. The earliest formulation predicted cosmic strings with a string tension larger than the critical value giving the angle deficit  $2\pi$  in Einstein's equations and thus excluded by General Relativity. The corrected value of  $CP_2$  radius predicts the value  $k/G$  for the cosmic string tension with  $k$  in the range  $10^{-7} - 10^{-6}$  as required by the TGD inspired model for the galaxy formation solving the galactic dark matter problem.
2. In the earlier formulation there was no idea as how to derive the p-adic length scale  $L \sim 10^{3.5} \sqrt{\hbar G}$  from the basic theory. Now this problem becomes trivial and one has to predict gravitational constant in terms of the p-adic length scale. This follows in principle as a prediction of quantum TGD. In fact, one can deduce  $G$  in terms of the p-adic length scale and the action exponential associated with the  $CP_2$  extremal and gets a correct value if  $\alpha_K$  approaches fine structure constant at electron length scale (due to the fact that electromagnetic field equals to the Kähler field if  $Z^0$  field vanishes).

Besides this, one obtains a precise prediction for the dependence of the Kähler coupling strength on the p-adic length scale by requiring that the gravitational coupling does not depend on the p-adic length scale. p-Adic prime  $p$  in turn has a nice physical interpretation: the critical value of  $\alpha_K$  is same for the zero modes with given  $p$ . As already found, the construction of graviton state allows to understand the small value of the gravitational constant in terms of a de-coherence caused by multi-p fractality reducing the value of the gravitational constant from  $L_p^2$  to  $G$ .

3. p-Adic length scale is also the length scale at which super-symmetry should be restored in standard super-symmetric theories. In TGD this scale corresponds to the transition to Euclidian field theory for  $CP_2$  type extremals. There are strong reasons to believe that sparticles are however absent and that super-symmetry is present only in the sense that super-generators have complex conformal weights with  $Re(h) = \pm 1/2$  rather than  $h = 0$ . The action of this super-symmetry changes the mass of the state by an amount of order  $CP_2$  mass.

### 5.3.3 Color degrees of freedom

The ground states for the Super Virasoro representations correspond to spinor harmonics in  $M^4 \times CP_2$  characterized by momentum and color quantum numbers. The correlation between color and electro-weak quantum numbers is wrong for the spinor harmonics and these states would be also hyper-massive. The super-symplectic generators allow to build color triplet states having negative vacuum conformal weights, and their values are such that p-adic massivation is consistent with the predictions of the earlier model differing from the recent one in the quark sector. In the following the construction and the properties of the color partial waves for fermions and bosons are considered. The discussion follows closely to the discussion of [A10].

### SKM algebra and counterpart of Super Virasoro conditions

The geometric part of SKM algebra is defined as an algebra respecting the light-likeness of the partonic 3-surface. It consists of  $X^3$ -local conformal transformations of  $M^4_{\pm}$  and  $SU(3)$ -local  $SU(3)$  rotations. The requirement that generators have well defined radial conformal weight with respect to the lightlike coordinate  $r$  of  $X^3$  restricts  $M^4$  conformal transformations to the group  $SO(3) \times E^3$ . This involves choice of preferred time coordinate. If the preferred  $M^4$  coordinate is chosen to correspond to a preferred light-like direction in  $\delta M^4_{\pm}$  characterizing the theory, a reduction to  $SO(2) \times E^2$  more familiar from string models occurs. The algebra decomposes into a direct sum of sub-algebras mapped to themselves by the Kac-Moody algebra generated by functions depending on  $r$  only. SKM algebra contains also  $U(2)_{ew}$  Kac-Moody algebra acting as holonomies of  $CP_2$  and having no bosonic counterpart.

p-Adic mass calculations require  $N = 5$  sectors of super-conformal algebra. These sectors correspond to the 5 tensor factors for the  $SO(3) \times E^3 \times SU(3) \times U(2)_{ew}$  (or  $SO(2) \times E^2 \times SU(3) \times U(2)_{ew}$ ) decomposition of the SKM algebra to gauge symmetries of gravitation, color and electro-weak interactions. These symmetries act on the intersections  $X^2 = X^3 \cap X^7$  of 3-D light like causal determinants

(CDs)  $X_l^3$  and 7-D light like CDs  $X^7 = \delta M_+^4 \times CP_2$ . This constraint leaves only the 2 transversal  $M^4$  degrees of freedom since the translations in light like directions associated with  $X_l^3$  and  $\delta M_+^4$  are eliminated.

The algebra differs from the standard one in that super generators  $G(z)$  carry lepton and quark numbers are not Hermitian as in super-string models (Majorana conditions are not satisfied). The counterparts of Ramond representations correspond to zero modes of a second quantized spinor field with vanishing radial conformal weight. Non-zero modes with generalized eigenvalues  $\lambda = 1/2 + iy$ ,  $y = \sum_k n_k y_k$ ,  $n_k \geq 0$ , of the modified Dirac operator with  $s_k = 1/2 + iy_k$  a zero or Riemann Zeta, define ground states of N-S type super Virasoro representations.

What is new is the imaginary part of conformal weight which means that the arrow of geometric time manifests itself via the sign of the imaginary part  $y$  already at elementary particle level. More concretely, positive energy particle propagating to the geometric future is not equivalent with negative energy particle propagating to the geometric past. The strange properties of the phase conjugate provide concrete physical demonstration of this difference. p-Adic mass calculations suggest the interpretation of  $y$  in terms of a decay width of the particle.

The Ramond or N-S type Virasoro conditions satisfied by the physical states in string model approach are replaced by the formulas expressing mass squared as a conformal weight. The condition is not equivalent with super Virasoro conditions since four-momentum does not appear in super Virasoro generators. It seems possible to assume that the commutator algebra  $[SKM, SC]$  and the commutator of  $[SKMV, SSV]$  of corresponding Super Virasoro algebras annihilate physical states. This would give rise to the analog of Super Virasoro conditions which could be seen as a Dirac equation in the world of classical worlds.

### 1. $CP_2$ CM degrees of freedom

Important element in the discussion are center of mass degrees of freedom parameterized by imbedding space coordinates. By the effective 2-dimensionality it is indeed possible to assign to partons momenta and color partial waves and they behave effectively as free particles. In fact, the technical problem of the earlier scenario was that it was not possible to assign symmetry transformations acting only on the boundary components of 3-surface.

One can assign to each eigen state of color quantum numbers a color partial wave in  $CP_2$  degrees of freedom. Thus color quantum numbers are not spin like quantum numbers in TGD framework except effectively in the length scales much longer than  $CP_2$  length scale. The correlation between color partial waves and electro-weak quantum numbers is not physical in general: only the covariantly constant right handed neutrino has vanishing color.

### 2. Mass formula, and condition determining the effective string tension

Mass squared eigenvalues are given by

$$M^2 = m_{CP_2}^2 + kL_0 . \quad (5.3.19)$$

The contribution of  $CP_2$  spinor Laplacian to the mass squared operator is in general not integer valued.

The requirement that mass squared spectrum is integer valued for color partial waves possibly representing light states fixes the possible values of  $k$  determining the effective string tension modulo integer. The value  $k = 1$  is the only possible choice. The earlier choice  $k_L = 1$  and  $k_q = 2/3$ ,  $k_B = 1$  gave integer conformal weights for the lowest possible color partial waves. The assumption that the total vacuum weight  $h_{vac}$  is conserved in particle vertices implied  $k_B = 1$ .

## General construction of solutions of Dirac operator of $H$

The construction of the solutions of massless spinor and other d'Alembertians in  $M_+^4 \times CP_2$  is based on the following observations.

1. d'Alembertian corresponds to a massless wave equation  $M^4 \times CP_2$  and thus Kaluza-Klein picture applies, that is  $M_+^4$  mass is generated from the momentum in  $CP_2$  degrees of freedom. This implies mass quantization:

$$M^2 = M_n^2 ,$$

where  $M_n^2$  are eigenvalues of  $CP_2$  Laplacian. Here of course, ordinary field theory is considered. In TGD the vacuum weight changes mass squared spectrum.

2. In order to get a respectable spinor structure in  $CP_2$  one must couple  $CP_2$  spinors to an odd integer multiple of the Kähler potential. Leptons and quarks correspond to  $n = 3$  and  $n = 1$  couplings respectively. The spectrum of the electromagnetic charge comes out correctly for leptons and quarks.
3. Right handed neutrino is covariantly constant solution of  $CP_2$  Laplacian for  $n = 3$  coupling to Kähler potential whereas right handed 'electron' corresponds to the covariantly constant solution for  $n = -3$ . From the covariant constancy it follows that all solutions of the spinor Laplacian are obtained from these two basic solutions by multiplying with an appropriate solution of the scalar Laplacian coupled to Kähler potential with such a coupling that a correct total Kähler charge results. Left handed solutions of spinor Laplacian are obtained simply by multiplying right handed solutions with  $CP_2$  Dirac operator: in this operation the eigenvalues of the mass squared operator are obviously preserved.
4. The remaining task is to solve scalar Laplacian coupled to an arbitrary integer multiple of Kähler potential. This can be achieved by noticing that the solutions of the massive  $CP_2$  Laplacian can be regarded as solutions of  $S^5$  scalar Laplacian.  $S^5$  can indeed be regarded as a circle bundle over  $CP_2$  and massive solutions of  $CP_2$  Laplacian correspond to the solutions of  $S^5$  Laplacian with  $\exp(is\tau)$  dependence on  $S^1$  coordinate such that  $s$  corresponds to the coupling to the Kähler potential:

$$s = n/2 .$$

Thus one obtains

$$D_5^2 = (D_\mu - iA_\mu \partial_\tau)(D^\mu - iA^\mu \partial_\tau) + \partial_\tau^2 \quad (5.3.20)$$

so that the eigen values of  $CP_2$  scalar Laplacian are

$$m^2(s) = m_5^2 + s^2 \quad (5.3.21)$$

for the assumed dependence on  $\tau$ .

5. What remains to do, is to find the spectrum of  $S^5$  Laplacian and this is an easy task. All solutions of  $S^5$  Laplacian can be written as homogenous polynomial functions of  $C^3$  complex coordinates  $Z^k$  and their complex conjugates and have a decomposition into the representations of  $SU(3)$  acting in natural manner in  $C^3$ .
6. The solutions of the scalar Laplacian belong to the representations  $(p, p + s)$  for  $s \geq 0$  and to the representations  $(p + |s|, p)$  of  $SU(3)$  for  $s \leq 0$ . The eigenvalues  $m^2(s)$  and degeneracies  $d$  are

$$\begin{aligned} m^2(s) &= \frac{2\Lambda}{3}[p^2 + (|s| + 2)p + |s|] , \quad p > 0 , \\ d &= \frac{1}{2}(p + 1)(p + |s| + 1)(2p + |s| + 2) . \end{aligned} \quad (5.3.22)$$

$\Lambda$  denotes the 'cosmological constant' of  $CP_2$  ( $R_{ij} = \Lambda s_{ij}$ ).

### Solutions of the leptonic spinor Laplacian

Right handed solutions of the leptonic spinor Laplacian are obtained from the ansatz of form

$$\nu_R = \Phi_{s=0} \nu_R^0 ,$$

where  $u_R$  is covariantly constant right handed neutrino and  $\Phi$  scalar with vanishing Kähler charge. Right handed 'electron' is obtained from the ansatz

$$e_R = \Phi_{s=3} e_R^0 ,$$

where  $e_R^0$  is covariantly constant for  $n = -3$  coupling to Kähler potential so that scalar function must have Kähler coupling  $s = n/2 = 3$  in order to get a correct Kähler charge. The d'Alembert equation reduces to

$$\begin{aligned} (D_\mu D^\mu - (1 - \epsilon)\Lambda)\Phi &= -m^2\Phi , \\ \epsilon(\nu) &= 1 , \quad \epsilon(e) = -1 . \end{aligned} \tag{5.3.23}$$

The two additional terms correspond to the curvature scalar term and  $J_{kl}\Sigma^{kl}$  terms in spinor Laplacian. The latter term is proportional to Kähler coupling and of different sign for  $\nu$  and  $e$ , which explains the presence of the sign factor  $\epsilon$  in the formula.

Right handed neutrinos correspond to  $(p, p)$  states with  $p \geq 0$  with mass spectrum

$$\begin{aligned} m^2(\nu) &= \frac{m_1^2}{3} [p^2 + 2p] , \quad p \geq 0 , \\ m_1^2 &\equiv 2\Lambda . \end{aligned} \tag{5.3.24}$$

Right handed 'electrons' correspond to  $(p, p+3)$  states with mass spectrum

$$m^2(e) = \frac{m_1^2}{3} [p^2 + 5p + 6] , \quad p \geq 0 . \tag{5.3.25}$$

Left handed solutions are obtained by operating with  $CP_2$  Dirac operator on right handed solutions and have the same mass spectrum and representational content as right handed leptons with one exception: the action of the Dirac operator on the covariantly constant right handed neutrino ( $(p=0, p=0)$  state) annihilates it.

### Quark spectrum

Quarks correspond to the second conserved  $H$ -chirality of  $H$ -spinors. The construction of the color partial waves for quarks proceeds along similar lines as for leptons. The Kähler coupling corresponds to  $n = 1$  (and  $s = 1/2$ ) and right handed  $U$  type quark corresponds to a right handed neutrino.  $U$  quark type solutions are constructed as solutions of form

$$U_R = u_R \Phi_{s=1} ,$$

where  $u_R$  possesses the quantum numbers of covariantly constant right handed neutrino with Kähler charge  $n = 3$  ( $s = 3/2$ ). Hence  $\Phi_s$  has  $s = -1$ . For  $D_R$  one has

$$D_R = d_r \Phi_{s=2} .$$

$d_R$  has  $s = -3/2$  so that one must have  $s = 2$ . For  $U_R$  the representations  $(p+1, p)$  with triality one are obtained and  $p = 0$  corresponds to color triplet. For  $D_R$  the representations  $(p, p+2)$  are obtained and color triplet is missing from the spectrum ( $p = 0$  corresponds to  $\bar{6}$ ).

The  $CP_2$  contributions to masses are given by the formula

$$\begin{aligned}
 m^2(U, p) &= \frac{m_1^2}{3} [p^2 + 3p + 2] \quad , \quad p \geq 0 \quad , \\
 m^2(D, p) &= \frac{m_1^2}{3} [p^2 + 4p + 4] \quad , \quad p \geq 0 \quad .
 \end{aligned}
 \tag{5.3.26}$$

Left handed quarks are obtained by applying Dirac operator to right handed quark states and mass formulas and color partial wave spectrum are the same as for right handed quarks.

The color contributions to p-adic mass squared are integer valued if  $m_0^2/3$  is taken as a fundamental p-adic unit of mass squared. This choice has an obvious relevance for p-adic mass calculations since canonical identification does not commute with a division by integer. More precisely, the images of number  $xp$  in canonical identification has a value of order 1 when  $x$  is a non-trivial rational whereas for  $x = np$  the value is  $n/p$  and extremely is small for physically interesting primes. This choice does not however affect the spectrum of massless states but can affect the spectrum of light states in case of electro-weak gauge bosons.

### 5.3.4 Spectrum of elementary particles

The assumption that  $k = 1$  holds true for all particles forces to modify the earlier construction of quark states. This turns out to be possible without affecting the p-adic mass calculations whose outcome depend in an essential manner on the ground state conformal weights  $h_{gr}$  of the fermions (which can be negative).

#### Leptonic spectrum

For  $k = 1$  the leptonic mass squared is integer valued in units of  $m_0^2$  only for the states satisfying

$$p \bmod 3 \neq 2 \quad .$$

Only these representations can give rise to massless states. Neutrinos correspond to  $(p, p)$  representations with  $p \geq 1$  whereas charged leptons correspond to  $(p, p + 3)$  representations. The earlier mass calculations demonstrate that leptonic masses can be understood if the ground state conformal weight is  $h_{gr} = -1$  for charged leptons and  $h_{gr} = -2$  for neutrinos.

The contribution of color partial wave to conformal weight is  $h_c = (p^2 + 2p)/3$ ,  $p \geq 1$ , for neutrinos and  $p = 1$  gives  $h_c = 1$  (octet). For charged leptons  $h_c = (p^2 + 5p + 6)/3$  gives  $h_c = 2$  for  $p = 0$  (decuplet). In both cases super-symplectic operator  $O$  must have a net conformal weight  $h_{sc} = -3$  to produce a correct conformal weight for the ground state. p-adic considerations suggests the use of operators  $O$  with super-symplectic conformal weight  $z = -1/2 - i \sum n_k y_k$ , where  $s_k = 1/2 + iy_k$  corresponds to zero of Riemann  $\zeta$ . If the operators in question are color Hamiltonians in octet representation net super-symplectic conformal weight  $h_{sc} = -3$  results. The tensor product of two octets with conjugate super-symplectic conformal weights contains both octet and decuplet so that singlets are obtained. What strengthens the hopes that the construction is not adhoc is that the same operator appears in the construction of quark states too.

Right handed neutrino remains essentially massless.  $p = 0$  right handed neutrino does not however generate  $N = 1$  space-time (or rather, imbedding space) super symmetry so that no sparticles are predicted. The breaking of the electro-weak symmetry at the level of the masses comes out basically from the anomalous color electro-weak correlation for the Kaluza-Klein partial waves implying that the weights for the ground states of the fermions depend on the electromagnetic charge of the fermion. Interestingly, TGD predicts leptohadron physics based on color excitations of leptons and color bound states of these excitations could correspond topologically condensed on string like objects but not fundamental string like objects.

#### Spectrum of quarks

Earlier arguments [K46] related to a model of CKM matrix as a rational unitary matrix suggested that the string tension parameter  $k$  is different for quarks, leptons, and bosons. The basic mass formula read as

$$M^2 = m_{CP_2}^2 + kL_0 .$$

The values of  $k$  were  $k_q = 2/3$  and  $k_L = k_B = 1$ . The general theory however predicts that  $k = 1$  for all particles.

1. By earlier mass calculations and construction of CKM matrix the ground state conformal weights of  $U$  and  $D$  type quarks must be  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$ . The formulas for the eigenvalues of  $CP_2$  spinor Laplacian imply that if  $m_0^2$  is used as unit, color conformal weight  $h_c \equiv m_{CP_2}^2$  is integer for  $p \bmod = \pm 1$  for  $U$  type quark belonging to  $(p+1, p)$  type representation and obeying  $h_c(U) = (p^2 + 3p + 2)/3$  and for  $p \bmod 3 = 1$  for  $D$  type quark belonging  $(p, p+2)$  type representation and obeying  $h_c(D) = (p^2 + 4p + 4)/3$ . Only these states can be massless since color Hamiltonians have integer valued conformal weights.
2. In the recent case  $p = 1$  states correspond to  $h_c(U) = 2$  and  $h_c(D) = 3$ .  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$  reproduce the previous results for quark masses required by the construction of CKM matrix. This forces the super-symplectic operator  $O$  to compensate the anomalous color to have a net conformal weight  $h_{sc} = -3$  just as in the leptonic case. The facts that the values of  $p$  are minimal for spinor harmonics and the super-symplectic operator is same for both quarks and leptons suggest that the construction is not had hoc. The real justification would come from the demonstration that  $h_{sc} = -3$  defines null state for SSV: this would also explain why  $h_{sc}$  would be same for all fermions.
3. It would seem that the tensor product of the spinor harmonic of quarks (as also leptons) with Hamiltonians gives rise to a large number of exotic colored states which have same thermodynamical mass as ordinary quarks (and leptons). Why these states have smaller values of p-adic prime than ordinary quarks and leptons, remains a challenge for the theory. Note that the decay widths of intermediate gauge bosons pose strong restrictions on the possible color excitations of quarks. On the other hand, the large number of fermionic color exotics can spoil the asymptotic freedom, and it is possible to have an entire p-adic length scale hierarchy of QCDs existing only in a finite length scale range without affecting the decay widths of gauge bosons.

The following table summarizes the color conformal weights and super-symplectic vacuum conformal weights for the elementary particles.

	$L$	$\nu_L$	$U$	$D$	$W$	$\gamma, G, g$
$h_{vac}$	-3	-3	-3	-3	-2	0
$h_c$	2	1	2	3	2	0

Table 2. The values of the parameters  $h_{vac}$  and  $h_c$  assuming that  $k = 1$ . The value of  $h_{vac} \leq -h_c$  is determined from the requirement that p-adic mass calculations give best possible fit to the mass spectrum.

### Photon, graviton and gluon

For photon, gluon and graviton the conformal weight of the  $p = 0$  ground state is  $h_{gr} = h_{vac} = 0$ . The crucial condition is that  $h = 0$  ground state is non-degenerate: otherwise one would obtain several physically more or less identical photons and this would be seen in the spectrum of black-body radiation. This occurs if one can construct several ground states not expressible in terms of the action of the Super Virasoro generators.

Masslessness or approximate masslessness requires low enough temperature  $T_p = 1/n$ ,  $n > 1$  at least and small enough value of the possible contribution coming from the ground state conformal weight.

In NS thermodynamics the only possibility to get exactly massless states in thermal sense is to have  $\Delta = 0$  state with one active sector so that NS thermodynamics becomes trivial due to the absence of the thermodynamical excitations satisfying the gauge conditions. For neutral gauge bosons this is indeed achieved. For  $T_p = 1/2$ , which is required by the mass spectrum of intermediate gauge bosons, the thermal contribution to the mass squared is however extremely small even for  $W$  boson.

### 5.3.5 Some probabilistic considerations

There are uniqueness problems related to the mapping of p-adic probabilities to real ones. These problems find a nice resolution from the requirement that the map respects probability conservation. The implied modification of the original mapping does not change measurably the predictions for the masses of light particles.

#### How unique the map of p-adic probabilities and mass squared values are mapped to real numbers is?

The mapping of p-adic thermodynamical probabilities and mass squared values to real numbers is not completely unique.

1. Canonical identification  $I : \sum x_n p^n \rightarrow \sum x_n p^{-n}$  takes care of this mapping but does not respect the sum of probabilities so that the real images  $I(p_n)$  of the probabilities must be normalized. This is a somewhat alarming feature.
2. The modification of the canonical identification mapping rationals by the formula  $I(r/s) = I(r)/I(s)$  has appeared naturally in various applications, in particular because it respects unitarity of unitary matrices with rational elements with  $r < p, s < p$ . In the case of p-adic thermodynamic the formula  $I(g(n)p^n/Z) \rightarrow I(g(n)p^n)/I(Z)$  would be very natural although  $Z$  need not be rational anymore. For  $g(n) < p$  the real counterparts of the p-adic probabilities would sum up to one automatically for this option. One cannot deny that this option is more convincing than the original one. The generalization of this formula to map p-adic mass squared to a real one is obvious.
3. Options 1) and 2) differ dramatically when the  $n = 0$  massless ground state has ground state degeneracy  $D > 1$ . For option 1) the real mass is predicted to be of order  $CP_2$  mass whereas for option 2) it would be by a factor  $1/D$  smaller than the minimum mass predicted by the option a). Thus option 2) would predict a large number of additional exotic states. For those states which are light for option 1), the two options make identical predictions as far as the significant two lowest order terms are considered. Hence this interpretation would not change the predictions of the p-adic mass calculations in this respect. Option 2) is definitely more in accord with the real physics based intuitions and the main role of p-adic thermodynamics would be to guarantee the quantization of the temperature and fix practically uniquely the spectrum of the "Hamiltonian".

#### Under what conditions the mapping of p-adic ensemble probabilities to real probabilities respects probability conservation?

One can consider also a more general situation. Assume that one has an ensemble consisting of independent elementary events such that the number of events of type  $i$  is  $N_i$ . The probabilities are given by  $p_i = N_i/N$  and  $N = \sum N_i$  is the total number of elementary events. Even in the case that  $N$  is infinite as a real number it is natural to map the p-adic probabilities to their real counterparts using the rational canonical identification  $I(p_i) = I(N_i)/I(N)$ . Of course,  $N_i$  and  $N$  exist as well defined p-adic numbers under very stringent conditions only.

The question is under what conditions this map respects probability conservation. The answer becomes obvious by looking at the pinary expansions of  $N_i$  and  $N$ . If the integers  $N_i$  (possibly infinite as real integers) have pinary expansions having no common pinary digits, the sum of probabilities is conserved in the map. Note that this condition can assign also to a finite ensemble with finite number of a unique value of  $p$ .

This means that the selection of a basis for independent events corresponds to a decomposition of the set of integers labelling pinary digits to disjoint sets and brings in mind the selection of orthonormalized basis of quantum states in quantum theory. What is physically highly non-trivial that this "orthogonalization" alone puts strong constraints on probabilities of the allowed elementary events. One can say that the probabilities define distributions of pinary digits analogous to non-negative probability amplitudes in the space of integers labelling pinary digits, and the probabilities of independent events must be orthogonal with respect to the inner product defined by point-wise multiplication in the space of pinary digits.

p-Adic thermodynamics for which Boltzman weights  $g(E)exp(-E/T)$  are replaced by  $g(E)p^{E/T}$  such that one has  $g(E) < p$  and  $E/T$  is integer valued, satisfies this constraint. The quantization of  $E/T$  to integer values implies quantization of both  $T$  and "energy" spectrum and forces so called super conformal invariance in TGD applications, which is indeed a basic symmetry of the theory.

There are infinitely many ways to choose the elementary events and each choice corresponds to a decomposition of the infinite set of integers  $n$  labelling the powers of  $p$  to disjoint subsets. These subsets can be also infinite. One can assign to this kind of decomposition a resolution which is the poorer the larger the subsets involved are. p-Adic thermodynamics would represent the situation in which the resolution is maximal since each set contains only single binary digit. Note the analogy with the basis of completely localized wave functions in a lattice.

## 5.4 Modular contribution to the mass squared

The success of the p-adic mass calculations gives convincing support for the generation-genus correspondence. The basic physical picture is following.

1. Fermionic mass squared is dominated by partonic contribution, which is sum of cm and modular contributions:  $M^2 = M^2(cm) + M^2(mod)$ . Here 'cm' refers to the thermal contribution. Modular contribution can be assumed to depend on the genus of the boundary component only.
2. If Higgs contribution for diagonal  $(g, g)$  bosons (singlets with respect to "topological"  $SU(3)$ ) dominates, the genus dependent contribution can be assumed to be negligible. This should be due to the bound state character of the wormhole contacts reducing thermal motion and thus the p-adic temperature.
3. Modular contribution to the mass squared can be estimated apart from an overall proportionality constant. The mass scale of the contribution is fixed by the p-adic length scale hypothesis. Elementary particle vacuum functionals are proportional to a product of all even theta functions and their conjugates, the number of even theta functions and their conjugates being  $2N(g) = 2^g(2^g + 1)$ . Also the thermal partition function must also be proportional to  $2N(g)$ :th power of some elementary partition function. This implies that thermal/ quantum expectation  $M^2(mod)$  must be proportional to  $2N(g)$ . Since single handle behaves effectively as particle, the contribution must be proportional to genus  $g$  also. The success of the resulting mass formula encourages the belief that the argument is essentially correct.

The challenge is to construct theoretical framework reproducing the modular contribution to mass squared. There are two alternative manners to understand the origin modular contribution.

1. The realization that super-symplectic algebra is relevant for elementary particle physics leads to the idea that two thermodynamics are involved with the calculation of the vacuum conformal weight as a thermal expectation. The first thermodynamics corresponds to Super Kac-Moody algebra and second thermodynamics to super-symplectic algebra. This approach allows a first principle understanding of the origin and general form of the modular contribution without any need to introduce additional structures in modular degrees of freedom. The very fact that super-symplectic algebra does not commute with the modular degrees of freedom explains the dependence of the super-symplectic contribution on moduli.
2. The earlier approach was based on the idea that the modular contribution could be regarded as a quantum mechanical expectation value of the Virasoro generator  $L_0$  for the elementary particle vacuum functional. Quantum treatment would require generalization the concepts of the moduli space and theta function to the p-adic context and finding an acceptable definition of the Virasoro generator  $L_0$  in modular degrees of freedom. The problem with this interpretation is that it forces to introduce, not only Virasoro generator  $L_0$ , but the entire super Virasoro algebra in modular degrees of freedom. One could also consider of interpreting the contribution of modular degrees of freedom to vacuum conformal weight as being analogous to that of  $CP_2$  Laplacian but also this would raise the challenge of constructing corresponding Dirac operator. Obviously this approach has become obsolete.

The thermodynamical treatment taking into account the constraints from that p-adicization is possible might go along following lines.

1. In the real case the basic quantity is the thermal expectation value  $h(M)$  of the conformal weight as a function of moduli. The average value of the deviation  $\Delta h(M) = h(M) - h(M_0)$  over moduli space  $\mathcal{M}$  must be calculated using elementary particle vacuum functional as a modular invariant partition function. Modular invariance is achieved if this function is proportional to the logarithm of elementary particle vacuum functional: this reproduces the qualitative features basic formula for the modular contribution to the conformal weight. p-Adicization leads to a slight modification of this formula.
2. The challenge of algebraically continuing this calculation to the p-adic context involves several sub-tasks. The notions of moduli space  $\mathcal{M}_p$  and theta function must be defined in the p-adic context. An appropriately defined logarithm of the p-adic elementary particle vacuum functional should determine  $\Delta h(M)$ . The average of  $\Delta h(M)$  requires an integration over  $\mathcal{M}_p$ . The problems related to the definition of this integral could be circumvented if the integral in the real case could be reduced to an algebraic expression, or if the moduli space is discrete in which case integral could be replaced by a sum.
3. The number theoretic existence of the p-adic  $\Theta$  function leads to the quantization of the moduli so that the p-adic moduli space is discretized. Accepting the sharpened form of Riemann hypothesis [?], the quantization means that the imaginary *resp.* real parts of the moduli are proportional to integers *resp.* combinations of imaginary parts of zeros of Riemann Zeta. This quantization could occur also for the real moduli for the maxima of Kähler function. This reduces the problematic p-adic integration to a sum and the resulting sum defining  $\langle \Delta h \rangle$  converges extremely rapidly for physically interesting primes so that only the few lowest terms are needed.

### 5.4.1 Conformal symmetries and modular invariance

The full SKM invariance means that the super-conformal fields depend only on the conformal moduli of 2-surface characterizing the conformal equivalence class of the 2-surface. This means that all induced metrics differing by a mere Weyl scaling have same moduli. This symmetry is extremely powerful since the space of moduli is finite-dimensional and means that the entire infinite-dimensional space of deformations of parton 2-surface  $X^2$  degenerates to a finite-dimensional moduli spaces under conformal equivalence. Obviously, the configurations of given parton correspond to a fiber space having moduli space as a base space. Super-symplectic degrees of freedom could break conformal invariance in some appropriate sense.

#### Conformal and SKM symmetries leave moduli invariant

Conformal transformations and super Kac Moody symmetries must leave the moduli invariant. This means that they induce a mere Weyl scaling of the induced metric of  $X^2$  and thus preserve its non-diagonal character  $ds^2 = g_{z\bar{z}} dz d\bar{z}$ . This is indeed true if

1. the Super Kac Moody symmetries are holomorphic isometries of  $X^7 = \delta M_{\pm}^4 \times CP_2$  made local with respect to the complex coordinate  $z$  of  $X^2$ , and
2. the complex coordinates of  $X^7$  are holomorphic functions of  $z$ .

Using complex coordinates for  $X^7$  the infinitesimal generators can be written in the form

$$J^{An} = z^n j^{Ak} D_k + \bar{z}^n j^{A\bar{k}} D_{\bar{k}} . \quad (5.4.1)$$

The intuitive picture is that it should be possible to choose  $X^2$  freely. It is however not always possible to choose the coordinate  $z$  of  $X^2$  in such a manner that  $X^7$  coordinates are holomorphic functions of  $z$  since a consistency of inherent complex structure of  $X^2$  with that induced from  $X^7$  is required. Geometrically this is like meeting of two points in the space of moduli.

Lorentz boosts produce new inequivalent choices of  $S^2$  with their own complex coordinate: this set of complex structures is parameterized by the hyperboloid of future light cone (Lobatchevski space or

mass shell), but even this is not enough. The most plausible manner to circumvent the problem is that only the maxima of Kähler function correspond to the holomorphic situation so that super-symplectic algebra representing quantum fluctuations would induce conformal anomaly.

### The isometries of $\delta M_+^4$ are in one-one correspondence with conformal transformations

For  $CP_2$  factor the isometries reduce to  $SU(3)$  group acting also as symplectic transformations. For  $\delta M_+^4 = S^2 \times R_+$  one might expect that isometries reduce to Lorentz group containing rotation group of  $SO(3)$  as conformal isometries. If  $r_M$  corresponds to a macroscopic length scale, then  $X^2$  has a finite sized  $S^2$  projection which spans a rather small solid angle so that group  $SO(3)$  reduces in a good approximation to the group  $E^2 \times SO(2)$  of translations and rotations of plane.

This expectation is however wrong! The light-likeness of  $\delta M_+^4$  allows a dramatic generalization of the notion of isometry. The point is that the conformal transformations of  $S^2$  induce a conformal factor  $|df/dw|^2$  to the metric of  $\delta M_+^4$  and the local radial scaling  $r_M \rightarrow r_M/|df/dw|$  compensates it. Hence the group of conformal isometries consists of conformal transformations of  $S^2$  with compensating radial scalings. This compensation of two kinds of conformal transformations is the deep geometric phenomenon which translates to the condition  $L_{SC} - L_{SKM} = 0$  in the sub-space of physical states. Note that an analogous phenomenon occurs also for the light-like CDs  $X_l^3$  with respect to the metrically 2-dimensional induced metric.

The  $X^2$ -local radial scalings  $r_M \rightarrow r_M(z, \bar{z})$  respect the conditions  $g_{zz} = g_{\bar{z}\bar{z}} = 0$  so that a mere Weyl scaling leaving moduli invariant results. By multiplying the conformal isometries of  $\delta M_+^4$  by  $z^n$  ( $z$  is used as a complex coordinate for  $X^2$  and  $w$  as a complex coordinate for  $S^2$ ) a conformal localization of conformal isometries would result. Kind of double conformal transformations would be in question. Note however that this requires that  $X^7$  coordinates are holomorphic functions of  $X^2$  coordinate. These transformations deform  $X^2$  unlike the conformal transformations of  $X^2$ . For  $X_l^3$  similar local scalings of the light like coordinate leave the moduli invariant but lead out of  $X^7$ .

### Symplectic transformations break the conformal invariance

In general, infinitesimal symplectic transformations induce non-vanishing components  $g_{zz}, g_{\bar{z}\bar{z}}$  of the induced metric and can thus change the moduli of  $X^2$ . Thus the quantum fluctuations represented by super-symplectic algebra and contributing to the configuration space metric are in general moduli changing. It would be interesting to know explicitly the conditions (the number of which is the dimension of moduli space for a given genus), which guarantee that the infinitesimal symplectic transformation is moduli preserving.

#### 5.4.2 The physical origin of the genus dependent contribution to the mass squared

Different p-adic length scales are not enough to explain the charged lepton mass ratios and an additional genus dependent contribution in the fermionic mass formula is required. The general form of this contribution can be guessed by regarding elementary particle vacuum functionals in the modular degrees of freedom as an analog of partition function and the modular contribution to the conformal weight as an analog of thermal energy obtained by averaging over moduli. p-Adic length scale hypothesis determines the overall scale of the contribution.

The exact physical origin of this contribution has remained mysterious but super-symplectic degrees of freedom represent a good candidate for the physical origin of this contribution. This would mean a sigh of relief since there would be no need to assign conformal weights, super-algebra, Dirac operators, Laplacians, etc.. with these degrees of freedom.

### Thermodynamics in super-symplectic degrees of freedom as the origin of the modular contribution to the mass squared

The following general picture is the simplest found hitherto.

1. Elementary particle vacuum functionals are defined in the space of moduli of surfaces  $X^2$  corresponding to the maxima of Kähler function. There some restrictions on  $X^2$ . In particular, p-adic length scale poses restrictions on the size of  $X^2$ . There is an infinite hierarchy of elementary

particle vacuum functionals satisfying the general constraints but only the lowest elementary particle vacuum functionals are assumed to contribute significantly to the vacuum expectation value of conformal weight determining the mass squared value.

2. The contribution of Super-Kac Moody thermodynamics to the vacuum conformal weight  $h$  coming from Virasoro excitations of the  $h = 0$  massless state is estimated in the previous calculations and does not depend on moduli. The new element is that for a partonic 2-surface  $X^2$  with given moduli, Virasoro thermodynamics is present also in super-symplectic degrees of freedom.

Super-symplectic thermodynamics means that, besides the ground state with  $h_{gr} = -h_{SC}$  with minimal value of super-symplectic conformal weight  $h_{SC}$ , also thermal excitations of this state by super-symplectic Virasoro algebra having  $h_{gr} = -h_{SC} - n$  are possible. For these ground states the SKM Virasoro generators creating states with net conformal weight  $h = h_{SKM} - h_{SC} - n \geq 0$  have larger conformal weight so that the SKM thermal average  $h$  depends on  $n$ . It depends also on the moduli  $M$  of  $X^2$  since the Beltrami differentials representing a tangent space basis for the moduli space  $\mathcal{M}$  do not commute with the super-symplectic algebra. Hence the thermally averaged SKM conformal weight  $h_{SKM}$  for given values of moduli satisfies

$$h_{SKM} = h(n, M) . \quad (5.4.2)$$

3. The average conformal weight induced by this double thermodynamics can be expressed as a super-symplectic thermal average  $\langle \cdot \rangle_{SC}$  of the SKM thermal average  $h(n, M)$ :

$$h(M) = \langle h(n, M) \rangle_{SC} = \sum p_n(M) h(n) , \quad (5.4.3)$$

where the moduli dependent probability  $p_n(M)$  of the super-symplectic Virasoro excitation with conformal weight  $n$  should be consistent with the p-adic thermodynamics. It is convenient to write  $h(M)$  as

$$h(M) = h_0 + \Delta h(M) , \quad (5.4.4)$$

where  $h_0$  is the minimum value of  $h(M)$  in the space of moduli. The form of the elementary particle vacuum functionals suggest that  $h_0$  corresponds to moduli with  $Im(\Omega_{ij}) = 0$  and thus to singular configurations for which handles degenerate to one-dimensional lines attached to a sphere.

4. There is a further averaging of  $\Delta h(M)$  over the moduli space  $\mathcal{M}$  by using the modulus squared of elementary particle vacuum functional so that one has

$$h = h_0 + \langle \Delta h(M) \rangle_{\mathcal{M}} . \quad (5.4.5)$$

Modular invariance allows to pose very strong conditions on the functional form of  $\Delta h(M)$ . The simplest assumption guaranteeing this and thermodynamical interpretation is that  $\Delta h(M)$  is proportional to the logarithm of the vacuum functional  $\Omega$ :

$$\Delta h(M) \propto -\log\left(\frac{\Omega(M)}{\Omega_{max}}\right) . \quad (5.4.6)$$

Here  $\Omega_{max}$  corresponds to the maximum of  $\Omega$  for which  $\Delta h(M)$  vanishes.

### Justification for the general form of the mass formula

The proposed general ansatz for  $\Delta h(M)$  provides a justification for the general form of the mass formula deduced by intuitive arguments.

1. The factorization of the elementary particle vacuum functional  $\Omega$  into a product of  $2N(g) = 2^g(2^g + 1)$  terms and the logarithmic expression for  $\Delta h(M)$  imply that the thermal expectation values is a sum over thermal expectation values over  $2N(g)$  terms associated with various even characteristics  $(a, b)$ , where  $a$  and  $b$  are  $g$ -dimensional vectors with components equal to  $1/2$  or  $0$  and the inner product  $4a \cdot b$  is an even integer. If each term gives the same result in the averaging using  $\Omega_{vac}$  as a partition function, the proportionality to  $2N_g$  follows.
2. For genus  $g \geq 2$  the partition function defines an average in  $3g - 3$  complex-dimensional space of moduli. The analogy of  $\langle \Delta h \rangle$  and thermal energy suggests that the contribution is proportional to the complex dimension  $3g - 3$  of this space. For  $g \leq 1$  the contribution the complex dimension of moduli space is  $g$  and the contribution would be proportional to  $g$ .

$$\begin{aligned} \langle \Delta h \rangle &\propto g \times X(g) \text{ for } g \leq 1 , \\ \langle \Delta h \rangle &\propto (3g - 3) \times X(g) \text{ for } g \geq 2 , \\ X(g) &= 2^g(2^g + 1) . \end{aligned} \tag{5.4.7}$$

If  $X^2$  is hyper-elliptic for the maxima of Kähler function, this expression makes sense only for  $g \leq 2$  since vacuum functionals vanish for hyper-elliptic surfaces.

3. The earlier argument, inspired by the interpretation of elementary particle vacuum functional as a partition function, was that each factor of the elementary particle vacuum functional gives the same contribution to  $\langle \Delta h \rangle$ , and that this contribution is proportional to  $g$  since each handle behaves like a particle:

$$\langle \Delta h \rangle \propto g \times X(g) . \tag{5.4.8}$$

The prediction following from the previous differs by a factor  $(3g - 3)/g$  for  $g \geq 2$ . This would scale up the dominant modular contribution to the masses of the third  $g = 2$  fermionic generation by a factor  $\sqrt{3/2} \simeq 1.22$ . One must of course remember, that these rough arguments allow  $g$ -dependent numerical factors of order one so that it is not possible to exclude either argument.

### 5.4.3 Generalization of $\Theta$ functions and quantization of p-adic moduli

The task is to find p-adic counterparts for theta functions and elementary particle vacuum functionals. The constraints come from the p-adic existence of the exponentials appearing as the summands of the theta functions and from the convergence of the sum. The exponentials must be proportional to powers of  $p$  just as the Boltzmann weights defining the p-adic partition function. The outcome is a quantization of moduli so that integration can be replaced with a summation and the average of  $\Delta h(M)$  over moduli is well defined.

It is instructive to study the problem for torus in parallel with the general case. The ordinary moduli space of torus is parameterized by single complex number  $\tau$ . The points related by  $SL(2, Z)$  are equivalent, which means that the transformation  $\tau \rightarrow (A\tau + B)/(C\tau + D)$  produces a point equivalent with  $\tau$ . These transformations are generated by the shift  $\tau \rightarrow \tau + 1$  and  $\tau \rightarrow -1/\tau$ . One can choose the fundamental domain of moduli space to be the intersection of the slice  $Re(\tau) \in [-1/2, 1/2]$  with the exterior of unit circle  $|\tau| = 1$ . The idea is to start directly from physics and to look whether one might some define p-adic version of elementary particle vacuum functionals in the p-adic counter part of this set or in some modular invariant subset of this set.

Elementary particle vacuum functionals are expressible in terms of theta functions using the functions  $\Theta^4[a, b] \overline{\Theta}^4[a, b]$  as a building block. The general expression for the theta function reads as

$$\Theta_{[a,b]}(\Omega) = \sum_n \exp(i\pi(n+a) \cdot \Omega \cdot (n+a)) \exp(2i\pi(n+a) \cdot b) . \tag{5.4.9}$$

The latter exponential phase gives only a factor  $\pm i$  or  $\pm 1$  since  $4a \cdot b$  is integer. For  $p \bmod 4 = 3$  imaginary unit exists in an algebraic extension of p-adic numbers. In the case of torus  $(a,b)$  has the values  $(0,0)$ ,  $(1/2,0)$  and  $(0,1/2)$  for torus since only even characteristics are allowed.

Concerning the p-adicization of the first exponential appearing in the summands in Eq. 5.4.9, the obvious problem is that  $\pi$  does not exist p-adically unless one allows infinite-dimensional extension.

1. Consider first the real part of  $\Omega$ . In this case the proper manner to treat the situation is to introduce an algebraic extension involving roots of unity so that  $Re(\Omega)$  is rational. This approach is proposed as a general approach to the p-adicization of quantum TGD in terms of harmonic analysis in symmetric spaces allowing to define integration also in p-adic context in a physically acceptable manner by reducing it to Fourier analysis. The simplest situation corresponds to integer values for  $Re(\Omega)$  and in this case the phase is equal to  $\pm i$  or  $\pm 1$  since  $a$  is half-integer valued. One can consider a hierarchy of variants of moduli space characterized by the allowed roots of unity. The physical interpretation for this hierarchy would be in terms of a hierarchy of measurement resolutions. Note that the real parts of  $\Omega$  can be assumed to be rationals of the form  $m/n$  where  $n$  is constructed as a product of a finite number of primes and therefore the allowed rationals are linear combinations of inverses  $1/p_i$  for a subset  $\{p_i\}$  of primes.
2. For the imaginary part of  $\Omega$  a different approach is required. One wants a rapid convergence of the sum formula and this requires that the exponents reduce in this case to positive powers of  $p$ . This is achieved if one has

$$Im(\Omega) = -n \frac{\log(p)}{\pi} , \tag{5.4.10}$$

Unfortunately this condition is not consistent with the condition  $Im(\Omega) > 0$ . A manner to circumvent the difficulty is to replace  $\Omega$  with its complex conjugate. A second approach is to define the real discretized variant of the theta function first and then map it by canonical identification to its p-adic counterpart: this would map phases to powers of  $p$  to their inverses. Note that a similar change of sign must be performed in p-adic thermodynamics for powers of  $p$  to map p-adic probabilities to real ones. By rescaling  $Im(\Omega) \rightarrow \frac{\log(p)}{\pi} Im(\Omega)$  one has a non-negative integer valued spectrum for  $Im(\Omega)$  making possible to reduce integration in moduli space to a summation over a finite number of rationals associated with the real part of  $\Omega$  and powers of  $p$  associated with the imaginary part of  $\Omega$ .

3. Since the exponents appearing in

$$p^{(n+a) \cdot Im(\Omega_{ij,p}) \cdot (n+a)} = p^{a \cdot Im(\Omega) \cdot a} \times p^{2a \cdot Im(\Omega) \cdot n} \times p^{+n \cdot Im(\Omega_{ij,p}) \cdot n}$$

are positive integers valued,  $\Theta_{[a,b]}$  exist in  $R_p$  and converges. The problematic factor is the first exponent since the components of the vector  $a$  can have values  $1/2$  and  $0$  and its existence implies a quantization of  $Im(\Omega_{ij})$  as

$$Im(\Omega) = -Kn \frac{\log(p)}{p} , \quad n \in Z , \quad n \geq 1 , \tag{5.4.11}$$

In p-adic context this condition must be formulated for the exponent of  $\Omega$  defining the natural coordinate.  $K = 4$  guarantees the existence of  $\Theta$  functions and  $K = 1$  the existence of the building blocks  $\Theta^4[a,b] \bar{\Theta}^4[a,b]$  of elementary particle vacuum functionals in  $R_p$ . The extension to higher genera means only replacement of  $\Omega$  with the elements of a matrix.

4. One can criticize this approach for the loss of the full modular covariance in the definition of theta functions. The modular transformations  $\Omega \rightarrow \Omega + n$  are consistent with the number theoretic constraints but the transformations  $\Omega \rightarrow -1/\Omega$  do not respect them. It seem that one can circumvent the difficulty by restricting the consideration to a fundamental domain satisfying the number theoretic constraints.

This variant of moduli space is discrete and p-adicity is reflected only in the sense that the moduli space makes sense also p-adically. One can consider also a continuum variant of the p-adic moduli space using the same prescription as in the construction of p-adic symmetric spaces [K71] .

1. One can introduce  $exp(i\pi Re(\Omega))$  as the counterpart of  $Re(\Omega)$  as a coordinate of the Teichmueller space. This coordinate makes sense only as a local coordinate since it does not differentiate between  $Re(\Omega)$  and  $Re(\Omega + 2n)$ . On the other hand, modular invariance states that  $\Omega$  abd  $\Omega + n$  correspond to the same moduli so that nothing is lost. In the similar manner one can introduce  $exp(\pi Im(\Omega)) \in \{p^n, n > 0\}$  as the counterpart of discretized version of  $Im(\Omega)$ .
2. The extension to continuum would mean in the case of  $Re(\Omega)$  the extension of the phase  $exp(i\pi Re(\Omega))$  to a product  $exp(i\pi Re(\Omega))exp(ipx) = exp(i\pi Re(\Omega) + exp(ipx))$ , where  $x$  is p-adic integer which can be also infinite as a real integer. This would mean that each root of unity representing allowed value  $Re(\Omega)$  would have a p-adic neighborhood consisting of p-adic integers. This neighborhood would be the p-adic counterpart for the angular integral  $\Delta\phi$  for a given root of unity and would not make itself visible in p-adic integration.
3. For the imaginary part one can also consider the extension of  $exp(\pi Im(\Omega))$  to  $p^n \times exp(np\pi x)$  where  $x$  is a p-adic integer. This would assign to each point  $p^n$  a p-adic neighborhood defined by p-adic integers. This neighborhood is same all integers  $n$  with same p-adic norm. When  $n$  is proportional to  $p^k$  one has  $exp(np\pi x) - 1 \propto p^k$ .

The quantization of moduli characterizes precisely the conformal properties of the partonic 2-surfaces corresponding to different p-adic primes. In the real context -that is in the intersection of real and p-adic worlds- the quantization of moduli of torus would correspond to

$$\tau = K \left[ \sum q + i \times n \frac{\log(p)}{\pi} \right] , \tag{5.4.12}$$

where  $q$  is a rational number expressible as linear combination of inverses of a finite fixed set of primes defining the allowed roots of unity.  $K = 1$  guarantees the existence of elementary particle vacuum functionals and  $K = 4$  the existence of Theta functions. The ratio for the complex vectors defining the sides of the plane parallelogram defining torus via the identification of the parallel sides is quantized. In other words, the angles  $\Phi$  between the sides and the ratios of the sides given by  $|\tau|$  have quantized values.

The quantization rules for the moduli of the higher genera is of exactly same form

$$\Omega_{ij} = K \left[ \sum q_{ij} + i \times n_{ij} \times \frac{\log(p)}{\pi} \right] , \tag{5.4.13}$$

If the quantization rules hold true also for the maxima of Kähler function in the real context or more precisely- in the intersection of real and p-adic variants of the "world of classical worlds" identified as partonic 2-surfaces at the boundaries of causal diamond plus the data about their 4-D tangent space, there are good hopes that the p-adicized expression for  $\Delta h$  is obtained by a simple algebraic continuation of the real formula. Thus p-adic length scale would characterize partonic surface  $X^2$  rather than the light like causal determinant  $X_l^3$  containing  $X^2$ . Therefore the idea that various p-adic primes label various  $X_l^3$  connecting fixed partonic surfaces  $X_i^2$  would not be correct.

Quite generally, the quantization of moduli means that the allowed 2-dimensional shapes form a lattice and are thus additive. It also means that the maxima of Kähler function would obey a linear superposition in an extreme abstract sense. The proposed number theoretical quantization is

expected to apply for any complex space allowing some preferred complex coordinates. In particular, configuration space of 2-surfaces could allow this kind of quantization in the complex coordinates naturally associated with isometries and this could allow to define configuration space integration, at least the counterpart of integration in zero mode degrees of freedom, as a summation.

Number theoretic vision leads to the notion of multi-p-adicity in the sense that the same partonic 2-surface can correspond to several p-adic primes and that infinite primes code for these primes [?, ?]. At the level of the moduli space this corresponds to the replacement of  $p$  with an integer in the formulas so that one can interpret the formulas both in real sense and p-adic sense for the primes  $p$  dividing the integer. Also the exponent of given prime in the integer matters. The construction of generalized eigen modes of Chern-Simons Dirac operator leads to the proposal that the collection of infinite primes characterizing infinite prime characterizes the geometry of the orbit of partonic 2-surface [?]. It would not be too surprising if this connection would reduce to the proposed discretization of the modular parameters of the partonic 2-surface.

#### 5.4.4 The calculation of the modular contribution $\langle \Delta h \rangle$ to the conformal weight

The quantization of the moduli implies that the integral over moduli can be defined as a sum over moduli. The theta function  $\Theta[a, b](\Omega)_p(\tau_p)$  is proportional to  $p^{a \cdot a \text{Im}(\Omega_{ij,p})} = p^{Kn_{ij}m(a)/4}$  for  $a \cdot a = m(a)/4$ , where  $K = 1$  resp.  $K = 4$  corresponds to the existence of elementary particle vacuum functionals resp. theta functions in  $R_p$ . These powers of  $p$  can be extracted from the thetas defining the vacuum functional. The numerator of the vacuum functional gives  $(p^n)^{2K \sum_{a,b} m(a)}$ . The denominator gives  $(p^n)^{2K \sum_{a,b} m(a_0)}$ , where  $a_0$  corresponds to the minimum value of  $m(a)$ .  $a_0 = (0, 0, \dots, 0)$  is allowed and gives  $m(a_0) = 0$  so that the p-adic norm of the denominator equals to one. Hence one has

$$|\Omega_{vac}(\Omega_p)|_p = p^{-2nK \sum_{a,b} m(a)} \quad (5.4.14)$$

The sum converges extremely rapidly for large values of  $p$  as function of  $n$  so that in practice only few moduli contribute.

The definition of  $\log(\Omega_{vac})$  poses however problems since  $\log(p)$  does not exist as a p-adic number in any p-adic number field. The argument of the logarithm should have a unit p-adic norm. The simplest manner to circumvent the difficulty is to use the fact that the p-adic norm  $|\Omega_p|_p$  is also a modular invariant, and assume that the contribution to conformal weight depends on moduli as

$$\Delta h_p(\Omega_p) \propto \log\left(\frac{\Omega_{vac}}{|\Omega_{vac}|_p}\right). \quad (5.4.15)$$

The sum defining  $\langle \Delta h_p \rangle$  converges extremely rapidly and gives a result of order  $O(p)$  p-adically as required.

The p-adic expression for  $\langle \Delta h_p \rangle$  should result from the corresponding real expression by an algebraic continuation. This encourages the conjecture that the allowed moduli are quantized for the maxima of Kähler function, so that the integral over the moduli space is replaced with a sum also in the real case, and that  $\Delta h$  given by the double thermodynamics as a function of moduli can be defined as in the p-adic case. The positive power of  $p$  multiplying the numerator could be interpreted as a degeneracy factor. In fact, the moduli are not primary dynamical variables in the case of the induced metric, and there must be a modular invariant weight factor telling how many 2-surfaces correspond to given values of moduli. The power of  $p$  could correspond to this factor.

## 5.5 General mass formulas for non-Higgsy contributions

In the sequel various contributions to the mass squared are discussed.

### 5.5.1 General mass squared formula

The thermal independence of Super Virasoro and modular degrees of freedom implies that mass squared for elementary particle is the sum of Super Virasoro, modular and Higgsy contributions:

$$M^2 = M^2(\text{color}) + M^2(\text{SV}) + M^2(\text{mod}) + M^2(\text{Higgsy}) . \quad (5.5.1)$$

Also small renormalization correction contributions might be possible.

### 5.5.2 Color contribution to the mass squared

The mass squared contains a non-thermal color contribution to the ground state conformal weight coming from the mass squared of  $CP_2$  spinor harmonic. The color contribution is an integer multiple of  $m_0^2/3$ , where  $m_0^2 = 2\Lambda$  denotes the 'cosmological constant' of  $CP_2$  ( $CP_2$  satisfies Einstein equations  $G^{\alpha\beta} = \Lambda g^{\alpha\beta}$ ).

The color contribution to the p-adic mass squared is integer valued only if  $m_0^2/3$  is taken as a fundamental p-adic unit of mass squared. This choice has an obvious relevance for p-adic mass calculations since the simplest form of the canonical identification does not commute with a division by integer. More precisely, the image of number  $xp$  in canonical identification has a value of order 1 when  $x$  is a non-trivial rational number whereas for  $x = np$  the value is  $n/p$  and extremely is small for physically interesting primes.

The choice of the p-adic mass squared unit are no effects on zeroth order contribution which must vanish for light states: this requirement eliminates quark and lepton states for which the  $CP_2$  contribution to the mass squared is not integer valued using  $m_0^2$  as a unit. There can be a dramatic effect on the first order contribution. The mass squared  $m^2 = p/3$  using  $m_0^2/3$  means that the particle is light. The mass squared becomes  $m^2 = p/3$  when  $m_0^2$  is used as a unit and the particle has mass of order  $10^{-4}$  Planck masses. In the case of  $W$  and  $Z^0$  bosons this problem is actually encountered. For light states using  $m_0^2/3$  as a unit only the second order contribution to the mass squared is affected by this choice.

### 5.5.3 Modular contribution to the mass of elementary particle

The general form of the modular contribution is derivable from p-adic partition function for conformally invariant degrees of freedom associated with the boundary components. The general form of the vacuum functionals as modular invariant functions of Teichmuller parameters was derived in [K16] and the square of the elementary particle vacuum functional can be identified as a partition function. Even theta functions serve as basic building blocks and the functionals are proportional to the product of all even theta functions and their complex conjugates. The number of theta functions for genus  $g > 0$  is given by

$$N(g) = 2^{g-1}(2^g + 1) . \quad (5.5.2)$$

One has  $N(1) = 3$  for muon and  $N(2) = 10$  for  $\tau$ .

1. Single theta function is analogous to a partition function. This implies that the modular contribution to the mass squared must be proportional to  $2N(g)$ . The factor two follows from the presence of both theta functions and their conjugates in the partition function.
2. The factorization properties of the vacuum functionals imply that handles behave effectively as particles. For example, at the limit, when the surface splits into two pieces with  $g_1$  and  $g - g_1$  handles, the partition function reduces to a product of  $g_1$  and  $g - g_1$  partition functions. This implies that the contribution to the mass squared is proportional to the genus of the surface. Altogether one has

$$\begin{aligned} M^2(\text{mod}, g) &= 2k(\text{mod})N(g)g\frac{m_0^2}{p} , \\ k(\text{mod}) &= 1 . \end{aligned} \quad (5.5.3)$$

Here  $k(mod)$  is some integer valued constant (in order to avoid ultra heavy mass) to be determined.  $k(mod) = 1$  turns out to be the correct choice for this parameter.

Summarizing, the real counterpart of the modular contribution to the mass of a particle belonging to  $g + 1$ :th generation reads as

$$\begin{aligned} M^2(mod) &= 0 \text{ for } e, \nu_e, u, d \text{ ,} \\ M^2(mod) &= 9 \frac{m_0^2}{p(X)} \text{ for } X = \mu, \nu_\mu, c, s \text{ ,} \\ M^2(mod) &= 60 \frac{m_0^2}{p(X)} \text{ for } X = \tau, \nu_\tau, t, b \text{ .} \end{aligned} \quad (5.5.4)$$

The requirement that hadronic mass spectrum and CKM matrix are sensible however forces the modular contribution to be the same for quarks, leptons and bosons. The higher order modular contributions to the mass squared are completely negligible if the degeneracy of massless state is  $D(0, mod, g) = 1$  in the modular degrees of freedom as is in fact required by  $k(mod) = 1$ .

#### 5.5.4 Thermal contribution to the mass squared

One can deduce the value of the thermal mass squared in order  $O(p^2)$  (an excellent approximation) using the general mass formula given by p-adic thermodynamics. Assuming maximal p-adic temperature  $T_p = 1$  one has

$$\begin{aligned} M^2 &= k(sp + Xp^2 + O(p^3)) \text{ ,} \\ s_\Delta &= \frac{D(\Delta + 1)}{D(\Delta)} \text{ ,} \\ X_\Delta &= 2 \frac{D(\Delta + 2)}{D(\Delta)} - \frac{D^2(\Delta + 1)}{D^2(\Delta)} \text{ ,} \\ k &= 1 \text{ .} \end{aligned} \quad (5.5.5)$$

$\Delta$  is the conformal weight of the operator creating massless state from the ground state.

The ratios  $r_n = D(n + 1)/D(n)$  allowing to deduce the values of  $s$  and  $X$  have been deduced from p-adic thermodynamics in [K39]. Light state is obtained only provided  $r(\Delta)$  is an integer. The remarkable result is that for lowest lying states this is the case. For instance, for Ramond representations the values of  $r_n$  are given by

$$(r_0, r_1, r_2, r_3) = (8, 5, 4, \frac{55}{16}) \text{ .} \quad (5.5.6)$$

The values of  $s$  and  $X$  are

$$\begin{aligned} (s_0, s_1, s_2) &= (8, 5, 4) \text{ ,} \\ (X_0, X_1, X_2) &= (16, 15, 11 + 1/2) \text{ .} \end{aligned} \quad (5.5.7)$$

The result means that second order contribution is extremely small for quarks and charged leptons having  $\Delta < 2$ . For neutrinos having  $\Delta = 2$  the second order contribution is non-vanishing.

#### 5.5.5 The contribution from the deviation of ground state conformal weight from negative integer

The interpretation inspired by p-adic mass calculations is that the squares  $\lambda_i^2$  of the eigenvalues of the modified Dirac operator correspond to the conformal weights of ground states. Another natural physical interpretation of  $\lambda$  is as an analog of the Higgs vacuum expectation. The instability of the Higgs=0 phase would correspond to the fact that  $\lambda = 0$  mode is not localized to any region in which

ew magnetic field or induced Kähler field is non-vanishing. A good guess is that induced Kähler magnetic field  $B_K$  dictates the magnitude of the eigenvalues which is thus of order  $h_0 = \sqrt{B_K R}$ ,  $R$   $CP_2$  radius. The first guess is that eigenvalues in the first approximation come as  $(n + 1/2)h_0$ . Each region where induced Kähler field is non-vanishing would correspond to different scale mass scale  $h_0$ .

1. The vacuum expectation value of Higgs is only proportional to an eigenvalue  $\lambda$ , not equal to it. Indeed, Higgs and gauge bosons as elementary particles correspond to wormhole contacts carrying fermion and antifermion at the two wormhole throats and must be distinguished from the space-time correlate of its vacuum expectation as something proportional to  $\lambda$ . In the fermionic case the vacuum expectation value of Higgs does not seem to be even possible since fermions do not correspond to wormhole contacts between two space-time sheets but possess only single wormhole throat (p-adic mass calculations are consistent with this).
2. Physical considerations suggest that the vacuum expectation of Higgs field corresponds to a particular eigenvalue  $\lambda_i$  of modified Dirac operator so that the eigenvalues  $\lambda_i$  would define TGD counterparts for the minima of Higgs potential. Since the vacuum expectation of Higgs corresponds to a condensate of wormhole contacts giving rise to a coherent state, the vacuum expectation cannot be present for topologically condensed  $CP_2$  type vacuum extremals representing fermions since only single wormhole throat is involved. This raises a hen-egg question about whether Higgs contributes to the mass or whether Higgs is only a correlate for massivation having description using more profound concepts. From TGD point of view the most elegant option is that Higgs does not give rise to mass but Higgs vacuum expectation value accompanies bosonic states and is naturally proportional to  $\lambda_i$ . With this interpretation  $\lambda_i$  could give a contribution to both fermionic and bosonic masses.
3. If the coset construction for super-symplectic and super Kac-Moody algebra implying Equivalence Principle is accepted, one encounters what looks like a problem. p-Adic mass calculations require negative ground state conformal weight compensated by Super Virasoro generators in order to obtain massless states. The tachyonicity of the ground states would mean a close analogy with both string models and Higgs mechanism.  $\lambda_i^2$  is very natural candidate for the ground state conformal weights identified but would have wrong sign if the effective metric of  $X_i^3$  defined by the inner products  $T_K^{k\alpha} T_K^{l\beta} h_{kl}$  of the Kähler energy momentum tensor  $T^{k\alpha} = h^{kl} \partial L_K / \partial h_\alpha^l$  and appearing in the modified Dirac operator  $D_K$  has Minkowskian signature.

The situation changes if the effective metric has Euclidian signature. This seems to be the case for the light-like surfaces assignable to the known extremals such as MEs and cosmic strings. In this kind of situation light-like coordinate possesses Euclidian signature and real eigenvalue spectrum is replaced with a purely imaginary one. Since Dirac operator is in question both signs for eigenvalues are possible and one obtains both exponentially increasing and decreasing solutions. This is essential for having solutions extending from the past end of  $X_i^3$  to its future end. Non-unitary time evolution is possible because  $X_i^3$  does not strictly speaking represent the time evolution of 2-D dynamical object but actual dynamical objects (by light-likeness both interpretation as dynamical evolution and dynamical object are present). The Euclidian signature of the effective metric would be a direct analog for the tachyonicity of the Higgs in unstable minimum and the generation of Higgs vacuum expectation would correspond to the compensation of ground state conformal weight by conformal weights of Super Virasoro generators.

4. In accordance with this  $\lambda_i^2$  would give constant contribution to the ground state conformal weight. What contributes to the thermal mass squared is the deviation of the ground state conformal weight from half-odd integer since the negative integer part of the total conformal weight can be compensated by applying Virasoro generators to the ground state. The first guess motivated by cyclotron energy analogy is that the lowest conformal weights are of form  $h_c = \lambda_i^2 = -1/2 - n + \Delta h_c$  so that lowest ground state conformal weight would be  $h_c = -1/2$  in the first approximation. The negative integer part of the net conformal weight can be canceled using Super Virasoro generators but  $\Delta h_c$  would give to mass squared a contribution analogous to Higgs contribution. The mapping of the real ground state conformal weight to a p-adic number by canonical identification involves some delicacies.

5. p-Adic mass calculations are consistent with the assumption that Higgs type contribution is vanishing (that is small) for fermions and dominates for gauge bosons. This requires that the deviation of  $\lambda_i^2$  with smallest magnitude from half-odd integer value in the case of fermions is considerably smaller than in the case of gauge bosons in the scale defined by p-adic mass scale  $1/L(k)$  in question. Somehow this difference could relate to the fact that bosons correspond to pairs of wormhole throats.

### 5.5.6 General mass formula for Ramond representations

By taking the modular contribution from the boundaries into account the general p-adic mass formulas for the Ramond type states read for states for which the color contribution to the conformal weight is integer valued as

$$\begin{aligned}
 \frac{m^2(\Delta = 0)}{m_0^2} &= (8 + n(g))p + Yp^2 , \\
 \frac{m^2(\Delta = 1)}{m_0^2} &= (5 + n(g))p + Yp^2 , \\
 \frac{m^2(\Delta = 2)}{m_0^2} &= (4 + n(g))p + (Y + \frac{23}{2})p^2 , \\
 n(g) &= 3g \cdot 2^{g-1}(2^g + 1) .
 \end{aligned} \tag{5.5.8}$$

Here  $\Delta$  denotes the conformal weight of the operators creating massless states from the ground state and  $g$  denotes the genus of the boundary component. The values of  $n(g)$  for the three lowest generations are  $n(0) = 0$ ,  $n(1) = 9$  and  $n(2) = 60$ . The value of second order thermal contribution is nontrivial for neutrinos only. The value of the rational number  $Y$  can, which corresponds to the renormalization correction to the mass, can be determined using experimental inputs.

Using  $m_0^2$  as a unit, the expression for the mass of a Ramond type state reads in terms of the electron mass as

$$\begin{aligned}
 M(\Delta, g, p)_R &= K(\Delta, g, p) \sqrt{\frac{M_{127}}{p}} m_e \\
 K(0, g, p) &= \sqrt{\frac{n(g) + 8 + Y_R}{X}} \\
 K(1, g, p) &= \sqrt{\frac{n(g) + 5 + Y_R}{X}} \\
 K(2, g, p) &= \sqrt{\frac{n(g) + 4 + Y_R}{X}} , \\
 X &= \sqrt{5 + Y(e)_R} .
 \end{aligned} \tag{5.5.9}$$

$Y$  can be assumed to depend on the electromagnetic charge and color representation of the state and is therefore same for all fermion families. Mathematica provides modules for calculating the real counterpart of the second order contribution and for finding realistic values of  $Y$ .

### 5.5.7 General mass formulas for NS representations

Using  $m_0^2/3$  as a unit, the expression for the mass of a light NS type state for  $T_p = 1$  and  $k_B = 1$  reads in terms of the electron mass as

$$\begin{aligned}
M(\Delta, g, p, N)_R &= K(\Delta, g, p, N) \sqrt{\frac{M_{127}}{p}} m_e \\
K(0, g, p, 1) &= \sqrt{\frac{n(g) + Y_R}{X}} , \\
K(0, g, p, 2) &= \sqrt{\frac{n(g) + 1 + Y_R}{X}} , \\
K(1, g, p, 3) &= \sqrt{\frac{n(g) + 3 + Y_R}{X}} , \\
K(2, g, p, 4) &= \sqrt{\frac{n(g) + 5 + Y_R}{X}} , \\
K(2, g, p, 5) &= \sqrt{\frac{n(g) + 10 + Y_R}{X}} , \\
X &= \sqrt{5 + Y(e)_R} .
\end{aligned} \tag{5.5.10}$$

Here  $N$  is the number of the 'active' NS sectors (sectors for which the conformal weight of the massless state is non-vanishing).  $Y$  denotes the renormalization correction to the boson mass and in general depends on the electro-weak and color quantum numbers of the boson.

The thermal contribution to the mass of  $W$  boson is too large by roughly a factor  $\sqrt{3}$  for  $T_p = 1$ . Hence  $T_p = 1/2$  must hold true for gauge bosons and their masses must have a non-thermal origin perhaps analogous to Higgs mechanism. Alternatively, the non-covariant constancy of charge matrices could induce the boson mass [K39] .

It is interesting to notice that the minimum mass squared for gauge boson corresponds to the p-adic mass unit  $M^2 = m_0^2 p/3$  and this just what is needed in the case of  $W$  boson. This forces to ask whether  $m_0^2/3$  is the correct choice for the mass squared unit so that non-thermally induced  $W$  mass would be the minimal  $m_W^2 = p$  in the lowest order. This choice would mean the replacement

$$Y_R \rightarrow \frac{(3Y)_R}{3}$$

in the preceding formulas and would affect only neutrino mass in the fermionic sector.  $m_0^2/3$  option is excluded by charged lepton mass calculation. This point will be discussed later.

### 5.5.8 Primary condensation levels from p-adic length scale hypothesis

p-Adic length scale hypothesis states that the primary condensation levels correspond to primes near prime powers of two  $p \simeq 2^k$ ,  $k$  integer with prime values preferred. Black hole-elementary particle analogy [?] suggests a generalization of this hypothesis by allowing  $k$  to be a power of prime. The general number theoretical vision discussed in [K71] provides a first principle justification for p-adic length scale hypothesis in its most general form. The best fit for the neutrino mass squared differences is obtained for  $k = 13^2 = 169$  so that the generalization of the hypothesis might be necessary.

A particle primarily condensed on the level  $k$  can suffer secondary condensation on a level with the same value of  $k$ : for instance, electron ( $k = 127$ ) suffers secondary condensation on  $k = 127$  level.  $u, d, s$  quarks ( $k = 107$ ) suffer secondary condensation on nuclear space-time sheet having  $k = 113$ ). All quarks feed their color gauge fluxes at  $k = 107$  space-time sheet. There is no deep reason forbidding the condensation of  $p$  on  $p$ . Primary and secondary condensation levels could also correspond to different but nearly identical values of  $p$  with the same value of  $k$ .

## 5.6 Fermion masses

In the earlier model the coefficient of  $M^2 = kL_0$  had to be assumed to be different for various particle states.  $k = 1$  was assumed for bosons and leptons and  $k = 2/3$  for quarks. The fact that  $k = 1$  holds true for all particles in the model including also super-symplectic invariance forces to modify the earlier construction of quark states. This turns out to be possible without affecting the earlier

p-adic mass calculations whose outcome depend in an essential manner on the ground state conformal weights  $h_{gr}$  of the fermions ( $h_{gr}$  can be negative). The structure of lepton and quark states in color degrees of freedom was discussed in [K39].

### 5.6.1 Charged lepton mass ratios

The overall mass scale for lepton and quark masses is determined by the condensation level given by prime  $p \simeq 2^k$ ,  $k$  prime by length scale hypothesis. For charged leptons  $k$  must correspond to  $k = 127$  for electron,  $k = 113$  for muon and  $k = 107$  for  $\tau$ . For muon  $p = 2^{113} - 1 - 4 * 378$  is assumed (smallest prime below  $2^{113}$  allowing  $\sqrt{2}$  but not  $\sqrt{3}$ ). So called Gaussian primes are to complex integers what primes are for the ordinary integers and the Gaussian counterparts of the Mersenne primes are Gaussian primes of form  $(1 \pm i)^k - 1$ . Rather interestingly,  $k = 113$  corresponds to a Gaussian Mersenne so that all charged leptons correspond to generalized Mersenne primes.

For  $k = 1$  the leptonic mass squared is integer valued in units of  $m_0^2$  only for the states satisfying

$$p \text{ mod } 3 \neq 2 .$$

Only these representations can give rise to massless states. Neutrinos correspond to  $(p, p)$  representations with  $p \geq 1$  whereas charged leptons correspond to  $(p, p + 3)$  representations. The earlier mass calculations demonstrate that leptonic masses can be understood if the ground state conformal weight is  $h_{gr} = -1$  for charged leptons and  $h_{gr} = -2$  for neutrinos.

The contribution of color partial wave to conformal weight is  $h_c = (p^2 + 2p)/3$ ,  $p \geq 1$ , for neutrinos and  $p = 1$  gives  $h_c = 1$  (octet). For charged leptons  $h_c = (p^2 + 5p + 6)/3$  gives  $h_c = 2$  for  $p = 0$  (decuplet). In both cases super-symplectic operator  $O$  must have a net conformal weight  $h_{sc} = -3$  to produce a correct conformal weight for the ground state. p-adic considerations suggests the use of operators  $O$  with super-symplectic conformal weight  $z = -1/2 - i \sum n_k y_k$ , where  $s_k = 1/2 + iy_k$  corresponds to zero of Riemann  $\zeta$ . If the operators in question are color Hamiltonians in octet representation net super-symplectic conformal weight  $h_{sc} = -3$  results. The tensor product of two octets with conjugate super-symplectic conformal weights contains both octet and decuplet so that singlets are obtained. What strengthens the hopes that the construction is not adhoc is that the same operator appears in the construction of quark states too.

Using  $CP_2$  mass scale  $m_0^2$  [K39] as a p-adic unit, the mass formulas for the charged leptons read as

$$\begin{aligned} M^2(L) &= A(\nu) \frac{m_0^2}{p(L)} , \\ A(e) &= 5 + X(p(e)) , \\ A(\mu) &= 14 + X(p(\mu)) , \\ A(\tau) &= 65 + X(p(\tau)) . \end{aligned} \tag{5.6.1}$$

$X(\cdot)$  corresponds to the yet unknown second order corrections to the mass squared.

The following table gives the basic parameters as determined from the mass of electron for some values of  $Y_e$ . The mass of top quark favors as maximal value of  $CP_2$  mass which corresponds to  $Y_e = 0$ .

$Y_e$	0	.5	.7798
$(m_0/m_{Pl}) \times 10^3$	.2437	.2323	.2266
$K \times 10^{-7}$	2.5262	2.7788	2.9202
$(L_R/\sqrt{G}) \times 10^{-4}$	3.1580	3.3122	3.3954

Table 1. Table gives the values of  $CP_2$  mass  $m_0$  using Planck mass  $m_{Pl} = 1/\sqrt{G}$  as unit, the ratio  $K = R^2/G$  and  $CP_2$  geodesic length  $L = 2\pi R$  for  $Y_e \in \{0, 0.5, 0.7798\}$ .

The following table lists the lower and upper bounds for the charged lepton mass ratios obtained by taking second order contribution to zero or allowing it to have maximum possible value. The values of lepton masses are  $m_e = .510999$  MeV,  $m_\mu = 105.76583$  MeV,  $m_\tau = 1775$  MeV.

$$\begin{aligned}
\frac{m(\mu)_+}{m(\mu)} &= \sqrt{\frac{15}{5}} 2^7 \frac{m_e}{m(\mu)} \simeq 1.0722 , \\
\frac{m(\mu)_-}{m(\mu)} &= \sqrt{\frac{14}{6}} 2^7 \frac{m_e}{m(\mu)} \simeq 0.9456 , \\
\frac{m(\tau)_+}{m(\tau)} &= \sqrt{\frac{66}{5}} 2^{10} \frac{m_e}{m(\tau)} \simeq 1.0710 , \\
\frac{m(\tau)_-}{m(\tau)} &= \sqrt{\frac{65}{6}} 2^{10} \frac{m_e}{m(\tau)} \simeq .9703 .
\end{aligned}
\tag{5.6.2}$$

For the maximal value of  $CP_2$  mass the predictions for the mass ratio are systematically too large by a few per cent. From the formulas above it is clear that the second order corrections to mass squared can be such that correct masses result.

$\tau$  mass is least sensitive to  $X(p(e)) \equiv Y_e$  and the maximum value of  $Y_e \equiv Y_{e,max}$  consistent with  $\tau$  mass corresponds to  $Y_{e,max} = .7357$  and  $Y_\tau = 1$ . This means that the  $CP_2$  mass is at least a fraction .9337 of its maximal value. If  $Y_L$  is same for all charged leptons and has the maximal value  $Y_{e,max} = .7357$ , the predictions for the mass ratios are

$$\begin{aligned}
\frac{m(\mu)_{pr}}{m(\mu)} &= \sqrt{\frac{14 + Y_{e,max}}{5 + Y_{e,max}}} \times 2^7 \frac{m_e}{m(\mu)} \simeq .9922 , \\
\frac{m(\tau)_{pr}}{m(\tau)} &= \sqrt{\frac{65 + Y_{e,max}}{5 + Y_{e,max}}} \times 2^{10} \frac{m_e}{m(\tau)} \simeq .9980 .
\end{aligned}
\tag{5.6.3}$$

The error is .8 per cent *resp.* .2 per cent for muon *resp.*  $\tau$ .

The argument leading to estimate for the modular contribution to the mass squared [K39] leaves two options for the coefficient of the modular contribution for  $g = 2$  fermions: the value of coefficient is either  $X = g$  for  $g \leq 1$ ,  $X = 3g - 3$  for  $g \geq 2$  or  $X = g$  always. For  $g = 2$  the predictions are  $X = 2$  and  $X = 3$  in the two cases. The option  $X = 3$  allows slightly larger maximal value of  $Y_e$  equal to  $Y_{e,max}^1 = Y_{e,max} + (5 + Y_{e,max})/66$ .

### 5.6.2 Neutrino masses

The estimation of neutrino masses is difficult at this stage since the prediction of the primary condensation level is not yet possible and neutrino mixing cannot yet be predicted from the basic principles. The cosmological bounds for neutrino masses however help to put upper bounds on the masses. If one takes seriously the LSND data on neutrino mass measurement of [?, ?] and the explanation of the atmospheric  $\nu$ -deficit in terms of  $\nu_\mu - \nu_\tau$  mixing [?, ?] one can deduce that the most plausible condensation level of  $\mu$  and  $\tau$  neutrinos is  $k = 167$  or  $k = 13^2 = 169$  allowed by the more general form of the p-adic length scale hypothesis suggested by the blackhole-elementary particle analogy. One can also deduce information about the mixing matrix associated with the neutrinos so that mass predictions become rather precise. In particular, the mass splitting of  $\mu$  and  $\tau$  neutrinos is predicted correctly if one assumes that the mixing matrix is a rational unitary matrix.

#### Super Virasoro contribution

Using  $m_0^2/3$  as a p-adic unit, the expression for the Super Virasoro contribution to the mass squared of neutrinos is given by the formula

$$\begin{aligned}
 M^2(SV) &= (s + (3Yp)_{R/3}) \frac{m_0^2}{p} , \\
 s &= 4 \text{ or } 5 , \\
 Y &= \frac{23}{2} + Y_1 ,
 \end{aligned}
 \tag{5.6.4}$$

where  $m_0^2$  is universal mass scale. One can consider two possible identifications of neutrinos corresponding to  $s(\nu) = 4$  with  $\Delta = 2$  and  $s(\nu) = 5$  with  $\Delta = 1$ . The requirement that CKM matrix is sensible forces the asymmetric scenario in which quarks and, by symmetry, also leptons correspond to lowest possible excitation so that one must have  $s(\nu) = 4$ .  $Y_1$  represents second order contribution to the neutrino mass coming from renormalization effects coming from self energy diagrams involving intermediate gauge bosons. Physical intuition suggest that this contribution is very small so that the precise measurement of the neutrino masses should give an excellent test for the theory.

With the above described assumptions and for  $s = 4$ , one has the following mass formula for neutrinos

$$\begin{aligned}
 M^2(\nu) &= A(\nu) \frac{m_0^2}{p(\nu)} , \\
 A(\nu_e) &= 4 + \frac{(3Y(p(\nu_e)))_R}{3} , \\
 A(\nu_\mu) &= 13 + \frac{(3Y(p(\nu_\mu)))_R}{3} , \\
 A(\nu_\tau) &= 64 + \frac{(3Y(p(\nu_\tau)))_R}{3} , \\
 3Y &\simeq \frac{1}{2} .
 \end{aligned}
 \tag{5.6.5}$$

The predictions must be consistent with the recent upper bounds [?] of order 10 eV, 270 keV and 0.3 MeV for  $\nu_e$ ,  $\nu_\mu$  and  $\nu_\tau$  respectively. The recently reported results of LSND measurement [?] for  $\nu_e \rightarrow \nu_\mu$  mixing gives string limits for  $\Delta m^2(\nu_e, \nu_\mu)$  and the parameter  $\sin^2(2\theta)$  characterizing the mixing: the limits are given in the figure 30 of [?]. The results suggests that the masses of both electron and muon neutrinos are below 5 eV and that mass squared difference  $\Delta m^2 = m^2(\nu_\mu) - m^2(\nu_e)$  is between .25 - 25 eV<sup>2</sup>. The simplest possibility is that  $\nu_\mu$  and  $\nu_e$  have common condensation level (in analogy with d and s quarks). There are three candidates for the primary condensation level: namely  $k = 163, 167$  and  $k = 169$ . The p-adic prime associated with the primary condensation level is assumed to be the nearest prime below  $2^k$  allowing p-adic  $\sqrt{2}$  but not  $\sqrt{3}$  and satisfying  $p \text{ mod } 4 = 3$ . The following table gives the values of various parameters and unmixed neutrino masses in various cases of interest.

k	p	$(3Y)_{R/3}$	$m(\nu_e)/eV$	$m(\nu_\mu)/eV$	$m(\nu_\tau)/eV$
163	$2^{163} - 4 * 144 - 1$	1.36	1.78	3.16	6.98
167	$2^{167} - 4 * 144 - 1$	.34	.45	.79	1.75
169	$2^{169} - 4 * 210 - 1$	.17	.22	.40	.87

**Could neutrino topologically condense also in other p-adic length scales than  $k = 169$ ?**

One must keep mind open for the possibility that there are several p-adic length scales at which neutrinos can condense topologically. Biological length scales are especially interesting in this respect. In fact, all intermediate p-adic length scales  $k = 151, 157, 163, 167$  could correspond to metastable neutrino states. The point is that these p-adic lengths scales are number theoretically completely exceptional in the sense that there exist Gaussian Mersenne  $2^k \pm i$  (prime in the ring of complex integers) for all these values of  $k$ . Since charged leptons, atomic nuclei ( $k = 113$ ), hadrons and intermediate gauge bosons correspond to ordinary or Gaussian Mersennes, it would not be surprising if the biologically important Gaussian Mersennes would correspond to length scales giving rise to metastable neutrino states. Of course, one can keep mind open for the possibility that  $k = 167$  rather than  $k = 13^2 = 169$  is the length scale defining the stable neutrino physics.

### Neutrino mixing

Consider next the neutrino mixing. A quite general form of the neutrino mixing matrix  $D$  given by the table below will be considered.

	$\nu_e$	$\nu_\mu$	$\nu_\tau$
$\nu_e$	$c_1$	$s_1 c_3$	$s_1 s_3$
$\nu_\mu$	$-s_1 c_2$	$c_1 c_2 c_3 - s_2 s_3 \exp(i\delta)$	$c_1 c_2 s_3 + s_2 c_3 \exp(i\delta)$
$\nu_\tau$	$-s_1 s_2$	$c_1 s_2 c_3 + c_2 s_3 \exp(i\delta)$	$c_1 s_2 s_3 - c_2 c_3 \exp(i\delta)$

Physical intuition suggests that the angle  $\delta$  related to CP breaking is small and will be assumed to be vanishing. Topological mixing is active only in modular degrees of freedom and one obtains for the first order terms of mixed masses the expressions

$$\begin{aligned}
 s(\nu_e) &= 4 + 9|U_{12}|^2 + 60|U_{13}|^2 = 4 + n_1 , \\
 s(\nu_\mu) &= 4 + 9|U_{22}|^2 + 60|U_{23}|^2 = 4 + n_2 , \\
 s(\nu_\tau) &= 4 + 9|U_{32}|^2 + 60|U_{33}|^2 = 4 + n_3 .
 \end{aligned}
 \tag{5.6.6}$$

The requirement that resulting masses are not ultraheavy implies that  $s(\nu)$  must be small integers. The condition  $n_1 + n_2 + n_3 = 69$  follows from unitarity. The simplest possibility is that the mixing matrix is a rational unitary matrix. The same ansatz was used successfully to deduce information about the mixing matrices of quarks. If neutrinos are condensed on the same condensation level, rationality implies that  $\nu_\mu - \nu_\tau$  mass squared difference must come from the first order contribution to the mass squared and is therefore quantized and bounded from below.

The first piece of information is the atmospheric  $\nu_\mu/\nu_e$  ratio, which is roughly by a factor 2 smaller than predicted by standard model [?]. A possible explanation is the CKM mixing of muon neutrino with  $\tau$ -neutrino, whereas the mixing with electron neutrino is excluded as an explanation. The latest results from Kamiokande [?] are in accordance with the mixing  $m^2(\nu_\tau) - m^2(\nu_\mu) \simeq 1.6 \cdot 10^{-2} eV^2$  and mixing angle  $\sin^2(2\theta) = 1.0$ : also the zenith angle dependence of the ratio is in accordance with the mixing interpretation. If mixing matrix is assumed to be rational then only  $k = 169$  condensation level is allowed for  $\nu_\mu$  and  $\nu_\tau$ . For this level  $\nu_\mu - \nu_\tau$  mass squared difference turns out to be  $\Delta m^2 \simeq 10^{-2} eV^2$  for  $\Delta s \equiv s(\nu_\tau) - s(\nu_\mu) = 1$ , which is the only acceptable possibility and predicts  $\nu_\mu - \nu_\tau$  mass squared difference correctly within experimental uncertainties! The fact that the predictions for mass squared differences are practically exact, provides a precision test for the rationality assumption.

What is measured in LSND experiment is the probability  $P(t, E)$  that  $\nu_\mu$  transforms to  $\nu_e$  in time  $t$  after its production in muon decay as a function of energy  $E$  of  $\nu_\mu$ . In the limit that  $\nu_\tau$  and  $\nu_\mu$  masses are identical, the expression of  $P(t, E)$  is given by

$$\begin{aligned}
 P(t, E) &= \sin^2(2\theta) \sin^2\left(\frac{\Delta E t}{2}\right) , \\
 \sin^2(2\theta) &= 4c_1^2 s_1^2 c_2^2 ,
 \end{aligned}
 \tag{5.6.7}$$

where  $\Delta E$  is energy difference of  $\nu_\mu$  and  $\nu_e$  neutrinos and  $t$  denotes time. LSND experiment gives stringent conditions on the value of  $\sin^2(2\theta)$  as the figure 30 of [?] shows. In particular, it seems that  $\sin^2(2\theta)$  must be considerably below  $10^{-1}$  and this implies that  $s_1^2$  must be small enough.

The study of the mass formulas shows that the only possibility to satisfy the constraints for the mass squared and  $\sin^2(2\theta)$  given by LSND experiment is to assume that the mixing of the electron neutrino with the tau neutrino is much larger than its mixing with the muon neutrino. This means that  $s_3$  is quite near to unity. At the limit  $s_3 = 1$  one obtains the following (nonrational) solution of

the mass squared conditions for  $n_3 = n_2 + 1$  (forced by the atmospheric neutrino data)

$$\begin{aligned} s_1^2 &= \frac{69 - 2n_2 - 1}{60} , \\ c_2^2 &= \frac{n_2 - 9}{2n_2 - 17} , \\ \sin^2(2\theta) &= \frac{4(n_2 - 9)(34 - n_2)(n_2 - 4)}{51 \cdot 30^2} , \\ s(\nu_\mu) - s(\nu_e) &= 3n_2 - 68 . \end{aligned} \quad (5.6.8)$$

The study of the LSND data shows that there is only one acceptable solution to the conditions obtained by assuming maximal mass squared difference for  $\nu_e$  and  $\nu_\mu$

$$\begin{aligned} n_1 &= 2 \quad n_2 = 33 \quad n_3 = 34 , \\ s_1^2 &= \frac{1}{30} \quad c_2^2 = \frac{24}{49} , \\ \sin^2(2\theta) &= \frac{24}{49} \frac{2}{15} \frac{29}{30} \simeq .0631 , \\ s(\nu_\mu) - s(\nu_e) &= 31 \leftrightarrow .32 \text{ eV}^2 . \end{aligned} \quad (5.6.9)$$

That  $c_2^2$  is near  $1/2$  is not surprise taking into account the almost mass degeneracy of  $\nu_{mu}$  and  $\nu_\tau$ . From the figure 30 of [?] it is clear that this solution belongs to 90 per cent likelihood region of LSND experiment but  $\sin^2(2\theta)$  is about two times larger than the value allowed by Bugey reactor experiment. The study of various constraints given in [?] shows that the solution is consistent with bounds from all other experiments. If one assumes that  $k > 169$  for  $\nu_e \nu_\mu - \nu_e$  mass difference increases, implying slightly poorer consistency with LSND data.

There are reasons to hope that the actual rational solution can be regarded as a small deformation of this solution obtained by assuming that  $c_3$  is non-vanishing.  $s_1^2 = \frac{69-2n_2-1}{60-51c_3^2}$  increases in the deformation by  $O(c_3^2)$  term but if  $c_3$  is positive the value of  $c_2^2 \simeq \frac{24-102c_1^0 c_2^0 s_2^0 c_3}{49} \sim \frac{24-61c_3}{49}$  decreases by  $O(c_3)$  term so that it should be possible to reduce the value of  $\sin^2(2\theta)$ . Consistency with Bugey reactor experiment requires  $.030 \leq \sin^2(2\theta) < .033$ .  $\sin^2(2\theta) = .032$  is achieved for  $s_1^2 \simeq .035, s_2^2 \simeq .51$  and  $c_3^2 \simeq .068$ . The construction of U and D matrices for quarks shows that very stringent number theoretic conditions are obtained and as in case of quarks it might be necessary to allow complex CP breaking phase in the mixing matrix. One might even hope that the solution to the conditions is unique.

For the minimal rational mixing one has  $s(\nu_e) = 5$ ,  $s(\nu_\mu) = 36$  and  $s(\nu_\tau) = 37$  if unmixed  $\nu_e$  corresponds to  $s = 4$ . For  $s = 5$  first order contributions are shifted by one unit. The masses ( $s = 4$  case) and mass squared differences are given by the following table.

k	$m(\nu_e)$	$m(\nu_\mu)$	$m(\nu_\tau)$	$\Delta m^2(\nu_\mu - \nu_e)$	$\Delta m^2(\nu_\tau - \nu_\mu)$
169	.27 eV	.66 eV	.67 eV	.32 eV <sup>2</sup>	.01 eV <sup>2</sup>

Predictions for neutrino masses and mass squared splittings for  $k = 169$  case.

### Evidence for the dynamical mass scale of neutrinos

In recent years (I am writing this towards the end of year 2004 and much later than previous lines) a great progress has been made in the understanding of neutrino masses and neutrino mixing. The pleasant news from TGD perspective is that there is a strong evidence that neutrino masses depend on environment [?]. In TGD framework this translates to the statement that neutrinos can suffer topological condensation in several p-adic length scales. Not only in the p-adic length scales suggested by the number theoretical considerations but also in longer length scales, as will be found.

The experiments giving information about mass squared differences can be divided into three categories [?].

1. There along baseline experiments, which include solar neutrino experiments [?, ?, ?] and [?] as well as earlier studies of solar neutrinos. These experiments see evidence for the neutrino

mixing and involve significant propagation through dense matter. For the solar neutrinos and KamLAND the mass splittings are estimated to be of order  $O(8 \times 10^{-5}) \text{ eV}^2$  or more cautiously  $8 \times 10^{-5} \text{ eV}^2 < \delta m^2 < 2 \times 10^{-3} \text{ eV}^2$ . For K2K and atmospheric neutrinos the mass splittings are of order  $O(2 \times 10^{-3}) \text{ eV}^2$  or more cautiously  $\delta m^2 > 10^{-3} \text{ eV}^2$ . Thus the scale of mass splitting seems to be smaller for neutrinos in matter than in air, which would suggest that neutrinos able to propagate through a dense matter travel at space-time sheets corresponding to a larger p-adic length scale than in air.

2. There are null short baseline experiments including CHOOZ, Bugey, and Palo Verde reactor experiments, and the higher energy CDHS, JARME, CHORUS, and NOMAD experiments, which involve muonic neutrinos (for references see [?]). No evidence for neutrino oscillations have been seen in these experiments.
3. The results of LSND experiment [?] are consistent with oscillations with a mass splitting greater than  $3 \times 10^{-2} \text{ eV}^2$ . LSND has been generally been interpreted as necessitating a mixing with sterile neutrino. If neutrino mass scale is dynamical, situation however changes.

If one assumes that the p-adic length scale for the space-time sheets at which neutrinos can propagate is different for matter and air, the situation changes. According to [?] a mass  $3 \times 10^{-2} \text{ eV}$  in air could explain the atmospheric results whereas mass of order  $.1 \text{ eV}$  and  $.07 \text{ eV}^2 < \delta m^2 < .26 \text{ eV}^2$  would explain the LSND result. These limits are of the same order as the order of magnitude predicted by  $k = 169$  topological condensation.

Assuming that the scale of the mass splitting is proportional to the p-adic mass scale squared, one can consider candidates for the topological condensation levels involved.

1. Suppose that  $k = 169 = 13^2$  is indeed the condensation level for LSND neutrinos.  $k = 173$  would predict  $m_{\nu_e} \sim 7 \times 10^{-2} \text{ eV}$  and  $\delta m^2 \sim .02 \text{ eV}^2$ . This could correspond to the masses of neutrinos propagating through air. For  $k = 179$  one has  $m_{\nu_e} \sim .8 \times 10^{-2} \text{ eV}$  and  $\delta m^2 \sim 3 \times 10^{-4} \text{ eV}^2$  which could be associated with solar neutrinos and KamLAND neutrinos.
2. The primes  $k = 157, 163, 167$  associated with Gaussian Mersennes would give  $\delta m^2(157) = 2^6 \delta m^2(163) = 2^{10} \delta m^2(167) = 2^{12} \delta m^2(169)$  and mass scales  $m(157) \sim 22.8 \text{ eV}$ ,  $m(163) \sim 3.6 \text{ eV}$ ,  $m(167) \sim .54 \text{ eV}$ . These mass scales are unrealistic or propagating neutrinos. The interpretation consistent with TGD inspired model of condensed matter in which neutrinos screen the classical  $Z^0$  force generated by nucleons would be that condensed matter neutrinos are confined inside these space-time sheets whereas the neutrinos able to propagate through condensed matter travel along  $k > 167$  space-time sheets.

### The results of MiniBooNE group as a support for the energy dependence of p-adic mass scale of neutrino

The basic prediction of TGD is that neutrino mass scale can depend on neutrino energy and the experimental determinations of neutrino mixing parameters support this prediction. The newest results (11 April 2007) about neutrino oscillations come from MiniBooNE group which has published its first findings [?] concerning neutrino oscillations in the mass range studied in LSND experiments [?].

#### 1. The motivation for MiniBooNE

Neutrino oscillations are not well-understood. Three experiments LSND, atmospheric neutrinos, and solar neutrinos show oscillations but in widely different mass regions ( $1 \text{ eV}^2$ ,  $3 \times 10^{-3} \text{ eV}^2$ , and  $8 \times 10^{-5} \text{ eV}^2$ ).

In TGD framework the explanation would be that neutrinos can appear in several p-adically scaled up variants with different mass scales and therefore different scales for the differences  $\Delta m^2$  for neutrino masses so that one should not try to explain the results of these experiments using single neutrino mass scale. In single-sheeted space-time it is very difficult to imagine that neutrino mass scale would depend on neutrino energy since neutrinos interact so extremely weakly with matter. The best known attempt to assign single mass to all neutrinos has been based on the use of so called sterile neutrinos which do not have electro-weak couplings. This approach is an ad hoc trick and rather ugly mathematically and excluded by the results of MiniBooNE experiments.

### 2. The result of MiniBooNE experiment

The purpose of the MiniBooNE experiment was to check whether LSND result  $\Delta m^2 = 1\text{eV}^2$  is genuine. The group used muon neutrino beam and looked whether the transformations of muonic neutrinos to electron neutrinos occur in the mass squared region  $\Delta m^2 \simeq 1\text{eV}^2$ . No such transitions were found but there was evidence for transformations at low neutrino energies.

What looks first as an over-diplomatic formulation of the result was *MiniBooNE researchers showed conclusively that the LSND results could not be due to simple neutrino oscillation, a phenomenon in which one type of neutrino transforms into another type and back again.* rather than direct refutation of LSND results.

### 3. LSND and MiniBooNE are consistent in TGD Universe

The habitant of the many-sheeted space-time would not regard the previous statement as a mere diplomatic use of language. It is quite possible that neutrinos studied in MiniBooNE have suffered topological condensation at different space-time sheet than those in LSND if they are in different energy range (the preferred rest system fixed by the space-time sheet of the laboratory or Earth). To see whether this is the case let us look more carefully the experimental arrangements.

1. In LSND experiment 800 MeV proton beam entering in water target and the muon neutrinos resulted in the decay of produced pions. Muonic neutrinos had energies in 60-200 MeV range [?].
2. In MiniBooNE experiment [?] 8 GeV muon beam entered Beryllium target and muon neutrinos resulted in the decay of resulting pions and kaons. The resulting muonic neutrinos had energies the range 300-1500 GeV to be compared with 60-200 MeV.

Let us try to make this more explicit.

1. Neutrino energy ranges are quite different so that the experiments need not be directly comparable. The mixing obeys the analog of Schrödinger equation for free particle with energy replaced with  $\Delta m^2/E$ , where  $E$  is neutrino energy. The mixing probability as a function of distance  $L$  from the source of muon neutrinos is in 2-component model given by

$$P = \sin^2(\theta)\sin^2(1.27\Delta m^2 L/E) .$$

The characteristic length scale for mixing is  $L = E/\Delta m^2$ . If  $L$  is sufficiently small, the mixing is fifty-fifty already before the muon neutrinos enter the system, where the measurement is carried out and no mixing is detected. If  $L$  is considerably longer than the size of the measuring system, no mixing is observed either. Therefore the result can be understood if  $\Delta m^2$  is much larger or much smaller than  $E/L$ , where  $L$  is the size of the measuring system and  $E$  is the typical neutrino energy.

2. MiniBooNE experiment found evidence for the appearance of electron neutrinos at low neutrino energies (below 500 MeV) which means direct support for the LSND findings and for the dependence of neutron mass scale on its energy relative to the rest system defined by the space-time sheet of laboratory.
3. Uncertainty Principle inspires the guess  $L_p \propto 1/E$  implying  $m_p \propto E$ . Here  $E$  is the energy of the neutrino with respect to the rest system defined by the space-time sheet of the laboratory. Solar neutrinos indeed have the lowest energy (below 20 MeV) and the lowest value of  $\Delta m^2$ . However, atmospheric neutrinos have energies starting from few hundreds of MeV and  $\Delta m^2$  is by a factor of order 10 higher. This suggests that the the growth of  $\Delta m^2$  with  $E^2$  is slower than linear. It is perhaps not the energy alone which matters but the space-time sheet at which neutrinos topologically condense. For instance, MiniBooNE neutrinos above 500 MeV would topologically condense at space-time sheets for which the p-adic mass scale is higher than in LSND experiments and one would have  $\Delta m^2 \gg 1\text{eV}^2$  implying maximal mixing in length scale much shorter than the size of experimental apparatus.
4. One could also argue that topological condensation occurs in condensed matter and that no topological condensation occurs for high enough neutrino energies so that neutrinos remain massless. One can even consider the possibility that the p-adic length scale  $L_p$  is proportional

to  $E/m_0^2$ , where  $m_0$  is proportional to the mass scale associated with non-relativistic neutrinos. The p-adic mass scale would obey  $m_p \propto m_0^2/E$  so that the characteristic mixing length would be by a factor of order 100 longer in MiniBooNE experiment than in LSND.

### Comments

Some comments on the proposed scenario are in order: some of the are written much later than the previous text.

1. Mass predictions are consistent with the bound  $\Delta m(\nu_\mu, \nu_e) < 2 eV^2$  coming from the requirement that neutrino mixing does not spoil the so called r-process producing heavy elements in Super Novae [?].
2. TGD neutrinos cannot solve the dark matter problem: the total neutrino mass required by the cold+hot dark matter models would be about 5 eV. In [K18] a model of galaxies based on string like objects of galaxy size and providing a more exotic source of dark matter, is discussed.
3. One could also consider the explanation of LSND data in terms of the interaction of  $\nu_\mu$  and nucleon via the exchange of  $g = 1$  W boson. The fraction of the reactions  $\bar{\nu}_\mu + p \rightarrow e^+ + n$  is at low neutrino energies  $P \sim \frac{m_W^4(g=0)}{m_W^4(g=1)} \sin^2(\theta_c)$ , where  $\theta_c$  denotes Cabibbo angle. Even if the condensation level of  $W(g = 1)$  is  $k = 89$ , the ratio is by a factor of order .05 too small to explain the average  $\nu_\mu \rightarrow \nu_e$  transformation probability  $P \simeq .003$  extracted from LSND data.
4. The predicted masses exclude MSW and vacuum oscillation solutions to the solar neutrino problem unless one assumes that several condensation levels and thus mass scales are possible for neutrinos. This is indeed suggested by the previous considerations.

### 5.6.3 Quark masses

The prediction of quark masses is more difficult due to the facts that the deduction of even the p-adic length scale determining the masses of these quarks is a non-trivial task, and the original identification was indeed wrong. Second difficulty is related to the topological mixing of quarks. The new scenario leads to a unique identification of masses with top quark mass as an empirical input and the thermodynamical model of topological mixing as a new theoretical input. Also CKM matrix is predicted highly uniquely.

#### Basic mass formulas

By the earlier mass calculations and construction of CKM matrix the ground state conformal weights of  $U$  and  $D$  type quarks must be  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$ . The formulas for the eigenvalues of  $CP_2$  spinor Laplacian imply that if  $m_0^2$  is used as a unit, color conformal weight  $h_c \equiv m_{CP_2}^2$  is integer for  $p \bmod = \pm 1$  for  $U$  type quark belonging to  $(p + 1, p)$  type representation and obeying  $h_c(U) = (p^2 + 3p + 2)/3$  and for  $p \bmod 3 = 1$  for  $D$  type quark belonging  $(p, p + 2)$  type representation and obeying  $h_c(D) = (p^2 + 4p + 4)/3$ . Only these states can be massless since color Hamiltonians have integer valued conformal weights.

In the recent case the minimal  $p = 1$  states correspond to  $h_c(U) = 2$  and  $h_c(D) = 3$ .  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$  reproduce the previous results for quark masses required by the construction of CKM matrix. This requires super-symplectic operators  $O$  with a net conformal weight  $h_{sc} = -3$  just as in the leptonic case. The facts that the values of  $p$  are minimal for spinor harmonics and the super-symplectic operator is same for both quarks and leptons suggest that the construction is not had hoc. The real justification would come from the demonstration that  $h_{sc} = -3$  defines null state for SCV: this would also explain why  $h_{sc}$  would be same for all fermions.

Consider now the mass squared values for quarks. For  $h(D) = 0$  and  $h(U) = -1$  and using  $m_0^2/3$  as a unit the expression for the thermal contribution to the mass squared of quark is given by the formula

$$\begin{aligned}
M^2 &= (s + X) \frac{m_0^2}{p} , \\
s(U) &= 5 , \quad s(D) = 8 , \\
X &\equiv \frac{(3Yp)_R}{3} ,
\end{aligned} \tag{5.6.10}$$

where the second order contribution  $Y$  corresponds to renormalization effects coming and depending on the isospin of the quark. When  $m_0^2$  is used as a unit  $X$  is replaced by  $X = (Y_p)_R$ .

With the above described assumptions one has the following mass formula for quarks

$$\begin{aligned}
M^2(q) &= A(q) \frac{m_0^2}{p(q)} , \\
A(u) &= 5 + X_U(p(u)) , \quad A(c) = 14 + X_U(p(c)) , \quad A(t) = 65 + X_U(p(t)) , \\
A(d) &= 8 + X_D(p(d)) , \quad A(s) = 17 + X_D(p(s)) , \quad A(b) = 68 + X_D(p(b)) .
\end{aligned} \tag{5.6.11}$$

p-Adic length scale hypothesis allows to identify the p-adic primes labelling quarks whereas topological mixing of U and D quarks allows to deduce topological mixing matrices U and D and CKM matrix V and precise values of the masses apart from effects like color magnetic spin orbit splitting, color Coulombic energy, etc..

Integers  $n_{q_i}$  satisfying  $\sum_i n(U_i) = \sum_i n(D_i) = 69$  characterize the masses of the quarks and also the topological mixing to high degree. The reason that modular contributions remain integers is that in the p-adic context non-trivial rationals would give  $CP_2$  mass scale for the real counterpart of the mass squared. In the absence of mixing the values of integers are  $n_d = n_u = 0$ ,  $n_s = n_c = 9$ ,  $n_b = n_t = 60$ .

The fact that CKM matrix  $V$  expressible as a product  $V = U^\dagger D$  of topological mixing matrices is near to a direct sum of  $2 \times 2$  unit matrix and  $1 \times 1$  unit matrix motivates the approximation  $n_b \simeq n_t$ . The large masses of top quark and of  $t\bar{t}$  meson encourage to consider a scenario in which  $n_t = n_b = n \leq 60$  holds true.

The model for topological mixing matrices and CKM matrix predicts U and D matrices highly uniquely and allows to understand quark and hadron masses in surprisingly detailed level.

1.  $n_d = n_u = 60$  is not allowed by number theoretical conditions for  $U$  and  $D$  matrices and by the basic facts about CKM matrix but  $n_t = n_b = 59$  allows almost maximal masses for  $b$  and  $t$ . This is not yet a complete hit. The unitarity of the mixing matrices and the construction of CKM matrix to be discussed in the next section forces the assignments

$$(n_d, n_s, n_b) = (5, 5, 59) , \quad (n_u, n_c, n_t) = (5, 6, 58) . \tag{5.6.12}$$

fixing completely the quark masses apart possible Higgs contribution [K46] . Note that top quark mass is still rather near to its maximal value.

2. The constraint that valence quark contribution to pion mass does not exceed pion mass implies the constraint  $n(d) \leq 6$  and  $n(u) \leq 6$  in accordance with the predictions of the model of topological mixing.  $u - d$  mass difference does not affect  $\pi^+ - \pi^0$  mass difference and the quark contribution to  $m(\pi)$  is predicted to be  $\sqrt{(n_d + n_u + 13)/24} \times 136.9$  MeV for the maximal value of  $CP_2$  mass (second order p-adic contribution to electron mass squared vanishes).

### The p-adic length scales associated with quarks and quark masses

The identification of p-adic length scales associated with the quarks has turned to be a highly non-trivial problem. The reasons are that for light quarks it is difficult to deduce information about quark masses for hadron masses and that the unknown details of the topological mixing (unknown until the

advent of the thermodynamical model [K46] ) made possible several p-adic length scales for quarks. It has also become clear that the p-adic length scale can be different for free quark and bound quark and that bound quark p-adic scale can depend on hadron.

Two natural constraints have however emerged from the recent work.

1. Quark contribution to the hadron mass cannot be larger than color contribution and for quarks having  $k_q \neq 107$  quark contribution to mass is added to color contribution to the mass. For quarks with same value of  $k$  conformal weight rather than mass is additive whereas for quarks with different value of  $k$  masses are additive. An important implication is that for diagonal mesons  $M = q\bar{q}$  having  $k(q) \neq 107$  the condition  $m(M) \geq \sqrt{2}m_q$  must hold true. This gives strong constraints on quark masses.
2. The realization that scaled up variants of quarks explain elegantly the masses of light hadrons allows to understand large mass splittings of light hadrons without the introduction of strong isospin-isospin interaction.

The new model for quark masses is based on the following identifications of the p-adic length scales.

1. The nuclear p-adic length scale  $L(k)$ ,  $k = 113$ , corresponds to the p-adic length scale determining the masses of u, d, and s quarks. Note that  $k = 113$  corresponds to a so called Gaussian Mersenne. The interpretation is that quark massivation occurs at nuclear space-time sheet at which quarks feed their em fluxes. At  $k = 107$  space-time sheet, where quarks feed their color gauge fluxes, the quark masses are vanishing in the first p-adic order. This could be due to the fact that the p-adic temperature is  $T_p = 1/2$  at this space-time sheet so that the thermal contribution to the mass squared is negligible. This would reflect the fact that color interactions do not involve any counterpart of Higgs mechanism.

p-Adic mass calculations turn out to work remarkably well for massive quarks. The reason could be that  $M_{107}$  hadron physics means that *all* quarks feed their color gauge fluxes to  $k = 107$  space-time sheets so that color contribution to the masses becomes negligible for heavy quarks as compared to Super-Kac Moody and modular contributions corresponding to em gauge fluxes fed to  $k > 107$  space-time sheets in case of heavy quarks. Note that  $Z^0$  gauge flux is fed to space-time sheets at which neutrinos reside and screen the flux and their size corresponds to the neutrino mass scale. This picture might throw some light to the question of whether and how it might be possible to demonstrate the existence of  $M_{89}$  hadron physics.

One might argue that  $k = 107$  is not allowed as a condensation level in accordance with the idea that color and electro-weak gauge fluxes cannot be fed at the space-time sheet since the classical color and electro-weak fields are functionally independent. The identification of  $\eta'$  meson as a bound state of scaled up  $k = 107$  quarks is not however consistent with this idea unless one assumes that  $k = 107$  space-time sheets in question are separate.

2. The requirement that the masses of diagonal pseudoscalar mesons of type  $M = q\bar{q}$  are larger but as near as possible to the quark contribution  $\sqrt{2}m_q$  to the valence quark mass, fixes the p-adic primes  $p \simeq 2^k$  associated with  $c$ ,  $b$  quarks but not  $t$  since toponium does not exist. These values of  $k$  are "nominal" since  $k$  seems to be dynamical.  $c$  quark corresponds to the p-adic length scale  $k(c) = 104 = 2^3 \times 13$ .  $b$  quark corresponds to  $k(b) = 103$  for  $n(b) = 5$ . Direct determination of p-adic scale from top quark mass gives  $k(t) = 94 = 2 \times 47$  so that secondary p-adic length scale is in question.

Top quark mass tends to be slightly too low as compared to the most recent experimental value of  $m(t) = 169.1$  GeV with the allowed range being [164.7, 175.5] GeV [?]. The optimal situation corresponds to  $Y_e = 0$  and  $Y_t = 1$  and happens to give top mass exactly equal to the most probable experimental value. It must be emphasized that top quark is experimentally in a unique position since toponium does not exist and top quark mass is that of free top.

In the case of light quarks there are good reasons to believe that the p-adic mass scale of quark is different for free quark and bound state quark and that in case of bound quark it can also depend on hadron. This would explain the notions of valence (constituent) quark and current quark mass as

masses of bound state quark and free quark and leads also to a TGD counterpart of Gell-Mann-Okubo mass formula [K46] .

1. Constituent quark masses

Constituent quark masses correspond to masses derived assuming that they are bound to hadrons. If the value of  $k$  is assumed to depend on hadron one obtains nice mass formula for light hadrons as will be found later. The table below summarizes constituent quark masses as predicted by this model.

2. Current quark masses

Current quark masses would correspond to masses of free quarks which tend to be lower than valence quark masses. Hence  $k$  could be larger in the case of light quarks. The table of quark masses in Wikipedia [?] gives the value ranges for current quark masses depicted in the table below together with TGD predictions for the spectrum of current quark masses.

$q$	d	u	s
$m(q)_{exp}/MeV$	4-8	1.5-4	80-130
$k(q)$	(122,121,120)	(125,124,123,122)	(114,113,112)
$m(q)/MeV$	(4.5,6.6,9.3)	(1.4,2.0,2.9,4.1)	(74,105,149)
$q$	c	b	t
$m(q)_{exp}/MeV$	1150-1350	4100-4400	1691
$k(q)$	(106,105)	(105,104)	92
$m(q)/MeV$	(1045,1477)	(3823,5407)	$167.8 \times 10^3$

Table 3. The experimental value ranges for current quark masses [?] and TGD predictions for their values assuming  $(n_d, n_s, n_b) = (5, 5, 59)$ ,  $(n_u, n_c, n_t) = (5, 6, 58)$ , and  $Y_e = 0$ . For top quark  $Y_t = 0$  is assumed.  $Y_t = 1$  would give 169.2 GeV.

Some comments are in order.

1. The long p-adic length associated with light quarks seem to be in conflict with the idea that quarks have sizes smaller than hadron size. The paradox disappears when one realized that  $k(q)$  characterizes the electromagnetic "field body" of quark having much larger size than hadron.
2.  $u$  and  $d$  current quarks correspond to a mass scale not much higher than that of electron and the ranges for mass estimates suggest that  $u$  could correspond to scales  $k(u) \in (125, 124, 123, 122) = (5^3, 4 \times 31, 3 \times 41, 2 \times 61)$ , whereas  $d$  would correspond to  $k(d) \in (122, 121, 120) = (2 \times 61, 11^2, 3 \times 5 \times 8)$ .
3. The TGD based model for nuclei based on the notion of nuclear string leads to the conclusion that exotic copies of  $k = 113$  quarks having  $k = 127$  are present in nuclei and are responsible for the color binding of nuclei [K69, L3] , [L3] .
4. The predicted values for  $c$  and  $b$  masses are slightly too low for  $(k(c), k(b)) = (106, 105) = (2 \times 53, 3 \times 5 \times 7)$ . Second order Higgs contribution could increase the  $c$  mass into the range given in [?] but not that of  $b$ .
5. The mass of top quark has been slightly below the experimental estimate for long time. The experimental value has been coming down slowly and the most recent value obtained by CDF [?] is  $m_t = 165.1 \pm 3.3 \pm 3.1$  GeV and consistent with the TGD prediction for  $Y_e = Y_t = 0$ .

One can talk about constituent and current quark masses simultaneously only if they correspond to dual descriptions.  $M^8 - H$  duality [K39] has been indeed suggested to relate the old fashioned low energy description of hadrons in terms of  $SO(4)$  symmetry (Skyrme model) and higher energy description of hadrons based on QCD. In QCD description the mass of say baryon would be dominated by the mass associated with super-symplectic quanta carrying color. In  $SO(4)$  description constituent quarks would carry most of the hadron mass.

**Can Higgs field develop a vacuum expectation in fermionic sector at all?**

An important conclusion following from the calculation of lepton and quark masses is that if Higgs contribution is present, it can be of second order p-adically and even negligible, perhaps even vanishing. There is indeed an argument forcing to consider this possibility seriously. The recent view about elementary particles is following.

1. Fermions correspond to  $CP_2$  type vacuum extremals topologically condensed at positive/negative energy space-time sheets carrying quantum numbers at light-like wormhole throat. Higgs and gauge bosons correspond to wormhole contacts connecting positive and negative energy space-time sheets and carrying fermion and anti-fermion quantum numbers at the two light-like wormhole throats.
2. If the values of p-adic temperature are  $T_p = 1$  and  $T_p = 1/n$ ,  $n > 1$  for fermions and bosons the thermodynamical contribution to the gauge boson mass is negligible.
3. Different p-adic temperatures and Kähler coupling strengths for fermions and bosons make sense if bosonic and fermionic partonic 3-surfaces meet only along their ends at the vertices of generalized Feynman diagrams but have no other common points [K17]. This forces to consider the possibility that fermions cannot develop Higgs vacuum expectation value although they can couple to Higgs. This is not in contradiction with the modification of sigma model of hadrons based on the assumption that vacuum expectation of  $\sigma$  field gives a small contribution to hadron mass [K43] since this field can be assigned to some bosonic space-time sheet pair associated with hadron.
4. Perhaps the most elegant interpretation is that ground state conformal is equal to the square of the eigenvalue of the modified Dirac operator. The ground state conformal weight is negative and its deviation from half odd integer value gives contribution to both fermion and boson masses. The Higgs expectation associated with coherent state of Higgs like wormhole contacts is naturally proportional to this parameter since no other parameter with dimensions of mass is present. Higgs vacuum expectation determines gauge boson masses only apparently if this interpretation is correct. The contribution of the ground state conformal weight to fermion mass square is near to zero. This means that  $\lambda$  is very near to negative half odd integer and therefore no significant difference between fermions and gauge bosons is implied.

$q$	d	u	s	c	b	t
$n_q$	4	5	6	6	59	58
$s_q$	12	10	14	11	67	63
$k(q)$	113	113	113	104	103	94
$m(q)/GeV$	.105	.092	.105	2.191	7.647	167.8

Table 2. Constituent quark masses predicted for diagonal mesons assuming  $(n_d, n_s, n_b) = (5, 5, 59)$  and  $(n_u, n_c, n_t) = (5, 6, 58)$ , maximal  $CP_2$  mass scale ( $Y_e = 0$ ), and vanishing of second order contributions.

**5.7 Higgsy aspects of particle massivation**

**5.7.1 Can p-adic thermodynamics explain the masses of intermediate gauge bosons?**

The requirement that the electron-intermediate gauge boson mass ratios are sensible, serves as a stringent test for the hypothesis that intermediate gauge boson masses result from the p-adic thermodynamics. It seems that the only possible option is that the parameter  $k$  has same value for both bosons, leptons, and quarks:

$$k_B = k_L = k_q = 1 .$$

In this case all gauge bosons have  $D(0) = 1$  and there are good changes to obtain boson masses correctly.  $k = 1$  together with  $T_p = 1$  implies that the thermal masses of very many boson states are extremely heavy so that the spectrum of the boson exotics is reduced drastically. For  $T_p = 1/2$  the thermal contribution to the mass squared is completely negligible.

Contrary to the original optimistic beliefs based on calculational error, it turned out impossible to predict  $W/e$  and  $Z/e$  mass ratios correctly in the original p-adic thermodynamics scenario. Although the errors are of order 20-30 percent, they seemed to exclude the explanation for the massivation of gauge bosons using p-adic thermodynamics.

1. The thermal mass squared for a boson state with  $N$  active sectors (non-vanishing vacuum weight) is determined by the partition function for the tensor product of  $N$  NS type Super Virasoro algebras. The degeneracies of the excited states as a function of  $N$  and the weight  $\Delta$  of the operator creating the massless state are given in the table below.
2. Both  $W$  and  $Z$  must correspond to  $N = 2$  active Super Virasoro sectors for which  $D(1) = 1$  and  $D(2) = 3$  so that (using the formulas of p-adic thermodynamics the thermal mass squared is  $m^2 = k_B(p + 5p^2)$  for  $T_p = 1$ . The second order contribution to the thermal mass squared is extremely small so that Weinberg angle vanishes in the thermal approximation.  $k_B = 1$  gives  $Z/e$  mass-ratio which is about 22 per cent too high. For  $T_p = 1/2$  thermal masses are completely negligible.
3. The thermal prediction for W-boson mass is the same as for  $Z^0$  mass and thus even worse since the two masses are related  $M_W^2 = M_Z^2 \cos^2(\theta_W)$ .

### 5.7.2 Comparison of TGD Higgs and with MSSM Higgs

The notion of Higgs in TGD framework differs from that of standard model and super-symmetric extension in several respects. Very concisely, the two complex  $SU(2)_V$  doublets are replaced with scalar and pseudoscalar triplet and singlet so that the number of field components is same. The Higgs possibly developing vacuum expectation is now uniquely the scalar singlet unless one allows parity breaking. The number of remaining Higgs field components is 5 as in the minimal supersymmetric extension of the standard model.

#### TGD based particle concept very briefly

Before attempt to clarify the differences between TGD and standard model Higgs it is good to list the basic ideas behind TGD based notion of particle.

1. Bosonic emergence means that gauge bosons and Higgs and their super partners can be in the first approximation regarded as wormhole contacts with the throats carrying quantum numbers of fermion and antifermion. A given throat carrying fermionic quantum numbers. Also many fermion states are possible and have interpretation in terms of a supersymmetry extending the ordinary space-time supersymmetry in which super-generators are simply the fermionic oscillator operators assignable to the partonic 2-surface. These generators can be used to construct various super-conformal algebras. Right-handed neutrinos define the analog of ordinary space-time super-supersymmetry as it is encountered in MSSM. In topological condensation also fermions become wormhole contacts with second throat carrying purely bosonic quantum numbers.
2. The weak form of electric magnetic duality forces the conclusion that wormhole throats carry Kähler magnetic charges which much be neutralized by opposite Kähler magnetic charge. The natural idea is that monopole confinement is also behind color confinement and electroweak screening. In the case of color confinement the valence quarks would form wormhole throats connected by color magnetic flux tubes having total Kähler magnetic charge. Weak screening would mean that the throat compensating the Kähler magnetic charge of fermionic throat contains a neutrino-antineutrino pairs screening the weak isospin. This leaves to  $Z^0$  coupling  $I_L^3 + \sin^2(\theta_W)Q_{em}$  and if classical  $Z^0$  field is present this leads to an interaction distinguishing between TGD and standard model.

3. Particle massivation is described by p-adic thermodynamics. p-Adic thermodynamics cannot explain gauge boson masses and if it contributes the contribution is small and corresponds to low p-adic temperatures  $T_p = 1/n$ . It is not yet completely clear whether the generation of vacuum contribution to ground state conformal weight implying deviation from half-integer value is responsible for weak gauge boson masses. It might be sensible to speak about coherent state of Higgs bosons in zero energy ontology and also in the case of fermions if interacting fermions have suffered topological condensation. If this is the case Higgs vacuum expectation value defining the coherent state can contribute to the particle mass but only in the case of weak gauge bosons give a dominating contribution. It is not clear whether the generation of non-half-integer vacuum conformal weight and Higgs mechanisms could be seen descriptions of one and same thing.

### Scalar and pseudo-scalar triplet and singlet instead of two doublets

TGD based notion of Higgs differs from its standard model and MSSM counterpart because the notion of spinor is different. If one believes on the following arguments, the basic implication is that two Higgs doublets of MSSM are replaced with scalar and pseudo-scalar triplet and singlet.

1. In TGD framework space-time spinors are induced spinors and therefore spinors of 8-D space  $M^4 \times CP_2$ . The mixing of  $M^4$  chiralities in the modified Dirac equation in the space-time interior serves as a tell-tale signature for the massivation and does not imply mixing of the imbedding space chiralities identified in terms of leptons and quarks.
2. Group theoretically gauge bosons and Higgs itself corresponds to a tensor product of two  $M^4 \times CP_2$  spinors giving rise to a spin singlet. In electroweak degrees of freedom one has a tensor product of right and left handed doublets decomposing to triplet and singlet under  $SU(2)_V$ . The first guess would be that one obtains just triplet 3 and singlet 1 whereas in standard model one has a complex  $SU(2)_V$  doublet. In MSSM the cancellation of anomalies requires two doublets. As noticed, TGD allows supersymmetry generalizing the usual space-time supersymmetry and also no anomaly cancellation argument allows to expect a pairs of triplets and singlets.
3. One can assign fermion with "upper" throat and antifermion with the "lower" throat or vice versa and one can have both the sum or difference of these two states. This does not however imply additional degeneracy. Fermionic statistics requires the antisymmetry of the state with respect to the exchange of all quantum numbers. Spin and isospin triplets (singlets) are symmetric (antisymmetric) under the exchange of spin quantum numbers and singlets antisymmetric. In the case of Higgs triplet (singlet) the sum (difference) of these states must be assumed and there is no additional degeneracy.
4. One can construct gauge bosons and Higgs type particles from both quarks and leptons. The requirement that the gauge bosons couple to both quarks and leptons implies that they correspond to sums of these Higgses and behave like  $H$ -vectors for one has  $\Gamma_9 = 1$ . One can however ask whether also  $H$ -axial vector gauge bosons and Higgs with  $\Gamma_9 = -1$  should be allowed. They are not suggested by the study of the modified Dirac equation and it seems that this leads to physically non-sensical results. First of all, the exchanges of vectorial and axial Higgses between leptons and quarks would be of opposite sign and at high energies the sum over these exchanges would approach zero so that quark and lepton sectors would separate into non-interacting worlds. It is also difficult to imagine how one could avoid  $H$ -axial massless photon. p-Adic thermodynamics would allow the  $H$ -axial photon to become massive but it is not possible to understand how the  $H$ -axial scalar Higgs could transform to a longitudinal degree of freedom of the resulting  $H$ -axial photon.
5. One can construct the most general candidate for a Higgs particle using as charge matrix contracted between spinors associated with the opposite wormhole throats the product of a vector in the tangent space of  $CP_2$  represented as sum of constant gamma matrices  $\gamma_A$  and electroweak charge matrix. One can express the products of the  $CP_2$  gamma matrices and charge matrices in terms of  $CP_2$  gamma matrices  $\gamma_A$  and  $\gamma_5(CP_2)\gamma_A$ . The action of  $CP_2$  gamma matrix  $\gamma_5$  however reduces to that of  $\epsilon\gamma_5(M^4)$ , where the sign factor  $\epsilon = \pm 1$  depends on H-chirality. Therefore one would have scalar Higgs and pseudo-scalar Higgs and the couplings of pseudo-scalar

Higgs are of opposite sign for quarks and leptons. In unitary gauge one would have neutral scalar Higgs and 4 pseudo-scalar Higgses with the same charge spectrum as in MSSM. One can indeed construct Higgs particles as fermion-antifermion pairs by using products of charge matrices and  $CP_2$  tangent space vector and transform them to scalar and pseudoscalar multiplets.

6. In Higgs mechanism the key idea is that one can represent the directional degrees of freedom of Higgs field in terms of coset space  $G/H$ , now  $SU(2)_L \times U(1)/U(1)_{em}$ . Therefore Higgs field can be written as in the form  $exp(\sum_{T_a \in t} T^a \xi_a / v)(\rho + v)$ ,  $t = g - h$ , where  $v$  is the expectation value of the Higgs field fixing a preferred direction. The gauge transformation  $g = exp(-\sum_{T_a \in t} T^a \xi_a / v)$  transforms Higgs to  $\rho + v$  so that the degrees of freedom corresponding to the direction of Higgs are "eaten" by charge gauge potentials. In the resulting gauge the action contains only the YM part and Higgs term restricted to the fluctuations of Higgs around vacuum in the direction of  $v$ . In the recent case the coset space would be the coset space of the holonomy group of  $CP_2$  divided by the subgroup defined by electromagnetic charge commuting with the vacuum expectation value which is therefore linear combination of  $\gamma_0$  and  $\gamma_3$  in the most general case. The condition that entire  $SU(2)_V$  leaves invariant the preferred direction fixes this direction to  $\gamma_0$  which corresponds to the radial coordinate of  $CP_2$  in the standard vielbein basis. In the recent case  $CP_2$  holonomy group naturally defines a preferred direction of Higgs field and it seems that vacuum expectation value is not necessary for the elimination of the charged Higgs. Neutral Higgs would essentially correspond to the magnitude of the Higgs field.
7. If the TGD based description of radiative corrections relying on the notion of generalized Feynman diagram is approximately equivalent with QFT based description and if should not differ too dramatically from those of MSSM in the approximation of  $N = 1$  supersymmetry meaning that only the super partners obtained using right handed neutrinos and antineutrinos are taken into account. At high energies the the action of  $\gamma_5$  gives only a minus sign telling the  $M^4$  chirality of approximately massless particle and one has right to expect that the effects of pseudo-scalar exchange in loops do not differ dramatically from those of a scalar exchange.

### Can one identify a classical correlate for the Higgs?

The natural question is whether one can identify classical correlates for the Higgs field and massivation. Kähler action does not allow to identify any obvious correlates whereas Kähler Dirac action does.

1. Kähler Dirac action in the interior of space-time surface should contain the counterpart of Higgs term whose signature is that it mixes  $M^4$  chiralities. The interaction term analogous to that appearing in the ordinary Dirac action coupled to gauge fields is

$$\begin{aligned}
 L_{int} &= \bar{\Psi} \hat{\Gamma}^\alpha A_\alpha \Psi , \\
 \hat{\Gamma}^\alpha &= T^{\alpha k} \gamma_k = T^{\alpha k} \gamma_k(M^4) + T^{\alpha k} \gamma_k(CP_2) , \\
 T^{\alpha k} &= \frac{\partial L_K}{\partial(\partial_\alpha h^k)} .
 \end{aligned} \tag{5.7.1}$$

Here  $A_\alpha$  are the components of the induced spinor connection.  $T^{\alpha k}$  denotes canonical momentum densities and conserved momentum and color currents are closely related to them. They are required by internal consistency (in particular, by the consistency with the vacuum degeneracy of Kähler action) and super-symmetry. If action were defined by the volume of space-time surface in the induced metric, modified gamma matrices would reduce to induced gamma matrices coding information about classical gravitational fields. Also now information about gravitation is coded besides the dynamics of Kähler action associated with zero modes. Kähler field can indeed be said to characterize zero modes locally whereas quantum fluctuating degrees contributing to the WCW metric and therefore identifiable as gravitational degrees of freedom in generalized sense of the word [?] .

The modified gamma matrices decompose to two parts corresponding to  $M^4$  and  $CP_2$  gamma matrices and the presence of  $CP_2$  gamma matrices implies the mixing of  $M^4$  chiralities so that

massivation is unavoidable once one has a space-time surface which does not correspond to the canonically imbedded  $M^4$ . Also the kinetic part of  $\bar{\Gamma}^\alpha \partial_\alpha$  contains a term mixing  $M^4$  chiralities having no obvious counterpart in the ordinary Dirac equation. The important conclusion is that whatever the dynamical details of massivation are it must take place.

2. The interaction term  $T^{\alpha k} \gamma_k (CP_2) A_\alpha$  of the modified Dirac action defined by the contraction of canonically conjugate momenta with gauge potentials mixes  $M^4$  chiralities so that it is in this sense analogous to Higgs coupling. In gauge transformations the gauge potentials however transform inhomogeneously. Does this mean that the term in question can be interpreted only as a signature for the presence of particle massivation or is also the identification as the classical counterpart of Higgs field sensical?

Optimist could argue that there is a natural preferred gauge associated with the classical spinor connection. For instance, the Coulomb interaction term for Kähler action vanishes in preferred gauge for the general solution ansatz implying the reduction of Kähler function to Chern-Simons term for extremal in presence of a constraint expressing the weak form of electric-magnetic duality. For Kähler gauge potential this gauge is highly unique. Also, if one imagines adding to the induced gauge potential quantum fluctuating part representing the quantum field, one could say that the classical Higgs field transforms homogeneously and that quantum part is gauge transformed inhomogeneously. The situation remains unsettled.

3. The classical correlate for the Higgs field in TGD is not a genuine scalar field but defines a vector in the 4-D tangent space of  $CP_2$ . This allows to speak about  $CP_2$  polarization. If the notion of unitary gauge meaning that an electro-weak gauge rotation takes Higgs to a standard direction invariant under  $SU(2)_V$  rotations - in particular those induced by the vectorial isospin  $I_V^3$  appearing in electromagnetic charge- then one can say that  $CP_2$  polarization is always in the same direction for the scalar Higgs. In the case of pseudo-scalar Higgs all four  $CP_2$  polarizations are possible.

### 5.7.3 How TGD based description of particle massivation relates to Higgs mechanism

In TGD framework p-adic thermodynamics gives the dominating contribution to fermion masses, which is something completely new. In the case of gauge bosons thermodynamic contribution is small since the inverse integer valued p-adic temperature is  $T = 1/2$  for bosons or even lower: for fermions one has  $T = 1$ .

Whether Higgs can contribute to the masses is not completely clear. In TGD framework Mexican hat potential however looks like trick. One must however keep in mind that any other mechanism must explain the ratio of W and  $Z^0$  masses and how these bosons receive their longitudinal polarizations. One must also consider seriously the possibility that all components for the TGD counterpart of Higgs boson are transformed to the longitudinal polarizations of the gauge bosons. Twistorial approach to TGD indeed strongly suggests that also the gauge bosons regarded usually as massless have a small mass guaranteeing cancellation of IR singularities. As I started write to write this piece of text I believed that photon does not eat Higgs but had to challenge my beliefs. Maybe there is no Higgs to be found at LHC! Only pseudo-scalar partner of Higgs would remain to be discovered.

The weak form of electric magnetic duality implying that each wormhole throat carrying fermionic quantum numbers is accompanied by a second wormhole throat carrying opposite magnetic charge and neutrino pair screening weak isospin and making gauge bosons massive. Concerning the implications the following view looks the most plausible one at this moment.

1. Neutral Higgs-if not eaten by photon- could develop a coherent state meaning vacuum expectation value and this is naturally proportional to the inverse of the p-adic length scale as are boson masses. This contribution can be assigned to the magnetic flux tube mentioned above since it screens weak force - or equivalently - makes them massive. Higgs expectation would not cause boson massivation. Rather, massivation and Higgs vacuum expectation would be caused by the presence of the magnetic flux tubes. Standard model would suffer from a causal illusion. Even a worse illusion is possible if the photon eats the neutral Higgs.

2. The "stringy" magnetic flux tube connecting fermion wormhole throat and the wormhole throat containing neutrino pair would give to the vacuum conformal weight a small contribution and therefore to the mass squared of both fermions and gauge bosons (dominating one for the latter). This contribution would be small in the p-adic sense (proportional  $1/p^2$  rather than  $1/p$ ). I cannot calculate this "stringy" contribution but stringy formula in weak scale is very suggestive.
3. In the case of light fermions and massless gauge bosons the stringy contribution must vanish and therefore must correspond to  $n = 0$  string excitation (string does not vibrate at all) : otherwise the mass of fermion would be of order weak boson mass. For weak bosons  $n = 1$  would look like a natural identification but also  $n = 0$  makes sense since  $h \pm 1$  states corresponds opposite three-momenta for massless fermion and antifermion so that the state is massive. The mechanism bringing in the  $h = 0$  helicity of gauge boson would be the TGD counterpart for the transformation of Higgs component to a longitudinal polarization.  $n \geq 0$  excited states of fermions and  $n \geq 1$  excitations of bosons having masses above weak boson masses are predicted and would mean new physics becoming possibly visible at LHC.

#### 5.7.4 The identification of Higgs

Consider now the identification of Higgs in TGD framework.

1. In TGD framework Higgs particles do not correspond to complex  $SU(2)$  doublets but to triplet and singlet having same quantum numbers as gauge bosons. Therefore the idea that photon eats neutral Higgs is suggestive. Also a pseudo-scalar variant of Higgs is predicted. Let us see how these states emerge from weak strings.
2. The two kinds of massive states corresponding to  $n = 0$  and  $n = 1$  give rise to massive spin 1 and spin 2 particles. First of all, the helicity doublet  $(1, -1)$  is necessarily massive since the 3-momenta for massless fermion and anti-fermion are opposite. For  $n = L = 0$  this gives two states but helicity zero component is lacking. For  $n = L = 1$  one has tensor product of doublet  $(1, -1)$  and angular momentum triplet formed by  $L = 1$  rotational state of the weak string. This gives  $2 \times 3$  states corresponding to  $J = 0$  and  $J = 2$  multiplets. Note however than in spin degrees of freedom the Higgs candidate is not a genuine elementary scalar particle.
3. Fermion and antifermion can have parallel three momenta summing up to a massless 4-momentum. Spin vanishes so that one has Higgs like particle also now. This particle is however pseudo-scalar being group theoretically analogous to meson formed as a pair of quark and antiquark. p-Adic thermodynamics gives a contribution to the mass squared. By taking a tensor product with rotational states of strings one would obtain Regge trajectory containing pseudoscalar Higgs as the lowest state.

#### 5.7.5 Do all gauge bosons possess small mass?

Consider now the problem how the gauge bosons can eat the Higgs boson to get their longitudinal component.

1. ( $J = 0, n = 1$ ) Higgs state can be combined with  $n = 0$   $h = \pm 1$  doublet to give spin 1 massive triplet provided the masses of the two states are same. This will be discussed below.
2. Also gauge bosons usually regarded as massless can eat the scalar Higgs so that Higgs like particle could disappear completely. There would be no Higgs to be discovered at LHC! But is this a real prediction? Could it be that it is not possible to have exactly massless photons and gluons? The mixing of  $M^4$  chiralities for Chern-Simons Dirac equation implies that also collinear massless fermion and antifermion can have helicity  $\pm 1$ . The problem is that the mixing of the chiralities is a signature of massivation!

Could it really be that even the gauge bosons regarded as massless have a small mass characterized by the length scale of the causal diamond defining the physical IR cutoff and that the remaining Higgs component would correspond to the longitudinal component of photon? This would mean the number of particles in the final states for a particle reaction with a fixed

initial state is always bounded from above. This is important for the twistorial aesthetics of generalized Feynman diagrammatics implied by zero energy ontology. Also the vanishing of IR divergences is guaranteed by a small physical mass [?] . Maybe internal consistency allows only pseudo-scalar Higgs.

### 5.7.6 Weak Regge trajectories

The weak form of electric-magnetic duality suggests strongly the existence of weak Regge trajectories.

1. The most general mass squared formula with spin-orbit interaction term  $M_{L-S}^2 L \cdot S$  reads as

$$M^2 = nM_1^2 + M_0^2 + M_{L-S}^2 L \cdot S, \quad n = 0, 2, 4 \text{ or } n = 1, 3, 5, \dots, \quad (5.7.2)$$

$M_1^2$  corresponds to string tension and  $M_0^2$  corresponds to the thermodynamical mass squared and possible other contributions. For a given trajectory even (odd) values of  $n$  have same parity and can correspond to excitations of same ground state. From ancient books written about hadronic string model one vaguely recalls that one can have several trajectories (satellites) and if one has something called exchange degeneracy, the even and odd trajectories define single line in  $M^2 - J$  plane. As already noticed TGD variant of Higgs mechanism combines together  $n = 0$  states and  $n = 1$  states to form massive gauge bosons so that the trajectories are not independent.

2. For fermions, possible Higgs, and pseudo-scalar Higgs and their super partners also p-adic thermodynamical contributions are present.  $M_0^2$  must be non-vanishing also for gauge bosons and be equal to the mass squared for the  $n = L = 1$  spin singlet. By applying the formula to  $h = \pm 1$  states one obtains

$$M_0^2 = M^2(\text{boson}) . \quad (5.7.3)$$

The mass squared for transversal polarizations with  $(h, n, L) = (\pm 1, n = L = 0, S = 1)$  should be same as for the longitudinal polarization with  $(h = 0, n = L = 1, S = 1, J = 0)$  state. This gives

$$M_1^2 + M_0^2 + M_{L-S}^2 L \cdot S = M_0^2 . \quad (5.7.4)$$

From  $L \cdot S = [J(J+1) - L(L+1) - S(S+1)]/2 = -2$  for  $J = 0, L = S = 1$  one has

$$M_{L-S}^2 = -\frac{M_1^2}{2} . \quad (5.7.5)$$

Only the value of weak string tension  $M_1^2$  remains open.

3. If one applies this formula to arbitrary  $n = L$  one obtains total spins  $J = L + 1$  and  $L - 1$  from the tensor product. For  $J = L - 1$  one obtains

$$M^2 = (2n + 1)M_1^2 + M_0^2 .$$

For  $J = L + 1$  only  $M_0^2$  contribution remains so that one would have infinite degeneracy of the lightest states. Therefore stringy mass formula must contain a non-linear term making Regge trajectory curved. The simplest possible generalization which does not affect  $n=0$  and  $n=1$  states is of from

$$M^2 = n(n-1)M_2^2 + \left(n - \frac{L \cdot S}{2}\right)M_1^2 + M_0^2 . \quad (5.7.6)$$

The challenge is to understand the ratio of W and  $Z^0$  masses, which is purely group theoretic and provides a strong support for the massivation by Higgs mechanism.

1. The above formula and empirical facts require

$$\frac{M_0^2(W)}{M_0^2(Z)} = \frac{M^2(W)}{M^2(Z)} = \cos^2(\theta_W) . \quad (5.7.7)$$

in excellent approximation. Since this parameter measures the interaction energy of the fermion and antifermion decomposing the gauge boson depending on the net quantum numbers of the pair, it would look very natural that one would have

$$M_0^2(W) = g_W^2 M_{SU(2)}^2 , \quad M_0^2(Z) = g_Z^2 M_{SU(2)}^2 . \quad (5.7.8)$$

Here  $M_{SU(2)}^2$  would be the fundamental mass squared parameter for  $SU(2)$  gauge bosons. p-Adic thermodynamics of course gives additional contribution which is vanishing or very small for gauge bosons.

2. The required mass ratio would result in an excellent approximation if one assumes that the mass scales associated with  $SU(2)$  and  $U(1)$  factors suffer a mixing completely analogous to the mixing of  $U(1)$  gauge boson and neutral  $SU(2)$  gauge boson  $W_3$  leading to  $\gamma$  and  $Z^0$ . Also Higgs, which consists of  $SU(2)$  triplet and singlet in TGD Universe, would very naturally suffer similar mixing. Hence  $M_0(B)$  for gauge boson  $B$  would be analogous to the vacuum expectation of corresponding mixed Higgs component. More precisely, one would have

$$\begin{aligned} M_0(W) &= M_{SU(2)} , \\ M_0(Z) &= \cos(\theta_W) M_{SU(2)} + \sin(\theta_W) M_{U(1)} , \\ M_0(\gamma) &= -\sin(\theta_W) M_{SU(2)} + \cos(\theta_W) M_{U(1)} . \end{aligned} \quad (5.7.9)$$

The condition that photon mass is very small and corresponds to IR cutoff mass scale gives  $M_0(\gamma) = \epsilon \cos(\theta_W) M_{SU(2)}$ , where  $\epsilon$  is very small number, and implies

$$\begin{aligned} \frac{M_{U(1)}}{M(W)} &= \tan(\theta_W) + \epsilon , \\ \frac{M(\gamma)}{M(W)} &= \epsilon \times \cos(\theta_W) , \\ \frac{M(Z)}{M(W)} &= \frac{1 + \epsilon \times \sin(\theta_W) \cos(\theta_W)}{\cos(\theta_W)} . \end{aligned} \quad (5.7.10)$$

There is a small deviation from the prediction of the standard model for W/Z mass ratio but by the smallness of photon mass the deviation is so small that there is no hope of measuring it. One can of course keep mind open for  $\epsilon = 0$ . The formulas allow also an interpretation in terms of Higgs vacuum expectations as it must. The vacuum expectation would most naturally correspond to interaction energy between the massless fermion and antifermion with opposite 3-momenta at the throats of the wormhole contact and the challenge is to show that the proposed formulas characterize this interaction energy. Since  $CP_2$  geometry codes for standard model symmetries and their breaking, it would not be surprising if this would happen. One cannot exclude the possibility that p-adic thermodynamics contributes to  $M_0^2(boson)$ . For instance,  $\epsilon$  might characterize the p-adic thermal mass of photon.

If the mixing applies to the entire Regge trajectories, the above formulas would apply also to weak string tensions, and also photons would belong to Regge trajectories containing high spin excitations.

3. What one can one say about the value of the weak string tension  $M_1^2$ ? The naive order of magnitude estimate is  $M_1^2 \simeq m_W^2 \simeq 10^4 \text{ GeV}^2$  is by a factor 1/25 smaller than the direct scaling up of the hadronic string tension about  $1 \text{ GeV}^2$  scaled up by a factor  $2^{18}$ . The above argument however allows also the identification as the scaled up variant of hadronic string tension in which case the higher states at weak Regge trajectories would not be easy to discover since the mass scale defined by string tension would be 512 GeV to be compared with the recent beam energy 7 TeV. Weak string tension need of course not be equal to the scaled up hadronic string tension. Weak string tension - unlike its hadronic counterpart- could also depend on the electromagnetic charge and other characteristics of the particle.

### 5.7.7 Is the earlier conjectured pseudoscalar Higgs there at all?

Spin 1 gauge bosons and Higgs differ only by different spin direction of fermions at opposite wormhole throats. For spin 1 gauge bosons the 3-momenta at two wormhole throats cannot be parallel if one wants non-vanishing spin component in the direction of moment. 3-momenta are most naturally opposite for the massless states at throats. This forces massivation for all gauge bosons and even graviton and this in turn requires Higgs even in the case of gluons.

This inspires the question whether the parity properties of the couplings of gauge boson and corresponding Higgs transforming like 3+1 under SU(2) (this is due to the special character of imbedding space spinors) could be exactly the same? Higgs would couple like a mixture of scalar and pseudoscalar to fermions just as weak gauge bosons couple and the mixture would be just the same. If there are no axial variants of vector gauge bosons there should exist no pseudoscalar Higgs. The nonexistence of axial variants of vector gauge bosons is suggested by quantum classical correspondence: only gauge bosons having classical space-time correlates as induced gauge potentials should be allowed, nothing else. Note that color variant of Higgs would exist and would be eaten by gluons to get mass.

The similarity of the construction of gauge bosons and Higgsinos as pairs of wormhole throats containing fermion and antifermion encourages to think that Higgs mechanism is invariant under supersymmetries. If so, also Higgsinos would be eaten and one would have massive super-symmetric gauge theory with fermions with photon and other massless particle possessing a tiny mass. This looks very simple. The testable implication would be that only weak gauginos should contribute to muon g-2 anomaly.

### 5.7.8 Higgs issue after Europhysics 2011

The general feeling at the Eve of Europhysics 2011 conference was that this meeting might become one of the key events in the history of physics. This might turn out to be the case. CDF and D0 were the groups representing the data from p-pbar collisions at Tevatron whereas ATLAS and CMS represented the data about p-p collisions at LHC. The blog participation transformed the conference from a closed meeting of specialists to a media event inspiring intense blog discussions and viXra log became the most interesting discussion forum thanks to the excellent postings of Phil Gibbs giving focused summaries of various reports about SUSY and Higgs.

The hope was that two basic questions would receive a unique answer. Does Higgs exist and if so what is its mass? Is the standard view about SUSY correct: in other words do the super-partners exist with masses below TeV scale? It was clear that negative answer to even the Higgs issue would force a thorough reconsideration of the status of not only MSSM but also that of super string theory and M-theory because of the general role of Higgs mechanism in the description massivation and symmetry breaking for the QFT limits of these theories. The implications are far reaching also for the inflationary cosmology where scalar fields and Higgs mechanism are taken as granted. Actually the non-existence of Higgs forces to reconsider the entire quantum field theoretic description of particle massivation.

Already before the conference several anomalies had emerged and the question was whether LHC data gives a support for these anomalies.

- A 145 GeV bump with 4 sigma significance in the mass distribution of jet pairs jj in Wjj final states was reported by CDF [?] but not confirmed by D0 [?]. The interpretation as Higgs was excluded and some of the proposed identifications of 145 GeV bump was as decay products of leptophobic Z' boson or of technicolor pion. There were also indications for 300 GeV bump in the mass distribution of Wjj states themselves suggesting cascade like decay.

- Both CDF and D0 had reported two bumps at almost same mass about 325 GeV [?, ?] having no obvious interpretation in standard model framework. Technicolor approach and also TGD suggests an interpretation as pionlike state.
- CDF and D0 had also reported anomalous forward-backward asymmetry in top-pair production in p-pbar collisions suggesting the existence of new kind of flavor changing colored neutral currents [?, ?]. TGD based explanation of family replication phenomenon combined with bosonic emergence predicts that gauge bosons should appear as flavor singlets and octets. Octets would indeed induce flavor changing currents and asymmetry. Also many other indications for new physics such as anomalously large CP breaking in BBbar system had been reported and one should not forget long list of forgotten anomalies from previous years, say the two and half year old CDF anomaly which D0 failed to observe. Recall also that proton has shown no signs of decaying.

What did we learn during these days? Already before the conference it was clear that standard SUSY had transformed from the healer of the standard model to a patient. The parameter space for MSSM (minimal supersymmetric extension of standard model predicting two Higgs multiplets) had been narrowed down by strong lower limits on squark and gluino masses to the extent that the original basic motivation for MSSM (stability of Higgs mass against radiative corrections) had been lost as well as the explanation for the anomaly of  $g-2$  of muon. During the conference the bounds on SUSY parameters were tightened further and the rough conclusion is that squark and gluino masses must be above 1 TeV. Even Lubos Motl was forced to conclude that the probability that LHC discovers standard SUSY is 50 per cent instead of 90 per cent or more of 2008 blog posting. In TGD framework simple p-adic scaling arguments lead to the proposal that the only sfermions with mass below 1 TeV are selectron and sneutrinos with selectron having mass equal to 262 GeV. Low sneutrino masses allow in principle to understand  $g-2$  of muon. Selectron could decay to electron plus neutralino for which mass must be larger than 46 GeV neutralino would eventually decay to photon or virtual Z plus neutrino.

The Higgs issue became the central theme of the conference and the three days from Thursday to Sunday were loaded with excitement. After many twists, the final conclusion was that there is 2.5 sigma evidence from ATLAS for a state in the mass range 140-150 GeV, which might be Higgs or something else. The press release of Fermi lab at Friday announced that they have confined Higgs to the interval 120-137 GeV. After the announcement of ATLAS both D0 and CDF discovered suddenly evidence for Higgs in 140-150 GeV mass range. The evidence for this mass range emerged from the decays of a might-be Higgs to WW pairs decaying in turn to lepton pairs. The proponent of technicolor would of course see this as evidence for an off mass shell state of a neutral pion like state explaining also the jj bump in Wjj system and at 145 GeV mass and not allowing an interpretation as Higgs. In TGD framework the experience with earlier anomalies such as two year old CDF anomaly encouraged the interpretation in terms p-adic mass octaves of the pion of p-adically scaled up variant of hadron physics with mass scale 512 times higher than that of the ordinary hadron physics. Somewhat frustratingly, the final conclusion about the Higgs issue was promised to emerge only towards the end of the next year but it is clear that already now standard model might well be inconsistent with all data irrespective of the mass of Higgs. MSSM would allow additional flexibility but is also in difficulties.

The surprise of the first conference day was additional evidence for the bump at 327 GeV reported already earlier by CDF. This state is a complete mystery in standard model framework and therefore extremely interesting. The proponents of technicolor would probably suggest interpretation as exotic  $\rho$  or  $\omega$  meson. In TGD framework both 145 GeV pion and 325 GeV  $\rho$  and  $\omega$  appear as mesons of  $M_{89}$  hadron physics if one assumes that the  $u$  and  $d$  quarks of  $M_{89}$  physics have masses corresponding to the p-adic length scale  $k = 93$  (mass is 102 GeV and should be visible as a preferred quark jet mass). I would not be surprised if technicolor models would experience a brief renaissance but fail experimentally since a lot of new states and elementary particles is implied by the extension of the color gauge group. The mere p-adic scaling does not imply anything like this.

Also super string inspired predictions of various exotics such as microscopic black holes, strong gravity, large extra dimensions, Randall-Sundrum gravitons, split supersymmetry, and whatever were tested. No evidence was found. Neither there was evidence for lepto-quarks, heavier partners of intermediate gauge bosons, and various other exotics.

To my view, the results of the conference force to re-consider the basic assumptions of the approach followed during last more than three decades. Is it possible to find a more realistic physical interpretation of the mathematically extremely attractive supersymmetry? Unitarity requires new physics in TeV scale: is this new physics technicolor or its TGD analog without gauge group extension or something else? To me however the mother of all questions concerns the microscopic description of massivation. The description in terms of Higgs is after all a phenomenological description borrowed from condensed matter physics. It does not work for extended objects like strings but require quantum field theory limit. p-Adic thermodynamics for conformal weight (to which mass squared is proportional to) should be an essential element of the microscopic approach too since it is a description working for the fundamental objects and in presence of super-conformal invariance.

What actually happens in the massivation: could it be that all components of Higgs, of its super partners, and of its higher spin generalizations are eaten in a process in which massless multiplets with various spins combine to form only massive multiplets? Here twistor approach might provide the guideline since its applicability requires that massive particles should allow an interpretation as bound states of massless ones. Perhaps the simple observation that spin one bound states of massless fermion and anti-fermion are automatically massive might help to get to the deeper waters.

What next? Standard model Higgs is more or less excluded and the same fate is very probably waiting the SUSY Higgs. I would not be surprised if technicolor models would experience a brief renaissance but fail experimentally since very many new hadronlike states and new elementary particles are implied by the extension of the color gauge group. Sooner or later the simple p-adic scaling of the ordinary hadron physics probably turns out to be the only realistic option. If technicolor becomes in fashion, the hadrons of  $M_{89}$  hadron physics will be however found as a side product of this search.

Eventually this requires giving up the Planck length scale reductionism as the basic philosophy and replacing it with p-adic fractality as the basic guiding principle tying together physics at very short and at very long length scales making possible the long search for ultraviolet completion of known physics. This led to the landscape catastrophe in M-theory since very many physics in long length scales had the same UV completion. Some general principle fixing the long range physics is obviously missing. p-Adic smoothness for which infinite in real sense is infinitesimal selects the unique long length scale physics among infinitely many alternatives. The real problems are really much much deeper than finding proper parameters for SUSY and it would be a high time for theoreticians to finally realize this.

## Chapter 6

# p-Adic Particle Massivation: Hadron Masses

### 6.1 Introduction

In this chapter the results of the calculation of elementary particle masses will be used to construct a model predicting hadron masses. The new elements are a revised identification for the p-adic length scales of quarks and the realization that number theoretical constraints on topological mixing can be realized by assuming that topological mixing leads to a thermodynamical equilibrium. This gives an upper bound of 1200 for the number of different  $U$  and  $D$  matrices and the input from top quark mass and  $\pi^+ - \pi^0$  mass difference implies that physical  $U$  and  $D$  matrices can be constructed as small perturbations of matrices expressible as a direct sum of essentially unique  $2 \times 2$  and  $1 \times 1$  matrices.

The assumption about the presence of scaled up variants of light quarks in light hadrons leads to a surprisingly successful model for pseudo scalar meson masses in terms of only quark masses. This conforms with the idea that at least light pseudo scalar mesons are Goldstone bosons in the sense that color Coulombic and magnetic contributions to the mass cancel each other. Also the mass differences between baryons containing different numbers of strange quarks can be understood if  $s$  quark appears as three scaled up versions. The earlier model for the purely hadronic contributions to hadron masses simplifies dramatically and only the color Coulombic and magnetic contributions to color conformal weight are needed.

#### 6.1.1 Construction of U and D matrices

The basic constraint on the topological mixing that the modular contributions to the conformal weight defining the mass squared remain integer valued in the proper units: if this condition does not hold true, the order of magnitude for the real counterpart of the p-adic mass squared corresponds to  $10^{-4}$  Planck masses.

Number theory gives strong constraints on CKM matrix. p-Adicization requires that  $U$  and  $D$  matrix elements are algebraic numbers. A strong constraint would be that the mixing probabilities are rational numbers implying that matrices defined by the moduli of  $U$  and  $D$  involve only square roots of rationals. The phases of matrix elements should belong to a finite extension of complex rationals.

Little can be said about the details of the dynamics of topological mixing. Nothing however prevents for constructing a thermodynamical model for the mixing. A thermodynamical model for  $U$  and  $D$  matrices maximizing the entropy defined by the mixing probabilities subject to the constraints fixing the values of  $n_{q_i}$  and the sums of row/column probabilities to one gives a thermodynamical ensemble with two quantized temperatures and two quantized chemical potentials. The resulting polynomial equations allow at most 1200 different solutions so that the number of  $U$  and  $D$  matrices is relatively small. The fact that matrix elements are algebraic numbers guarantees that the matrices are continuable to p-adic number fields as required.

The detailed study of quark mass spectrum leads to a tentative identification  $(n_d, n_s, n_b) = (5, 5, 59)$  and  $(n_u, n_c, n_t) = (5, 6, 58)$  of the modular contributions of conformal weights of quarks: note that

in absence of mixing the contributions would be  $(0, 9, 60)$  for both U and D type quarks. That  $b$  and  $t$  quark masses are nearly maximal and thus mix very little with lighter quarks is forced by the masses of  $t$  quark and  $t\bar{t}$  meson. The values of  $n_{q_i}$  for light quarks follow by considering  $\pi^+ - \pi^0$  mass difference.

One might consider the possibility that  $n_{q_i}$  for slightly dynamical and can vary in light mesons in order to guarantee that  $u\bar{u}$ ,  $d\bar{d}$  and  $s\bar{s}$  give identical modular contributions to the conformal weight in states which are linear combinations of quark pairs. It turns out that unitarity does not allow the choices  $(n_1 = 4, n_2 < 9)$ , and that the choice  $(n_d, n_s) = (5, 5)$ ,  $(n_u, n_c) = (5, 6)$  is the unique choice producing a realistic CKM matrix. The requirement that quark contribution to pseudo scalar meson mass is smaller than meson mass is possible to satisfy and gives a constraint on  $CP_2$  mass scale consistent with the prediction of leptonic masses when second order p-adic contribution to lepton mass is allowed to be non-vanishing.

The small mixing with  $b$  and  $t$  quarks is natural since the modular conformal weight of unmixed state having spectrum  $\{0, 9, 60\}$  is analogous to energy so that Boltzmann weight for  $n(g = 3)$  thermal excitation is small for  $g = 1, 2$  ground states.

The maximally entropic solutions can be found numerically by using the fact that only the probabilities  $p_{11}$  and  $p_{21}$  can be varied freely. The solutions are unique in the accuracy used, which suggests that the system allows only single thermodynamical phase.

The matrices  $U$  and  $D$  associated with the probability matrices can be deduced straightforwardly in the standard gauge. The  $U$  and  $D$  matrices derived from the probabilities determined by the entropy maximization turn out to be unitary for most values of  $n_1$  and  $n_2$ . This is a highly non-trivial result and means that mass and probability constraints together with entropy maximization define a sub-manifold of  $SU(3)$  regarded as a sub-manifold in 9-D complex space. The choice  $(n_u, n_c) = (4, n)$ ,  $n < 9$ , does not allow unitary  $U$  whereas  $(n_u, n_c) = (5, 6)$  does. This choice is still consistent with top quark mass and together with  $n_d = n_s = 5$  it leads to a rather reasonable CKM matrix with a value of CP breaking invariant within experimental limits. The elements  $V_{i3}$  and  $V_{3i}$ ,  $i = 1, 2$  are however roughly twice larger than their experimental values deduced assuming standard model.  $V_{31}$  is too large by a factor 1.6. The possibility of scaled up variants of light quarks could lead to too small experimental estimates for these matrix elements. The whole parameter space has not been scanned so that better candidates for CKM matrices might well exist.

### 6.1.2 Observations crucial for the model of hadron masses

The evolution of the model for hadron masses involves several key observations made during the more decade that I have been working with p-adic mass calculations.

#### The p-adic mass scales of quarks are dynamical

The existence of scaled up variants of quarks is suggested by various anomalies such as Aleph anomaly [?] and the strange bumpy structure of the distribution of the mass of the top quark candidate. This leads to the idea that the the integer  $k(q)$  characterizing the p-adic mass scale of quark is different for free quarks and bound quarks and that  $k(q)$  can depend on hadron. Hence one can understand not only the notions of current quark mass and constituent quark mass but reproduce also the p-adic counterpart of Gell-Mann-Okubo mass formula. Indeed, the assumption about scaled up variants of u, d, s, and even c quarks in light hadrons leads to an excellent fit of meson masses with quark contribution explaining almost all of meson mass.

#### Quarks give dominating contribution to the masses of pseudoscalar mesons

The interpretation is that color Coulombic and color magnetic interaction conformal weights (rather than interaction energies) cancel each other in a approximation for pseudoscalar mesons in accordance with the idea that pseudo scalar mesons are massless as far as color interactions are considered. In the case of baryons the assumption that  $s$  quark appears in three different scaled up versions (which are  $\Lambda$ ,  $\{\Sigma, \Xi\}$ , and  $\Omega$ ) allows to understand the mass differences between baryons with different  $s$  quark content. The dominating contribution to baryon mass has however remained hitherto unidentified.

### What it means that Higgs like contribution to fermion masses is negligible?

The failure of the simplest form of p-adic thermodynamics for intermediate gauge bosons led to the unsatisfactory conclusion that p-adic thermodynamics is not enough and the coupling to Higgs bosons contributes to the gauge boson masses. This option had its own problems.

1. There are good, purely topological - reasons to believe that Higgs expectation for the fermionic space-time sheets is vanishing although fermions couple to Higgs. p-Adic thermodynamics would explain fermion masses completely: this indeed turns out to be the case within experimental uncertainties. The absence of Higgs contribution to fermion masses would however mean asymmetry between fermions and bosons.
2. After the understanding of the spectrum of the modified Dirac operator it became clear that ground state conformal weight is proportional to the square of the eigenvalue of the Dirac operator, and that it is the deviation of the ground state conformal weight from negative half odd integer which is responsible for the Higgs type contribution. This contribution to the mass squared is present for both fermions and bosons but the contribution must be small for fermions and dominate for gauge bosons.
3. In the case of gauge bosons Higgs vacuum expectation is proportional to this deviation for the simple reason that there is no other fundamental parameters with dimensions of mass available. Hence the role of Higgs boson would be misunderstood in standard model framework.

The fact that the prediction of the model for the top quark mass is consistent with the most recent limits on it [?], fixes the  $CP_2$  mass scale with a high accuracy to the maximal one obtained if second order contribution to electron's p-adic mass squared vanishes. This is very valuable constraint on the model.

### Conformal weights are additive for quarks with same p-adic prime

An essential element of the new understanding is that conformal weight (mass squared is additive) for quarks with the same p-adic length scale whereas mass is additive for quarks with different values of  $p$ . For instance, the masses of heavy  $q\bar{q}$  mesons are equal to  $\sqrt{2} \times m(q)$  rather than  $2m(q)$ . Since  $k = 107$  for hadronic space-time sheet, for quarks with  $k(q) \neq 107$ , additivity holds true for the quark and color contributions for mass rather than mass squared.

This hypothesis yields surprisingly good fit for meson masses but for some mesons the predicted mass is slightly too high. The reduction of  $CP_2$  mass scale to cure the situation is not possible since top quark mass would become too low. In case of diagonal mesons for which quarks correspond to same p-adic prime, quark contribution to mass squared can be reduced by ordinary color interactions and in case of non-diagonal mesons one can require that quark contribution is not larger than meson mass.

### A remark about terminology

Before continuing a remark about terminology is in order.

1. In the generalized coset construction the symplectic algebra of  $\delta M_{\pm}^4 \times CP_2$  and Super-Kac Moody algebras at light-like partonic surfaces  $X^3$  are lifted to hyper-complex algebras inside the causal diamond of  $M^4 \times CP_2$  carrying the zero energy states.  $SKM$  is identified as a sub-algebra of  $SC$  and the differences of  $SC$  and  $SKM$  Super-Virasoro generators annihilate the physical states. All purely geometric contributions and their super-counterparts can be regarded as  $SC$  contributions. The fermionic contributions in electro-weak and spin degrees of freedom responsible also for color partial waves are trivially one and same. One could say that there is no other contribution than  $SC$  which can be however divided into a contribution from imbedded  $SKM$  subalgebra and a genuine  $SC$  contribution.
2. In the coset construction a tachyonic ground state of negative  $SC$  conformal weight from which  $SKM$  generators create massless states must have a negative conformal weight also in  $SKM$  sense. Therefore the earlier idea that genuine  $SC$  generators create the ground states with a negative conformal weight assignable to elementary particles does not work anymore: the

negative conformal weight must be due to *SKM* generators with conformal weight which is most naturally of form  $h = -1/2 + iy$ .

3. super-symplectic contribution with a positive conformal weight can be regarded also as a product of genuine *SC* contribution with a vanishing conformal weight and a contribution having also interpretation as *SKM* contribution. What motivates the term "super-symplectic bosons" used in the sequel is that in a non-perturbative situation this contribution is most naturally calculated by regarding it as a super-symplectic contribution. This contribution is highly constrained since it comes solely from generators which are color octets and singlets have spin one or spin zero. Genuine *SC* contribution with a zero conformal weight comes from the products of super-Hamiltonians in higher representations of  $SU(3) \times SO(3)$  containing both positive and negative conformal weights compensating each other. This contribution must have vanishing color quantum numbers and spin since otherwise Dirac operators of *H* in *SKM* and *SC* degrees of freedom could not act on it in the same manner. Note that gluons do not correspond to *SKM* generators but to pairs of quark and antiquark at throats of a wormhole contact.

### Super-symplectic bosons at hadronic space-time sheet can explain the constant contribution to baryonic masses

Quarks explain only a small fraction of the baryon mass and that there is an additional contribution which in a good approximation does not depend on baryon. This contribution should correspond to the non-perturbative aspects of QCD.

A possible identification of this contribution is in terms of super-symplectic gluons predicted by TGD. Baryonic space-time sheet with  $k = 107$  would contain a many-particle state of super-symplectic gluons with net conformal weight of 16 units. This leads to a model of baryons masses in which masses are predicted with an accuracy better than 1 per cent. super-symplectic gluons also provide a possible solution to the spin puzzle of proton.

Hadronic string model provides a phenomenological description of non-perturbative aspects of QCD and a connection with the hadronic string model indeed emerges. Hadronic string tension is predicted correctly from the additivity of mass squared for  $J = 2$  bound states of super-symplectic quanta. If the topological mixing for super-symplectic bosons is equal to that for *U* type quarks then a 3-particle state formed by 2 super-symplectic quanta from the first generation and 1 quantum from the second generation would define baryonic ground state with 16 units of conformal weight.

In the case of mesons pion could contain super-symplectic boson of first generation preventing the large negative contribution of the color magnetic spin-spin interaction to make pion a tachyon. For heavier bosons super-symplectic boson is not absolutely necessary but a very precise prediction for hadron masses results by assuming that the spin of hadron correlates with its super-symplectic particle content.

### Color magnetic spin-spin splitting formulated in terms of conformal weight

What remains to be understood are the contributions of color Coulombic and magnetic interactions to the mass squared. There are several delicate points to be taken into account.

1. The QCD based formula for the color magnetic interaction energy fails completely since the dependence of color magnetic spin-spin splittings on quark mass scale is nearer to logarithmic dependence on p-adic length scale than being of form  $1/m(q_i)m(q_j) \propto L(k_i)L(k_j)$ . This finding supports the decade old idea that the proper notion is not color interaction energy but color conformal weight. A model based on this assumption is constructed assuming that all pseudoscalars are Goldstone boson like states. The predictions for the masses of mesons are not so good than for baryons, and one might criticize the application of the format of perturbative QCD in an essentially non-perturbative situation.
2. The comparison of the super-symplectic conformal weights associated with spin 0 and spin 1 states and spin 1/2 and spin 3/2 states shows that the different masses of these states could be understood in terms of the super-symplectic particle contents of the state correlating with the total quark spin. The resulting model allows excellent predictions also for the meson masses and implies that only pion and kaon can be regarded as Goldstone boson like states. The model based on spin-spin splittings is consistent with the model.

To sum up, the model provides an excellent understanding of baryon and meson masses. This success is highly non-trivial since the fit involves only the integers characterizing the p-adic length scales of quarks and the integers characterizing color magnetic spin-spin splitting plus p-adic thermodynamics and topological mixing for super-symplectic gluons. The next challenge would be to predict the correlation of hadron spin with super-symplectic particle content in the case of long-lived hadrons.

### 6.1.3 A possible model for hadron

These findings suggest that the following model for hadrons deserves a testing. Hadron can be characterized in terms of  $k \geq 113$  partonic 2-surfaces  $X^2(q_i)$  connected by join along boundaries bonds (JABs, flux tubes) to  $k = 107$  2-surface  $X^2(H)$  corresponding to hadron. These flux tubes which for  $k = 113$  have size much larger than hadron can be regarded as "field bodies" of quarks which themselves have sub-hadronic size. Color flux tubes between quarks are replaced with pairs of flux tubes from  $X^2(q_1) \rightarrow X^2(H) \rightarrow X^2(q_2)$  mediating color Coulombic and magnetic interactions between quarks. In contrast to the standard model, mesons are characterized by two flux tubes rather than only one flux tube. Certainly this model gives nice predictions for hadron masses and even the large color Coulombic contribution to baryon masses can be deduced from  $\rho - \pi$  mass splitting in a good approximation.

## 6.2 Quark masses

The prediction of quark masses is more difficult due to the facts that the deduction of even the p-adic length scale determining the masses of these quarks is a non-trivial task, and the original identification was indeed wrong. Second difficulty is related to the topological mixing of quarks. The new scenario leads to a unique identification of masses with top quark mass as an empirical input and the thermodynamical model of topological mixing as a new theoretical input. Also CKM matrix is predicted highly uniquely.

### 6.2.1 Basic mass formulas

By the earlier mass calculations and construction of CKM matrix the ground state conformal weights of  $U$  and  $D$  type quarks must be  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$ . The formulas for the eigenvalues of  $CP_2$  spinor Laplacian imply that if  $m_0^2$  is used as a unit, color conformal weight  $h_c \equiv m_{CP_2}^2$  is integer for  $p \bmod 3 = \pm 1$  for  $U$  type quark belonging to  $(p+1, p)$  type representation and obeying  $h_c(U) = (p^2 + 3p + 2)/3$  and for  $p \bmod 3 = 1$  for  $D$  type quark belonging to  $(p, p+2)$  type representation and obeying  $h_c(D) = (p^2 + 4p + 4)/3$ . Only these states can be massless since color Hamiltonians have integer valued conformal weights.

In the recent case the minimal  $p = 1$  states correspond to  $h_c(U) = 2$  and  $h_c(D) = 3$ .  $h_{gr}(U) = -1$  and  $h_{gr}(D) = 0$  reproduce the previous results for quark masses required by the construction of CKM matrix. This requires super-symplectic operators  $O$  with a net conformal weight  $h_{sc} = -3$  to compensate the anomalous color just as in the leptonic case. The facts that the values of  $p$  are minimal for spinor harmonics and the super-symplectic operator is same for both quarks and leptons suggest that the construction is not had hoc.

Consider now the mass squared values for quarks. For  $h(D) = 0$  and  $h(U) = -1$  and using  $m_0^2/3$  as a unit the expression for the thermal contribution to the mass squared of quark is given by the formula

$$\begin{aligned} M^2 &= (s + X) \frac{m_0^2}{p} , \\ s(U) &= 5 , \quad s(D) = 8 , \\ X &\equiv \frac{(3Yp)_R}{3} , \end{aligned} \tag{6.2.1}$$

where the second order contribution  $Y$  corresponds to renormalization effects coming and depending on the isospin of the quark.

With the above described assumptions one has the following mass formula for quarks

$$M^2(q) = A(q) \frac{m_0^2}{p(q)} ,$$

$$\begin{aligned} A(u) &= 5 + X_U(p(u)) , & A(c) &= 14 + X_U(p(c)) , & A(t) &= 65 + X_U(p(t)) , \\ A(d) &= 8 + X_D(p(d)) , & A(s) &= 17 + X_D(p(s)) , & A(b) &= 68 + X_D(p(b)) . \end{aligned} \quad (6.2.2)$$

p-Adic length scale hypothesis allows to identify the p-adic primes labeling quarks whereas topological mixing of U and D quarks allows to deduce topological mixing matrices U and D and CKM matrix V and precise values of the masses apart from effects like color magnetic spin orbit splitting, color Coulombic energy, etc..

Integers  $n_{q_i}$  satisfying  $\sum_i n(U_i) = \sum_i n(D_i) = 69$  characterize the masses of the quarks and also the topological mixing to high degree. The reason that modular contributions remain integers is that in the p-adic context non-trivial rationals would give  $CP_2$  mass scale for the real counterpart of the mass squared. In the absence of mixing the values of integers are  $n_d = n_u = 0$ ,  $n_s = n_c = 9$ ,  $n_b = n_t = 60$ .

The fact that CKM matrix  $V$  expressible as a product  $V = U^\dagger D$  of topological mixing matrices is near to a direct sum of  $2 \times 2$  unit matrix and  $1 \times 1$  unit matrix motivates the approximation  $n_b \simeq n_t$ .

The model for topological mixing matrices and CKM matrix predicts U and D matrices highly uniquely and allows to understand quark and hadron masses in surprisingly detailed level.

The large masses of top quark and of  $t\bar{t}$  meson encourage to consider a scenario in which  $n_t = n_b = n \leq 60$  holds true.

1.  $n_d = n_u = 60$  is not allowed by number theoretical conditions for  $U$  and  $D$  matrices and by the basic facts about CKM matrix but  $n_t = n_b = 59$  allows almost maximal masses for  $b$  and  $t$ . This is not yet a complete hit. The unitarity of the mixing matrices and the construction of CKM matrix to be discussed in the next section forces the assignments

$$(n_d, n_s, n_b) = (5, 5, 59) , \quad (n_u, n_c, n_t) = (5, 6, 58) . \quad (6.2.3)$$

fixing completely the quark masses apart from a possible few per cent renormalization effects of hadronic mass scale in topological condensation which seem to be present and will be discussed later <sup>1</sup>. Note that top quark mass is still rather near to its maximal value.

2. The constraint that quark contribution to pion mass does not exceed pion mass implies the constraint  $n(d) \leq 6$  and  $n(u) \leq 6$  in accordance with the predictions of the model of topological mixing. It is important to notice that  $u - d$  mass difference does not affect  $\pi^+ - \pi^0$  mass difference and the quark contribution to  $m(\pi)$  is predicted to be  $\sqrt{(n_d + n_u + 13)}/24 \times 136.9$  MeV for the maximal value of  $CP_2$  mass (second order p-adic contribution to electron mass squared vanishes).

### 6.2.2 The p-adic length scales associated with quarks and quark masses

The identification of p-adic length scales associated with the quarks has turned to be a highly non-trivial problem. The reasons are that for light quarks it is difficult to deduce information about quark masses for hadron masses and that the unknown details of the topological mixing (unknown until the advent of the thermodynamical model) made possible several p-adic length scales for quarks. It has also become clear that the p-adic length scale can be different from free quark and bound quark and that bound quark p-adic scale can depend on hadron.

Two natural constraints have however emerged from the recent work.

<sup>1</sup>As this was written I had not realized that there is also a Higgs contribution which tends to increase top quark mass

1. Quark contribution to the hadron mass cannot be larger than color contribution and for quarks having  $k_q \neq 107$  quark contribution to mass is added to color contribution to the mass. For quarks with same value of  $k$  conformal weight rather than mass is additive whereas for quarks with different value of  $k$  masses are additive. An important implication is that for diagonal mesons  $M = q\bar{q}$  having  $k(q) \neq 107$  the condition  $m(M) \geq \sqrt{2}m_q$  must hold true. This gives strong constraints on quark masses.
2. The realization that scaled up variants of quarks explain elegantly the masses of light hadrons allows to understand large mass splittings of light hadrons without the introduction of strong isospin-isospin interaction.

The new model for quark masses is based on the following identifications of the p-adic length scales.

1. The nuclear p-adic length scale  $L(k)$ ,  $k = 113$ , corresponds to the p-adic length scale determining the masses of u, d, and s quarks. Note that  $k = 113$  corresponds to a so called Gaussian Mersenne. The interpretation is that quark massivation occurs at nuclear space-time sheet at which quarks feed their em fluxes. At  $k = 107$  space-time sheet, where quarks feed their color gauge fluxes, the quark masses are vanishing in the first p-adic order. This could be due to the fact that the p-adic temperature is  $T_p = 1/2$  at this space-time sheet so that the thermal contribution to the mass squared is negligible. This would reflect the fact that color interactions do not involve any counterpart of Higgs mechanism.

p-Adic mass calculations turn out to work remarkably well for massive quarks. The reason could be that  $M_{107}$  hadron physics means that *all* quarks feed their color gauge fluxes to  $k = 107$  space-time sheets so that color contribution to the masses becomes negligible for heavy quarks as compared to Super-Kac Moody and modular contributions corresponding to em gauge flux feeded to  $k > 107$  space-time sheets in case of heavy quarks. Note that  $Z^0$  gauge flux is feeded to space-time sheets at which neutrinos reside and screen the flux and their size corresponds to the neutrino mass scale. This picture might throw some light to the question of whether and how it might be possible to demonstrate the existence of  $M_{89}$  hadron physics.

One might argue that  $k = 107$  is not allowed as a condensation level in accordance with the idea that color and electro-weak gauge fluxes cannot be feeded at the space-time space time sheet since the classical color and electro-weak fields are functionally independent. The identification of  $\eta'$  meson as a bound state of scaled up  $k = 107$  quarks is not however consistent with this idea unless one assumes that  $k = 107$  space-time sheets in question are separate.

2. The requirement that the masses of diagonal pseudoscalar mesons of type  $M = q\bar{q}$  are larger but as near as possible to the quark contribution  $\sqrt{2}m_q$  to the valence quark mass, fixes the p-adic primes  $p \simeq 2^k$  associated with  $c$ ,  $b$  quarks but not  $t$  since toponium does not exist. These values of  $k$  are "nominal" since  $k$  seems to be dynamical.  $c$  quark corresponds to the p-adic length scale  $k(c) = 104 = 2^3 \times 13$ .  $b$  quark corresponds to  $k(b) = 103$  for  $n(b) = 5$ . Direct determination of p-adic scale from top quark mass gives  $k(t) = 94 = 2 \times 47$  so that secondary p-adic length scale is in question.
3. Top quark is experimentally in a unique position since toponium does not exist and top quark mass is that of free top. The prediction for top quark mass (see Table 1 below) is 167.8 GeV for  $Y_t = Y_e = 0$  (second order contributions to mass vanish) and 169.1 GeV for  $Y_t = 1$  and  $Y_e = 0$  (maximal possible mass for top). The experimental estimate for  $m_t$  remained for a long time somewhat higher than the prediction but the estimates have gradually reduced. The previous experimental average value was  $m(t) = 169.1$  GeV with the allowed range being [164.7, 175.5] GeV [?, ?]. The fine tuning  $Y_e = 0, Y_t = 1$  giving 169.1 GeV is somewhat un-natural. The most recent value obtained by CDF and discussed in detail by Tommaso Dorigo [?] is  $m_t = 165.1 \pm 3.3 \pm 3.1$  GeV. This is value is consistent with the lower bound predicted by TGD for  $Y_e = Y_t = 0$  and increase of  $Y_t$  increases the value of the predicted mass. Clearly, TGD passes the stringent test posed by top quark.
4. There are good reasons to believe that the p-adic mass scale of quark is different for free quark and bound state quark and that in case of bound quark it can also depend on hadron. This

would explain the notions of valence (constituent) quark and current quark mass as masses of bound state quark and free quark and leads also to a TGD counterpart of Gell-Mann-Okubo mass formula.

1. Constituent quark masses

Constituent quark masses correspond to masses derived assuming that they are bound to hadrons. If the value of  $k$  is assumed to depend on hadron one obtains nice mass formula for light hadrons as will be found later. The following table summarizes constituent quark masses labelled by  $k_q$  deduced from the masses of diagonal mesons.

$q$	d	u	s	c	b	t
$n_q$	4	5	6	6	59	58
$s_q$	12	10	14	11	67	63
$k(q)$	113	113	113	104	103	94
$m(q)/GeV$	.105	.0923	.105	2.191	7.647	167.8

Table 1. Constituent quark masses predicted for diagonal mesons assuming  $(n_d, n_s, n_b) = (5, 5, 59)$  and  $(n_u, n_c, n_t) = (5, 6, 58)$ , maximal  $CP_2$  mass scale ( $Y_e = 0$ ), and vanishing of second order contributions.

2. Current quark masses

Current quark masses would correspond to masses of free quarks which tend to be lower than valence quark masses. Hence  $k$  could be larger in the case of light quarks. The table of quark masses in Wikipedia [?] gives the value ranges for current quark masses depicted in the table below together with TGD predictions for the spectrum of current quark masses.

$q$	d	u	s
$m(q)_{exp}/MeV$	4-8	1.5-4	80-130
$k(q)$	(122,121,120)	(125,124,123,122)	(114,113,112)
$m(q)/MeV$	(4.5,6.6,9.3)	(1.4,2.0,2.9,4.1)	(74,105,149)
$q$	c	b	t
$m(q)_{exp}/MeV$	1150-1350	4100-4400	1691
$k(q)$	(106,105)	(105,104)	92
$m(q)/MeV$	(1045,1477)	(3823,5407)	167.8

Table 2. The experimental value ranges for current quark masses [?] and TGD predictions for their values assuming  $(n_d, n_s, n_b) = (5, 5, 59)$ ,  $(n_u, n_c, n_t) = (5, 6, 58)$ ,  $Y_e = 0$ , and vanishing of second order contributions.

Some comments are in order.

1. The long p-adic length associated with light quarks seem to be in conflict with the idea that quarks have sizes smaller than hadron size. The paradox disappears when one realized that  $k(q)$  characterizes the electromagnetic "field body" of quark having much larger size than hadron.
2.  $u$  and  $d$  current quarks correspond to a mass scale not much higher than that of electron and the ranges for mass estimates suggest that  $u$  could correspond to scales  $k(u) \in (125, 124, 123, 122) = (5^3, 4 \times 31, 3 \times 41, 2 \times 61)$ , whereas  $d$  would correspond to  $k(d) \in (122, 121, 120) = (2 \times 61, 11^2, 3 \times 5 \times 8)$ .
3. The TGD based model for nuclei based on the notion of nuclear string leads to the conclusion that exotic copies of  $k = 113$  quarks having  $k = 127$  are present in nuclei and are responsible for the color binding of nuclei [K69, L3] , [L3] .
4. The predicted values for  $c$  and  $b$  masses are slightly too low for  $(k(c), k(b)) = (106, 105) = (2 \times 53, 3 \times 5 \times 7)$ . Second order Higgs contribution could increase the  $c$  mass into the range given in [?] but not that of  $b$ .

One can talk about constituent and current quark masses simultaneously only if they correspond to dual descriptions.  $M^8 - H$  duality [K39] has been indeed suggested to relate the old fashioned low energy description of hadrons in terms of  $SO(4)$  symmetry (Skyrme model) and higher energy description of hadrons based on QCD. In QCD description the mass of say baryon would be dominated by the mass associated with super-symplectic quanta carrying color. In  $SO(4)$  description constituent quarks would carry most of the hadron mass.

### 6.2.3 Are scaled up variants of quarks also there?

The following arguments suggest that p-adically scaled up variants of quarks might appear not only at very high energies but even in low energy hadron physics.

#### Aleph anomaly and scaled up copy of $b$ quark

The prediction for the  $b$  quark mass is consistent with the explanation of the Aleph anomaly [?] inspired by the finding that neutrinos seem to condense at several p-adic length scales [?]. If  $b$  quark condenses at  $k(b) = 97$  level, the predicted mass is  $m(b, 97) = 52.3$  GeV for  $n_b = 59$  for the maximal  $CP_2$  mass consistent with  $\eta'$  mass. If the the mass of the particle candidate is defined experimentally as one half of the mass of resonance,  $b$  quark mass is actually by a factor  $\sqrt{2}$  higher and scaled up  $b$  corresponds to  $k(b) = 96 = 2^5 \times 3$ . The prediction is consistent with the estimate 55 GeV for the mass of the Aleph particle and gives additional support for the model of topological mixing. Also the decay characteristics of Aleph particle are consistent with the interpretation as a scaled up  $b$  quark.

#### Scaled variants of top quark

Tony Smith has emphasized the fact that the distribution for the mass of the top quark candidate has a clear structure suggesting the existence of several states, which he interprets as excited states of top quark [?]. According to the figures 9.4.1 and 9.4.1 representing published FermiLab data, this structure is indeed clearly visible.

There is evidence for a sharp peak in the mass distribution of the top quark in 140-150 GeV range (Fig. 9.4.1). There is also a peak slightly below 120 GeV, which could correspond to a p-adically scaled down variant  $t$  quark with  $k = 95$  having mass 119.6 GeV for  $(Y_e = 0, Y_t = 1)$  There is also a small peak also around 265 GeV which could relate to  $m(t(93)) = 240.4$  GeV. There top could appear at least for the p-adic scales  $k = 93, 94, 95$  as also  $u$  and  $d$  quarks seem to appear as current quarks.

#### Scaled up variants of $d, s, u, c$ in top quark mass scale

The fact that all neutrinos seem to appear as scaled up versions in several scales, encourages to look whether also  $u, d, s,$  and  $c$  could appear as scaled up variants transforming to the more stable variants by a stepwise increase of the size scale involving the emission of electro-weak gauge bosons. In the following the scenario in which  $t$  and  $b$  quarks mix minimally is considered.

$q$	$m(92)/GeV$	$m(91)/GeV$	$m(90)/GeV$
$u$	134	189	267
$d$	152	216	304
$c$	140	198	280
$s$	152	216	304

Table 3. The masses of  $k = 92, 91$  and  $k = 90$  scaled up variants of  $u, d, c, s$  quarks assuming same integers  $n_{q_i}$  as for ordinary quarks in the scenario  $(n_d, n_s, n_b) = (5, 5, 59)$  and  $(n_u, n_c, n_t) = (5, 6, 58)$  and maximal  $CP_2$  mass consistent with the  $\eta'$  mass.

1. For  $k = 92$ , the masses would be  $m(q, 92) = 134, 140, 152, 152$  GeV in the order  $q = u, c, d, s$  so that all these quarks might appear in the critical region where the top quark mass has been wandering.

Figure 6.1: Fermilab semileptonic histogram for the distribution of the mass of top quark candidate (FERMILAB-PUB-94/097-E).

2. For  $k = 91$  copies would have masses  $m(q, 91) = 189, 198, 256, 256$  GeV in the order  $q = u, c, d, s$ . The masses of  $u$  and  $c$  are somewhat above the value of latest estimate 170 GeV for top quark mass [?] .

Note that it is possible to distinguish between scaled up quarks of  $M_{107}$  hadron physics and the quarks of  $M_{89}$  hadron physics since the unique signature of  $M_{89}$  hadron physics would be the increase of the scale of color Coulombic and magnetic energies by a factor of 512. As will be found, this allows to estimate the masses of corresponding mesons and baryons by a direct scaling. For instance,  $M_{89}$  pion and nucleon would have masses 71.7 GeV and 481 GeV.

It must be added that the detailed identifications are sensitive to the exact value of the  $CP_2$  mass scale. The possibility of at most 2.5 per cent downward scaling of masses occurs is allowed by the recent value range for top quark mass.

### Fractally scaled up copies of light quarks and low mass hadrons?

One can of course ask, whether the fractally scaled up quarks could appear also in low lying hadrons. The arguments to be developed in detail later suggest that  $u$ ,  $d$ , and  $s$  quark masses could be dynamical in the sense that several fractally scaled up copies can appear in low mass hadrons and explain the mass differences between hadrons.

In this picture the mass splittings of low lying hadrons with different flavors would result from fractally scaled up excitations of  $s$  and also  $u$  and  $d$  quarks in case of mesons. This notion would also throw light into the paradoxical presence of two kinds of quark masses: constituent quark masses and current quark masses having much smaller values than constituent quarks masses. That color spin-spin splittings are of same order of magnitude for all mesons supports the view that color gauge fluxes are feeded to  $k = 107$  space-time sheet.

The alert reader has probably already asked whether also proton mass could be understood in terms of scaled up copies of  $u$  and  $d$  quarks. This does not seem to be the case, and an argument

Figure 6.2: Fermilab D0 semileptonic histogram for the distribution of the mass of top quark candidate (hep-ex/9703008, April 26, 1994)

predicting with 23 per cent error proton mass scale from  $\rho - \pi$  and  $\Delta - N$  color magnetic splittings emerges.

To sum up, it seems quite possible that the scaled up quarks predicted by TGD have been observed for decade ago in FermiLab about that the prevailing dogmas has led to their neglect as statistical fluctuations. Even more, scaled up variants of  $s$  quarks might have been in front of our eyes for half century! Phenomenon is an existing phenomenon only if it is an understood phenomenon.

### The mystery of two $\Omega_b$ baryons

Tommaso Dorigo has three interesting postings [?] about the discovery of  $\Omega_b$  baryon containing two strange quarks and one bottom quark.  $\Omega_b$  has been discovered -even twice. This is not a problem. The problem is that the masses of these  $\Omega_b$ s differ quite too much. D0 collaboration discovered  $\Omega_b$  with a significance of 5.4 sigma and a mass of  $6165 \pm 16.4$  MeV [?]. Later CDF collaboration announced the discovery of the same particle with a significance of 5.5 sigma and a mass of  $6054.4 \pm 6.9$  MeV. Both D0 and CDF agree that the particle is there at better than 5 sigma significance and also that the other collaboration is wrong. They cant both be right Or could they? In some other Universe that that of standard model and all its standard generalizations, maybe in some less theoretically respected Universe, say TGD Universe?

The mass difference between the two  $\Omega_b$  candidates is 111 MeV, which represents the mass scale of strange quark. TDG inspired model for quark masses relies on p-adic thermodynamics and predicts that quarks can appear in several p-adic mass scales forming a hierarchy of half octaves - in other words mass scales comes as powers of square root of two. This property is absolutely essential for the TGD based model for masses of even low lying baryons and mesons where strange quarks indeed appear with several different p-adic mass scales. It also explains the large difference of the mass scales assigned to current quarks and constituent quarks. Light variants of quarks appear also in nuclear string model where nucleons are connected by color bonds containing light quark and antiquark at their ends.

$\Omega_b$  contains two strange quarks and the mass difference between the two candidates is of order of mass of strange quark. Could it be that both  $\Omega_b$  s are real and the discrepancy provides additional

support for p-adic length scale hypothesis? The prediction of p-adic mass calculations for the mass of s quark is 105 MeV (see Table 1) so that the mass difference can be understood if the second s-quark in  $\Omega_b$  has mass which is twice the "standard" value. Therefore the strange finding about  $\Omega_b$  could give additional support for quantum TGD. Before buying a bottle of champagne, one should however understand why D0 and CDF collaborations only one  $\Omega_b$  instead of both of them.

### 6.3 Topological mixing of quarks

The requirement that hadronic mass spectrum is physical requires mixing of  $U$  and  $D$  type boundary topologies. In this section quark masses and the mixing of the boundary topologies are considered on the general level and CKM matrix is derived using the existing empirical information plus the constraints on the quark masses to be derived from the hadronic mass spectrum in the later sections.

#### 6.3.1 Mixing of the boundary topologies

In TGD the different mixings of the boundary topologies for  $U$  and  $D$  type quarks provide the fundamental mechanism for CKM mixing and also CP breaking. In the determination of CKM matrix one can use following conditions.

1. Mass squared expectation values in order  $O(p)$  for the topologically mixed states must be integers and the study of the hadron mass spectrum leads to very stringent conditions on the values of these integers. Physical values for these integers imply essentially correct value for Cabibbo angle provided  $U$  and  $D$  matrices differ only slightly from the mixing matrices mixing only the two lowest generations.
2. The matrices  $U$  and  $D$  describing the mixing of  $U$  and  $D$  type boundary topologies are unitary in the p-adic sense. The requirement that the moduli squared of the matrix elements are rational numbers, is very attractive since it suggests equivalence of p-adic and real probability concepts and therefore could solve some conceptual problems related to the transition from the p-adic to real regime. It must be however immediately added that rationality assumption for the probabilities defined by S-matrix turns out to be non-physical. It turns out that the mixing scenario reproducing a physical CKM matrix is consistent with the rationality of the moduli squared of the matrix elements of  $U$  and  $D$  matrices but not with the rationality of the matrix elements themselves. The phase angles appearing in  $U$  and  $D$  matrix can be rational and in this case they correspond to Pythagorean triangles. In principle the rationality of the CKM matrix is possible.
3. The requirements that Cabibbo angle has correct value and that the elements  $V(t, d)$  and  $V(u, b)$  of the CKM matrix have small values not larger than  $10^{-2}$  fixes the integers  $n_i$  characterizing quark masses to a very high degree and in a good approximation one can estimate the angle parameters analytically. remains open at this stage. The requirement of a realistic CKM matrix leads to a scenario for the values of  $n_i$ , which seems to be essentially unique.

The mass squared constraints give for the  $D$  matrix the following conditions

$$\begin{aligned}
 9|D_{12}|^2 + 60|D_{13}|^2 &= n_1(D) \equiv n_d , \\
 9|D_{22}|^2 + 60|D_{23}|^2 &= n_2(D) \equiv n_s , \\
 9|D_{32}|^2 + 60|D_{33}|^2 &= n_3(D) \equiv n_b = 69 - n_2(D) - n_1(D) .
 \end{aligned}
 \tag{6.3.1}$$

The third condition is not independent since the sum of the conditions is identically true by unitarity.

For  $U$  matrix one has similar conditions:

$$\begin{aligned}
 9|U_{12}|^2 + 60|U_{13}|^2 &= n_1(U) \equiv n_u , \\
 9|U_{22}|^2 + 60|U_{23}|^2 &= n_2(U) \equiv n_c , \\
 9|U_{32}|^2 + 60|U_{33}|^2 &= n_3(U) \equiv n_t = 69 - n_2(U) - n_1(U) .
 \end{aligned}
 \tag{6.3.2}$$

The integers  $n_d, n_s$  and  $n_u, n_c$  characterize the masses of the physical quarks and the task is to derive the values of these integers by studying the spectrum of the hadronic masses. The second task is to find unitary mixing matrices satisfying these conditions.

The general form of U and D matrices can be deduced from the standard parametrization of the CKM matrix given by

$$V = \begin{bmatrix} c_1 & s_1 c_3 & s_1 s_3 \\ -s_1 c_2 & c_1 c_2 c_3 - s_2 s_3 \exp(i\delta_{CP}) & c_1 c_2 s_3 + s_2 c_3 \exp(i\delta_{CP}) \\ -s_1 s_2 & c_1 s_2 c_3 + c_2 s_3 \exp(i\delta_{CP}) & c_1 s_2 s_3 - c_2 c_3 \exp(i\delta_{CP}) \end{bmatrix} \quad (6.3.3)$$

This form of the CKM matrix is always possible to achieve by multiplying each U and D type quark fields with a suitable phase factor: this induces a multiplication U and D from left by a diagonal phase factor matrix inducing the multiplication of the columns of U and D by phase factors:

$$\begin{aligned} U &\rightarrow U \times d(\phi_1, \phi_2, \phi_3) \ , \\ D &\rightarrow D \times d(\chi_1, \chi_2, \chi_3) \ , \\ d(\phi_1, \phi_2, \phi_3) &\equiv \text{diag}(\exp(i\phi_1), \exp(i\phi_2), \exp(i\phi_3)) \ . \end{aligned}$$

The multiplication of the columns by the phase factors affects CKM matrix defined as

$$V = U^\dagger D \rightarrow d(-\phi_1, -\phi_2, -\phi_3) V d(\chi_1, \chi_2, \chi_3) \ . \quad (6.3.4)$$

By a suitable choice of the phases, the first row and column of  $V$  can be made real. The multiplication of the rows of U and D from the left by the same phase factors does not affect the elements of  $V$ . One can always choose D to be of the same general form as the CKM matrix but must allow U to have nontrivial phase overall factors on the second and third row so that the most general U matrix is parameterized by six parameters.

Mass squared conditions give two independent conditions on the values of the moduli of the matrix elements of U and D. This eliminates two coordinates so that the most general D matrix can be chosen to depend on 2 parameters, which can be taken to be  $r_{11} \equiv |D_{11}|$  and  $r_{21} \equiv |D_{21}|$ . U matrix contains also the overall phase angles associated with the second and third row and hence depends on four parameters altogether.

### 6.3.2 The constraints on $U$ and $D$ matrices from quark masses

The new view about quark masses allows a surprisingly simple model for U and D matrices predicting in the lowest order approximation that the probabilities defined by these matrices are identical and that the integers characterizing the masses of U and D type quarks are identical.

#### The constraints on $|U|$ and $|D|$ matrices from quark masses

The understanding of quark masses pose strong constraints on U and D matrices. The constraints are identical in the approximation that  $V$ -matrix is identity matrix and read in the case of  $D$ -matrix as

$$\begin{aligned} n_d &= 13 = P_{12}^D \times 9 + P_{13}^D \times 60 \ , \\ n_s &= 31 = P_{22}^D \times 9 + P_{23}^D \times 60 \ . \end{aligned} \quad (6.3.5)$$

The conditions for  $b$  quark give nothing new. The extreme cases when only  $g = 1$  or  $g = 2$  contributes to  $n_q$  gives the bounds

$$\begin{aligned} \frac{15}{36} &\leq P_{13}^D \leq \frac{15}{60} \ , \\ \frac{22}{60} &\leq P_{23}^D \leq \frac{31}{60} \ . \end{aligned} \quad (6.3.6)$$

### Unitarity conditions

The condition  $D = VU$  and the fact that  $V$  is in not too far from unit matrix being in a good approximation a direct sum of  $2 \times 2$  matrix and  $1 \times 1$  identity matrix, imply together that  $U$  and  $D$  cannot differ much from each other. At least the probabilities defined by the moduli squared of matrix elements are near to each other.

1. Instead of trying numerically to solve  $U$  and  $D$  matrices by a direct numerical search, it is more appropriate to try to deduce estimates for the probabilities  $P_{ij}^U = |U_{ij}|^2$  and  $P_{ij}^D = |D_{ij}|^2$  determined by the moduli squared of the matrix elements and satisfying the unitarity conditions  $\sum_j P_{ij}^X = 1$  and  $\sum_i P_{ij}^X = 1$ .
2. The formula  $D = UV$  using the fact that  $V_{i3}$  is small for  $i = 1, 2$  implies  $|D_{i3}| \simeq |U_{i3}|$ . By probability conservation also the condition  $|D_{33}| \simeq |U_{33}|$  must hold true so that the third columns of  $U$  and  $D$  are same in a reasonable approximation.

#### 1. Parametrization of $|U|$ and $|D|$ matrices

The following parametrization is natural for the matrices  $P_{ij}^X$ .

$$\begin{aligned} P_{12}^D &= \frac{k_D}{9} \quad , \quad P_{13}^D = \frac{n_d - k_D}{9} \quad , \\ P_{22}^D &= \frac{l_D}{9} \quad , \quad P_{23}^D = \frac{n_s - l_D}{60} \quad , \\ P_{32}^D &= \frac{9 - k_D - l_D}{9} \quad , \quad P_{33}^D = \frac{60 - n_s - n_d - k_D - l_D}{60} \quad . \end{aligned} \quad (6.3.7)$$

A similar parametrization holds true for  $P_{ij}^U$  but with  $n_d = n_u$  and  $n_s = n_c$  but possibly different values of  $k_U$  and  $l_U$ . Since  $l_D \ll n_s$  is expected to hold true,  $P_{23}^D$  is in a good approximation equal to  $P_{23}^D = n_s/60 = 31/60$ . Same applies to  $P_{23}^U$ .

$k_X = 2$  ( $k_X$  need not be an integer) gives a good first estimate for mixing probabilities of u and d quark. Thus only the parameter  $l_X$  remains free if  $k_D = 2$  is accepted.

The approximation  $P_{i3}^U = P_{i3}^D$  motivated by the near unit matrix property of  $V$ , gives the parametrization

$$P_{12}^D = P_{12}^U = \frac{k}{9} \quad , \quad P_{13}^D = P_{13}^U = \frac{n_d - k}{60} \quad . \quad (6.3.8)$$

#### 2. Constraints from CKM matrix in $|U| = |D|$ approximation

The condition  $D_{12} = (UV)_{12}$  when feeded to the condition

$$P_{12}^U = P_{12}^D \quad (6.3.9)$$

using the approximation  $k_D = k_U = k$   $l_D = l_U = l$  gives

$$|U_{i2}|^2 - |U_{i1}V_{12} + U_{i2}V_{22} + U_{i3}V_{32}|^2 = 0 \quad . \quad (6.3.10)$$

$i = 1, 2, 3$  In the approximation that the small  $V_{32}$  term does not contribute, this gives

$$|U_{i1}V_{12} + U_{i2}V_{22}|^2 = |U_{i2}|^2 \quad . \quad (6.3.11)$$

By dividing with  $|U_{i1}|^2|V_{22}|^2$  and using the approximation  $|V_{22}|^2 = 1$  this gives

$$\begin{aligned} v_i^2 + 2u_i v_i \cos(\Psi_i) &= 0 \quad , \\ \Psi_i &= \arg(V_{i2}) - \arg(V_{32}) + \arg(U_{i1}) - \arg(U_{i2}) \quad . \\ u_i &= \left| \frac{U_{i2}}{U_{i1}} \right| \quad , \quad v_i = \left| \frac{V_{i2}}{V_{22}} \right| \quad . \end{aligned} \quad (6.3.12)$$

This gives

$$\begin{aligned}
 \cos(\Psi_i) &= -\frac{v_i}{2u_i} = -\frac{v_i}{2} \sqrt{\frac{9x_i}{k_i}} , \\
 x_i &= P_{ii}^D = 1 - \frac{k_i}{9} - \frac{n(i) - k(i)}{60} , \\
 k(1) &= k , \quad k(2) = l , \quad n(1) = n_d , \quad n(2) \equiv n_s .
 \end{aligned} \tag{6.3.13}$$

The condition  $|\cos(\Psi)| \leq 1$  is trivially satisfied. For  $n_d = 13$  and  $k = 2$  the condition gives  $x = .59$  and  $\cos(\Psi_1) = .185$ .  $k = 1.45$  gives  $x = .65$  and  $\cos(\Psi) = .226$ , which is rather near to  $V_{12}$ .

### 6.3.3 Constraints from CKM matrix

Besides the constraints from hadron masses, there are constraints from CKM matrix  $V = U^\dagger D$  on  $U$  and  $D$  matrices.

1. The fact that CKM matrix is near unit matrix implies that  $U$  and  $D$  matrix are near to each other and the assumption  $n(U_i) = n(D_i)$  predicting quark masses correctly is consistent with this.
2. Cabibbo angle allows to derive the estimate for the difference  $|U_{11}| - |D_{11}|$ . Together with other conditions this difference fixes the scenario essentially uniquely.
3. The requirement that CP breaking invariant  $J$  has a correct order of magnitude gives a very strong constraint on  $D$  matrix. The smallness of  $J$  implies that  $V$  is nearly orthogonal matrix and same assumption can be made about  $U$  and  $D$  matrices.
4. The requirement that the moduli the first row (column) of CKM matrix are predicted correctly makes it possible to deduce for given  $D$  ( $U$ )  $U$  ( $D$ ) matrix essentially uniquely. Unitarity requirement poses very strong additional constraints. It must be emphasized that the constraints from the moduli of the CKM alone are sufficient to determine  $U$  and  $D$  matrices and hence also quark masses and hadron masses to very high degree.

#### 1. Bounds on CKM matrix elements

The most recent experimental information [?] concerning CKM matrix elements is summarized in table below

$ V_{13}  \equiv  V_{ub}  = (0.087 \pm 0.075)V_{cb} : 0.42 \cdot 10^{-3} <  V_{ub}  < 6.98 \cdot 10^{-3}$
$ V_{23}  \equiv  V_{cb}  = (41.2 \pm 4.5) \cdot 10^{-3}$
$ V_{31}  \equiv  V_{td}  = (9.6 \pm 0.9) \cdot 10^{-3}$
$ V_{32}  \equiv  V_{ts}  = (40.2 \pm 4.4) \cdot 10^{-3}$
$s_{Cab} = 0.226 \pm 0.002$

Table 4. The experimental constraints on the absolute values of the CKM matrix elements.

$$\begin{aligned}
 s_1 &= .226 \pm .002 , \\
 s_1 s_2 &= V_{31} = (9.6 \pm .9) \cdot 10^{-3} , \\
 s_1 s_3 &= V_{13} = (.087 \pm .075) \cdot V_{23} , \\
 V_{23} &= (40.2 \pm 4.4) \cdot 10^{-3} .
 \end{aligned} \tag{6.3.14}$$

The remaining parameter is  $\sin(\delta)$  or equivalently the CP breaking parameter  $J$ :

$$J = \text{Im}(V_{11}V_{22}\bar{V}_{12}\bar{V}_{21}) = c_1 c_2 c_3 s_2 s_3 s_1^2 \sin(\delta) , \tag{6.3.15}$$

where the upper bound is for  $\sin(\delta) = 1$  and the previous average values of the parameters  $s_i, c_i$  (note that the poor knowledge of  $s_3$  affects on the upper bound for  $J$  considerably). Unitary triangle [?] gives for the CP breaking parameter the limits

$$1.0 \times 10^{-4} \leq J \leq 1.7 \times 10^{-4} . \quad (6.3.16)$$

## 2. CP breaking in $M - \bar{M}$ systems as a source of information about CP breaking phase

Information about the value of  $\sin(\delta)$  as well as on the range of possible top quark masses comes from CP breaking in  $K - \bar{K}$  and  $B - \bar{B}$  systems.

The observables in  $K_L \rightarrow 2\pi$  system [?]

$$\begin{aligned} \eta_{+-} &= \frac{A(K_L \rightarrow \pi^+\pi^-)}{A(K_S \rightarrow \pi^+\pi^-)} = \epsilon + \frac{\epsilon'}{1 + \omega/\sqrt{2}} , \\ \eta_{00} &= \frac{A(K_L \rightarrow \pi^0\pi^0)}{A(K_S \rightarrow \pi^0\pi^0)} = \epsilon - 2 \frac{\epsilon'}{1 - \sqrt{2}\omega} , \\ \omega &\sim \frac{1}{20} , \\ \epsilon &= (2.27 \pm .02) \cdot 10^{-3} \cdot \exp(i43.7^\circ) , \\ \left| \frac{\epsilon'}{\epsilon} \right| &= (3.3 \pm 1.1) \cdot 10^{-3} . \end{aligned} \quad (6.3.17)$$

The phases of  $\epsilon$  and  $\epsilon'$  are in good approximation identical. CP breaking in  $K - \bar{K}$  mass matrix comes from the CP breaking imaginary part of  $\bar{s}d \rightarrow s\bar{d}$  amplitude  $M_{12}$  (via the decay to intermediate  $W^+W^-$  pair) whereas  $K^0\bar{K}^0$  mass difference  $\Delta m_K$  comes from the real part of this amplitude: the calculation of the real part cannot be done reliably for kaon since perturbative QCD does not work in the energy region in question. One can however relate the real part to the known mass difference between  $K_L$  and  $K_S$ :  $2Re(M_{12}) = \Delta m_K$ .

Using the results of [?] one can express  $\epsilon$  and  $\epsilon'/\epsilon$  in the following numerical form

$$\begin{aligned} |\epsilon| &= \frac{1}{\sqrt{2}} \frac{Im(M_{12}^{sd})}{\Delta m_K} - .05 \cdot \left| \frac{\epsilon'}{\epsilon} \right| = 2J(22.2B_K \cdot X(m_t) - .28B'_K) , \\ \left| \frac{\epsilon'}{\epsilon} \right| &= C \cdot J \cdot B'_K , \\ X(m_t) &= \frac{H(m_t)}{H(m_t = 60 \text{ GeV})} , \\ H(m_t) &= -\eta_1 F(x_c) + \eta_2 F(x_t)K + \eta_3 G(x_c, x_t) , \\ x_q &= \frac{m(q)^2}{m_W^2} , \\ K &= s_2^2 + s_2 s_3 \cos(\delta) . \end{aligned} \quad (6.3.13)$$

Here the values of QCD parameters  $\eta_i$  depend on top mass slightly.  $B'_K$  and  $B_K$  are strong interaction matrix elements and vary between 1/3 and 1. The functions  $F$  and  $G$  [?] are given by

$$\begin{aligned} F(x) &= x \left[ \frac{1}{4} + \frac{9}{4} \frac{1}{1-x} - \frac{3}{2} \frac{1}{(1-x)^2} \right] + \frac{3}{2} \left( \frac{x}{x-1} \right)^3 \log(x) , \\ G(x, y) &= xy \left[ \frac{1}{x-y} \left[ \frac{1}{4} + \frac{3}{2} \frac{1}{1-x} - \frac{3}{4} \frac{1}{(1-x)^2} \right] \log(x) + (y \rightarrow x) - \frac{3}{4} \frac{1}{(1-x)(1-y)} \right] . \end{aligned} \quad (6.3.12)$$

One can solve parameter  $B'_K$  by requiring that the value of  $\epsilon'/\epsilon$  corresponds to the experimental mean value:

$$B'_K = \frac{1}{C \times J} \frac{\epsilon'}{\epsilon} . \quad (6.3.13)$$

The most recent measurements by KTeV collaboration in Fermi Lab [?] give for the ratio  $|\epsilon'/\epsilon|$  the value  $|\epsilon'/\epsilon| = (28 \pm 1) \times 10^{-4}$ . The proposed standard model explanation for the large value of  $B'_K$  is that s-quark has running mass about  $m_s(m_c) \simeq .1$  GeV at  $m_c$  [?]. The explanation is marginally consistent with the TGD prediction  $m(s) = 127$  MeV for the mass of  $s$  quark. Also the effects caused by the predicted higher gluon generations having masses around 33 GeV can increase the value of  $\epsilon'/\epsilon$  by a factor 3 in the lowest approximation since the corrections involve sum over three different one-gluon loop diagrams with gluon mass small respect to intermediate boson mass scale [K43] .

A second source of information comes from  $B - \bar{B}$  mass difference. At the energies in question perturbative QCD is expected to be applicable for the calculation of the mass difference and mass difference is predicted correctly if the mass of the top quark is essentially the mass of the observed top candidate [?].

### 3. $U$ and $D$ matrices could be nearly orthogonal matrices

The smallness of the CP breaking phase angle  $\delta_{CP}$  means that  $V$  is very near to an orthogonal matrix. This raises the hope that in a suitable gauge also  $U$  and  $D$  are nearly orthogonal matrices and would be thus almost determined by single angle parameter  $\theta_X$ ,  $X = U, D$ . Cabibbo angle  $s_c = \sin(\theta_c) = .226$  which is not too far from  $\sin^2(\theta_W) \simeq .23$  and appears in  $V$  matrix rotating the rows of  $U$  to those of  $D$ . In very vague sense this angle would characterize between the difference of angle parameters characterizing  $U$  and  $D$  matrices. If  $U$  is orthogonal matrix then the decomposition

$$V = V_1 V_2 = \begin{bmatrix} c_1 & s_1 & 0 \\ -s_1 c_2 & c_1 c_2 & s_2 \exp(i\delta_{CP}) \\ -s_1 s_2 & c_1 s_2 & -c_2 \exp(i\delta_{CP}) \end{bmatrix} \times \begin{bmatrix} 1 & 0 & 0 \\ 0 & c_3 & s_3 \\ 0 & -s_3 & c_3 \end{bmatrix} \quad (6.3.14)$$

suggests that  $CP$  breaking can be visualized as a process in which first  $s$  and  $b$  quarks are slightly mixed to  $s'$  and  $b'$  by  $V_2$  ( $s_3 \simeq 1.4 \times 10^{-2}$ ) after which  $V_1$  induces a slightly CP-breaking mixing of  $d$  and  $s'$  with  $b'$  ( $s_2 \simeq .04$ ).

### 4. How the large mixing between $u$ and $c$ results

The prediction that  $u$  quark spends roughly 1/3 of time in  $g = 0$  state looks bizarre and it is desirable to understand this from basic principles. The basic observations are following.

1.  $V$  matrix is in good approximation direct sum of  $2 \times 2$  matrix inducing relatively large rotation with  $\sin(\theta_c) \simeq .23$  and unit matrix. In particular,  $V_{i3}$  are very small for  $i = 1, 2$ . Using the formula  $D = UV$  one finds that  $|U_{i3}| = |D_{i3}|$  in a good approximation for  $i = 1, 2$  and by unitarity also for  $I = 3$ . Thus the third columns of  $U$  and  $D$  are identical in a good approximation.
2. Assume that also  $U_{i3}$  and  $D_{i3}$  are small for  $i = 1, 2$ . A stronger assumption is that even the contribution of  $D_{13}$  and  $U_{13}$  are so small that they do not affect  $u$  and  $d$  masses. This implies

$$\begin{aligned} n_d &= 9|D_{12}|^2 + 60|D_{13}|^2 \simeq 9|D_{12}|^2 , \\ n_u &\simeq 9|U_{12}|^2 . \end{aligned} \quad (6.3.14)$$

Unitarity implies in this approximation

$$\begin{aligned} |U_{11}|^2 &\leq 1 - \frac{n_u}{9} = \frac{1}{3} , \\ |D_{11}|^2 &\leq 1 - \frac{n_d}{9} = \frac{5}{9} . \end{aligned} \quad (6.3.14)$$

3. It might be that there are also solutions for which mixing of  $u$  resp.  $d$  quark is mostly with  $t$  resp.  $b$  quarks but numerical experimentation does not favor this idea since CP breaking becomes extremely small. Since mixing presumably involves topology change, it seems obvious that topological mixing involving a creation or annihilation of two handles is improbable.

## 6.4 Construction of $U$ , $D$ , and CKM matrices

In this section it will be found that various mathematical and experimental constraints on  $U$  and  $D$  matrices determine them essentially uniquely.

### 6.4.1 The constraints from CKM matrix and number theoretical conditions

The requirement that  $U$ ,  $D$  and  $V$  allow an algebraic continuation to finite-dimensional extensions of various p-adic number fields provides a very strong additional constraints. The mathematical problem is to understand how many unitary  $V$  matrices acting on  $U$  as  $U \rightarrow D = UV$  respect the number theoretic constraints plus the constraints  $n_u = n_d + 2$  and  $n_c = n_d - 2$ .

It is instructive to what happens in much simpler 2-dimensional case. In this case the conditions boil down to the conditions on  $n(i)$  imply  $|U| = |D|$  and this condition is equivalent with (say) the condition  $|U_{11}| = D_{11}$ .  $U$  and  $D$  can be parameterized as

$$U = \begin{pmatrix} \cos(\theta)\exp(i\psi) & \sin(\theta)\exp(i\phi) \\ -\sin(\theta)\exp(-i\phi) & \cos(\theta)\exp(-i\psi) \end{pmatrix}.$$

If  $\cos(\theta)^2$  and  $\sin(\theta)^2$  are rational numbers,  $\exp(i\theta)$  is associated with a Gaussian integer. A more general requirement is that  $\exp(i\theta)$  belongs to a finite-dimensional extension of rational numbers and thus corresponds to a products of a phase associated with Gaussian integer and a phase in a finite-dimensional algebraic extension of rational numbers.

Eliminating the trivial multiplicative phases gives a set of matrices  $U$  identifiable as a double coset space  $X^2 = SU(2)/U(1)_R \times U(1)_L$ . The value of  $\cos(\theta) = |U_{11}|$  serving as a coordinate for  $X^2$  is respected by the right multiplication with  $V$ . Eliminating trivial  $U(1)_R$  phase multiplication, the space of  $V$ :s reduces to  $S^2 = SU(2)/U(1)_R$ . The condition that  $\cos(\theta)$  is not changed leaves one parameter set of allowed matrices  $V$ .

The translation of these results to 3-dimensional case is rather straightforward. In the 3-dimensional case the probabilities  $P_{i2}, P_{i3}$ ,  $i = 1, 2$  characterize a general matrix  $|U|$ , and  $V$  can affect these probabilities subject to constraints on  $n(I)$ . When trivial phases affecting the probabilities are eliminated, the matrices  $U$  correspond naturally to points of the 4-dimensional double coset space  $X^4 = SU(3)/(U(1) \times U(1))_R \times U(1) \times U(1)_L$  having dimension  $D = 4$ .

The two constraints on the probabilities mean that allowed solutions for given values of  $n(I)$  define a 2-dimensional surface  $X^2$  in  $X^4$ . The allowed unitary transformations  $V$  must be such that they move  $U$  along this surface. Certainly they exist since  $X^2$  can be regarded as a local section in  $SU(3) \rightarrow X^2$  bundle obtained as a restriction of  $SU(3) \rightarrow X^4$  bundle. The action of  $V$  on rows of  $U$  is ordinary unitary transformation plus a 2-dimensional unitary transformation preserving the Hermitian degenerate lengths  $L_i = 9|U_{i2}|^2 + 60|U_{i3}|^2 = n_i$  defining the sub-bundle  $SU(3) \rightarrow X^2$ . Note for  $L_1 = 0$  ( $L_2 = 0$ ) the situation becomes 2-dimensional and solutions correspond to points in  $S^2$ . Thus these points seem to represent a conical singularity of  $X^2$ .

The 2-dimensionality of the solution space means that two moduli (probabilities) of any row or column of  $U$  or  $D$  matrix characterize the matrix apart from the non-uniqueness due to the gauge choice allowing  $U(1)_L \times U(1)_R$  transformation of  $U$ . Of course, discrete sign degeneracy might be present.

A highly non-trivial problem is whether the set  $X^2$  contains rational points and what is the number of these points. For instance, Fermat's theorem says that no rational solutions to the equation  $x^n + y^n - z^n = 0$  exist for  $n > 2$ . The fact that the degenerate situation allows infinite number of rational solutions suggest that they exist also in the general case. Note also that the additional conditions are second order polynomial equations with rational coefficients so that  $SU(3, Q)$  should contain non-trivial solutions to the equations.

It is possible to write  $|U|$  in a form containing minimal number of square roots:

$$\begin{aligned}
|U_{11}| &= \sqrt{n_u} \frac{p_1}{N_1} , & |U_{12}| &= \sqrt{\frac{n_u}{9}} \frac{r_1}{N_1} , & |U_{13}| &= \sqrt{\frac{n_u}{60}} \frac{s_1}{N_1} , \\
|U_{21}| &= \sqrt{n_c} \frac{p_2}{N_2} , & |U_{22}| &= \sqrt{\frac{n_c}{9}} \frac{r_2}{N_2} , & |U_{23}| &= \sqrt{\frac{n_c}{60}} \frac{s_2}{N_2} , \\
|U_{31}| &= \sqrt{n_t} \frac{p_3}{N_3} , & |U_{32}| &= \sqrt{\frac{n_t}{9}} \frac{r_3}{N_3} , & |U_{33}| &= \sqrt{\frac{n_t}{60}} \frac{s_3}{N_3} .
\end{aligned} \tag{6.4.1}$$

Completely analogous expression holds true for  $D$ .  $r_i$ ,  $s_i$  and  $N_i$  are integers, and the defining equations reduce in both cases to equations generalizing those satisfied by Pythagorean triangles

$$\begin{aligned}
r_1^2 + s_1^2 &= N_1^2 , \\
r_2^2 + s_2^2 &= N_2^2 , \\
r_3^2 + s_3^2 &= N_3^2 .
\end{aligned} \tag{6.4.0}$$

The square roots of  $n_i$  are also eliminated from the unitarity conditions which become equations with rational coefficients for the phases appearing in  $U$  and  $D$ . Hence there are good hopes that even rational solutions to the conditions might exist.

#### 6.4.2 How strong number theoretic conditions one can pose on $U$ and $D$ matrices?

It is not quite clear how strong the number theoretic conditions on  $U$  and  $D$  matrices are. An attractive working hypothesis is that mixing probabilities are rational. This leaves a lot of freedom concerning the mixing matrices themselves since square roots of rationals, Pythagorean phases, and finite roots of unity can appear in the mixing matrices.

1. The most stringent requirement would be that  $U$  and  $D$  matrices are rational unitary matrices. p-Adicization without algebraic extension allows only matrices for which various phases and trigonometric functions are products of Pythagorean phases. This option will be found to be too restrictive. The minimal extension allows square roots requiring a finite-dimensional extension of p-adic numbers: geometrically this means a generalization Pythagorean triangles to triangles for which short sides are integer valued and long side is square root of integer. Pythagorean phases and their generalizations span infinite discrete subgroups of  $SU(3)$ .
2. Both the phases and also cosines and sines appearing in the mixing matrices could be restricted to algebraic roots of unit that is of form  $\exp(i2\pi/N)$  requiring finite algebraic extension of rationals and p-adic numbers. Roots of unity could define finite discrete subgroup of  $SU(3)$  implying rather stringent conditions on the model. Root of unity option is highly suggestive in light of the most recent developments (more than decade after development of the model) related to the p-adicization in terms of harmonic analysis in symmetric spaces relying on the counterparts of plane waves defined in terms of roots of unity and leading to a p-adic version of real symmetric space [K71]. Finite roots of unity define as a special case discrete subgroups of  $SU(3)$  implying rather stringent conditions on the model. For instance, in case of  $SU(2)$  these finite groups are well-known.

#### 6.4.3 Could rational unitarity make sense?

In this section the considerations are restricted mostly to rational unitarity which at the time of writing of this chapter looked more attractive than the allowance of algebraic roots of unity. The number theoretic conditions following from the rational unitarity on the moduli of the  $U$  and  $D$  matrices are not completely independent of the parametrization used. The reason is that the products of the parameters in some algebraic extension of the rationals can combine to give a rational number. The safest parametrization to use is the one based on the moduli of the  $U$  and  $D$  matrix.

### Parameterization of moduli in the case of rational unitarity

If one assumes rationality for the mixing matrix then all moduli can be written in the form

$$|D_{ij}| = \frac{n_{ij}}{N} . \quad (6.4.1)$$

If only moduli squared are required to be rational, the condition is replaced with a milder one:

$$|D_{ij}| = \frac{n_{ij}}{\sqrt{N}} . \quad (6.4.2)$$

Here  $\sqrt{N}$  belongs to square root allowing algebraic extension of the p-adic numbers but is not an integer itself. An even milder condition is

$$|D_{ij}| = \sqrt{\frac{n_{ij}}{N}} . \quad (6.4.3)$$

The following arguments show that only this option or more general option allowing roots of unity with rational mixing probabilities is allowed. These options is also natural in light or preceding general considerations.

### Unitary and mass conditions modulo 8 for rational unitarity

For  $p_{ij} = (\sqrt{\frac{n_{ij}}{N}})^k$ ,  $k = 1$  or  $2$ , the requirement that the rows are unit vectors implies

$$\begin{aligned} \sum_j n_{i,j}^k &= N^k , \\ k &= 1 \text{ or } 2 . \end{aligned} \quad (6.4.3)$$

The problem of finding vectors with integer valued components and with a given integer valued length squared  $m$  ( $k = 2$  case) is a well known and well understood problem of the number theory [?] . The basic idea is to write the conditions modulo 8 and use the fact that the square of odd (even) integer is 1 (0 or 4) modulo 8. The result is that one must have

$$m \in \{1, 2, 3, 5, 6\} , \quad (6.4.4)$$

for the conditions to possess nontrivial solutions. For  $m = N$  case this is the only condition needed. In  $m = N^2$  case the condition implies that  $N$  must be odd.

Using this result one can write the mass squared conditions modulo 8 for  $k = 2$  as

$$\begin{aligned} 3n_{i,2}^2 + 4n_{i,3}^2 &= n_i X , \\ X &= 1 \text{ for } m = N^2 , \\ X &\in \{1, 2, 3, 5, 6\} \text{ for } m = N . \end{aligned} \quad (6.4.3)$$

Here modulo 8 arithmetics is understood. In  $m = N^2$  case one must have  $n_i \in \{0, 3, 4\}$  modulo 8. These conditions are not satisfied in general. For  $m = N$  conditions allow considerably more general set of solutions. By summing the equations and using probability conservation one however obtains  $7N = 5N$  implying  $2N = 0$  so that the non-allowed value  $N = 4$  or  $0$  results.

For  $k = 1$  no obvious conditions result on the values of  $n_i$  and only this option is allowed by mass conditions for the physical masses.

### Rational unitarity cannot hold true for $U$ and $D$ matrices separately

The mixing scenario is not consistent with the assumption that the matrix elements of  $U$  and  $D$  matrix are complex rational numbers. If this were the case then matrix elements had to be proportional to a common denominator  $1/N$  such that  $N$  is odd integer (otherwise the conditions stating that the unit vector property of the rows is not satisfied). The conditions

$$\begin{aligned} \sum_j r_{ij} &= 1 , \\ 9r_{12} + 60r_{13} &= n_d , \\ 9r_{22} + 60r_{23} &= n_s , \\ 9r_{32} + 60r_{33} &= n_b , \\ r_{ij} &= \frac{n_{ij}}{N_i} , \end{aligned} \tag{6.4-1}$$

can be written modulo 8 as

$$\begin{aligned} \sum_j n_{ij}^k &= N^k , \\ n_{12}^k + 4n_{13}^k &= n_d N^k , \\ n_{22}^k + 4n_{23}^k &= n_s N^k , \\ n_{32}^k + 4n_{33}^k &= n_b N^k , \\ r_{ij} &= \left(\frac{n_{ij}}{N}\right)^{k/2} , \quad k = 1 \text{ or } 2 . \end{aligned} \tag{6.4-5}$$

1. Consider first the case  $k = 2$ . For odd  $n$   $n^2 = 1$  holds true and for even  $n$   $n^2 = 4$  or  $0$  holds true. It is easy to see that the conditions can be satisfied only if all integers are proportional to 4 but this cannot be possible since it would be possible since  $n_{ij}$  and  $N$  cannot contain common factors. Thus at least an extension allowing square roots is needed. Quite generally from  $N^2 = 1 \pmod{8}$  the above equations give

$$n_{q_i} \pmod{8} \in \{0, 3, 4, 7\} .$$

This condition fails to be satisfied by in the general case.

2. For the option  $k = 1$  for which only the probabilities are rational the sum of all three equations gives  $5N = 5N$  so that equations are consistent.

The result favors the possibility that roots of unity are the basic building bricks of the mixing matrices. This does not exclude the possibility that mixing probabilities are rational numbers.

### Rational unitarity for phase factors

The phase factors associated with the rows of the mixing matrix are rational provided the corresponding angles correspond to Pythagorean triangles. It must be however emphasized that roots of unity are highly suggestive in the recent vision about p-adicization. Combining this property with the orthogonality conditions for the rows of the  $U$  matrix, one obtains highly nontrivial conditions relating the integers characterizing the sides of the Pythagorean triangle to the integers  $n_{ij}$ . The requirement that the imaginary parts of the inner product vanish, gives the conditions

$$\frac{s_{i,2}}{s_{i3}} = \frac{n_{13}n_{i3}}{n_{12}n_{22}} , \quad i = 2, 3 . \tag{6.4-4}$$

Combining this conditions with the general representation for the sines of the Pythagorean triangle

$$\sin(\phi) = \frac{2rs}{r^2 + s^2} \text{ or } \frac{r^2 - s^2}{r^2 + s^2} , \quad (6.4.-3)$$

one obtains conditions relating the integers appearing characterizing the triangle to the integers on the right hand side.

An interesting possibility is that the lengths of the hypotenusae of the triangles associated with  $s(i, 2)$  ( $(r(i), s(i))$ ) and  $s_{i3}$  ( $(r_1(i), s_1(i))$ ) are the same and sines correspond to the products  $2rs$ :

$$\begin{aligned} r^2(i) + s^2(i) &= r_1^2(i) + s_1^2(i) , \\ s_{i,2} &= 2r(i)s(i)/(r^2(i) + s^2(i)) , \\ s_{i,3} &= 2r_1(i)s_1(i)/(r_1^2(i) + s_1^2(i)) . \end{aligned} \quad (6.4.-4)$$

In this case the conditions give

$$\frac{r(i)s(i)}{r_1(i)s_1(i)} = \frac{n_{13}n_{i3}}{n_{12}n_{22}} . \quad (6.4.-3)$$

The conditions are satisfied if one has

$$\begin{aligned} r(i)s(i) &= n_{13}n_{i3} , \\ r_1(i)s_1(i) &= n_{12}n_{22} . \end{aligned} \quad (6.4.-3)$$

This implies that  $r(i)$  and  $s(i)$  are products of the factors contained in the product  $n_{13}n_{i3}$ . Analogous conclusion applies to  $r_1(i)$  and  $s_1(i)$ .

Additional number theoretic conditions are obtained from the requirement that the real parts of the inner products between first row and second and third rows vanish:

$$n_{11}n_{i1} + c_{i,2}n_{12}n_{i2} + c_{i,3}n_{13}n_{i3} = 0 , \quad i = 2, 3 . \quad (6.4.-2)$$

#### 6.4.4 The parametrization suggested by the mass squared conditions

To understand the consequences of the mass squared conditions, it is useful to use a parametrization, which is more natural for the treatment of the mass squared conditions than the standard parametrization:

$$U = \begin{bmatrix} r_{11} & r_{12} & r_{13} \\ r_{21}x_2 & r_{22}x_2 \exp(i\phi_{22}) & r_{23}x_2 \exp(i\phi_{23}) \\ r_{31}x_3 & r_{32}x_3 \exp(i\phi_{32}) & r_{33}x_3 \exp(i\phi_{33}) \end{bmatrix} \quad (6.4.-1)$$

$$\begin{aligned} x_2 &= \exp(i\phi_2) , \\ x_3 &= \exp(i\phi_3) . \end{aligned}$$

In case of D matrix, the phase factors  $x_2$  and  $x_3$  can be chosen to be trivial. As far as the treatment of the mass conditions and unitarity conditions for the rows is considered, one can restrict the consideration to the case, when the overall phase factors are trivial. The remaining parameters are not independent and one can deduce the formulas relating the moduli  $r_{ij}$  as well as the phase angles  $\phi_{ij}$  to the parameters  $r_{11}$  and  $r_{12}$ . In general, the resulting parameters are not real and unitarity is broken.

Mass squared conditions and the requirement that the rows are unit vectors:

$$\begin{aligned} 9r_{i2}^2 + 60r_{i3}^2 &= n_i , \quad i = 1, 2 , \\ \sum_k r_{ik}^2 &= 1 , \end{aligned} \quad (6.4.-1)$$

allows one to express  $r_{i2}$  and  $r_{i3}$  in terms of  $r_{i1}$

$$\begin{aligned} r_{i2} &= \sqrt{\left[-\frac{n_i}{51} + \frac{20}{17}(1 - r_{i1}^2)\right]} , \\ r_{i3} &= \sqrt{\left[\frac{n_i}{51} - \frac{3}{17}(1 - r_{i1}^2)\right]} . \end{aligned} \quad (6.4-1)$$

The requirement that the rows are orthogonal to each other, relates the phase angles  $\phi_{ij}$  in terms to  $r_{11}$  and  $r_{21}$ . Using the notations  $\sin(\phi_{ij}) = s_{ij}$  and  $\cos(\phi_{ij}) = c_{ij}$ , one has

$$\begin{aligned} c_{i2} &= \frac{a_i}{b_i} , & c_{i3} &= -\frac{(A_{1i} + c_{i2}A_{2i})}{A_{3i}} , \\ s_{i2} &= \epsilon(i)\sqrt{1 - c_{i2}^2} , & s_{i3} &= -\frac{A_{2i}}{A_{3i}}s_{i2} , \\ A_{1i} &= r_{11}r_{i1} , & A_{2i} &= r_{12}r_{i2} \\ A_{3i} &= r_{13}r_{i3} , & \epsilon(i) &= \pm 1 . \\ a_i &= A_{3i}^2 - A_{1i}^2 - A_{2i}^2 , & b_i &= 2A_{1i}A_{2i} , \end{aligned} \quad (6.4.0)$$

The sign factors  $\epsilon(i)$  are not completely free and must be chosen so that the second and third row are orthogonal.

The mass conditions imply the following bounds for the parameters  $r_{i1}$

$$\begin{aligned} m_i &\leq r_{i1} \leq M_i , \\ m_i &= \sqrt{1 - \frac{n_i}{9}} \text{ for } n_i \leq 9 , \\ m_i &= 0 \text{ for } n_i \geq 9 , \\ M_i &= \sqrt{1 - \frac{n_i}{60}} . \end{aligned} \quad (6.4-2)$$

The boundaries for the regions of the solution manifold in  $(r_{11}, r_{21})$  plane can be understood as follows. For given values of  $r_{11}$  and  $r_{21}$  there are in general two solutions corresponding to the sign factor  $\epsilon(i)$  appearing in the equations defining the solutions of the mass squared conditions. This means just that complex conjugation gives a new solution from a given one. These two branches become degenerate, when the phase factors become  $\pm 1$  so that  $(s_{i2}, s_{i3})$  vanishes for  $i = 2$  or  $i = 3$ . Thus the curves at which one has  $(s_{i2} = 0, s_{i3} = 0)$  define the boundaries of the projection of the solution manifold to  $(r_{11}, r_{21})$  plane. At the boundaries the orthogonality conditions reduce to the form

$$\begin{aligned} r_{11}r_{i1} + \epsilon(i, 2)r_{12}r_{i2} + \epsilon_{i3}r_{13}r_{i3} &= 0 , \quad i = 2 \text{ or } 3 , \\ \epsilon_{22} &= \epsilon_{32} , \\ \epsilon_{23} &= -\epsilon_{33} \end{aligned} \quad (6.4-1)$$

where  $\epsilon_{ij}$  corresponds to the value of the cosine of the phase angle in question. Consistency requires that either second or third row becomes real on the boundary of the unitarity region and that the matrices reduce to orthogonal matrices at the dip of the region allowed by unitarity.

### 6.4.5 Thermodynamical model for the topological mixing

What would be needed is a physical model for the topological mixing allowing to deduce  $U$  and  $D$  matrices from first principles. The physical mechanism behind the mixing is change of the topology of  $X^2$  in the dynamical evolution defined by the light like 2-surface  $X_l^3$  defining parton orbit. This suggests that the topology changes  $g \rightarrow g \pm 1$  dominate the dynamics so that matrix elements  $U_{13}$  and  $D_{13}$  should be indeed small so that the weird looking result  $P_{11}^U \simeq 1/3$  follows from the requirement  $n_u = 6$ . This model however suggests that the matrix elements  $U_{23}$  and  $D_{23}$  could be large unlike in the original model for  $U$  and  $D$  matrices.

### Solution of thermodynamical model

A possible approach to the construction of mixing matrices is based on the idea that the interactions causing the mixing lead to a thermal equilibrium so that the entropies for the ensemble defined by the probabilities  $p_{ij}^U$  and  $p_{ij}^D$  matrix is maximized (the subscripts  $U$  and  $D$  are dropped in the sequel).

1. The elements in the three rows of the mixing matrix represent probabilities for three states of the system with energies  $(E_{i1}, E_{i2}, E_{i3}) = (0, 9, 60)$  and average energy is fixed to  $\langle E \rangle = 69$ .
2. There are usual constraints from probability conservation for each row plus two independent constraints from columns. The latter constraints can be regarded as a constraint on a second quantity equal to 1 for each column and brings in variable analogous to chemical potential besides temperature.

The constraint from mass squared for the third row follows from these constraints. The independent constraints can be chosen to be the following ones

$$\begin{aligned} \sum_j p_{ij} - 1 = 0, \quad i = 1, 2, 3 & \quad \sum_i p_{ij} - 1 = 0, \quad j = 1, 2, \\ 9p_{i2} + 60p_{i3} - n_{q_i} = 0, \quad i = 1, 2. \end{aligned} \quad (6.4.0)$$

The obvious notations  $(q_1, q_2) = (d, s)$  and  $(q_1, 2_2) = (u, c)$  are introduced. The conditions on mass squared are completely analogous to the conditions fixing the energy of the ensemble and thus its temperature, and thermodynamical intuition suggests that the probabilities  $p_{ij}$  decrease exponentially as function of  $E_j$  in the absence of additional constraints coming from the probability conservation for the columns and meaning presence of chemical potential.

The variational principle maximizing entropy in presence of these constraints can be expressed as

$$\begin{aligned} L &= S + S_c \\ S &= \sum_{i,j} p_{ij} \times \log(p_{ij}) \\ S_c &= \sum_i \lambda_i (\sum_j p_{ij} - 1) + \sum_{j=1,2} \mu_j (\sum_i p_{ij} - 1) + \sum_{i=1,2} \sigma_i (9p_{i2} + 60p_{i3} - n_{q_i}). \end{aligned} \quad (6.4.-2)$$

The variational equation is

$$\partial_{p_{ij}} L = 0, \quad (6.4.-1)$$

and gives the probabilities as

$$\begin{aligned} p_{11} &= \frac{1}{Z_1}, \quad p_{12} = \frac{xx_1^3}{Z_1^3}, \quad p_{13} = \frac{yx_1^{20}}{Z_1^{20}}, \\ p_{21} &= \frac{1}{Z_2}, \quad p_{22} = \frac{xx_2^3}{Z_2^3}, \quad p_{23} = \frac{yx_2^{20}}{Z_2^{20}}, \\ p_{31} &= \frac{1}{Z_3}, \quad p_{32} = \frac{x}{Z_3}, \quad p_{33} = \frac{y}{Z_3}, \end{aligned} \quad (6.4.-1)$$

Here the parameters  $x, y, x_1, x_2$  are defined as

$$\begin{aligned} x &= \exp(-\mu_2), \quad y = \exp(-\mu_3), \\ x_1 &= \exp(-3\sigma_1), \quad x_2 = \exp(-3\sigma_2). \end{aligned} \quad (6.4.-1)$$

whereas the row partition functions  $Z_i$  are defined as

$$Z_1 = 1 + xx_1^3 + yx_1^{20} , \quad Z_2 = 1 + xx_2^3 + yx_2^{20} , \quad Z_3 = 1 + x + y . \quad (6.4.0)$$

Note that the parameters  $\lambda_i$  have been eliminated. There are four parameters  $\mu_2, \mu_3, \sigma_2, \sigma_3$  and 2 conditions from columns and 2 mass conditions so that the number of solutions is discrete and only finite number of  $U$  and  $D$  matrices are possible in the thermodynamical approximation.

### Mass squared conditions

The mass squared conditions read as

$$9xx_1^3 + 60yx_1^{20} = n(q_1)Z_1 , \quad 9xx_2^3 + 60yx_2^{20} = n(q_2)Z_2 . \quad (6.4.1)$$

These equations allow to solve  $y$  as a simple linear function of  $x$

$$y = \frac{n(q_1) - xx_1^3(9 - n(q_1))}{(60 - n(q_1))x_1^{20}} \equiv kx + l , \quad y = \frac{n(q_2) - xx_2^3(9 - n(q_2))}{(60 - n(q_2))x_2^{20}} . \quad (6.4.2)$$

The identification of the two expressions for  $y$  allows to solve  $x_1$  in terms of  $x_2$  using equation of form  $x_1^{20} - bx_1^3 + c = 0$ :

$$\begin{aligned} & [60 - n(q_2)x_2^{20}] [n(q_1) - xx_1^3(9 - n(q_1))] \\ &= [60 - n(q_1)x_1^{20}] [n(q_2) - xx_2^3(9 - n(q_2))] . \end{aligned} \quad (6.4.2)$$

In the most general case the equation allows 20 roots  $x_1 = x_2(x_1)$ .

### Probability conservation

Probability conditions give additional information. By solving  $1/Z_3$  from the first column gives

$$Z_1Z_2Z_3 - Z_1Z_2 - Z_2Z_3 - Z_1Z_3 = 0 , \quad (6.4.3)$$

$$(6.4.4)$$

This equation is a polynomial equation in  $x_1$  and  $x_2$  with degree 20 and together with Eq. 6.4.2 having same degree determines and  $(x_1, x_2)$  the possible values of  $x_1$  and  $x_2$  as function of  $x$ . The number of real positive roots is at most  $20^2 = 400$ .

Probability conservation for the second column gives

$$x [(1 - x^3)Z_2 + (1 - x_2^3)Z_1] + (1 - x)Z_1Z_2 = 0 . \quad (6.4.5)$$

The row partition functions  $Z_i$  are linear functions of  $x$  and  $y$  and mass squared conditions give  $y = kx + l$  (see Eq. 6.4.2) so that a third order polynomial equation for  $x$  results and gives the roots as functions of control parameters  $x_1$  and  $x_2$ . Either 1 or 3 real roots are obtained for  $x$ . The values of  $x_1$  and  $x_2$  are determined by the probability constraint Eq. 6.4.4 for the first column and Eq. 6.4.2 relating  $x_1$  and  $x_2$ .

### The analogy with spontaneous magnetization

Physically the situation is analogous to a spontaneous symmetry breaking with  $y$  representing the external magnetizing field and  $x$  linear magnetization or vice versa.  $x_1$  and  $x_2$  are control parameters characterizing the interaction between spins. For single real root for  $x$  no spontaneous magnetization occurs but for 3 real roots there are two directions of spontaneous magnetization plus unstable state. In the recent case the roots must be positive. Since the maximal number of roots for  $(x_1, x_2)$  is 400, the maximal number of real roots is 1200. The trivial solution to the conditions is  $p_{11} = 1, p_{22} = 1, p_{33} = 1$  with  $x = y = 0$  represents corresponds to the absence of external magnetizing field and of magnetization.

### Catastrophe theoretic description of the system

In the catastrophe theoretic approach one can see that situation as a cusp catastrophe with  $x$  as a behavior variable and  $x_1, x_2$  in the role of control variables. In the standard parametrization of the cusp catastrophe [A16] the conditions correspond to the equation

$$x^3 - a - bx = 0 , \quad (6.4.5)$$

In the recent case a more general polynomial  $P_3(x)$  easily transformable to the standard form is in question. The coefficients of the polynomial  $P_3(x) = Dx^3 + Cx^2 + Bx + A$  are

$$\begin{aligned} A &= Q(x_1)Q(x_2) , \\ B &= P(x_1)Q(x_2) + P(x_2)Q(x_1) + R(x_2) + R(x_1) , \\ C &= P(x_1)R(x_2) + P(x_2)R(x_1) - R(x_1)Q(x_2) - R(x_2)Q(x_1) , \\ D &= R(x_1)R(x_2) , \\ P(u) &= 1 - u^3 , \quad Q(u) = 1 + lu^{20} , \quad R(u) = u^3 + ku^{20} . \end{aligned} \quad (6.4.2)$$

The trivial scaling transformation  $A \rightarrow A/D = \hat{A}$ ,  $B \rightarrow B/D = \hat{B}$ ,  $C \rightarrow C/D = \hat{C}$  and the shift  $x \rightarrow x + \hat{C}/3$  casts the equation in the standard form and gives

$$\begin{aligned} a &= -\hat{A} + \frac{\hat{C}^3}{9} , \\ b &= -\hat{B} + \frac{\hat{C}^2}{3} . \end{aligned} \quad (6.4.1)$$

The curve

$$a = \pm 2\left(\frac{b}{3}\right)^{3/2} , b \geq 0 \quad (6.4.2)$$

represents the bifurcation set for the solutions. For  $b \geq 0$ ,  $|a| \leq (\frac{b}{3})^{3/2}$  three roots are obtained for  $x$ .  $a = b = 0$  corresponds to the dip of the cusp. Three solutions result under the conditions

$$\begin{aligned} \frac{\hat{C}^2}{3} &\geq 3\hat{B} , \\ \left(-\hat{B} + \frac{\hat{C}^2}{3}\right)^3 &\leq \frac{(-\hat{A} + \frac{\hat{C}^3}{9})^2}{4} , \\ \hat{A} &= \frac{Q(x_1)Q(x_2)}{R(x_1)R(x_2)} , \\ \hat{B} &= \frac{P(x_1)Q(x_2) + P(x_2)Q(x_1) + R(x_2) + R(x_1)}{R(x_1)R(x_2)} , \\ \hat{C} &= \frac{P(x_1)R(x_2) + P(x_2)R(x_1) - R(x_1)Q(x_2) - R(x_2)Q(x_1)}{R(x_1)R(x_2)} , \\ P(u) &= 1 - u^3 , \quad Q(u) = 1 + lu^{20} , \quad R(u) = u^3 + ku^{20} . \end{aligned} \quad (6.4.-2)$$

The boundaries of the regions are defined by polynomial equations for  $x_1$  and  $x_2$ . . The two mass squared conditions and the probability conservation for the first row select a discrete set of parameter combinations.

One might ask whether  $U$  and  $D$  matrices could correspond to different solutions of these equations for same values of  $n_{q_i}$ . This cannot be the case since this would predict too large  $u - d$  mass difference.

Orthogonalization conditions for the rows should determine the phases more or less uniquely and could force CP breaking. The requirement that probabilities are rational valued implies that  $x_1$ ,  $x_2$ ,  $x$  and  $y$  are rational and poses very strong additional conditions to the solutions. The roots should correspond to very special solutions possessing symmetries so that the solutions of polynomial equations give probabilities as rational numbers. Note however that the solutions of polynomial equations with integer coefficients are in question and the solutions are algebraic numbers: this is enough as far as the p-adicization of the theory is considered.

### Maximization of entropy solving constraint equations explicitly

The mass squared conditions allow to express the probabilities  $p_{ij}$  in terms of  $p_{11}$  and  $p_{21}$  (for instance) and this allows a rather concise representation for the solution to the maximization the entropy of topological mixing. The key formulas are following.

$$\begin{aligned} p_{31} &= 1 - p_{11} - p_{12} \ , \\ p_{i2} &= -\frac{n_i}{51} + \frac{20}{17}(1 - p_{i1}) \ , \quad i = 1, 2 \ , \\ p_{i3} &= \frac{n_i}{51} - \frac{3}{17}(1 - p_{i1}) \ , \quad i = 1, 2 \ . \end{aligned} \quad (6.4-3)$$

Expressing entropy directly in terms of  $p_{11}$  and  $p_{21}$ , the conditions for the maximization of entropy imply the equations

$$\log(p_{ij})X^{ij} = 0 \ , \quad \log(p_{ij})Y^{ij} = 0 \ , \quad (6.4-2)$$

where a summation over repeated indices is carried out. The matrices  $X^{ij} = \partial_{p_{11}} p_{ij}$  and  $Y^{ij} = \partial_{p_{21}} p_{ij}$  are given by

$$\begin{aligned} X &= \begin{pmatrix} 1 & -\frac{20}{17} & \frac{3}{17} \\ 0 & 0 & 0 \\ -1 & \frac{20}{17} & -\frac{3}{17} \end{pmatrix} \\ Y &= \begin{pmatrix} 0 & 0 & 0 \\ 1 & -\frac{20}{17} & \frac{3}{17} \\ -1 & \frac{20}{17} & -\frac{3}{17} \end{pmatrix} \end{aligned} \quad (6.4-3)$$

The equations can be transformed into the form

$$\prod_{ij} p_{ij}^{X^{ij}} = 1 \ , \quad \prod_{ij} p_{ij}^{Y^{ij}} = 1 \ . \quad (6.4-2)$$

When written explicitly, these equations read as

$$\begin{aligned} \frac{p_{11}}{1-p_{11}-p_{21}} \times \left( \frac{-n_1+60(1-p_{11})}{-n_3+60(p_{11}+p_{21})} \right)^{-20/17} \times \left( \frac{n_1-9(1-p_{11})}{n_3-9(p_{11}+p_{21})} \right)^{3/17} &= 1 \ , \\ \frac{p_{21}}{1-p_{11}-p_{21}} \times \left( \frac{-n_2+60(1-p_{21})}{-n_3+60(p_{11}+p_{21})} \right)^{-20/17} \times \left( \frac{n_2-9(1-p_{21})}{n_3-9(p_{11}+p_{21})} \right)^{3/17} &= 1 \ . \end{aligned} \quad (6.4-2)$$

The equations can be cast into polynomial equations in  $p_{11}$  and  $p_{21}$  by taking 17:th power of both equations. This gives polynomial equations of degree  $d = 17 + 20 + 3 = 40$ . The total number of solutions to the equations is at most  $40 \times 40 = 1600$ . The previous estimate gave upper bound  $3 \times 20 \times 20 = 1200$  for the number of solution. It might be that some symmetry is involved and reduces the upper bound by a factor  $3/4$ .

The solutions can be sought using gradient dynamics in which system in  $(p_{11}, p_{21})$  plane drifts in the force field defined by the gradient  $\nabla S$  of the entropy  $S = -\sum_{ij} p_{ij} \log(p_{ij})$  and ends up to the maximum of  $S$ ,  $S = -\sum_{ij} p_{ij} \log(p_{ij})$ .

$$\begin{aligned} \frac{dp_{11}}{dt} &= \partial_{p_{11}} S = -X^{ij} \log(p_{ij}) , \\ \frac{dp_{21}}{dt} &= \partial_{p_{21}} S = -Y^{ij} \log(p_{ij}) , \end{aligned} \quad (6.4.-2)$$

The conditions that the probabilities are positive give the constraints

$$\begin{aligned} 1 - \frac{n_1}{9} &\leq p_{11} \leq 1 - \frac{n_1}{60} , \\ 1 - \frac{n_2}{9} &\leq p_{21} \leq 1 - \frac{n_2}{60} , \\ 0 &\leq p_{21} \leq 1 - p_{11} , \\ \frac{69 - n_1 - n_2}{60} - p_{11} &\leq p_{21} \leq \frac{69 - n_1 - n_2}{9} - p_{11} \end{aligned} \quad (6.4.-5)$$

on the region containing the solutions.

#### 6.4.6 $U$ and $D$ matrices from the knowledge of top quark mass alone?

As already found, a possible resolution to the problems created by top quark is based on the additivity of mass squared so that top quark mass would be about 230 GeV, which indeed corresponds to a peak in mass distribution of top candidate, whereas  $t\bar{t}$  meson mass would be 163 GeV. This requires that top quark mass changes very little in topological mixing. It is easy to see that the mass constraints imply that for  $n_t = n_b = 60$  the smallness of  $V_{i3}$  and  $V(3i)$  matrix elements implies that both  $U$  and  $D$  must be direct sums of  $2 \times 2$  matrix and  $1 \times 1$  unit matrix and that  $V$  matrix would have also similar decomposition. Therefore  $n_b = n_t = 59$  seems to be the only number theoretically acceptable option. The comparison with the predictions with pion mass led to a unique identification  $(n_d, n_b, n_t) = (5, 5, 59), (n_u, n_c, n_t) = (4, 6, 59)$ .

#### $U$ and $D$ matrices as perturbations of matrices mixing only the first two genera

This picture suggests that  $U$  and  $D$  matrices could be seen as small perturbations of very simple  $U$  and  $D$  matrices satisfying  $|U| = |D|$  corresponding to  $n = 60$  and having  $(n_d, n_b, n_t) = (4, 5, 60), (n_u, n_c, n_t) = (4, 5, 60)$  predicting  $V$  matrix characterized by Cabibbo angle alone. For instance, CP breaking parameter would characterize this perturbation. The perturbed matrices should obey thermodynamical constraints and it could be possible to linearize the thermodynamical conditions and in this manner to predict realistic mixing matrices from first principles. The existence of small perturbations yielding acceptable matrices implies also that these matrices be near a point at which two different matrices resulting as a solution to the thermodynamical conditions coincide.

$D$  matrix can be deduced from  $U$  matrix since  $9|D_{12}|^2 \simeq n_d$  fixes the value of the relative phase of the two terms in the expression of  $D_{12}$ .

$$\begin{aligned} |D_{12}|^2 &= |U_{11}V_{12} + U_{12}V_{22}|^2 \\ &= |U_{11}|^2|V_{12}|^2 + |U_{12}|^2|V_{22}|^2 \\ &\quad + 2|U_{11}||V_{12}||U_{12}||V_{22}|\cos(\Psi) = \frac{n_d}{9} , \\ \Psi &= \arg(U_{11}) + \arg(V_{12}) - \arg(U_{12}) - \arg(V_{22}) . \end{aligned} \quad (6.4.-8)$$

Using the values of the moduli of  $U_{ij}$  and the approximation  $|V_{22}| = 1$  this gives for  $\cos(\Psi)$

$$\begin{aligned}
\cos(\Psi) &= \frac{A}{B} , \\
A &= \frac{n_d - n_u}{9} - \frac{9 - n_u}{9} |V_{12}|^2 , \\
B &= \frac{2}{9|V_{12}|} \sqrt{n_u(9 - n_u)} .
\end{aligned} \tag{6.4-9}$$

The experimentation with different values of  $n_d$  and  $n_u$  shows that  $n_u = 6, n_d = 4$  gives  $\cos(\Psi) = -1.123$ . Of course,  $n_u = 6, n_d = 4$  option is not even allowed by  $n_t = 60$ . For  $n_d = 4, n_u = 5$  one has  $\cos(\Psi) = -0.5958$ .  $n_d = 5, n_u = 6$  corresponding to the perturbed solution gives  $\cos(\Psi) = -0.6014$ .

Hence the initial situation could be  $(n_u = 5, n_s = 4, n_b = 60)$ ,  $(n_d = 4, n_s = 5, n_t = 60)$  and the physical  $U$  and  $D$  matrices result from  $U$  and  $D$  matrices by a small perturbation as one unit of  $t$  ( $b$ ) mass squared is transferred to  $u$  ( $s$ ) quark and produces symmetry breaking as  $(n_d = 5, n_s = 5, n_b = 59)$ ,  $(n_u = 6, n_c = 4, n_t = 59)$ .

The unperturbed matrices  $|U|$  and  $|D|$  would be identical with  $|U|$  given by

$$|U_{11}| = |U_{22}| = \frac{2}{3} , \quad |U_{12}| = |U_{21}| = \frac{\sqrt{5}}{3} , \tag{6.4-8}$$

The thermodynamical model allows solutions reducing to a direct sum of  $2 \times 2$  and  $1 \times 1$  matrices, and since  $|U|$  matrix is fixed completely by the mass constraints, it is trivially consistent with the thermodynamical model.

#### Direct search of $U$ and $D$ matrices

The general formulas for  $p^U$  and  $p^D$  in terms of the probabilities  $p_{11}$  and  $p_{21}$  allow straightforward search for the probability matrices having maximum entropy just by scanning the  $(p_{11}, p_{21})$  plane constrained by the conditions that all probabilities are positive and smaller than 1. In the physically interesting case the solution is sought near a solution for which the non-vanishing probabilities are  $p_{11} = p_{22} = (9 - n_1)/9$ ,  $p_{12} = p_{21} = n_1/9$ ,  $p_{33} = 1$ ,  $n_1 = 4$  or 5. The inequalities allow to consider only the values  $p_{11} \geq (9 - n_1)/9$ .

##### 1. Probability matrices $p^U$ and $p^D$

The direct search leads to maximally entropic  $p^D$  matrix with  $(n_d, n_s) = (5, 5)$ :

$$p^D = \begin{pmatrix} 0.4982 & 0.4923 & 0.0095 \\ 0.4981 & 0.4924 & 0.0095 \\ 0.0037 & 0.0153 & 0.9810 \end{pmatrix} , \quad p_0^D = \begin{pmatrix} 0.5556 & 0.4444 & 0 \\ 0.4444 & 0.5556 & 0 \\ 0 & 0 & 1 \end{pmatrix} . \tag{6.4-8}$$

$p_0^D$  represents the unperturbed matrix  $p_0^D$  with  $n(d = 4), n_s = 5$  and is included for the purpose of comparison. The entropy  $S(p^D) = 1.5603$  is larger than the entropy  $S(p_0^D) = 1.3739$ . A possible interpretation is in terms of the spontaneous symmetry breaking induced by entropy maximization in presence of constraints.

A maximally entropic  $p^U$  matrix with  $(n_u, n_c) = (5, 6)$  is given by

$$p^U = \begin{pmatrix} 0.5137 & 0.4741 & 0.0122 \\ 0.4775 & 0.4970 & 0.0254 \\ 0.0088 & 0.0289 & 0.9623 \end{pmatrix} \tag{6.4-8}$$

The value of entropy is  $S(p^U) = 1.7246$ . There could be also other maxima of entropy but in the range covering almost completely the allowed range of the parameters and in the accuracy used only single maximum appears.

The probabilities  $p_{ii}^D$  resp.  $p_{ii}^U$  satisfy the constraint  $p(i, i) \geq .492$  resp.  $p_{ii} \geq .497$  so that the earlier proposal for the solution of proton spin crisis must be given up and the solution discussed in [K27] remains the proposal in TGD framework.

### 2. Near orthogonality of $U$ and $D$ matrices

An interesting question whether  $U$  and  $D$  matrices can be transformed to approximately orthogonal matrices by a suitable  $(U(1) \times U(1))_L \times (U(1) \times U(1))_R$  transformation and whether CP breaking phase appearing in CKM matrix could reflect the small breaking of orthogonality. If this expectation is correct, it should be possible to construct from  $|U|$  ( $|D|$ ) an approximately orthogonal matrix by multiplying the matrix elements  $|U_{ij}|$ ,  $i, j \in \{2, 3\}$  by appropriate sign factors. A convenient manner to achieve this is to multiply  $|U|$  ( $|D|$ ) in an element wise manner  $((A \circ B)_{ij} = A_{ij}B_{ij})$  by a sign factor matrix  $S$ .

1. In the case of  $|U|$  the matrix  $U = S \circ |U|$ ,  $S(2, 2) = S(2, 3) = S(3, 2) = -1$ ,  $S_{ij} = 1$  otherwise, is approximately orthogonal as the fact that the matrix  $U^T U$  given by

$$U^T U = \begin{pmatrix} 1.0000 & 0.0006 & -0.0075 \\ 0.0006 & 1.0000 & -0.0038 \\ -0.0075 & -0.0038 & 1.0000 \end{pmatrix}$$

is near unit matrix, demonstrates.

2. For  $D$  matrix there are two nearly orthogonal variants. For  $D = S \circ |D|$ ,  $S(2, 2) = S(2, 3) = S(3, 2) = -1$ ,  $S_{ij} = 1$  otherwise, one has

$$D^T D = \begin{pmatrix} 1.0000 & -0.0075 & 0.0604 \\ -0.0075 & 1.0000 & 0.0143 \\ 0.0604 & 0.0143 & 1.0000 \end{pmatrix} .$$

The choice  $D = S \circ D$ ,  $S(2, 2) = S(2, 3) = S(3, 3) = -1$ ,  $S_{ij} = 1$  otherwise, is slightly better

$$D^T D = \begin{pmatrix} 1.0000 & -0.0075 & 0.0604 \\ -0.0075 & 1.0000 & 0.0143 \\ 0.0601 & 0.0143 & 1.0000 \end{pmatrix} .$$

### 3. The matrices $U$ and $D$ in the standard gauge

Entropy maximization indeed yields probability matrices associated with unitary matrices. 8 phase factors are possible for the matrix elements but only 4 are relevant as far as the unitarity conditions are considered. The vanishing of the inner products between row vectors, gives 6 conditions altogether so that the system seems to be over-determined. The values of the parameters  $s_1, s_2, s_3$  and phase angle  $\delta$  in the "standard gauge" can be solved in terms of  $r_{11}$  and  $r_{21}$ .

The requirement that the norms of the parameters  $c_i$  are not larger than unity poses non-trivial constraints on the probability matrices. This should be the case since the number of unitarity conditions is 9 whereas probability conservation for columns and rows gives only 5 conditions so that not every probability matrix can define unitary matrix. It would seem that that the constraints are satisfied only if the the 2 mass squared conditions and 2 conditions from the entropy maximization are equivalent with 4 unitarity conditions so that the number of conditions becomes  $5+4=9$ . Therefore entropy maximization and mass squared conditions would force the points of complex 9-dimensional space defined by  $3 \times 3$  matrices to a 9-dimensional surface representing group  $U(3)$  so that these conditions would have a group theoretic meaning.

The formulas

$$\begin{aligned} r_{i2} &= \sqrt{\left[-\frac{n_i}{51} + \frac{20}{17}(1 - r_{i1}^2)\right]} , \\ r_{i3} &= \sqrt{\left[\frac{n_i}{51} - \frac{3}{17}(1 - r_{i1}^2)\right]} . \end{aligned} \tag{6.4.-8}$$

and

$$U = \begin{bmatrix} c_1 & s_1 c_3 & s_1 s_3 \\ -s_1 c_2 & c_1 c_2 c_3 - s_2 s_3 \exp(i\delta) & c_1 c_2 s_3 + s_2 c_3 \exp(i\delta) \\ -s_1 s_2 & c_1 s_2 c_3 + c_2 s_3 \exp(i\delta) & c_1 s_2 s_3 - c_2 c_3 \exp(i\delta) \end{bmatrix} \quad (6.4-7)$$

give

$$\begin{aligned} c_1 &= r_{11} \quad , \quad c_2 = \frac{r_{21}}{\sqrt{1-r_{11}^2}} \quad , \\ s_3 &= \frac{r_{13}}{\sqrt{1-r_{11}^2}} \quad , \quad \cos(\delta) = \frac{c_1^2 c_2^2 c_3^2 + s_2^2 s_3^2 - r_{22}^2}{2c_1 c_2 c_3 s_2 s_3} \quad . \end{aligned} \quad (6.4-6)$$

Preliminary calculations show that for  $n_1 = n_2 = 5$  case the matrix of moduli allows a continuation to a unitary matrix but that for  $n_1 = 4, n_2 = 6$  the value of  $\cos(\delta)$  is larger than one. This would suggest that unitarity indeed gives additional constraints on the integers  $n_i$ . The unitary (in the numerical accuracy used)  $(n_d, n_s) = (5, 5)$   $D$  matrix is given by

$$D = \begin{pmatrix} 0.7059 & 0.7016 & 0.0975 \\ -0.7057 & 0.7017 - 0.0106i & 0.0599 + 0.0766i \\ -0.0608 & 0.0005 + 0.1235i & 0.4366 - 0.8890i \end{pmatrix} .$$

The unitarity of this matrix supports the view that for certain integers  $n_i$  the mass squared conditions and entropy maximization reduce to group theoretic conditions. The numerical experimentation shows that the necessary condition for the unitarity is  $n_1 > 4$  for  $n_2 < 9$  whereas for  $n_2 \geq 9$  the unitarity is achieved also for  $n_1 = 4$ .

#### Direct search for CKM matrices

The standard gauge in which the first row and first column of unitary matrix are real provides a convenient representation for the topological mixing matrices: it is convenient to refer to these representations as  $U_0$  and  $D_0$ . The possibility to multiply the rows of  $U_0$  and  $D_0$  by phase factors ( $U(1) \times U(1)$ ) $_R$  transformations) provides 2 independent phases affecting the values of  $|V|$ . The phases  $\exp(i\phi_j)$ ,  $j = 2, 3$  multiplying the second and third row of  $D_0$  can be estimated from the matrix elements of  $|V|$ , say from the elements  $|V_{11}| = \cos(\theta_c) \equiv v_{11}$ ,  $\sin\theta_c = .226 \pm .002$  and  $|V_{31}| = (9.6 \pm .9) \cdot 10^{-3} \equiv v_{31}$ . Hence the model would predict two parameters of the CKM matrix, say  $s_3$  and  $\delta_{CP}$ , in its standard representation.

The fact that the existing empirical bounds on the matrix elements of  $V$  are based on the standard model physics raises the question about how seriously they should be taken. The possible existence of fractally scaled up versions of light quarks could effectively reduce the matrix elements for the electro-weak decays  $b \rightarrow c + W$ ,  $b \rightarrow u + W$  resp.  $t \rightarrow s + W$ ,  $t \rightarrow d + W$  since the decays involving scaled up versions of light quarks can be counted as decays  $W \rightarrow bc$  resp.  $W \rightarrow tb$ . This would favor too small experimental estimates for the matrix elements  $V_{i3}$  and  $V_{3i}$ ,  $i = 1, 2$ . In particular, the matrix element  $V_{31} = V_{td}$  could be larger than the accepted value.

Various constraints do not leave much freedom to choose the parameters  $n_{q_i}$ . The preliminary numerical experimentation shows that the choice  $(n_d, n_s) = (5, 5)$  and  $(n_u, n_c) = (5, 6)$  yields realistic  $U$  and  $D$  matrices. In particular, the conditions  $|U(1, 1)| > .7$  and  $|D(1, 1)| > .7$  hold true and mean that the original proposal for the solution of spin puzzle of proton must be given up. In [K27] an alternative proposal based on more recent findings is discussed. Only for this choice reasonably realistic CKM matrices have been found.

1. The requirement that the parameters  $|V_{11}|$  (or equivalently, Cabibbo angle and  $|V_{31}|$ ) are produced correctly, yields CKM matrices for which CP breaking parameter  $J$  is roughly one half of its accepted value. The matrix elements  $V_{23} \equiv V_{cb}$ ,  $V_{32} \equiv V_{tc}$ , and  $V_{13} \equiv V_{ub}$  are roughly twice their accepted value. This suggests that the condition on  $V_{31}$  should be loosened.
2. The following tables summarize the results of the search requiring that
  - i) the value of the Cabibbo angle  $s_{Cab}$  is within the experimental limits  $s_{Cab} = .223 \pm .002$  ,
  - ii)  $V_{31} = (9.6 \pm .9) \cdot 10^{-3}$ , is allowed to have value at most twice its upper bound,

iii)  $V_{13}$  whose upper bound is determined by probability conservation, is within the experimental limits  $.42 \cdot 10^{-3} < |V_{ub}| < 6.98 \cdot 10^{-3}$  whereas  $V_{23} \simeq 4 \times 10^{-3}$  should come out as a prediction, iv) the CP breaking parameter satisfies the condition  $|(J - J_0)/J_0| < .6$ , where  $J_0 = 10^{-4}$  represents the lower bound for  $J$  (the experimental bounds for  $J$  are  $J \times 10^4 \in (1 - 1.7)$ ).

The pairs of the phase angles  $(\phi_1, \phi_2)$  defining the phases  $(\exp(i\phi_1), \exp(i\phi_2))$  are listed below

$$\begin{array}{l}
 \text{class 1: } \begin{array}{ccccc} \phi_1 & 0.1005 & 0.1005 & 4.8129 & 4.8129 \\ \phi_2 & 0.0754 & 1.4828 & 4.7878 & 6.1952 \end{array} \\
 \text{class 2: } \begin{array}{ccccc} \phi_1 & 0.1005 & 0.1005 & 4.8129 & 4.8129 \\ \phi_2 & 2.3122 & 5.5292 & 0.7414 & 3.9584 \end{array}
 \end{array} \tag{6.4.-6}$$

The phase angle pairs correspond to two different classes of  $U$ ,  $D$ , and  $V$  matrices. The  $U$ ,  $D$  and  $V$  matrices inside each class are identical at least up to 11 digits(!). Very probably the phase angle pairs are related by some kind of symmetry.

The values of the fitted parameters for the two classes are given by

$$\begin{array}{l}
 \begin{array}{cccc} |V_{11}| & |V_{31}| & |V_{13}| & J/10^{-4} \\ \text{class 1} & 0.9740 & 0.0157 & 0.0069 & .93953 \\ \text{class 2} & 0.9740 & 0.0164 & 0.0067 & 1.0267 \end{array}
 \end{array}$$

$V_{31}$  is predicted to be about 1.6 times larger than the experimental upper bound and for both classes  $V_{23}$  and  $V_{32}$  are roughly too times too large. Otherwise the fit is consistent with the experimental limits for class 2. For class 1 the CP breaking parameter is 7 per cent below the experimental lower bound. In fact, the value of  $J$  is fixed already by the constraints on  $V_{31}$  and  $V_{11}$  and reduces by a factor of one half if  $V_{31}$  is required to be within its experimental limits.

$U$ ,  $D$  and  $|V|$  matrices for class 1 are given by

$$\begin{array}{l}
 U = \begin{bmatrix} 0.7167 & 0.6885 & 0.1105 \\ -0.6910 & 0.7047 - 0.0210i & 0.0909 + 0.1310i \\ -0.0938 & 0.0696 + 0.1550i & 0.1747 - 0.9653i \end{bmatrix} \\
 D = \begin{bmatrix} 0.7059 & 0.7016 & 0.0975 \\ -0.6347 - 0.3085i & 0.6358 + 0.2972i & 0.0203 + 0.0951i \\ -0.0587 - 0.0159i & -0.0317 + 0.1194i & 0.6534 - 0.7444i \end{bmatrix} \\
 |V| = \begin{bmatrix} 0.9740 & 0.2265 & 0.0069 \\ 0.2261 & 0.9703 & 0.0862 \\ 0.0157 & 0.0850 & 0.9963 \end{bmatrix}
 \end{array} \tag{6.4.-8}$$

$U$ ,  $D$  and  $|V|$  matrices for class 2 are given by

$$\begin{array}{l}
 U = \begin{bmatrix} 0.7167 & 0.6885 & 0.1105 \\ -0.6910 & 0.7047 - 0.0210i & 0.0909 + 0.1310i \\ -0.0938 & 0.0696 + 0.1550i & 0.1747 - 0.9653i \end{bmatrix} \\
 D = \begin{bmatrix} 0.7059 & 0.7016 & 0.0975 \\ -0.6347 - 0.3085i & 0.6358 + 0.2972i & 0.0203 + 0.0951i \\ -0.0589 - 0.0151i & -0.0302 + 0.1198i & 0.6440 - 0.7525i \end{bmatrix} \\
 |V| = \begin{bmatrix} 0.9740 & 0.2265 & 0.0067 \\ 0.2260 & 0.9704 & 0.0851 \\ 0.0164 & 0.0838 & 0.9963 \end{bmatrix}
 \end{array} \tag{6.4.-10}$$

What raises worries is that the values of  $|V_{23}| = |V_{cb}|$  and  $|V_{32}| = |V_{ts}|$  are roughly twice their experimental estimates. This, as well as the discrepancy related to  $V_{31}$ , might be understood in terms of the electro-weak decays of  $b$  and  $t$  to scaled up quarks causing a reduction of the branching ratios

$b \rightarrow c + W$ ,  $t \rightarrow s + W$  and  $t \rightarrow t + d$ . The attempts to find more successful integer combinations  $n_i$  has failed hitherto. The model for pseudoscalar meson masses, the predicted relatively small masses of light quarks, and the explanation for  $t\bar{t}$  meson mass supports this mixing scenario.

## 6.5 Hadron masses

Besides the quark contributions already discussed, hadron mass squared can contain several other contributions and the task is to find a model allowing to identify and estimate these contributions. There are several guidelines for the numerical experimentation.

1. Conformal weight, that is mass squared, is assumed to be additive for quarks corresponding to the same p-adic prime. For instance, in case of  $q\bar{q}$  mesons the mass would be  $\sqrt{2}m(q)$  and the contribution of  $k = 113$   $u, d, s$  quarks to nucleon mass would be  $< \sqrt{3} \times 100$  MeV and thus surprisingly small. For  $cd$  meson quark masses would be additive.
2. Old fashioned quark model explains reasonably well hadron masses in terms of constituent quark masses. Effective 2-dimensionality of partons suggests an interpretation for the constituent quark as a composite structure formed by the current quark identified as a partonic 2-surface  $X^2$  characterized by  $k(q)$  and by join along boundaries bond, kind of a gluonic "rubber band" characterized by  $k = 107$  and connecting  $X^2$  to the  $k = 107$  hadronic 2-surface  $X^2(H)$  representing hadron.  $X^2(q_i)$  could be perhaps regarded as a hole in  $k = k(q)$  3-surface. The 2-dimensional visualization for a 3-dimensional topological condensation would become much more than a mere visualization. This view about hadrons brings in mind unavoidably the surreal 2-dimensional structures formed by organs like retina. Of course, effective 2-dimensionality allows to characterize the entire Universe as an extremely complex fractal 2-surface.

The large mass of the constituent quark would be due to the color Coulombic and spin-spin interaction conformal weights of join along boundaries bond. Quark mass and the mass due to the color interaction conformal weight would be additive unless  $k = 107$  for the quark (it seems that for  $\eta'$  this is indeed the case!). Classical color gauge fluxes would flow between  $k = 107$  and  $k \neq 107$  space-time sheets along the bonds. Color dynamics would take place at  $k = 107$  space-time sheet in the sense that color gauge flux between quarks  $q_1$  and  $q_2$  flows first from  $X^2(k(q_1))$  to the hadronic 2-surface  $X^2(k = 107)$  and then back to  $X^2(k(q_2))$ . The induced Kähler field is always accompanied by a classical color gauge field and the classical color gauge flux would represent non-perturbative aspects of color interactions at space-time level.

3. A crucial observation is that the mass of  $\eta$  meson is rather precisely 4 times the pion mass whereas the mass of its spin excited companion  $\omega$  is very nearly the same as the mass of  $\rho$  meson. This suggests that  $u, d$  quarks correspond to  $k = 109$  inside  $\eta$  but to  $k = 113$  inside  $\omega$ . This inspires the idea that the p-adic mass scale of quarks is dynamical and sensitive to small perturbations as the fact that for  $CP_2$  type extremals the operators corresponding to different p-adic primes reduce to one and same operator forces to suspect. If  $k$  characterizes the length scale associated with the elementary particle horizon as  $\sqrt{k}$  multiple of  $CP_2$  length scale, quark mass would be characterized by the size of elementary particle horizon sensitive to the dynamics in hadronic mass scale.

The physical states would result as small perturbations of this degenerate ground state and the value of  $k(q)$  would be sensitive to the perturbation. A rather nice fit for meson and baryon masses results by assuming that the p-adic length scale of the quark is dynamical.

4. In the case of pseudoscalar mesons the scaled up versions of light quarks identifiable as constituent quarks, turn out to explain almost all of the pseudo scalar meson mass, and this inspires a new formulation for the old vision about pseudoscalar mesons as Goldstone bosons. At least light pseudoscalar mesons are Goldstone bosons in the sense that the color Coulombic and spin-spin interaction energies cancel in a good approximation so that quarks at  $k \neq 107$  space-time sheets are responsible for most of the meson mass. The assumption that only  $k(s)$  is dynamical for light baryons is enough to understand the mass differences between baryons having different numbers of strange quarks.

5. Color magnetic spin-spin interaction energies are indeed surprisingly constant among baryons. Also for mesons spin-spin interaction energies vary much less than the scaling of quark masses would predict on basis of QCD formula. This motivates the replacement of the interaction energy with interaction conformal weight in the case of color interactions. The interaction conformal weight is assignable to  $k = 107$  space-time sheet, and the fact that spin-spin splittings of also heavy hadrons can be measured in few hundred MeVs, supports this identification. The mild dependence of color Coulombic conformal weight and spin-spin interaction conformal weight on hadron would be due to their dependence on the primes  $k(q_i)$  and  $k = 107$  characterizing space-time sheets connected by the the color bonds  $q_i \rightarrow 107$  and  $107 \rightarrow q_j$ .
6. The values for the parameters  $s_{ij}^c$  and  $S_{ij}$  characterizing color Coulombic and color magnetic interaction conformal weights can be deduced from the mass squared differences for hadrons and assuming definite values for the parameters  $k(q_i)$  characterizing quark masses. It seems that no other sources to meson mass (or at least pion mass) are needed.
7. In the case of nucleons the understanding of nucleon mass requires a large additional contribution about 780 MeV since quarks contribute only about 160 MeV to the mass of nucleon. This contribution can be assumed to be same for all baryons as the possibility to understand baryon mass differences in terms of quark masses demonstrates. The most plausible identification of this contribution is in terms of 2- or 3-particle state formed by super-symplectic gluons assignable to  $k = 107$  hadronic space-time sheet and having conformal weight  $s = 16$  corresponding to mass 934.2 MeV (rather near to nucleon mass and  $\eta'$  mass). This leads to a vision about non-perturbative aspects of color interactions and allows to understand baryon masses with accuracy better than one per cent. Also a connection with hadronic string model emerges and hadronic string tension is predicted correctly.

### 6.5.1 The definition of the model for hadron masses

The defining assumptions of the model of hadron masses are following.  $CP_2$  mass defines the overall elementary particle mass scale. Electron mass determines this mass only in certain limits.

#### Model for hadronic quarks

The numerical construction of  $U$  and  $D$  matrices using the thermodynamical model for the topological mixing justifies the assumptions  $n_d = n_s = 5, n_b = 59$  and  $n_u = 5, n_c = 6, n_t = 58$ .

Quarks can appear both as free quarks and bound state quarks and the value of  $k(q)$  is in general different for free and bound state quarks and can depend on hadron in case of bound state quarks. This allows to understand satisfactorily the masses of low lying hadrons.

#### Quark mass contribution to the mass of the hadron

Quark mass squared is p-adically additive for quarks with same value of p-adic prime. In the case of meson one has

$$m_M^2(p_1 = p_2) = m_{q_1}^2 + m_{q_2}^2 . \quad (6.5.1)$$

$m_q$  denotes constituent quark mass which is larger than current quark mass due to the smaller value of  $k$ .

Masses are additive for different values of  $p$ .

$$m_M(p_1 \neq p_2) = m_{q_1} + m_{q_2} . \quad (6.5.2)$$

The generalization of these formulas to the case of baryons is trivial.

### Super-symplectic gluons and non-perturbative aspects of hadron physics

At least in the case of light pseudoscalar mesons the contribution of quark masses to the mass squared of meson dominates whereas spin 1 mesons contain a large contribution identified as color interaction conformal weight (color magnetic spin-spin interaction conformal weight and color Coulombic conformal weight). This conformal weight cannot however correspond to the ordinary color interactions alone and is negative for pseudoscalars and compensated by some unknown contribution in the case of pion in order to avoid tachyonic mass. Quite generally this realizes the idea about light pseudoscalar mesons as Goldstone bosons. Analogous mass formulas hold for baryons but in this case the additional contribution which dominates.

The unknown contribution can be assigned to the  $k = 107$  hadronic space-time sheet and must correspond to the non-perturbative aspects of QCD and the failure of the quantum field theory approach at low energies. In TGD the failure of QFT picture corresponds to the presence of configuration space degrees of freedom ("world of classical worlds") in which super-symplectic algebra acts. The failure of the approximation assuming single fixed background space-time is in question.

The purely bosonic generators carry color and spin quantum numbers: spin has however the character of orbital angular momentum. The only electro-weak quantum numbers of super-generators are those of right-handed neutrino. If the super-generators degrees carry the quark spin at high energies, a solution of proton spin puzzle emerges [K43].

The presence of these degrees of freedom means that there are two contributions to color interaction energies corresponding to the ordinary gluon exchanges and exchanges of super-symplectic gluons. For  $g = 0$  these gluons are massless and in absence of topological mixing could form a contribution analogous to sea or Bose-Einstein condensate. For  $g = 1$  their mass can be calculated. It turns out the model assuming same topological mixing as in case of  $U$  quarks leads to excellent understanding of baryon masses assuming that hadron spin correlates with the super-symplectic particle content of the hadronic space-time sheet.

### Top quark mass as a fundamental constraint

$CP_2$  mass is an important parameter of the model. The vanishing second order contribution to electron mass gives an upper bound for  $CP_2$  mass. The bound  $Y_e \leq .7357$  can be derived from the requirement that it is possible to reproduce  $\tau$  mass in p-adic thermodynamics. Maximal second order contribution corresponds to a minimal  $CP_2$  mass reduced by a factor  $\sqrt{5/6} = .9129$  from its maximal value. There is a natural mechanism making second order contribution negligible. Leptonic masses tend to be predicted to be few per cent too high [K39] if the second order contribution from p-adic thermodynamics to the electron mass vanishes, which suggests that second order contribution might be there.

For  $Y_e = 0$  and  $Y_t = 1$  the most recent experimental best estimate 169.1 GeV [?] for top quark mass is reproduced exactly. Even  $Y_t = 0$  allows a prediction in the allowed range. For too large  $Y_e$  top quark mass is predicted to be too small unless one allows first order Higgs contribution to the top quark mass. This means that  $CP_2$  mass can be scaled down from its maximal value at most 2.5 per cent. This translates to the condition  $Y_e < .26$ . It is possible to understand quark masses satisfactorily by assuming that Higgs contribution is second order p-adically and even negligible. In fact, there are good arguments suggesting that Higgs does not develop vacuum expectation at fermionic space-time sheets [K39]. If this is the case, top quark mass gives a very strong constraint to the model.

The super-symplectic color interactions associated with  $k = 107$  space-time sheet give rise to the dominant reduction of the color conformal weight having interpretation in terms of color magnetic and electric conformal weights. Canonical correspondence implies that this contribution is always non-negative. Therefore the simple additive formula can lead to a situation in which the contribution of quarks to the meson mass can be slightly larger than meson mass and it is not obvious whether it is possible to reduce this contribution by any means since the reduction of  $CP_2$  mass scale makes top quark mass too small.

For diagonal mesons for which quarks have the same value of p-adic prime, ordinary color interaction between quarks can contribute negative conformal weight reducing the contribution to the mass squared. In the case of non-diagonal mesons it is not clear whether this kind of color interaction exists. This kind of gluons would correspond to pairs of light-like partonic 3-surfaces for which throats correspond to different values of p-adic prime  $p$ . These are in principle possible but could couple weakly

to matter. It seems that the parameters of the model, essentially  $CP_2$  mass scale strongly constrained by the top quark mass, allow the quark contributions of non-diagonal mesons to be below the mass of the meson.

The fact that standard QCD model for color binding energies works rather well for heavy mesons suggests that the notion of negative color binding energy might make sense and could explain the discrepancy. The mixing of real and p-adic physics descriptions is however aesthetically very unappealing but might be the only way out of the problem. The p-adic counterpart of this description in case of heavy diagonal mesons would be based on the introduction of a negative color Coulombic contribution to the the conformal weight of quark pair.

### Smallness of isospin splittings

The smallness of isospin splittings inside  $I_s = 1/2$  doublets poses an further constraint.  $d_{113} - u_{113}$  mass difference is about  $\Delta m_{d-u} = 13$  MeV and larger than typical isospin splitting. The repulsive Coulomb interaction between quarks typically tends to reduce the mass differences due to  $\Delta m_{d-u}$  and the the sign of  $\Delta m_{d-u}$  explains the "wrong" sign of n-p mass difference equal to  $\Delta m_{n-p} = 1.3$  MeV. Non-diagonal hadrons containing scaled up u and d quarks would have anomalously large isospin splittings. On the other hand, for a diagonal meson containing  $b$  quark and scaled up  $u$  and  $d$  quark isospin splitting is proportional to  $(m_d^2 - m_u^2)/m_b$  and small.  $B$  meson corresponds to this kind of situation.

### 6.5.2 The anatomy of hadronic space-time sheet

Although the presence of the hadronic space-time sheet having  $k = 107$  has been obvious from the beginning, the questions about its anatomy emerged only quite recently after the vision about the spectrum of Kähler coupling strength had emerged [K2, K43] .

In the case of pseudoscalar mesons quarks give the dominating contribution to the meson mass. This is not true for spin 1/2 baryons and the dominating contribution must have some other origin. TGD allows to identify this contribution in terms of states created by purely bosonic generators of super-symplectic algebra and having as a space-time correlate  $CP_2$  type vacuum extremals topologically condensed at  $k = 107$  hadronic space-time sheet (or having this space-time sheet as field body). Proton and neutron masses are predicted with .5 per cent accuracy and  $\Delta - N$  mass splitting with .6 per cent accuracy. A further outcome is a possible solution to the spin puzzle of proton proposed already earlier [K43] .

### Quark contribution cannot dominate light baryon mass

The first guess would be that the masses give dominating contribution to the mass of baryon. Since mass squared is additive, this would require rather large quark masses for proton and neutron.  $k(d) = k(u) = k(s) = 108$  would give  $(m(d), m(u), m(s)) = (571.3, 520.4, 616.6)$  MeV and  $(m(n), m(p)) = (961.1, 931.7)$  MeV to be compared with the actual masses  $(m(n), m(p)) = (939.6, 938.3)$  MeV. The difference looks too large to be explainable in terms of Coulombic self-interaction energy.  $\lambda - n$  mass splitting would be 27.6 MeV for  $k(s) = 108$  which is much smaller than the real mass splitting 176.0 MeV. For  $k(s) = 110$  one would have 120.0 MeV.

### Does $k = 107$ hadronic space-time sheet give the large contribution to baryon mass?

In the sigma model for baryons the dominating contribution to the mass of baryon results as a vacuum expectation value of scalar field and light pseudoscalar mesons are analogous to Goldstone bosons whose masses are basically due to the masses of light quarks.

This would suggest that  $k = 107$  gluonic/hadronic space-time sheet gives a large contribution to the mass squared of baryon. p-Adic thermodynamics allows to expect that the contribution to the mass squared is in a good approximation of form

$$\Delta m^2 = nm^2(107) ,$$

where  $m^2(107)$  is the minimum possible p-adic mass mass squared and  $n$  a positive integer. One has  $m(107) = 2^{10}m(127) = 2^{10}m_e/\sqrt{(5)} = 233.55$  MeV for  $Y_e = 0$  favored by the top quark mass.

1.  $n = 11$  predicts  $(m(n), m(p)) = (944.5, 939.3)$  MeV for  $k = 113$  quarks: the actual masses are  $(m(n), m(p)) = (939.6, 938.3)$  MeV. Coulombic repulsion between u quarks could reduce the p-n difference to a realistic value.
2.  $\lambda - n$  mass splitting would be 184.7 MeV for  $k(s) = 111$  to be compared with the real difference which is 176.0 MeV. Note however that color magnetic spin-spin splitting requires that the ground state mass squared is larger than  $11m_0^2(107)$ .

### What is responsible for the large ground state mass of the baryon?

The observations made above do not leave much room for alternative models. The basic problem is the identification of the large contribution to the mass squared coming from the hadronic space-time sheet with  $k = 107$ . This contribution could have the energy of classical color field as a space-time correlate.

1. The assignment of the energy to the vacuum expectation value of sigma boson does not look very promising since the very existence sigma boson is questionable and it does not relate naturally to classical color gauge fields. More generally, since no gauge symmetry breaking is involved, the counterpart of Higgs mechanism as a development of a coherent state of scalar bosons does not look a plausible idea.
2. One can however consider the possibility of a Bose-Einstein condensate or of a more general many-particle state of massive bosons possibly carrying color quantum numbers. A many-boson state of exotic bosons at  $k = 107$  space-time sheet having net mass squared

$$m^2 = nm_0^2(107) \quad , \quad n = \sum_i n_i$$

could explain the baryonic ground state mass. Note that the possible values of  $n_i$  are predicted by p-adic thermodynamics with  $T_p = 1$ .

### Glueballs cannot be in question

Glueballs [?, ?] define the first candidate for the exotic boson in question. There are however several objections against this idea.

1. QCD predicts that lightest glue-balls consisting of two gluons have  $J^{PC} = 0^{++}$  and  $2^{++}$  and have mass 1650 MeV [?]. If one takes QCD seriously, one must exclude this option. One can also argue that light glue balls should have been observed long ago and wonder why their Bose-Einstein condensate is not associated with mesons.
2. There are also theoretical objections in TGD framework.
  - i) Can one really apply p-adic thermodynamics to the bound states of gluons? Even if this is possible, can one assume the p-adic temperature  $T_p = 1$  for them if  $T_p < 1$  holds true for gauge bosons consisting of fermion-antifermion pairs [K2, K43].
  - ii) Baryons are fermions and one can argue that they must correspond to single space-time sheet rather than a pair of positive and negative energy space-time sheets required by the glueball Bose-Einstein condensate realized as wormhole contacts connecting these space-time sheets. This argument should be taken with a big grain of salt.

### Do exotic colored bosons give rise to the ground state mass of baryon?

The objections listed above lead to an identification of bosons responsible for the ground state mass, which looks much more promising.

#### 1. Super-symplectic gluons

TGD predicts exotic bosons and their super-conformal partners. The bosons created by the purely bosonic part of super-symplectic algebra [?, K15], whose generators belong to the representations of the color group and 3-D rotation group but have vanishing electro-weak quantum numbers. Their

spin is analogous to orbital angular momentum whereas the spin of ordinary gauge bosons reduces to fermionic spin. The super-partners of the super-symplectic bosons have quantum numbers of a right handed neutrino and have no electro-weak couplings. Recall that super-symplectic algebra is crucial for the construction of configuration space Kähler geometry.

Exotic bosons are single-sheeted structures meaning that they correspond to a single wormhole throat associated with a  $CP_2$  type vacuum extremal. The assignment of these bosons to hadronic space-time having  $k = 107$  is an attractive idea. The only contribution to the mass would come from the genus and  $g = 0$  state would be massless in absence of topological mixing. In this case  $g = 0$  bosons could condense on the ground state and define the analog of gluonic contribution to the parton sea. If they mix situation changes.

In the following calculations it is assumed that the contributions to mass from different p-adic primes sum up linearly whereas for contributions with same value of p-adic prime mass squared is additive. This rule is required if one wants to understand the mass differences of mesons and baryons in terms of mass differences due to quark flavor and the dependence of the p-adic length scale of quark on hadron. If one assumes that all contributions to masses sum up quadratically, unreasonably large quark mass differences are required. The objection from QCD based approach is that quarks contribute less than 2 per cent to the mass of the hadron. In TGD sea quarks would correspond to large value of p-adic prime and only their contribution would be so small whereas the contribution of the valence quarks would be of the order of largest quark mass present.

$g = 1$  unmixed super-symplectic boson would have mass squared  $9m_0^2(k)$  (mass would be 700.7 MeV). For a ground state containing two  $g = 1$  exotic bosons, one would have ground state mass squared  $M_0^2 = 18m_0^2$  corresponding to  $(m(n), m(p)) = (1160.8, 1155.6)$  MeV. Negative color Coulombic conformal weight and color magnetic spin-spin splitting can reduce the mass of the system. Electromagnetic Coulomb interaction energy can reduce the p-n mass splitting to a realistic value.

1. Color magnetic spin-spin splitting for baryons gives a test for this hypothesis. The splitting of the conformal weight is by group theoretic arguments of the same general form as that of color magnetic energy and given by  $(m^2(N), m^2(\Delta)) = (18m_0^2 - X, 18m_0^2 + X)$  in absence of topological mixing.  $n = 11$  for nucleon mass implies  $X = 7$  and  $m(\Delta) = 5m_0(107) = 1338$  MeV to be compared with the actual mass  $m(\Delta) = 1232$  MeV. The prediction is too large by about 8.6 per cent.
2. If one allows negative color Coulombic conformal weight  $\Delta s = -2$  the mass squared reduces by 2 units. The alternative is topological mixing one can have  $m^2 = 8m_0^2$  instead of  $9m_0^2$ . This gives  $m(\Delta) = 1240$  MeV so that the error is only .6 per cent. The mass of topologically mixed exotic boson would be 660.6 MeV and equals to  $m_{104}$ .

One must consider also the possibility that super-symplectic gluons suffer topological mixing identical with that suffered by say  $U$  type quarks in which the conformal weights would be (5,6,58) for the three lowest generations.

1. For this option the ground state of baryon could consist of 2 gluons of lowest generation and one gluon of second generation ( $5 + 5 + 6 = 16$ ).
2. If the mixing is same as for D type quarks with weights (5,5,59), one can have only  $s = 15$  state. It turns out that this option allows to predict hadron masses with amazing precision if one assumes correlation between hadron spin and its super-symplectic particle content.
3. For this option one can even consider the possibility that super-symplectic gluons are able to represent also color Coulombic conformal weight so that model would simply considerably.

The conclusion is that a many-particle state of super-symplectic bosons could be responsible for the ground state mass of baryon. Also the baryonic spin puzzle caused by the fact that quarks give only a small contribution to the spin of baryons, could find a natural solution since these bosons could give to the spin of baryon an angular momentum like contribution having nothing to do with the angular momentum of quarks.

## 2. A connection with hadronic string model

Hadronic string model provides a phenomenological description of the non-perturbative aspects of hadron physics, and TGD was born also as a generalization of the hadronic string model. Hence one can ask whether something resembling hadronic string model might emerge from the super-symplectic sector. TGD allows string like objects but the fundamental string tension is gigantic, roughly a factor  $10^{-8}$  of that defined by Planck constant. The hypothesis motivated by the p-adic length scale hypothesis is that vacuum extremals deformed to non-vacuum extremals give to a hierarchy of string like structures with string tension  $T \propto 1/L_p^2$ ,  $L_p$  the p-adic length scale. The challenge has been the identification of quantum counterpart of this picture.

The fundamental mass formula of the string model relates mass squared and angular momentum of the stringy state. It has the form

$$M^2 = kJ, \quad k \simeq .9 \text{ GeV}^2. \quad (6.5.3)$$

A more general formula is  $M^2 = kn$ .

This kind of formula results from the additivity of the conformal weight (and thus mass squared) if one constructs a many particle state from  $g = 1$  super-symplectic bosons with a thermal mass squared  $M^2 = M_0^2 n$ ,  $M_0^2 = n_0 m_{107}^2$ . The angular momentum of the building blocks has some spectrum fixed by Virasoro conditions. If the basic building block has angular momentum  $J_0$  and mass squared  $M_0^2$ , one obtains  $M^2 = M_0^2 J$ ,  $k = M_0^2$ ,  $J = nJ_0$ . The values of  $n$  are even in old fashioned string model for a Regge trajectory with a fixed parity.  $J_0 = 2$  implies the same result so that basic unit might be called "strong graviton".

One can consider several candidates for the values of  $n_0$ . In the absence of topological mixing one has  $n_0 = 9$  for super-symplectic gluons. The bound state of two super-symplectic  $g = 1$  bosons with mass squared  $M_0^2 = 16m_{107}^2$  (two units of color binding conformal weight) could be responsible for the ground state mass of baryons. If topological mixing occurs and is same as for  $U$  type quarks then also a bound state of 2 gluons of first generation and 1 gluon of second generation gives  $M_0^2 = 16m_{107}^2$ .

The table below summarizes the prediction for the string tension in various cases. The identification of the basic excitations as many-particle states from bound states of super-symplectic gluons with  $M_0^2 = 16m_{107}^2$  predicts the nominal value of the .9 GeV with 3 per cent accuracy.

$n_0$	5	9	16	18
$M_0^2/\text{GeV}^2$	.273	.490	0.872	0.982

Table 6. The prediction for the hadronic string tension for some values of the mass squared of super-symplectic particle used to construct hadronic excitations.

Pomeron [?] represented an anomaly of the hadronic string model as a hadron like particle which was not accompanied by a Regge trajectory. A natural interpretation would be as a space-time sheet containing valence quarks as a structure connected by color flux tubes to single structure. There is recent quite direct experimental evidence for the existence of Pomeron [?, ?, ?] in proton photon collisions: Pomeron seems to leave the hadronic space-time sheet for a moment and collide with photon after which it topologically condenses back to the hadronic space-time sheet. For a more detailed discussion see [K43].

This picture allows also to consider a possible mechanism explaining spin puzzle of proton and I have already earlier considered an explanation in terms of super-symplectic spin [K43] assuming that state is superposition of ordinary ( $J = 0, J_q = 1/2$ ) state and ( $J = 2, J_q = 3/2$ ) state in which super-symplectic bound state has spin 2.

### 3. Some implications

If one accepts this picture, it becomes possible to derive general mass formulas also for the baryons of scaled up copies of QCD possibly associated with various Mersenne primes and Gaussian Mersennes. In particular, the mass formulas for leptobaryons, in particular "electro-baryons", can be deduced [?]. Good estimates for the masses of the mesons and baryons of  $M_{89}$  hadron physics are also obtained by simple scaling of the ordinary hadron masses by factor 512. Scaled up isospin splittings would be one signature of  $M_{89}$  hadron physics: for instance, n-p splitting of 1.3 MeV would scale up to 665.6 MeV.

### What about mesons?

The original short-lived belief was that only baryons are accompanied by a pair of super-symplectic bosons condensed at hadronic  $k = 107$  space-time sheet. By noticing that color magnetic spin-spin splitting requires an additional contribution to the conformal weight of meson cancelled by spin-spin splitting conformal weight in the case of pseudoscalar mesons to first order in  $p$ , one ends up with the conclusion that also mesons could possess the hadronic space-time sheet.

It is however unclear whether one must include besides the quantized contribution of super-symplectic gluons also color Coulombic contribution having interpretation as perturbative contribution. These contributions are of same form and one could argue that only super-symplectic contribution should be allowed. This would mean very strong quantization rules.

It however turns out that the contribution of super-symplectic massive boson is necessarily only in the case of  $\pi - \rho$  system and produces mere nuisance in the case of heavier mesons. The special role of  $\pi - \rho$  system could be understood in terms of color confinement which would make pion  $k = 107$  tachyon without the presence of additional mass squared.

Assuming topological mixing of super-symplectic bosons to be same as for U type quarks, the super-symplectic contribution must correspond to a conformal weight of 5 units in the case of pion and thus to *single* super-symplectic boson with  $m^2 = 5m_{107}^2$  instead of  $9m_{107}^2$  as for  $g = 1$  super-symplectic bosons. A possible interpretation is in terms of  $g = 0$  boson which has suffered a topological mixing. That 5 units of conformal weight result also in the topological mixing of  $u$  and  $d$  quarks supports this option and forces to ask whether also super-symplectic topological mixing is same inside baryons and mesons. If it is same for U type quarks and super-symplectic bosons one has  $(s_1, s_2, s_3) = (5, 6, 58)$  for the super-symplectic gluons. As noticed,  $S_{SC} = 16$  for baryons is obtained if one has a bound state of 2 bosons of first generation and one boson of second generation giving  $s_{SC} = 5 + 5 + 6 = 16$ . One can wonder how tightly the super-symplectic gluons are associated with baryonic valence quarks.

### 6.5.3 Pseudoscalar meson masses

The requirement that all contributions to the meson masses have p-adic origin allows to fix the model uniquely and also constraints on the value of the parameter  $Y_e$  emerge. In the following only pseudoscalar mesons will be considered.

#### Light pseudoscalar mesons as analogs of Goldstone bosons

Fractally scaled up versions of light quarks allow a rather simple model for hadron masses. In the old fashioned  $SU(3)$  based quark model  $\eta$  meson is regarded as a combination  $u\bar{u} + d\bar{d} - 2s\bar{s}$ . The basic observation is that  $\eta$  mass is rather precisely 4 times the mass of  $\pi$  whereas the mass of  $\omega$  is very near to  $\rho$  mass. This suggests that  $\eta$  results by a fractal scaling of quark masses obtained by the replacement  $k(q) = 113 \rightarrow 109$  for the quarks appearing in  $\eta$ . This inspires the idea that mesonic quarks are scaled up variants of light quarks and at least light pseudoscalar mesons are almost Goldstone bosons in the sense that quark contribution to the mass is as large as possible but smaller than meson mass. This idea must of course be taken as an interesting ansatz and in the end of the chapter it will be found that this idea might work only in the case of pion and kaon systems.

#### Quark contributions to meson masses

The following table summarizes the predictions for quark contributions to the masses of mesons assuming  $k(q)$  depending on meson and assuming  $Y_e = 0$  guaranteeing maximum value of top quark mass.

<i>Meson</i>	<i>scaled quarks</i>	$m_q(M)/MeV$	$m_{exp}/MeV$
$\pi^0$	$d_{113}, u_{113}$	140.0	135.0
$\pi^+$	$d_{113}, u_{113}$	140.0	139.6
$K^0$	$d_{114}, s_{109}$	495.5	497.7
$K^+$	$u_{114}, s_{109}$	486.3	493.7
$\eta$	$u_{109}, d_{109}, s_{109}$	522.2	548.9
$\eta'$	$u_{107}, d_{107}, s_{107}, c_{107}$	1144.2	957.6
$\eta' = B_{SC} + \sum_i q_i \bar{q}_i$	$q_{118}$	959.2	957.6
$\eta_c$	$c_{104}$	3098	2980
$D^0$	$c_{105}, u_{113}$	1642	1865
$D^+$	$c_{105}, d_{113}$	1654	1870
$\Upsilon$	$b_{103}$	10814	9460
$B$	$b_{104}, d_{104}, u_{104}$	5909	5270

Table 7. Summary of the model for contribution of quarks to the masses of mesons containing scaled up u,d, and s quarks. The model assumes the maximal value of  $CP_2$  mass allowed by  $\eta'$  mass and the condition  $Y_e = 0$  favored by top quark mass.

1. The quark contribution to pion mass is predicted to be 140 MeV, which is by few percent above the pion mass. Ordinary color interactions between pionic quarks can however reduce the conformal weight of pion by one unit. The reduction of  $CP_2$  mass scaled cannot be considered since it would reduce top quark mass to 163.3 GeV which is slightly below the favored range of values [?] .
2. The success of the fit requires that spin-spin splitting cancels the mass of super-symplectic boson in a good approximation for pseudoscalar mesons. This would be in accordance with the Goldstone boson interpretation of pseudoscalar mesons in the sense that color contribution to the mass from  $k = 107$  space-time sheet vanishes in the lowest p-adic order.
3. In the case of  $\eta$  resp.  $\eta'$  meson it has been assumed that the states have form  $(u\bar{u} + \bar{d} - 2s\bar{s})/\sqrt{6}$  resp.  $(u\bar{u} + \bar{d} + s\bar{s})/\sqrt{3}$ .
4.  $B$  mesons have anomalously large coupling to  $\eta'K$  and  $\eta'X$  [?], which indicates an anomalously large coupling of  $\eta'$  to gluons [?] . The interpretation has been in terms of a considerable mixing  $\eta'$  with gluon-gluon bound state.

$\eta'$  mass is only 2.5 per cent higher than the mass  $4m_{107}$  of super-symplectic boson  $B_{SC}$  associated with the hadronic space-time sheet of hadron. Large mixing scenario is however not consistent with the existence of  $\Phi$  with nearly the same mass. This encourages to consider the possibility that  $\eta'$  corresponds to a super-symplectic boson  $B_{SC}$  plus quark pair with  $k(d) = k(u) = k(s) = k(c) = 118$  with maximal mixing. In this case the contribution of quarks to the mass would be 25.1 MeV and one would have  $m(\eta') = 959.2$  MeV which coincides with the actual mass with 1 per mille accuracy. Note that this model predicts identical couplings to various quark pairs as does also the model assuming that  $\eta' - \Phi$  system is singlet with respect to flavor  $SU(3)$  (having no fundamental status in TGD).

It is clear from the above table that the quark contributions to the masses of  $\pi$ ,  $\eta'$  and  $B$  are slightly above the meson masses. In the case of  $B$  the discrepancy is largest and about 12 per cent. If one assumes that all contributions to the mass have p-adic origin, they are necessarily non-negative.

1. In the case of diagonal mesons the ordinary color interactions can reduce the contribution of quark masses to the mass of the meson. In the case of  $\eta'$  baruyonic super-symplectic gluon  $B_{SC}$  could resolve the problem.
2. In the case of non-diagonal mesons the only possible solution of the problem is that  $Y_e > 0$  holds true so that mass scale is reduced by a factor  $1 - P = \sqrt{5/(5 + Y_e)}$  giving  $Y_e \simeq .056$ . The prediction for top quark mass is reduced by 1.1 per cent to 167.2 GeV which belongs to the allowed range [?] .

3. In the case of  $B$  meson one is forced to assume  $k_b = k_d = k_u = 104$  although it would be possible to achieve smaller quark contribution by an alternative choice. This choice explains the observed very small isospin splitting and diagonality allows the ordinary color interaction to reduce the quark contribution to the  $B$  meson mass.
4. At the end of the chapter an alternative scenario in which quark masses give in good approximation only the masses of pion and kaon will be considered.

### An example about how the mesonic mass formula works

The mass of the  $B_c$  meson (bound state of  $b$  and  $c$  quark) has been measured with a precision by CDF (see the blog posting by Tommaso Dorigo [?]) and is found to be  $M(B_c) = 6276.5 \pm 4.8$  MeV. Dorigo notices that there is a strange "crackpottian" co-incidence involved. Take the masses of the fundamental mesons made of  $c\bar{c}$  ( $\Psi$ ) and  $b\bar{b}$  ( $\Upsilon$ ), add them, and divide by two. The value of mass turns out to be 6278.6 MeV, less than one part per mille away from the  $B_c$  mass!

The general p-adic mass formulas and the dependence of  $k_q$  on hadron explain the co-incidence. The mass of  $B_c$  is given as  $m(B_c) = m(c, k_c(B_c)) + m(b, k_b(B_c))$ , whereas the masses of  $\Psi$  and  $\Upsilon$  are given by  $m(\Psi) = \sqrt{2}m(c, k_\Psi)$  and  $m(\Upsilon) = \sqrt{2}m(b, k_\Upsilon)$ . Assuming  $k_c(B_c) = k_c(\Psi)$  and  $k_b(B_c) = k_b(\Upsilon)$  would give  $m(B_c) = [m(\Psi) + m(\Upsilon)]/\sqrt{2}$  which is by a factor  $\sqrt{2}$  higher than the prediction of the "crackpot" formula.  $k_c(B_c) = k_c(\Psi) + 1$  and  $k_b(B_c) = k_b(\Upsilon) + 1$  however gives the correct result.

As such the formula makes sense but the one part per mille accuracy must be an accident in TGD framework.

1. The predictions for  $\Psi$  and  $\Upsilon$  masses are too small by 2 *resp.* 5 per cent in the model assuming no effective scaling down of  $CP_2$  mass.
2. The formula makes sense if the quarks are effectively free inside hadrons and the only effect of the binding is the change of the mass scale of the quark. This makes sense if the contribution of the color interactions, in particular color magnetic spin-spin splitting, to the heavy meson masses are small enough.  $\Psi$  and  $\eta_c$  correspond to spin 1 and spin 0 states and their masses by 3.7 per cent ( $m(\eta_c) = 2980$  MeV and  $m(\Psi) = 3096.9$ ) so that color magnetic spin-spin splitting is measured using per cent as natural unit.

### 6.5.4 Baryonic mass differences as a source of information

The first step in the development of the model for the baryon masses was the observations that  $B - n$  mass differences can be understood if baryons are assumed to contain scaled versions of strange and heavy quarks. The deduction of precise values of  $k(q)$  is however not quite straightforward since the color magnetic contribution to the mass affects the situation. Thus a working hypothesis worth of studying is that ground state contribution is same for all baryons and that for spin 1/2 baryons quark contribution to the mass added to this contribution is near as possible to the real mass but smaller than it.

The purpose of the following explicit is to convince the reader that baryon mass difference can be indeed understood in terms of quark mass differences. This of course requires that quark space-time sheet is not the hadronic  $k = 107$  space-time sheet. Otherwise quadratic mass formula applies.

1.  $\Lambda - n$  mass difference is 176 MeV and ( $k(s) = 111, k(d) = 114$ ) for  $\lambda$  would predict the mass difference  $m(\lambda) - m(n) = m_q(\lambda) - m_q(n)$ , where one has  $m_q(\lambda) = m(s_{111}) + \sqrt{2}m(d_{114}) - m(n)$ ,  $m_q(n) = \sqrt{m(u_{113})^2 + 2m(d_{113})^2}$ . The prediction equals to 141 MeV. It is possible to achieve smaller discrepancy but more precise considerations support this identification. Note that the spin-spin interaction energy is same if  $u$  and  $d$  quark form the paired quark system which is in  $J = 0$  or  $J = 1$  state so that the mass difference indeed can be regarded as quark mass difference.
2.  $\Sigma - n$  mass difference is 257 MeV. If sigma contains  $s_{111}$ ,  $u_{114}$  and  $d_{114}$ , the mass difference is predicted to be  $m_q(\Sigma) - m_q(n)$ ,  $m_q(\Sigma) = m(s_{111}) + \sqrt{2}m(d_{114})$  and comes out as 228 MeV.
3. If  $\Xi$  contains two  $s_{110}$  quarks and  $u_{113}$  ( $d_{113}$ ), the mass difference comes out as 351 MeV to be compared with the experimental value 381 MeV.

4. Even single hadron, such as  $\Omega$ , could contain several scaled up variants of  $s$  quark.  $s_{108} + 2s_{111}$  decomposition would give mass difference 718 MeV to be compared with the real mass difference 734 MeV.
5. For  $\Lambda_c$  the mass is 2282 MeV. For  $k(c) = 105$  instead of  $k(c) = 104$  the predicted  $\Lambda_c - n$  mass difference is 1341 MeV whereas the experimental difference is 1344 MeV.
6. For  $\Lambda_b$  the mass is 5425 MeV. For  $k(b) = 104$  instead of  $k(b) = 103$  the predicted  $\Lambda_b - n$  mass difference is 4403 MeV. The experimental difference is 4485 MeV.

<i>Baryon</i>	<i>s content</i>	$\Delta m/MeV$	$\Delta m_{exp}/MeV$
$\Lambda$	$s_{111}$	141	176
$\Sigma$	$s_{110}$	228	257
$\Xi$	$s_{110} + s_{111}$	351	381
$\Omega$	$s_{108} + 2s_{110}$	718	734
$\Lambda_c$	$c_{105}, d_{112}, u_{112}$	1341	1344
$\Lambda_b$	$b_{105}, u_{106}, d_{106}$	4403	4485

Table 8. Summary of the model for the quark contribution to the masses of baryons containing strange quarks deduced from mass differences and neglecting second order contributions to the mass.  $\Delta m$  denotes the predicted  $B-n$  mass difference  $m(B) - m(n)$ . The subscript 'exp' refer to experimental value of the quantity in question.

### 6.5.5 Color magnetic spin-spin splitting

Color magnetic hyperfine splitting makes it possible to understand the  $\rho - \pi$ ,  $K^* - K$ ,  $\Delta - N$ , etc. mass differences [?]. That the order of magnitude for the splittings remains same over the entire spectrum of hadrons serves as a support for the idea that color fluxes are feeded to  $k = 107$  space-time sheet. This would suggest that color coupling strength does not run for the physical states and runs only for the intermediate states appearing in parton description of the hadron reactions. A possible manner to see the situation in terms of intermediate states feeding color gauge flux to space-time sheets with  $k > 107$  so that the additive color Coulombic interaction conformal weights  $s(q_i, q_j)$  would depend only on the integers  $k(q_i), k(q_j)$ . It will be found that the dependence is roughly of form  $1/(k(q_i) + k(q_j))$ , which brings in mind a logarithmic dependence of  $\alpha_s$  on p-adic length scales involved.

There are two approaches to the problem of estimating spin-spin splitting: the first one is based on spin-spin interaction energy and the second one on spin-spin interaction conformal weight. The latter one turns out to be the only working one.

#### The model based on spin-spin interaction energy fails

Classical model would apply real number based physics to estimate the splittings and calculate color magnetic interaction energies. Standard QCD approach predicts that the color magnetic interaction energy is of form

$$\Delta E = S \sum_{pairs} \frac{\bar{s}_i \cdot \bar{s}_j}{m_i m_j r_{ij}^3}. \quad (6.5.4)$$

The mass differences for hadrons allow to deduce information about the nature of color magnetic interaction and make some conclusions about the applicability this model.

1. For mesons the spin-spin splitting various from 630 MeV for  $\rho - \pi$  system to 120 MeV  $\Psi - \eta_c$  excludes the classical model predicting that the splitting should be proportional to  $1/m(q_1)m(q_2)$  (variation by a factor  $2^{113-106} = 128$  instead of 5 would be predicted if the size of the hadron remains same). Also the predicted ratio of  $K^* - K$  splitting to  $\rho - \pi$  splitting would be 1/4 rather than .63. The ratio of  $\eta - \omega$  splitting to  $\rho - \pi$  splitting would be 1/16 rather than .34. The ratio of  $\Phi - \eta'$  splitting to  $\rho - \pi$  splitting would be  $1/32 \simeq .03$  instead of .11.

The inspection of the spin-spin interaction energies would suggest that the interaction energy scales  $E(i, j)$  obey roughly the formula

$$E(i, j) \sim \frac{5}{2} \times \frac{1}{(\Delta k(q_1) + \Delta k(q_2))} =$$

$$5 \times \frac{1}{\log_2\{[L(113)/L(k(q_1))] \times [L(113)/L(k(q_2))]\}}$$

$$\Delta k(q) = 113 - k(q)$$

rather than being proportional to  $2^{-k(q_1) - k(q_2)}$ . The hypothesis that p-adic length scale  $L(k)$  of order  $CP_2$  length scale range corresponds to the size of elementary particle horizon associated with wormhole contacts feeding gauge fluxes of the  $CP_2$  type extremal representing particle to the larger space-time sheet with  $p \simeq 2^k$  might allow to understand this dependence.

2.  $\Delta - N$ ,  $\Sigma^* - \Sigma$ , and  $\Xi^* - \Xi$  mass differences are 291 MeV, 194 MeV, 220 MeV. If strange quark inside  $\Sigma$  corresponds to  $k = 110$ , the ratio of  $\Sigma^* - \Sigma$  splitting to  $\Delta - N$  splitting is predicted to be by a factor 1.17 larger than experimental ratio.  $\Xi^* - \Xi$  splitting assuming  $k(s) = 109$  the ratio would be .19 and quite too small. Assuming that  $s, u, d$  quarks have more or less same mass, the model would predict reasonably well the ratios of the splittings. Either the idea about scaled up variants of  $s$  is wrong or the notion of interaction energy must be replaced with interaction conformal weight in order to calculate the effects of color interactions to hadron masses.

### The modelling of color magnetic spin-spin interaction in terms of conformal weight

The model based on the notion of interaction conformal weight generalizes the formula for color magnetic interaction energy to the p-adic context so that color magnetic interaction contributes directly to the conformal weight rather than rest mass. The effect is so large that it must be p-adically first order (the maximal contribution in second order to hadron mass would be however only 224 MeV) and the generalization of the mass splitting formula is rather obvious:

$$\Delta s = \sum_{pairs} S_{ij} \bar{s}_i \cdot \bar{s}_j . \quad (6.5.5)$$

The coefficients  $S_{ij}$  depend must be such that integer valued  $\Delta s$  results and  $CP_2$  masses are avoided: this makes the model highly predictive. Coefficients can depend both on quark pair and on hadron since the size of hadron need not be constant. In any case, very limited range of possibilities remains for the coefficients.

This might be understood if the color flux carrying JAB connecting quark to  $k = 107$  hadronic space-time sheet is also characterized by a value of  $k \geq 113$ . This fixes practically completely the model in the case of mesons. If the interaction strengths  $s_c(i, j)$  characterizing color Coulombic interaction conformal weight between two quarks depends only on the flux tube pair connecting the quarks via  $k = 107$  space-time sheet via the integers  $k(q_i)$ , the model contains only very few parameters.

### The modelling of color magnetic- spin-spin splitting in terms of super-symplectic boson content

The recent variant for the model of the color magnetic spin-spin splitting replacing energy with conformal weight is considerably simpler than the earlier one. Still one can argue that a model using perturbative QCD as a format is not the optimal one in a genuinely non-perturbative situation.

The explicit comparison of the super-symplectic conformal weights associated with spin 0 and spin 1 states on one hand and spin 1/2 and spin 3/2 states on the other hand is carried out at the end of the chapter. The comparison demonstrates that the difference between these states could be understood in terms of super-symplectic particle contents of the states by introducing only single additional negative conformal weight  $s_c$  describing color Coulombic binding .  $s_c$  is constant for baryons ( $s_c = -4$ ) and in the case of mesons non-vanishing only for pions ( $s_c = -5$ ) and kaons ( $s_c = -12$ ). This leads to an excellent prediction for the masses also in the meson sector since pseudoscalar mesons heavier than kaon are not Goldstone boson like states in this model.

The correlation of the spin of quark-system with the particle content of the super-symplectic sector increases dramatically the predictive power of the model since the allowed conformal weights of super-symplectic bosons are (5,6,58). One can even consider the possibility that also exotic hadrons with different super-symplectic particle content exist: this means a natural generalization of the notion of Regge trajectories. This description will be summarized at the end of the chapter.

### 6.5.6 Color magnetic spin-spin interaction and super-symplectic contribution to the mass of hadron

Since  $k = 107$  contribution to hadron mass is always non-negative, spin-spin interaction conformal weight and also color Coulombic conformal weight must be subtracted from some additional contribution both in the case of pseudo-scalars and spin 1/2 baryons.

#### Baryonic case

In the case of baryons the additional contribution could be identified as a 2-particle state of super-symplectic bosons with mass squared  $9m_{107}^2$  in case of baryons. The net mass is  $s_{CS} = 18m_{107}^2$ . The study of  $N - \Delta$  system shows that color Coulombic interaction energy for single super-symplectic structural unit corresponds to  $\Delta s_{SC} = -2$  in the case of nucleon system so that one has  $s_{SC} = 18 \rightarrow 16$ . If topological mixing for super-symplectic bosons is same as for  $U$  type quarks with conformal weights (5,6,58), the already discussed three-particle state of would give  $s_{SC} = 5 + 5 + 6 = 16$ .

The basic requirement is that the the sum of spin-spin interaction conformal weight and  $s_{CS}$  reduces to the conformal weight corresponding to the difference of nucleon mass and quark contribution to 774.6 MeV and corresponds to  $s = 11$ .

One might hope that the situation could be the same for all baryons but it is safer to introduce an additional color Coulombic conformal weight  $s_c(B)$  which vanishes for  $N - \Delta$  system and hope that it is small as suggested by the fact that quark contributions explain quite satisfactorily the mass differences of baryons. This conformal weight could be assigned to the interaction of quarks via super-symplectic gluons and would represent a correction to the simplest model. Strictly speaking, the term "color Coulombic" should be taken as a mere convenient letter sequence.

#### Pseudo scalars

In the case of pseudoscalars the situation is not so simple. What is clear that quark masses determine the meson mass in good accuracy.

In this case  $s_{CS}$  can be determined uniquely from the requirement that in case of pion it is cancelled the conformal weight characterizing  $\rho - \pi$  color magnetic spin-spin splitting:

$$s_{SC} = |\Delta s(\pi, spin - spin)| . \quad (6.5.6)$$

This gives  $s_{SC} = 21/4 \simeq 5$ .

The conformal weights assignable to gluons and super-symplectic gluon must compensate the negative color magnetic spin-spin splitting making pion a tachyon. The following options represent the extremes

1. A positive color Coulombic conformal weight assignable to ordinary gluons compensates the negative conformal weight .
2. Conformal weight of the lightest topologically mixed super-symplectic gluon takes care of the compensation.

The interpretation as a bound state of unmixed super-symplectic  $g = 1$  with  $n = 9$  and massless  $g = 0$  gluon would require binding conformal weight by 4 units i which looks somewhat strange. The masslessness of  $g = 0$  gluon does not support the formation of this kind of bound state. An alternative option is in terms of topological mixing in which case  $g = 0$  boson should receive 5 units of conformal weight which is near to the .

Explicit calculations demonstrate that for mesons heavier than pion the role of  $s_c$  is to compensate  $s_{SC}$ . This suggests that the boson of lowest generation is present only inside  $\pi - \rho$  system and prevents

the large and negative color magnetic spin-spin interaction conformal weight to make pion a tachyon. The special role of pion could be understood in terms of a phase transition to color confining phase. Note however that the mass of  $\eta'$  could be understood by assuming baryonic super-symplectic boson of conformal weight  $s_{SC} = 16$  and fully mixed  $k = 118$  quarks.

### Formulas for $s_c(H)$ for mesons

There are two options to consider. For option I one has  $s_{SC} = 5$  for all mesons. For option II  $s_{CS}$  vanishes for all mesons except  $\pi$  and  $\rho$ . For option I one obtains the formula

$$s_c(M) = -s_{SC} - \Delta s(M_0, spin - spin) = -5 + |\Delta s(M_0, spin - spin)| . \quad (6.5.6)$$

For option II one has

$$s_c(M) = -5 + |\Delta s(M_0, spin - spin)| , \quad M = \pi, \rho , \quad (6.5.6)$$

$$s_c(M) = |\Delta s(M_0, spin - spin)| , \quad M \neq \pi, \rho . \quad (6.5.7)$$

$M_0$  refers to the pseudoscalar.

### Formulas for $s_c(H)$ for baryons

In the case of spin 1/2 baryons the requirement that the sum of color Coulombic and color magnetic conformal weights is same as for nucleons fixes the values of  $s_c(B)$ :

$$\begin{aligned} s_c(B) &= s_0 - s_{SC} - \Delta s(B_{1/2}, spin - spin) = -5 + |\Delta s(B_{1/2}, spin - spin)| , \\ s_{SC} &= 16 , \\ s_0 &= S(m(n) - m_q(n), 107) , \\ m_q(n) &= \sqrt{2m_d^2 + m_u^2} , \\ S(x, 107) &\equiv \left[ \left( \frac{x}{m_{107}} \right)^2 \right] . \end{aligned} \quad (6.5.4)$$

$s_0 = 11$  corresponds to the contribution difference of (say) neutron mass and quark contribution to the nucleon mass.  $s_{CS}$  corresponds to the conformal weight due to super-symplectic bosons. In the defining formula for  $S(x, 107)$   $[x]$  denotes the integer closest to  $x$ .

### The conformal weights associated with spin-spin splitting

The general formula for the spin-spin splitting allowing to determine the parameters  $S_{ij}$  from the masses of a pair  $H^* - H$  of hadrons (say  $\rho - \pi$  or  $\Delta - N$ ). The parameters can be deduced from the observation that the mass difference  $m(M^*) - m(M)$  for mesons corresponds to the difference of spin-splitting contributions to the mass:

$$\Delta s(M^*) - \Delta s(M) = S(m(M^*) - m(M), 107) . \quad (6.5.5)$$

For baryons one has

$$\begin{aligned} \Delta s(B^*) - \Delta s(B) &= X_1 - X_0 , \\ X_1 &= S(m(B^*) - m_q(B), 107) = , \\ X_0 &= S(m(B) - m_q(B), 107) . \end{aligned} \quad (6.5.4)$$

Here  $m_q(B) = m_q(B^*)$  denotes the quark contribution to the nucleon mass. The possibility to understand the mass differences of spin 1/2 baryons in terms of differences for  $m_q(B)$  inspires the hypothesis that  $X_0$  is constant also for baryons (it vanishes for mesons). If so  $X_0$  can be determined from neutron mass as

$$\begin{aligned} X_0 &= S(m(n) - m_q(n), 107) , \\ m_q(n) &= \sqrt{2m_d^2 + m_u^2} . \end{aligned} \quad (6.5.4)$$

Here  $m_q(n)$  is the contribution of quarks to neutron mass.

These formulas are *not* identical with those used in the earlier calculations and the difference is due to the fact that  $k = 107$  contributions and quark contributions are calculated separately unless quarks correspond  $k = 107$ . The formula allows to calculate second order contribution to the mass splitting.

p-Adicization brings in additional constraints. The requirement that the predicted mass of spin 1 boson and spin 3/2 fermion is not larger than than the experimental mass can pose strong constraints the scaling factor  $\sqrt{5/(5 + Y_e)}$  in the case of non-diagonal hadrons unless one is willing to modify the model for spin-spin splittings. It was already found that in case of  $\rho - \pi$  system this implies that top quark mass is at the lower limit of the allowed mass interval. One cannot take these constraints so seriously as the constraints that quark mass contribution is lower than meson mass in the case the quarks do not correspond to  $k = 107$ .

### General mass formula

The general formula for the mass of hadron can be written as a sum of perturbative and non-perturbative contributions as

$$m(H) = m_P + m_{NP} . \quad (6.5.5)$$

Preceding considerations lead to a simple formula for the non-perturbative contribution  $m_{NP}$  to the masses of spin 0 and spin 1 doublet of mesons:

$$\begin{aligned} m_{NP}(M) &= \sqrt{s_{NP}(M)} \times m_{107} , \\ s_{NP}(M_0) &= 0 , \\ s_{NP}(M_1) &= S(m(M^*) - m(M), 107) . \end{aligned} \quad (6.5.4)$$

For spin 1/2 and 3/2 doublet of baryons one has

$$\begin{aligned} m_{NP}(B) &= \sqrt{s_{NP}(B)} \times m_{107} , \\ s_{NP}(B_{1/2}) &= S(m_n - \sqrt{2m_d^2 + m_u^2}, 107) , \\ s_{NP}(B_{3/2}) &= S(m(B^*) - m_q(B), 107) . \end{aligned} \quad (6.5.3)$$

Perturbative contribution  $m_P$  contains in the lowest order approximation only the contribution of quark masses. In the case of diagonal mesons also a contribution from the ordinary color-Coulombic force and color magnetic spin-spin splitting can be present. For heavy mesons this contribution seems necessary since pure quark contribution is exceeds by few per cent the mass of meson.

### Spin-spin interaction conformal weights for baryons

Consider now the determination of  $S_{ij}$  in the case of baryons. The general splitting pattern for baryons resulting from color Coulombic, and spin-spin interactions is given by the following table. The following equations summarize spin-spin splittings for baryons in a form of a table.

<i>baryon</i>	$J$	$J_{12}$	$\Delta S^{spin}$
$N$	$\frac{1}{2}$	0	$-\frac{3}{4}S_{d,d}$
$\Delta$	$\frac{3}{2}$	1	$\frac{3}{4}S_{d,d}$
$\Lambda$	$\frac{1}{2}$	0	$-\frac{3}{4}S_{d,d}$
$\Sigma$	$\frac{1}{2}$	0	$-\frac{3}{4}S_{d,d}$
$\Sigma^*$	$\frac{1}{2}$	0	$\frac{1}{4}S_{d,d}$ $+\frac{1}{2}S_{d,s}$
$\Xi$	$\frac{1}{2}$	0	$-\frac{3}{4}S_{s,s}$
$\Xi^*$	$\frac{1}{2}$	0	$\frac{1}{4}S_{s,s}$ $+\frac{1}{2}S_{d,s}$
$\Omega$	$\frac{3}{2}$	1	$\frac{3}{4}S_{s,s}$

(6.5.3)

Spin-spin splittings are deduced from the formulas

$$\begin{aligned} \Delta S^{spin} &= S_{q_1, q_2} \left( \frac{J_{12}(J_{12} + 1)}{2} - \frac{3}{4} \right) , \\ &+ \frac{1}{4} (S_{q_1, q_3} + S_{q_2, q_3}) (J(J + 1) - J_{12}(J_{12} + 1) - \frac{3}{4}) , \end{aligned} \quad (6.5.2)$$

where  $J_{12}$  is the angular momentum eigenvalue of the 'first two quarks', whose value is fixed by the requirement that magnetic moments are of correct sign.

The masses determine the values of the parameters uniquely if one assumes that color binding energy is constant as indeed suggested by the very notion of  $M_{107}$  hadron physics. The requirement is that the mass difference squared for  $\Delta - N$ ,  $\Sigma^* - \Sigma$ , and  $\Xi^* - \Xi$  come out correctly.

Consider now the values of  $S_{ij}$  for the models assuming  $k = 113$  light quarks and dynamical  $k(s)$ .

1. For  $N - \Delta$  system the equation is

$$S_{d_{113}, d_{113}} = \frac{1}{3} S(m(\Delta) - m_q(N), 107) - S(m(N) - m_q(N), 107) .$$

Here  $m_q(N)$  refers to the quark contribution to the baryon mass.

2. For  $\Sigma^* - \Sigma$  system the basic equation can be written as

$$S_{d_{114}, s_{110}} = 2[S(m(\Sigma^*) - m_q(\Sigma), 107) - S(m(\Sigma) - m_q(\Sigma), 107) - S(d_{114}, d_{114})] .$$

One must make some assumption in order to find a unique solution. The simplest assumption is that  $S_{d_{114}, d_{114}} = S_{d_{114}, s_{110}}$ . This implies

$$S_{d_{114}, d_{114}} = \frac{1}{3} [S(m(\Sigma^*) - m_q(\Sigma), 107) - S(m(\Sigma) - m_q(\Sigma), 107)] .$$

3. In the case of  $\Xi^* - \Xi$  system the equation is

$$S_{s_{110}, s_{110}} = -\frac{1}{2} S_{d_{113}, s_{110}} + [S(m(\Xi^*) - m_q(\Xi), 107) - S(m(\Xi) - m_q(\Xi), 107)] .$$

If one assumes  $S_{s_{110}, s_{110}} = S_{d_{113}, s_{110}}$  one obtains

$$S_{s_{110}, s_{110}} = \frac{1}{3} [S(m(\Xi^*) - m_q(\Xi), 107) - S(m(\Xi) - m_q(\Xi), 107)] .$$

The resulting values of the parameters characterizing baryonic spin-spin splittings are in the table below. The parameters rela

$S_{d_{113},d_{113}}$	$S_{d_{114},d_{114}}$	$S_{d_{114},s_{110}}$	$S_{s_{110},s_{110}}$	$S_{d_{113},s_{110}}$
7	6	6	$\frac{8}{3}$	$\frac{8}{3}$

(6.5.3)

The mass squared unit used is  $m_0^2$  and  $k = 107$  defines the p-adic length scale used. The elements of  $S_{i,j}$  between different p-adic primes are assumed to be vanishing. The matrix elements are quite near to each other which raises the hope that the model indeed makes sense.

Color Coulombic binding conformal weights are given by the expression  $s_c = -5 + |\Delta s(B_{1/2}, spin - spin)|$ . The weights are given in the following table

<i>baryon</i>	$N$	$\Sigma$	$\Xi$
$s_c$	$\frac{1}{4}$	$-\frac{1}{2}$	$-3$

(6.5.3)

Some remarks are in order.

1. A good sign is that the values of  $s_c$  are small as compared to the value of  $s_{CS} = 18$  in all baryons so that only a small correction is in question.
2. The magnitude of  $s_c$  increases with the mass of baryon which does not conform with the expectations raised by ordinary QCD evolution. Could this mean that asymptotic freedom means that the color interaction between quarks occurs increasingly via super-symplectic gluons? For  $N - \Delta$  system the actual value of  $s_c$  should vanish.
3. One might worry about the fact the color binding conformal weights are not integral valued. The total conformal weights determining the mass squared are however integers.

### Spin-spin interaction conformal weights for mesons

The values of mesonic interaction strengths  $S_{i,j}$  can in principle deduced from the observed mass splittings. The following equations summarize the spin-spin splitting pattern for mesons in a form of table.

<i>meson</i>	$\Delta s^{spin}$
$\pi$	$-\frac{3}{4}S_{d,d}$
$\rho$	$\frac{1}{4}S_{d,d}$
$\eta$	$-\frac{3}{4}S_{d,d}$
$\omega$	$\frac{1}{4}S_{d,d}$
$K^\pm, K^0(CP = 1)$	$-\frac{3}{4}S_{d,s}$
$K^0(CP = -1)$	$-\frac{3}{4}S_{d,s}$
$K^{*,\pm}, K^{*,0}(CP = 1)$	$\frac{1}{4}S_{d,s}$
$K^{*,0}(CP = -1)$	$\frac{1}{4}S_{d,s}$
$\eta'$	$-\frac{3}{4}S_{s,s}$
$\Phi$	$\frac{1}{4}S_{s,s}$
$\eta_c$	$-\frac{3}{4}S_{c,c}$
$\Psi$	$\frac{1}{4}S_{c,c}$
$D^\pm, D^0(CP = 1)$	$-\frac{3}{4}S_{d,c}$
$D^0(CP = -1)$	$-\frac{3}{4}S_{d,c}$
$D^{*,\pm}, D^{*0}(CP = 1)$	$\frac{1}{4}S_{d,c}$
$D^{*0}(CP = -1)$	$\frac{1}{4}S_{d,c}$

(6.5.3)

Consider the spin-spin interaction for mesons.

1. For  $\rho - \pi$  system one has

$$S_{d_{113}, d_{113}} = s(m(\rho) - m_q(\pi)) .$$

Using  $s(\rho) = 14$  and  $s(\pi) = 0$  gives  $S(d_{113}, d_{113}) = 13$ .

2.  $\omega - \eta$  system one obtains

$$S_{q_{109}, q_{109}} = S(m(\omega) - m_q(\eta), 107)$$

3.  $K^* - K$ -splitting gives  $S_{d_{114}, s_{109}} = S(m(K^*) - m_q(K), 107)$ .

4.  $\Phi - \eta'$  splitting gives  $S_{q_{107}, q_{107}} = S(m(\Phi) - m_q(\eta'), 107)$ .

5.  $D^* - D$  mass splitting gives  $S_{d_{113}, c_{105}} = S(m(D^*) - m_q(D), 107)$ .

6.  $\Psi - \eta_c$  mass difference gives  $S_{c_{104}, c_{104}} = s(m(\Psi) - m_q(\eta_c), 107)$ .

The results for the spin-spin interaction strengths  $S_{ij}$  are summarized in the table below.  $q_{109}$  refers to  $u$ ,  $d$ , and  $s$  quarks.

$S_{d_{113}, d_{113}}$	$S_{q_{109}, q_{109}}$	$S_{q_{107}, q_{107}}$	$S_{d_{114}, s_{109}}$	$S_{d_{113}, c_{105}}$	$S_{c_{104}, c_{104}}$
7	1	0	3	2	0

(6.5.3)

Note that interaction strengths tend to be weaker for mesons than for baryons. For scaled up quarks the value of interaction strength tends to decrease and is smaller for non-diagonal than diagonal interactions. Since the values of  $k(q_i)$  maximize the quark contribution to hadron masses, the interaction strength produce a satisfactory mass fit for hadrons with errors of not larger than about five cent.

The color Coulombic binding conformal weights for meson states are given in the following table:

meson	$\pi$	$K$	$\eta$	$\eta'$	$D$	$\psi$
$s_c(I)$	+1/4	-4 - 1/4	-6	-3 - 1/4	-4 - 1/2	-5
$s_c(II)$	1/4	3/4	1	1 + 3/4	1/2	0

(6.5.3)

For option I  $g = 1$  boson is present in all mesons. The magnitude of  $s_c$  increases with the mass of the meson and more or less compensates  $s_{CS} = 5$ . This forces to consider the possibility that only pion contains the super-symplectic boson compensating the large and negative spin-spin interaction conformal weight making the state tachyon otherwise. The alternative possibility is that positive color Coulombic energy due to sea gluons does this. For option II  $s_c$  is relatively small and positive for this option.

### 6.5.7 Summary about the predictions for hadron masses

The following tables summarize the predictions for baryon masses following from the proposed model with optimal choices of the integers  $k(q)$  characterizing the mass scales of quarks and requiring that the predicted isospin splittings are of same order than the observed splittings. This condition is non-trivial: for instance, in case of  $B$  meson the smallness of splitting forces the condition  $k(b) = k(d) = k(u) = 104$  so that mass squared is additive and the large contribution of  $b$  quark minimizes the isospin splitting.

## Meson masses assuming that all pseudoscalars are Goldstone bosons

Meson	quarks	$m_{pr}(M)/MeV$	$m_{exp}/MeV$
$\pi^0$	$d_{113}, u_{113}$	140.0	135.0
$\pi^+$	$d_{113}, u_{113}$	140.0	139.6
$\rho^0$	$d_{113}, u_{113}$	756	772
$\rho^+$	$d_{113}, u_{113}$	756	770
$K^0$	$d_{114}, s_{109}$	496	498
$K^+$	$u_{114}, s_{109}$	486	494
$K^{0*}$	$d_{114}, s_{109}$	896	900
$K^{+*}$	$u_{114}, s_{109}$	892	891
$\eta$	$u_{109}, d_{109}, s_{109}$	522	549
$\omega^0$	$u_{109}, d_{109}, s_{109}$	817	783
$\eta'$	$u_{107}, d_{107}, s_{107}, c_{107}$	1144	958
$\Phi$	$u_{107}, d_{107}, s_{107}, c_{107}$	1144	1019
$\eta_c$	$c_{104}$	3098	2980
$D^0$	$c_{105}, u_{113}$	1642	1865
$D^+$	$c_{105}, d_{113}$	1655	1870
$D^{*0}$	$c_{105}, u_{114}$	1971	2007
$D^{*+}$	$c_{105}, d_{114}$	1985	2010
$F$	$c_{105}, s(106)$	1954	2021
$\Upsilon$	$b_{103}$	10814	9460
$B$	$b_{104}, d_{104}, u_{104}$	5909	5270

Table 9. The prediction of meson masses. The model assumes the maximal value of  $CP_2$  mass allowed by  $\eta'$  mass and the condition  $Y_e = 0$  favored by top quark mass.

In the case of meson masses the predictions for masses are not so good as for baryons. Errors are at worst about 5 per cent. For non-diagonal mesons the predicted masses are smaller than actual masses and in the case of kaons excellent. Also the prediction of pion mass is good but about 5 per cent too large. In the case of diagonal mesons ordinary color interactions could reduce the predicted masses in case that they are larger than actual ones.

## Meson masses assuming that only pion and kaon are Goldstone bosons

The Goldstone boson interpretation does not seem completely satisfactory. In order to make progress one can check whether the masses associated with super-symplectic bosons could serve as basic units for pseudoscalar and vector boson masses. A more general fit would be based on the use of fictive boson  $B_{107}$  with mass  $m_{107}$  as a basic unit in  $k = 107$  contribution to the mass. The table below gives very accurate formulas for the meson masses in terms of the scale  $m_{107}$  and quark contribution to the masses.

Meson	quarks	$m_{pr}(M)/MeV$	$m_{exp}/MeV$
$\pi^0$	$d_{113}, u_{113}$	140.0	135.0
$\pi^+$	$d_{113}, u_{113}$	140.0	139.6
$\rho^0$	$7B_{107} + d_{113}, u_{113}$	758	772
$\rho^+$	$7B_{107} + d_{113}, u_{113}$	758	770
$K^0$	$d_{114}, s_{109}$	496	498
$K^+$	$u_{114}, s_{109}$	486	494
$K^{0*}$	$3B_{107} + d_{114}, s_{109}$	901	900
$K^{+*}$	$3B_{107} + u_{114}, s_{109}$	891	891
$\eta$	$B_{SC,1} + u_{118}, d_{118}, s_{118}$	548	549
$\omega^0$	$2B_{SC,1} + u_{118}, d_{118}, s_{118}$	803	783
$\eta'$	$2B_{SC,1} + B_{SC,2} + q_{118}$	959	958
$\Phi$	$2B_{SC,1} + B_{SC,2} + q_{118}$	959	1019
$\eta_c$	$2B_{SC,1} + c_{105}$	2929	2980
$\Psi$	$3B_{SC,1} + c_{105}$	3098	3100
$D^0$	$2B_{SC,1} + c_{106}, u_{118}$	1853	1865
$D^+$	$2B_{SC,1} + c_{106}, d_{118}$	1850	1870
$D^{*0}$	$3B_{SC,1} + c_{106}, u_{118}$	2019	2007
$D^{*+}$	$3B_{SC,1} + c_{106}, d_{118}$	2016	2010
$F$	$3B_{SC,2} + c_{105}, s(113)$	2010	2021
$\Upsilon$	$B_{SC,3} + b_{104}$	9441	9460
$B^\pm$	$3B_{SC,2} + b_{105}, d_{105}, u_{105}$	5169	5270

Table 10. Table demonstrates that scalar and vector meson masses can be effectively regarded as expressible in terms of quark contribution and contribution coming from many particle states of super-symplectic bosons  $B_{SC,k}$ ,  $k = 1, 2, 3$ , with conformal weights (5,6,58) associated also with U type quarks.  $B_{107}$  denotes effective super-symplectic boson with conformal weight 1 and mass  $m_{107} = 233.6$  MeV.  $Y_e = 0$  favored by top quark mass is assumed.

The table demonstrates following.

1. For mesons heavier than kaons, the masses can be expressed effective sums of masses for quarks and many-particle state formed by super-symplectic bosons allowed by the topological mixing of U type quarks. For lighter mesons it is not possible to express the masses in terms of the conformal weights of quarks and super-symplectic gluons. This suggests that one must introduce positive color Coulombic conformal weight as the analog of positive Coulombic energy. The simplest assumption is that this conformal weight compensates for the color-magnetic spin-spin splitting in the case of pseudo-scalars and to the Goldstone boson option. This option indeed looks more reasonable.
2. For  $\pi - \rho$  resp.  $K - K^*$  systems the masses can be expressed using effective  $7B_{107}$  state resp.  $3B_{107}$  state. Second order contribution to the conformal weight from the super-symplectic color interaction can explain the too small mass of  $\rho$  and too large mass of  $\pi$  if it interferes with the corresponding quark mass contribution.
3. For pseudo-scalars heavier than kaon the mass of the super-symplectic meson is not completely compensated by spin-spin splitting for the pseudoscalar state so that Goldstone boson interpretation does not make sense anymore. In the case of heavy mesons the predicted masses of pseudoscalars are slightly below the actual mass.
4. The predicted masses are not larger than actual masses ( $\omega_0$  is the troublemaker) if one assumes 2.5 per cent reduction of  $CP_2$  mass scale for which top quark mass is at the lower bound of the allowed mass range.
5. Color magnetic spin-spin splitting parameters can be deduced from the differences of super-symplectic conformal weights for pseudoscalar and spin one boson. There is however no absolute need for this perturbative construct.

6. One can consider the possibility that the super-symplectic boson content is actual and correlates with the spin of quark-antiquark system for mesons heavier than kaons. The point would be that the representability in terms of super-symplectic bosons would make the model for the color magnetic spin-spin splittings highly predictive. This interpretation makes sense in the case of  $\pi - \rho$  and  $K - K^*$  systems only if one introduces negative color Coulombic conformal weight  $s_c$ . For heavier mesons only this contribution would be second order in  $p$  which is more or less consistent with the view about color coupling evolution.  $\pi - \rho$  would correspond to  $B_1$  ( $s = 5$ ) and  $2B_2$  ( $s = 12$ ) ground states with color Coulombic conformal weight  $s_c = -12$ .  $K - K^*$  would correspond to  $2B_2$  ( $s = 12$ ) and  $3B_1$  with  $s_c = -12$ . The presence of ground state bosons saves  $\pi$  and  $K$  from becoming tachyons.

Whatever the correct physical interpretation of the mass formulas represented by the table above is, it is clear that  $m_{107}$  defines a fundamental mass scale also for meson systems.

### Baryon masses

One can ask whether the representability of spin-spin splitting in terms of super-symplectic conformal boson content is possible also in the case of baryons so that perturbative formulas altogether would not be necessary. The physical interpretation would be that the total spin of baryonic quarks correlates with the content of super-symplectic bosons. The existence of this kind of representation would be one step towards understanding of also spin-spin splitting from first principles.

This is indeed the case if one accepts negative color Coulombic conformal weight  $s_c = -4$ . What is disturbing is that the sign of the corresponding parameter is positive for mesons and compensates color magnetic spin-spin splitting for pseudo-scalars (for Goldstone option). Spin 1/2 ground states would correspond to  $3B_1$  with conformal weight  $s = 15$ , one  $B_1$  for each valence quark. Spin 3/2 states would correspond to  $5B_1$  with  $s = 25$  in the case of  $\Delta$ , to  $2B_1 + B_2$  in the case of  $\Sigma^*$  with  $s = 23$ , and to  $B_1 + 3B_2$  with  $s = 24$  in case of  $\Xi^*$ .

Baryon	quarks	$m_{pr}(B)/MeV$	$m_{exp}/MeV$
$p$	$3B_1 + u_{113}, d_{113}$	942.3	938.3
$n$	$3B_1 + u_{113}, d_{113}$	949.8	939.6
$\Delta^{++}$	$5B_1 + u_{113}$	1230	1231
$\Delta^+$	$5B_1 + u_{113}, d_{113}$	1238	1235
$\Delta^0$	$5B_1 + u_{113}, d_{113}$	1245	1237
$\Delta^-$	$5B_1 + d_{113}$	1253	$\leq 1238$
$\Lambda$	$3B_1 + u_{114}, d_{114}, s_{111}$	1090	1116
$\Sigma^+$	$3B_1 + u_{114}, s_{110}$	1165	1189
$\Sigma^0$	$3B_1 + u_{114}, d_{113}, s_{110}$	1171	1192
$\Sigma^-$	$3B_1 + d_{114}, s_{110}$	1178	1197
$\Sigma^{*+}$	$2B_1 + 2B_2 + u_{114}, s_{110}$	1381	1385
$\Xi^0$	$2B_1 + 2B_2 + u_{113}, s_{110}, s_{111}$	1301	1315
$\Xi^-$	$3B_1 + d_{113}, s_{110}$	1288	1321
$\Xi^{*0}$	$B_1 + 3B_2 + u_{113}, s_{110}$	1531	1532
$\Xi^{*-}$	$B_1 + 3B_2 + d_{113}, s_{110}$	1505	1535
$\Omega^-$	$3B_1 + s_{108}, s_{111}$	1667	1672
$\Lambda_c$	$3B_1 + d_{110}, u_{110}, c_{106}$	2261	2282
$\Lambda_b$	$3B_1 + d_{108}, u_{108}, b_{105}$	5390	5425

Table11. The predictions for baryon masses assuming  $Y_e = 0$ . One can represent color magnetic spin-spin splittings by assuming different super-symplectic boson content for spin 1/2 and spin 3/2 states. The number of super-symplectic bosons need not be however different for them.

From the table for the predicted baryon masses one finds that the predicted masses are slightly below the experimental masses for all baryons except for some baryons in  $N - \Delta$  multiplet and for  $\Omega$ . The reduction of the  $CP_2$  mass scale by a factor of order per cent consistent with what is known about top quark mass cures this problem (also ordinary color interactions could take of the problem).

In principle the quark contribution to the hadron mass is measurable. Suppose that color binding conformal weight can be assigned to the color interaction in super-symplectic degrees of freedom alone. Above the "ionization" energy, which corresponds to the contribution of quarks to the mass of hadron, valence quark space-time sheet can separate from the hadronic space-time sheet in the collisions of hadrons. This threshold might be visible in the collision cross sections for say nucleon-nucleon collisions. For nucleons this energy corresponds to 170 MeV.

### 6.5.8 Some critical comments

The number theoretical model for quark masses and topological mixing matrices and CKM matrix as well as the simple model for hadron masses give strong support for the belief that the general vision is correct. One must bear in mind that the scenario need not be final so that the basic objections deserve an explicit articulation.

#### Is the canonical identification the only manner to map mass squared values to their real counterparts

In p-adic thermodynamics p-adic particle mass squared is mapped to its real counterpart by the canonical identification. If the  $O(p)$  contribution corresponds to non-trivial rational number, the real mass is of order  $CP_2$  mass. This allows to eliminate a large number of exotics. In particular, it implies that the modular contribution to the mass squared must be of form  $np$  rather than  $(r/s)p$ . This assumption is absolutely crucial in the model of topological mixing matrices and CKM matrix.

One can however question the use of the standard form of the canonical identification to map p-adic mass squared to its real counterpart. The requirement that p-adic and real S-matrix elements (in particular coupling constants) are related in a realistic manner, forces a modification of the canonical identification. Instead of a direct identification of real and p-adic rationals, the p-adic rationals in  $R_p$  are mapped to real rationals (or vice versa) using a variant of the canonical identification  $I_{R \rightarrow R_p}$  in which the expansion of rational number  $q = r/s = \sum r_n p^n / \sum s_n p^n$  is replaced with the rational number  $q_1 = r_1/s_1 = \sum r_n p^{-n} / \sum s_n p^{-n}$  interpreted as a p-adic number:

$$q = \frac{r}{s} = \frac{\sum_n r_n p^n}{\sum_m s_m p^m} \rightarrow q_1 = \frac{\sum_n r_n p^{-n}}{\sum_m s_m p^{-m}} = \frac{I(r)}{I(s)}. \quad (6.5.4)$$

The nice feature of this variant of the canonical identification is that it respects quantitative behavior of amplitudes, respects symmetries, and maps unitary matrices to unitary matrices if the matrix elements correspond to rationals (or generalized rationals in algebraic extension of rationals) if the p-adic integers involved are smaller than  $p$ . At the limit of infinitely large  $p$  this is always satisfied.

Quite generally, the thermodynamical contribution to the particle mass squared is in the lowest p-adic order of form  $rp/s$ , where  $r$  is the number of excitations with conformal weight 1 and  $s$  the number of massless excitations with vanishing conformal weight. The real counterpart of mass squared for the ordinary canonical identification is of order  $CP_2$  mass by  $r/s = R + r_1 p + \dots$  with  $R < p$  near to  $p$ . Hence the states for which massless state is degenerate become ultra heavy if  $r$  is not divisible by  $s$ . For the new variant of canonical identification these states would be light.

Even worse, the new form does not require the modular contribution to the p-adic mass squared to be of form  $np$ . Some other justification for this assumption would be needed. The first guess is that the conditions on mass squared plus probability conservation might not be consistent with unitarity unless the modular contribution to the mass squared remains integer valued in the mixing (note that all integer values are not possible). Direct numerical experimentation however shows that that this is not the case.

The predicted integer valued contributions to the mass squared are minimal in the case of  $u$  and  $d$  quarks and very nearly maximal in the case  $t$  and  $b$  quarks. This suggests a possible way out of the difficulty. Perhaps the rational valued p-adic mass squared of  $u$  and  $d$  quarks are minimal and those of  $b$  and  $t$  quarks maximal or nearly maximal. This might also allow to improve the prediction for the CKM matrix.

The objection against the use of the new variant of canonical identification is that the predictions of p-adic thermodynamics for mass squared are not rational numbers but infinite power series. p-Adic thermodynamics itself however defines a unique representation of probabilities as ratios of generalized

Boltzmann weights and partition function and thus the variant of canonical identification might indeed generalize. If this representation generalizes to the sum of modular and Virasoro contributions, then the new form of canonical identification becomes very attractive. Also an elegant model for the masses of intermediate gauge bosons results if  $O(p)$  contribution to mass squared is allowed to be a rational number.

#### Uncertainties related to the $CP_2$ length scale

The uncertainties related to the  $CP_2$  length scale mean that one cannot take the detailed model for hadron masses too literally unless one takes the recent value of top quark mass at face value and requiring  $(Y_e = 0, Y_t = 1)$  in rather high accuracy. This constraint allows at most 2.5 per cent reduction of the fundamental mass scale and baryonic masses suggest a 1 per cent reduction. The accurate knowledge of top quark mass is therefore of fundamental importance from the point of view of TGD.

# Chapter 7

## Higgs or Something Else?

### 7.1 Introduction

The question whether TGD predicts Higgs or not has been one of the longstanding issues of TGD. For 10 years ago I would not have hesitated to tell that TGD does not predict Higgs and had good looking arguments for my claim. During years my views have been alternating between Higgs and no-Higgs option.

#### 7.1.1 Why standard model Higgs is not needed?

There are several arguments against standard model Higgs, which by definition provides masses for both weak gauge bosons and fermions.

1. It is difficult to imagine any obvious classical geometric correlate for Higgs field although the proposal in the beginning was that  $CP_2$  part for the trace of the second fundamental form could be this correlate.
2. Zero energy ontology led much later to an argument against Higgs.
  - (a) The view about bosons as wormhole throats carrying fermionic quantum numbers are the opposite light-like wormhole throats of the contact makes it very difficult to assume that scalar particles would not exist. On the other hand, twistorial considerations force to assume that the wormhole throat as basic building bricks of particles are massless and that even virtual particles correspond to composites of on mass shell massless states with both signs of energy allowed.
  - (b) This argument seems to force the conclusion that spin 1 particles are necessary massive so that all Higgs like particles would be eaten by gauge bosons. This would make sense since Higgs and gauge bosons belong to same representations of electroweak symmetries. Even the super-partners of Higgs bosons would experience the same fate.
  - (c) One should not however make too hasty conclusions: photon could get very small mass from p-adic thermodynamics as also weak bosons: weak bosons get additional mass by eating three components of Higgs like particle.
  - (d) p-Adic thermodynamics could also provide massless particle with longitudinal mass squared assignable to  $M^2 \subset M^4$  projection of four-momentum. The most elegant formulation for p-adic thermodynamics is indeed for the longitudinal mass square as counterpart of energy. Zero energy ontology allows to overcome problems related to Lorentz invariance. This also leads to modification of gauge conditions so that that apply to longitudinal momentum and allow three polarizations.
3. Essentially one assumption, the separate conservation of quark and lepton numbers realized in terms of 8-D chiral invariance, excludes Higgs like states as also standard  $\mathcal{N} = 1$  SUSY: here Higgs likeness means that the couplings to fermions are proportional to fermion masses.

4. There are very general arguments requiring new physics at TeV scale. Also standard model Higgs has its difficulties with radiative corrections and standard SUSY has been the candidate for this new physics. The data from LHC however suggest that standard SUSY is not the choice of Nature. TGD proposal has been new hadron physics obtained as scaled up variant of standard hadron physics. The pion of this hadron physics could yield decay signatures suggesting interpretation as Higgs like state.

### 7.1.2 Why Higgs like particle is needed?

There are also several arguments in favor of Higgs like particle.

1. The  $W/Z$  mass ratio having group theoretic origin (Higgs should transform as  $2 + \bar{2}$  under  $U(2)$ ) and predicted correctly by Higgs mechanism is a strong argument in favor that gauge boson masses can be understood in terms of Higgs mechanism. In TGD framework the masses of fermions are predicted with amazing accuracy by p-adic thermodynamics which in turn fails to provide elegant explanation for  $W/Z$  mass ratio: it seems that the contribution of p-adic thermodynamics to gauge boson masses corresponds to same p-adic temperature as for photon and is therefore very small due to the lower p-adic temperature quantized as  $T = 1/n$  (for fermions one has  $T = 1$ ). Therefore one can consider the possibility that Higgs like state gives weak bosons their masses.
2. In fact, the experimental progress at LHC forced to seriously ask whether the pion of  $M_{89}$  physics could mimic Higgs. This might be possible if it develops vacuum expectation: something familiar from the model for the lepton [?].
  - (a) Suppose that the pion like state transforms like  $3 + 1$  under  $u(2) \subset su(3)$ . One obtains an elegant looking model for the production of Higgs like state in terms of generation of coherent state of pions utilized in the model for lepton. The original hope was that the masses of weak gauge bosons would result by some non-Higgsey mechanism.
  - (b) One however finds that one cannot avoid Higgs mechanism for gauge bosons! Higgs mechanism emerges automatically using Higgs potential, which contains neither the tachyonic mass of the free Higgs nor  $\pi^4$ . In many respects the resulting massivation looks reasonable. One avoids the difficulties due to the radiative corrections and SUSY is not needed for radiative stability of Higgs. The massivation would be caused by a linear coupling to instanton density and its vacuum expectation would give rise to the mass of Higgs.
  - (c) There is however a problem: contrary to the original expectations inspired by ZEO, QFT description strongly suggests that weak bosons also now "eat" two - rather than three - components of the pion-like state and leave only singlet and the neutral component from triplet. If all three components were eaten one could circumvent the problem by assuming that the pion-like state is not ordinary  $M_{89}$  pion. The problem is still that also  $Z^0$  remains massless.
  - (d) As noticed, ZEO predicts that also photon is massive or at least has non-vanishing longitudinal mass squared. This seems to suggest that photon - and also other gauge bosons - gets its mass from p-adic thermodynamics and that this mass is much smaller than the mass coming from Higgs mechanism.

The data from LHC and other accelerators have been very important inspiration in the development of ideas. The discovery of a new spinless particle at LHC often interpreted as Higgs is of course a good argument in favor of the existence of Higgs like state and this motivated the question whether Higgs like particle could be possible in TGD after all. There is evidence that the decay rates of this particle to gamma pairs and weak boson pairs are somewhat too high to allow identification as standard model Higgs. The decay rates are however of correct order of magnitude and support the view that Higgs like particle gives masses for weak bosons. Also the failure to find the decays to  $\tau$  pairs speaks against the identification as standard model Higgs.

1. The final solution (one can hope so!) came from the observation that TGD predicts two kinds of meson like states corresponding to Kähler magnetic flux tubes connecting wormhole throats

of separate wormhole contacts and to throats of same wormhole contact. The first meson like states are "long" and have Minkowskian signature. Second meson like states are very "short" and have Euclidian signature. It would be Euclidian pions which take the role of Higgs like state. It is essential that these states transform as  $2 + \bar{2}$  under  $u(2) \subset su(3)$ . In the first approximation Higgs potential is exactly the same and the massivation of gauge bosons proceeds in the same manner as in standard model. Hierarchy problem due to the instability of the tachyonic mass term for Higgs like particle is avoided since the direct couplings to fermions proportional to fermion masses are not needed since p-adic thermodynamics makes them massive. Also the predictions for the decay rates remain the same as for standard model Higgs.

2. What is new is that one can also find a microscopic description for the tachyonic mass term in terms of a bilinear coupling to a superposition  $a \times \text{YM} + b \times I$  of YM action density and instanton term most naturally restricted to the induced Kähler form. This term also predicts that - besides ordinary decays to electroweak gauge boson pairs mediated by same action as in the case of the ordinary Higgs - there are also decays mediated by linear perturbative couplings to  $a \times \text{YM} + b \times I$ . Instanton density brings in also CP breaking possibly related to the poorly understood CP breaking of hadronic physics. The quantitative estimate gives a result consistent with experimental data for reasonable parameter values. Also a connection with the dark matter researches reporting signal at 130 GeV and possibly also at 110 GeV suggests itself: maybe also these signals also correspond to Minkowskian and Euclidian pion-like states.

This chapter summarizes the evolution of ideas related to the status of Higgs in TGD. It is certainly not a summary of final results in a concise form and contains several contradictory arguments containing also delicate errors and reflecting how my beliefs have changed during years. Also the recent situation is critical and the experimental results from LHC will be decisive for future developments.

## 7.2 How TGD based description of particle massivation relates to Higgs mechanism?

In TGD framework p-adic thermodynamics gives the dominating contribution to fermion masses, which is something completely new. In the case of gauge bosons thermodynamic contribution is small since the inverse integer valued p-adic temperature is  $T = 1/2$  for bosons or even lower: for fermions one has  $T = 1$ .

Whether Higgs can contribute to the masses is not completely clear. In TGD framework Mexican hat potential however looks like trick. One must however keep in mind that any other mechanism must explain the ratio of W and  $Z^0$  masses and how these bosons receive their longitudinal polarizations. One must also consider seriously the possibility that all components for the TGD counterpart of Higgs boson are transformed to the longitudinal polarizations of the gauge bosons. Twistorial approach to TGD indeed strongly suggests that also the gauge bosons regarded usually as massless have a small mass guaranteing cancellation of IR singularities. As I started write to write this piece of text I believed that photon does not eat Higgs but had to challenge my beliefs. Maybe there is no Higgs to be found at LHC! Only pseudo-scalar partner of Higgs would remain to be discovered.

The weak form of electric magnetic duality implying that each wormhole throat carrying fermionic quantum numbers is accompanied by a second wormhole throat carrying opposite magnetic charge and neutrino pair screening weak isospin and making gauge bosons massive. Concerning the implications the following view looks the most plausible one at this moment.

1. Neutral Higgs-if not eaten by photon- could develop a coherent state meaning vacuum expectation value and this is naturally proportional to the inverse of the p-adic length scale as are boson masses. This contribution can be assigned to the magnetic flux tube mentioned above since it screens weak force - or equivalently - makes them massive. Higgs expectation would not cause boson massivation. Rather, massivation and Higgs vacuum expectation would be caused by the presence of the magnetic flux tubes. Standard model would suffer from a causal illusion. Even a worse illusion is possible if the photon eats the neutral Higgs.
2. The "stringy" magnetic flux tube connecting fermion wormhole throat and the wormhole throat containing neutrino pair would give to the vacuum conformal weight a small contribution and

therefore to the mass squared of both fermions and gauge bosons (dominating one for the latter). This contribution would be small in the p-adic sense (proportional  $1/p^2$  rather than  $1/p$ ). I cannot calculate this "stringy" contribution but stringy formula in weak scale is very suggestive.

3. In the case of light fermions and massless gauge bosons the stringy contribution must vanish and therefore must correspond to  $n = 0$  string excitation (string does not vibrate at all) : otherwise the mass of fermion would be of order weak boson mass. For weak bosons  $n = 1$  would look like a natural identification but also  $n = 0$  makes sense since  $h \pm 1$  states corresponds opposite three-momenta for massless fermion and antifermion so that the state is massive. The mechanism bringing in the  $h = 0$  helicity of gauge boson would be the TGD counterpart for the transformation of Higgs component to a longitudinal polarization.  $n \geq 0$  excited states of fermions and  $n \geq 1$  excitations of bosons having masses above weak boson masses are predicted and would mean new physics becoming possibly visible at LHC.

### 7.2.1 The identification of Higgs

Consider now the identification of Higgs in TGD framework.

1. In TGD framework Higgs particles do not correspond to complex  $SU(2)$  doublets but to triplet and singlet having same quantum numbers as gauge bosons. Therefore the idea that photon eats neutral Higgs is suggestive. Also a pseudo-scalar variant of Higgs is predicted. Let us see how these states emerge from weak strings.
2. The two kinds of massive states corresponding to  $n = 0$  and  $n = 1$  give rise to massive spin 1 and spin 2 particles. First of all, the helicity doublet  $(1, -1)$  is necessarily massive since the 3-momenta for massless fermion and anti-fermion are opposite. For  $n = L = 0$  this gives two states but helicity zero component is lacking. For  $n = L = 1$  one has tensor product of doublet  $(1, -1)$  and angular momentum triplet formed by  $L = 1$  rotational state of the weak string. This gives  $2 \times 3$  states corresponding to  $J = 0$  and  $J = 2$  multiplets. Note however than in spin degrees of freedom the Higgs candidate is not a genuine elementary scalar particle.
3. Fermion and antifermion can have parallel three momenta summing up to a massless 4-momentum. Spin vanishes so that one has Higgs like particle also now. This particle is however pseudo-scalar being group theoretically analogous to meson formed as a pair of quark and antiquark. p-Adic thermodynamics gives a contribution to the mass squared. By taking a tensor product with rotational states of strings one would obtain Regge trajectory containing pseudoscalar Higgs as the lowest state.

### 7.2.2 Do all gauge bosons possess small mass?

Consider now the problem how the gauge bosons can eat the Higgs boson to get their longitudinal component.

1. ( $J = 0, n = 1$ ) Higgs state can be combined with  $n = 0$   $h = \pm 1$  doublet to give spin 1 massive triplet provided the masses of the two states are same. This will be discussed below.
2. Also gauge bosons usually regarded as massless can eat the scalar Higgs so that Higgs like particle could disappear completely. There would be no Higgs to be discovered at LHC! But is this a real prediction? Could it be that it is not possible to have exactly massless photons and gluons? The mixing of  $M^4$  chiralities for Chern-Simons Dirac equation implies that also collinear massless fermion and antifermion can have helicity  $\pm 1$ . The problem is that the mixing of the chiralities is a signature of massivation!

Could it really be that even the gauge bosons regarded as massless have a small mass characterized by the length scale of the causal diamond defining the physical IR cutoff and that the remaining Higgs component would correspond to the longitudinal component of photon? This would mean the number of particles in the final states for a particle reaction with a fixed initial state is always bounded from above. This is important for the twistorial aesthetics of generalized Feynman diagrammatics implied by zero energy ontology. Also the vanishing of IR

divergences is guaranteed by a small physical mass [?] . Maybe internal consistency allows only pseudo-scalar Higgs.

### 7.2.3 Weak Regge trajectories

The weak form of electric-magnetic duality suggests strongly the existence of weak Regge trajectories.

1. The most general mass squared formula with spin-orbit interaction term  $M_{L-S}^2 L \cdot S$  reads as

$$M^2 = nM_1^2 + M_0^2 + M_{L-S}^2 L \cdot S , \quad n = 0, 2, 4 \quad \text{or} \quad n = 1, 3, 5, \dots \quad (7.2.1)$$

$M_1^2$  corresponds to string tension and  $M_0^2$  corresponds to the thermodynamical mass squared and possible other contributions. For a given trajectory even (odd) values of  $n$  have same parity and can correspond to excitations of same ground state. From ancient books written about hadronic string model one vaguely recalls that one can have several trajectories (satellites) and if one has something called exchange degeneracy, the even and odd trajectories define single line in  $M^2 - J$  plane. As already noticed TGD variant of Higgs mechanism combines together  $n = 0$  states and  $n = 1$  states to form massive gauge bosons so that the trajectories are not independent.

2. For fermions, possible Higgs, and pseudo-scalar Higgs and their super partners also p-adic thermodynamical contributions are present.  $M_0^2$  must be non-vanishing also for gauge bosons and be equal to the mass squared for the  $n = L = 1$  spin singlet. By applying the formula to  $h = \pm 1$  states one obtains

$$M_0^2 = M^2(boson) \quad (7.2.2)$$

The mass squared for transversal polarizations with  $(h, n, L) = (\pm 1, n = L = 0, S = 1)$  should be same as for the longitudinal polarization with  $(h = 0, n = L = 1, S = 1, J = 0)$  state. This gives

$$M_1^2 + M_0^2 + M_{L-S}^2 L \cdot S = M_0^2 \quad (7.2.3)$$

From  $L \cdot S = [J(J + 1) - L(L + 1) - S(S + 1)]/2 = -2$  for  $J = 0, L = S = 1$  one has

$$M_{L-S}^2 = -\frac{M_1^2}{2} \quad (7.2.4)$$

Only the value of weak string tension  $M_1^2$  remains open.

3. If one applies this formula to arbitrary  $n = L$  one obtains total spins  $J = L + 1$  and  $L - 1$  from the tensor product. For  $J = L - 1$  one obtains

$$M^2 = (2n + 1)M_1^2 + M_0^2 \quad (7.2.5)$$

For  $J = L + 1$  only  $M_0^2$  contribution remains so that one would have infinite degeneracy of the lightest states. Therefore stringy mass formula must contain a non-linear term making Regge trajectory curved. The simplest possible generalization which does not affect  $n=0$  and  $n=1$  states is of from

$$M^2 = n(n - 1)M_2^2 + (n - \frac{L \cdot S}{2})M_1^2 + M_0^2 \quad (7.2.5)$$

The challenge is to understand the ratio of W and  $Z^0$  masses, which is purely group theoretic and provides a strong support for the massivation by Higgs mechanism.

1. The above formula and empirical facts require

$$\frac{M_0^2(W)}{M_0^2(Z)} = \frac{M^2(W)}{M^2(Z)} = \cos^2(\theta_W) . \quad (7.2.6)$$

in excellent approximation. Since this parameter measures the interaction energy of the fermion and antifermion decomposing the gauge boson depending on the net quantum numbers of the pair, it would look very natural that one would have

$$M_0^2(W) = g_W^2 M_{SU(2)}^2 , \quad M_0^2(Z) = g_Z^2 M_{SU(2)}^2 . \quad (7.2.7)$$

Here  $M_{SU(2)}^2$  would be the fundamental mass squared parameter for  $SU(2)$  gauge bosons. p-Adic thermodynamics of course gives additional contribution which is vanishing or very small for gauge bosons.

2. The required mass ratio would result in an excellent approximation if one assumes that the mass scales associated with  $SU(2)$  and  $U(1)$  factors suffer a mixing completely analogous to the mixing of  $U(1)$  gauge boson and neutral  $SU(2)$  gauge boson  $W_3$  leading to  $\gamma$  and  $Z^0$ . Also Higgs, which consists of  $SU(2)$  triplet and singlet in TGD Universe, would very naturally suffer similar mixing. Hence  $M_0(B)$  for gauge boson  $B$  would be analogous to the vacuum expectation of corresponding mixed Higgs component. More precisely, one would have

$$\begin{aligned} M_0(W) &= M_{SU(2)} , \\ M_0(Z) &= \cos(\theta_W) M_{SU(2)} + \sin(\theta_W) M_{U(1)} , \\ M_0(\gamma) &= -\sin(\theta_W) M_{SU(2)} + \cos(\theta_W) M_{U(1)} . \end{aligned} \quad (7.2.6)$$

The condition that photon mass is very small and corresponds to IR cutoff mass scale gives  $M_0(\gamma) = \epsilon \cos(\theta_W) M_{SU(2)}$ , where  $\epsilon$  is very small number, and implies

$$\begin{aligned} \frac{M_{U(1)}}{M(W)} &= \tan(\theta_W) + \epsilon , \\ \frac{M(\gamma)}{M(W)} &= \epsilon \times \cos(\theta_W) , \\ \frac{M(Z)}{M(W)} &= \frac{1 + \epsilon \times \sin(\theta_W) \cos(\theta_W)}{\cos(\theta_W)} . \end{aligned} \quad (7.2.5)$$

There is a small deviation from the prediction of the standard model for W/Z mass ratio but by the smallness of photon mass the deviation is so small that there is no hope of measuring it. One can of course keep mind open for  $\epsilon = 0$ . The formulas allow also an interpretation in terms of Higgs vacuum expectations as it must. The vacuum expectation would most naturally correspond to interaction energy between the massless fermion and antifermion with opposite 3-momenta at the throats of the wormhole contact and the challenge is to show that the proposed formulas characterize this interaction energy. Since  $CP_2$  geometry codes for standard model symmetries and their breaking, it would not be surprising if this would happen. One cannot exclude the possibility that p-adic thermodynamics contributes to  $M_0^2(boson)$ . For instance,  $\epsilon$  might characterize the p-adic thermal mass of photon.

If the mixing applies to the entire Regge trajectories, the above formulas would apply also to weak string tensions, and also photons would belong to Regge trajectories containing high spin excitations.

3. What one can one say about the value of the weak string tension  $M_1^2$ ? The naive order of magnitude estimate is  $M_1^2 \simeq m_W^2 \simeq 10^4 \text{ GeV}^2$  is by a factor 1/25 smaller than the direct scaling up of the hadronic string tension about  $1 \text{ GeV}^2$  scaled up by a factor  $2^{18}$ . The above argument however allows also the identification as the scaled up variant of hadronic string tension in which case the higher states at weak Regge trajectories would not be easy to discover since the mass scale defined by string tension would be 512 GeV to be compared with the recent beam energy 7 TeV. Weak string tension need of course not be equal to the scaled up hadronic string tension. Weak string tension - unlike its hadronic counterpart- could also depend on the electromagnetic charge and other characteristics of the particle.

#### 7.2.4 Is the earlier conjectured pseudoscalar Higgs there at all?

Spin 1 gauge bosons and Higgs differ only by different spin direction of fermions at opposite wormhole throats. For spin 1 gauge bosons the 3-momenta at two wormhole throats cannot be parallel if one wants non-vanishing spin component in the direction of moment. 3-momenta are most naturally opposite for the massless states at throats. This forces massivation for all gauge bosons and even graviton and this in turn requires Higgs even in the case of gluons.

This inspires the question whether the parity properties of the couplings of gauge boson and corresponding Higgs transforming like 3+1 under SU(2) (this is due to the special character of imbedding space spinors) could be exactly the same? Higgs would couple like a mixture of scalar and pseudoscalar to fermions just as weak gauge bosons couple and the mixture would be just the same. If there are no axial variants of vector gauge bosons there should exist no pseudoscalar Higgs. The nonexistence of axial variants of vector gauge bosons is suggested by quantum classical correspondence: only gauge bosons having classical space-time correlates as induced gauge potentials should be allowed, nothing else. Note that color variant of Higgs would exist and would be eaten by gluons to get mass.

The similarity of the construction of gauge bosons and Higgsinos as pairs of wormhole throats containing fermion and antifermion encourages to think that Higgs mechanism is invariant under supersymmetries. If so, also Higgsinos would be eaten and one would have massive super-symmetric gauge theory with fermions with photon and other massless particle possessing a tiny mass. This looks very simple. The testable implication would be that only weak gauginos should contribute to muon g-2 anomaly.

#### 7.2.5 Higgs issue after Europhysics 2011

The general feeling at the Eve of Europhysics 2011 conference was that this meeting might become one of the key events in the history of physics. This might turn out to be the case. CDF and D0 were the groups representing the data from p-pbar collisions at Tevatron whereas ATLAS and CMS represented the data about p-p collisions at LHC. The blog participation transformed the conference from a closed meeting of specialists to a media event inspiring intense blog discussions and viXra log became the most interesting discussion forum thanks to the excellent postings of Phil Gibbs giving focused summaries of various reports about SUSY and Higgs.

The hope was that two basic questions would receive a unique answer. Does Higgs exist and if so what is its mass? Is the standard view about SUSY correct: in other words do the super-partners exist with masses below TeV scale? It was clear that negative answer to even the Higgs issue would force a thorough reconsideration of the status of not only MSSM but also that of super string theory and M-theory because of the general role of Higgs mechanism in the description massivation and symmetry breaking for the QFT limits of these theories. The implications are far reaching also for the inflationary cosmology where scalar fields and Higgs mechanism are taken as granted. Actually the non-existence of Higgs forces to reconsider the entire quantum field theoretic description of particle massivation.

Already before the conference several anomalies had emerged and the question was whether LHC data gives a support for these anomalies.

- A 145 GeV bump with 4 sigma significance in the mass distribution of jet pairs jj in Wjj final states was reported by CDF [?] but not confirmed by D0 [?]. The interpretation as Higgs was excluded and some of the proposed identifications of 145 GeV bump was as decay products of leptophobic Z' boson or of technicolor pion. There were also indications for 300 GeV bump in the mass distribution of Wjj states themselves suggesting cascade like decay.

- Both CDF and D0 had reported two bumps at almost same mass about 325 GeV [?, ?] having no obvious interpretation in standard model framework. Technicolor approach and also TGD suggests an interpretation as pionlike state.
- CDF and D0 had also reported anomalous forward-backward asymmetry in top-pair production in p-pbar collisions suggesting the existence of new kind of flavor changing colored neutral currents [?, ?]. TGD based explanation of family replication phenomenon combined with bosonic emergence predicts that gauge bosons should appear as flavor singlets and octets. Octets would indeed induce flavor changing currents and asymmetry. Also many other indications for new physics such as anomalously large CP breaking in BBbar system had been reported and one should not forget long list of forgotten anomalies from previous years, say the two and half year old CDF anomaly which D0 failed to observe. Recall also that proton has shown no signs of decaying.

What did we learn during these days? Already before the conference it was clear that standard SUSY had transformed from the healer of the standard model to a patient. The parameter space for MSSM (minimal supersymmetric extension of standard model predicting two Higgs multiplets) had been narrowed down by strong lower limits on squark and gluino masses to the extent that the original basic motivation for MSSM (stability of Higgs mass against radiative corrections) had been lost as well as the explanation for the anomaly of  $g-2$  of muon. During the conference the bounds on SUSY parameters were tightened further and the rough conclusion is that squark and gluino masses must be above 1 TeV. Even Lubos Motl was forced to conclude that the probability that LHC discovers standard SUSY is 50 per cent instead of 90 per cent or more of 2008 blog posting. In TGD framework simple p-adic scaling arguments lead to the proposal that the only sfermions with mass below 1 TeV are selectron and sneutrinos with selectron having mass equal to 262 GeV. Low sneutrino masses allow in principle to understand  $g-2$  of muon. Selectron could decay to electron plus neutralino for which mass must be larger than 46 GeV neutralino would eventually decay to photon or virtual Z plus neutrino.

The Higgs issue became the central theme of the conference and the three days from Thursday to Sunday were loaded with excitement. After many twists, the final conclusion was that there is 2.5 sigma evidence from ATLAS for a state in the mass range 140-150 GeV, which might be Higgs or something else. The press release of Fermi lab at Friday announced that they have confined Higgs to the interval 120-137 GeV. After the announcement of ATLAS both D0 and CDF discovered suddenly evidence for Higgs in 140-150 GeV mass range. The evidence for this mass range emerged from the decays of a might-be Higgs to WW pairs decaying in turn to lepton pairs. The proponent of technicolor would of course see this as evidence for an off mass shell state of a neutral pion like state explaining also the jj bump in Wjj system and at 145 GeV mass and not allowing an interpretation as Higgs. In TGD framework the experience with earlier anomalies such as two year old CDF anomaly encouraged the interpretation in terms p-adic mass octaves of the pion of p-adically scaled up variant of hadron physics with mass scale 512 times higher than that of the ordinary hadron physics. Somewhat frustratingly, the final conclusion about the Higgs issue was promised to emerge only towards the end of the next year but it is clear that already now standard model might well be inconsistent with all data irrespective of the mass of Higgs. MSSM would allow additional flexibility but is also in difficulties.

The surprise of the first conference day was additional evidence for the bump at 327 GeV reported already earlier by CDF. This state is a complete mystery in standard model framework and therefore extremely interesting. The proponents of technicolor would probably suggest interpretation as exotic  $\rho$  or  $\omega$  meson. In TGD framework both 145 GeV pion and 325 GeV  $\rho$  and  $\omega$  appear as mesons of  $M_{89}$  hadron physics if one assumes that the  $u$  and  $d$  quarks of  $M_{89}$  physics have masses corresponding to the p-adic length scale  $k = 93$  (mass is 102 GeV and should be visible as a preferred quark jet mass). I would not be surprised if technicolor models would experience a brief renaissance but fail experimentally since a lot of new states and elementary particles is implied by the extension of the color gauge group. The mere p-adic scaling does not imply anything like this.

Also super string inspired predictions of various exotics such as microscopic black holes, strong gravity, large extra dimensions, Randall-Sundrum gravitons, split supersymmetry, and whatever were tested. No evidence was found. Neither there was evidence for lepto-quarks, heavier partners of intermediate gauge bosons, and various other exotics.

To my view, the results of the conference force to re-consider the basic assumptions of the approach followed during last more than three decades. Is it possible to find a more realistic physical interpretation of the mathematically extremely attractive supersymmetry? Unitarity requires new physics in TeV scale: is this new physics technicolor or its TGD analog without gauge group extension or something else? To me however the mother of all questions concerns the microscopic description of massivation. The description in terms of Higgs is after all a phenomenological description borrowed from condensed matter physics. It does not work for extended objects like strings but require quantum field theory limit. p-Adic thermodynamics for conformal weight (to which mass squared is proportional to) should be an essential element of the microscopic approach too since it is a description working for the fundamental objects and in presence of super-conformal invariance.

What actually happens in the massivation: could it be that all components of Higgs, of its super partners, and of its higher spin generalizations are eaten in a process in which massless multiplets with various spins combine to form only massive multiplets? Here twistor approach might provide the guideline since its applicability requires that massive particles should allow an interpretation as bound states of massless ones. Perhaps the simple observation that spin one bound states of massless fermion and anti-fermion are automatically massive might help to get to the deeper waters.

What next? Standard model Higgs is more or less excluded and the same fate is very probably waiting the SUSY Higgs. I would not be surprised if technicolor models would experience a brief renaissance but fail experimentally since very many new hadronlike states and new elementary particles are implied by the extension of the color gauge group. Sooner or later the simple p-adic scaling of the ordinary hadron physics probably turns out to be the only realistic option. If technicolor becomes in fashion, the hadrons of  $M_{89}$  hadron physics will be however found as a side product of this search.

Eventually this requires giving up the Planck length scale reductionism as the basic philosophy and replacing it with p-adic fractality as the basic guiding principle tying together physics at very short and at very long length scales making possible the long search for ultraviolet completion of known physics. This led to the landscape catastrophe in M-theory since very many physics in long length scales had the same UV completion. Some general principle fixing the long range physics is obviously missing. p-Adic smoothness for which infinite in real sense is infinitesimal selects the unique long length scale physics among infinitely many alternatives. The real problems are really much much deeper than finding proper parameters for SUSY and it would be a high time for theoreticians to finally realize this.

## 7.3 Higgs and me

We have been told that a seminar to be held 13 December in CERN will represent results making possible a significant progress in Higgs research but that no answer to the question about the existence of Higgs exists will be provided. This could be the only politically correct manner to say that no Higgs has been found nor will be found. There might be however something else there as TGD indeed predicts. Therefore I feel that it is good time to clarify my own views about the Higgs issue.

My attitude to Higgs has developed from original denial to almost acceptance and back to denial. This denial has nothing to do with bets: anyone can bet that Higgs exists or does not exist. Without genuine justifications this kind of statements contain just single bit of information or disinformation.

### 7.3.1 Denying Higgs

My original attitude was a denial based on the following arguments natural in sub-manifold gravity.

1. TGD does not allow Higgs as a scalar in 8-D sense: this state would be leptoquark: Minkowski scalars are always H-vectors and have generalized polarization.
2. If Higgs is there it should behave like a  $SO(4)$  vector in  $CP_2$  tangent space with different directions analogous to polarizations. One can have 3+1 decomposition for tangent vectors of  $CP_2$  under electro-weak  $SU(2)$  but the problem is that there is no manner to build covariants or invariants in this manner.  $CP_2$  does not allow covariantly constant vector fields. The contractions of color isometry generators with the trace of second fundamental form would be general coordinate invariants but would give a color octet rather than complex electro-weak doublet (triplet plus singlet would result only if one identifies  $U(2) \subset SU(3)$  as electroweak gauge group). The

contractions of  $CP_2$  vierbein vectors with the trace of the second fundamental form would give a candidate for Higgs and its contraction with  $CP_2$  gamma matrices appears in the Dirac equation for induced spinor fields and makes it inconsistent unless the trace of the second fundamental form and thus Higgs vanishes (minimal surface property). For non-minimal surfaces this identification would make Higgs contribution to mass square tachyonic. Thus this identification is not promising.

3. Higgs is not needed to give mass for fermions since p-adic thermodynamics [K45] takes care of this. There are however some problems in the understanding of gauge boson masses. Some additional sources of mass seem to be necessary: p-adic thermodynamics in its basic form would give extremely small second order contribution to the gauge boson masses since the inverse integer valued p-adic temperature cannot be larger than  $T = 1/2$ . For fermions one has  $T = 1$ .

For these reasons I believed for a long time that TGD does not predict Higgs. I could have promoted this as a dramatic prediction of sub-manifold gravitation.

### 7.3.2 Could Higgs exist after all?

The last five years in blogs have been endless n-sigma talk related to rumors about Higgs and also now this kind of rumors are around. As a genuine skeptic I became skeptic also about my basic belief and asked whether Higgs might exist also in TGD Universe. I had also to understand the additional contribution to the mass of gauge bosons and how gauge bosons get their additional polarization state. Maybe Higgs might be necessary to achieve this. The identification of the basic objects as wormhole throats and contacts carrying quantum numbers was a decisive step of progress. The irony was that the progress began with the idea that Higgs could correspond to wormhole contact! Only later came the realization that this makes sense also for gauge bosons.

1. Free fermions are in this picture wormhole throat pairs and topological condensation makes them massive. The throats formed in the topological condensation of fermions have vanishing magnetic charge. One has throat pair at both sheets but only the members of the second pair are connected by a Kähler magnetic flux tube.
2. Bosonic emergence means that bosons consist of bound states of massless on mass shell fermion and anti-fermion associated with wormhole throats of wormhole contacts connecting space-time sheets. Also virtual particles consist of massless on mass-shell states in ZEO. Also bosons consist of two wormhole contacts since the total monopole charge must vanish. The throat pairs at both sheets are connected by Kähler magnetic flux tubes carrying monopole magnetic flux. Neutrino pair at the second wormhole throat neutralizes weak isospin for both bosons and fermions.
3. Kähler magnetic flux tubes contribute to the mass of the particle stringy contribution. For elementary fermions the contribution from wormhole throat pair carrying fermion quantum numbers dominates the mass. In the case of hadrons the reconnection process for color magnetic flux tubes is responsible for non-perturbative aspects of hadron physics and making possible to understand what happens in the formation of jets and in hadronization. The physics in question involves new physics: contrary to the general belief jet QCD does not follow from QCD as QFT. Color magnetic flux tubes make themselves visible via what has become known as quark-gluon plasma [?]. This terminology is misleading and based on wrong expectations: the attribute "strongly interacting" does not help much. In TGD Universe the ideal quark-gluon plasma in TGD is like a big hadron containing very many quarks and gluons rather than gas of partons as it would be in QCD proper.
4. In TGD the *possibly* existing Higgs 4-plet would have same quantum numbers as electro-weak gauge bosons  $3 \oplus 1$  as  $SU(2)$  multiplets. There would be a nice 1-1 correspondence between Higgses and gauge bosons in  $CP_2$  degrees of freedom. Only spin would be different. Sub-manifold gravity would be at work again.
5. Higgses *could* be there but gauge bosons would eat them to get longitudinal polarizations. All Higgs components would become longitudinal polarizations of Higgs boson. Also gauge bosons which are usually regarded a massless would have a small mass. Same applies to graviton and

all super-partners. The assumption that all physical particles have at least small mass resolves the infrared singularities and there are excellent hopes about a beautiful realization of twistorial approach in zero energy ontology (ZEO).

The problem is that one must postulate a lot of Higgs like particles and also their super-partners. And all of them would be eaten. Why the trouble of preparing all these Higgses if all of them end up to the plate?

### 7.3.3 Return to Higgs denialism

Now I am becoming a Higgs denialist again. There is no need for Higgs in TGD and TGD does not allow any natural mechanism transforming Higgs like states to longitudinal components of gauge bosons.

1. In ZEO just the condition that boson has spin 1 implies that it is massive and has therefore also the third polarization. The argument is simple: if one wants the composite system of on mass shell massless fermion and antifermion to have helicity 1 one must assume that either the 3-momenta or energies have opposite sign or at least that the directions of 3-momenta are different. There is no need to assume that gauge bosons get the additional polarization state by eating Higgs. This applies to all states with spin.
2. The recent advances in the formulation of generalized Feynman diagrams (see this) lead to the identification of the analog of the gauge condition eliminating unphysical polarizations. This condition allows three polarizations in the case of spin 1 states. Analogous conclusion applies in the case of higher spins.
3. One can express the condition on polarizations more precisely. One can assign to each causal diamond (CD) a preferred sub-manifold  $M^2$  (2-D Minkowski space) of  $M^4$  defining preferred time direction and spin quantization axis: there are many choices and these correspond to non-equivalent CD's. This 2-plane defines the analog for the plane in which Feynman graphs live and allows to realize the vision about generalized Feynman graphs as sub-manifold braids [?].  $M^2$  corresponds in the number theoretical vision to hyper-complex numbers regarded as a 2-plane in the space of hyper-octonions.
4. The gauge condition  $p \cdot \epsilon = 0$  is modified. The modified condition says that the allowed polarization vectors are orthogonal to the *projection*  $p_{M^2}$  of the momentum of boson to  $M^2$ :  $p_{M^2} \cdot \epsilon = 0$ . Three polarization states are allowed instead of 2. All physical particles with spin are massive.

The conclusion is simple: no Higgs like states are needed! Just as I believed in the beginning. The prodigal son has returned back to his home! For reasons easy to understand, I am waiting eagerly the December 13:th. We know that 13 is the unlucky number but who will be the unlucky one? Higgs or me?

## 7.4 Higgs or $M_{89}$ hadron physics?

The newest results about Higgs search using 4.9/fb of data were published yesterday and there are many articles in arXiv. The overall view is that there is evidence for something around 125 GeV. Whether this something is Higgs or some other particle decaying to Higgs remains to my opinion an open question. Lubos of course is strong in this faith on Higgs. Somewhat surprisingly Tommaso Dorigo seems the result as a firm evidence for Higgs. Matt Strassler is skeptic. The evidence comes basically from Higgs to  $\gamma\gamma$  decays. There are some ZZ and WW events. CMS represented also data for more rare events. There are also indications about something at higher masses and the interpretation of them depends on the belief system of the blogger.

Bloggers were very active and Phil Gibbs certainly the most active one.

- Phil Gibbs [?] gave online comments and combinations of various data in his blog. In particular, Phil produced a combination of data from ATLAS, CMS, LEP, and Tevatron clearly supporting the existence of bump around 124 GeV. Also the other plots by Phil are very illustrative of the situation: for instance this.

- Tommaso Dorigo commented the results. Tommaso gives many illustrations and sees the results as firm evidence for standard model Higgs and is skeptic about SUSY Higgs.
- Lubos Motl has a nice -abit over-optimistic from SUSY point of view- summary about the results and useful links to the articles by ATLAS and CMS.
- I liked very much about Matt Strassler's critical comments making clear what is known and what is not known. Also Resonaances had added comments on Higgs. And many other bloggers.

In TGD framework Higgs like states seem to be un-necessary. Zero energy ontology predicts that all states with spin 1 are massive and the third polarization state is allowed by the generalization of the gauge condition excluding the third polarization in the case of massless states [?]. If one assumes Higgs like states, the particles which become massive "eat" all of them. Also photon, gluon, and graviton become massive and the small mass allows to get rid of infrared divergences plaguing gauge theories.

The basic question is whether the data could be interpreted as signatures of Higgs or of  $M_{89}$  hadron physics. This question is discussed in detail in [K43]. Here I represent just the main arguments.

1. The basic observation is that the generalization of PCAC hypothesis leads to very similar predictions for the direct couplings of pseudo-scalar mesons as Higgs has and the decay rates are of the same form. The generalization of the hadronic sigma model with vacuum expectation value of sigma field replacing that of Higgs field makes it easy to understand the close resemblance but does not seem to be absolutely necessary unless one wants additional predictions. What is remarkable that the vacuum expectation of sigma field equals apart from sign to W boson mass.
2. If one believes in the indications about structures at higher masses than 125 GeV, one must conclude that standard Higgs hypothesis fails.  $M_{89}$  hadron physics might be able to explain these structures but the coupling  $X$  defined by  $f_\pi = Xm_\pi$  would be smaller for these higher pion-like states. One of them would be around 139 GeV.
3. TGD suggests that the spartners of quarks correspond to the same mass scale as quarks. The pion-like states with masses 139 GeV and 125 GeV would correspond to pion and spion (pair of squarks) which could have suffered mixing by exchange of gluino. The original proposal that spartners are generated by covariantly constant right-handed neutrino and antineutrino has the problem that it might produce just the same missing energy signatures of SUSY as ordinary SUSY and thus be excluded experimentally.

The simplest way out is the assumption that covariantly constant neutrino generates gauge supersymmetry and thus creates zero norm states. It would be color octet state of neutrino that would generate the dynamical supersymmetry and states with a non-vanishing norm. Color confinement would not allow the usual missing energy signature so that everything would be consistent with what we have learned from LHC. Lepto-hadrons [?] would consist of pairs of sleptons which would be color octets so that same picture would apply to both leptons and quarks.

4. This is however not quite enough. There is evidence for a bumpy structure of signal cross section. The easy explanation is in terms of statistical fluctuations and time will show whether this explanation works. The bumpy structure suggests the existence of additional states not explainable in terms of the doubling predicted by TGD SUSY. Rather remarkably, the already mentioned quite recent anomaly suggests that similar phenomenon is encountered also in ordinary hadron physics.

According to a three-year old discovery [?], there is evidence for narrow pion-like and nucleon like states with a mass splitting which is of order few tens of MeV. p-Adic fractality predicts the same in the case of  $M_{89}$  hadron physics and the observed bumpy structure might have interpretation in terms of "infra-red" Regge trajectory with string tension assignable to the color magnetic flux tubes accompanying light quarks. This string tension is dramatically smaller than the hadronic string tension of order 1 GeV and measured using 10 MeV as a unit.

Needless to say, the existence of the exotic hadrons would kill QCD as a theory of strong interactions and provide a strong support for the notion of color magnetic flux tube central for TGD vision about hadrons.

An alternative explanation would be rely on Shnoll effect [?] implying the splitting of resonances to separate peaks. It is not clear whether the explanations exclude each other. The question "Higgs or  $M_{89}$  hadron physics or something else?" will be probably answered within a year as the statistics from LHC improves.

### 7.4.1 The new data about Higgs candidate

#### 1. Overall view

It is good to try to summarize what has been found.

1. According to ATLAS the bump is at 126 GeV. Altogether gamma-gamma and ZZ events give 3.6 sigma deviation reducing to 2.3-2.5 sigma by look-elsewhere effect.
2. According to CMS the bump resides at 124 GeV. CMS has 2.6 sigma deviation reducing to 1.9 sigma when look- elsewhere effect is taken into account.
3. The positions of bumps reported by ATLAS and CMS are not quite same so that there is still room for the possibility that the bumps are artifacts.
4. Both collaborations publish also the results about signal for Higgs to ZZ decays. Fig 7 in ATLAS eprint [?]eports three candidates Higgs to ZZ events at 123.6 GeV, 124.3 GeV , and 124.8 GeV. CMS reports results about decays to  $b\bar{b}$ ,  $\tau\bar{\tau}$ , WW, ZZ, $\gamma\gamma$ , combines the data from various channels, and compares signal cross sections to those predicted by standard model Higgs. There is structure around 145 GeV in some channels. There is also data about higher energies bump like structures both below and above 300 GeV. Maybe the standard model Higgs is not enough. SUSY indeed predicts several Higgs like states and  $M_{89}$  hadron physics entire meson spectroscopy.

#### 2. $\gamma\gamma$ channel

Both ATLAS [?] and CMS [?] have published an reprint in arXiv about Higgs to  $\gamma\gamma$  signal.

The ratio of the  $\gamma\gamma$  signal cross section to the cross section predicted by standard model is given together with 1 and 2 sigma bands describing the background signal without Higgs contributions.

1. Fig 8 in ATLAS paper gives the observed and expected 95 per cent confidence level limits as a function of hypothesized Higgs boson mass.
2. Fig 3 of CMS paper gives bump around 124 GeV.

I wish I would understand the strange oscillating behavior for the ratio of signal cross section to cross section for signals mimicking Higgs predicted in absence of Higgs. There are bumps around 126 GeV, 139 GeV and 146 GeV. Is this an artifact produced - say - by a discretization in the data processing. There is also a small bump around 113 GeV.

I am a statistical dilettante so that I can make an innocent and possibly stupid question: Could these bumps be something real? For standard model Higgs this is certainly not the case but what about TGD inspired view [K43] about new physics at LHC. Going to another extreme: could all bumps with 126 GeV bump included be only data processing artifacts? We do not know yet.

Also the probability  $p_0$  that standard model without Higgs could explain the signal cross section is plotted.

1. Fig 7 of ATLAS paper [?] gives the observed and expected  $p_0$  values as a function of the mass of hypothesized Higgs. Small  $p_0$  tells that standard model without Higgs contribution requires upwards fluctuation whose probability is  $p_0$  to explain the observed signal. There are strong downwards bumps at about 126 GeV and around 145 GeV. They are deeper than the prediction of standard model Higgs which might give rise to worries. There is also something very small at 139 GeV.
2. Fig 4 of CMS paper [?] gives similar plot. Now the bumps of  $p_0$  are around 123.5 GeV, 137 GeV, and 147.5 GeV.

If taken at face value, also these figures suggest three-bump structure. This might well be a statistical artifact but one can make questions and one fool like me can make more or them than the wise guys are able to answer. Here are two of them.

1. Could  $M_{89}$  pion have higher excitations with a mass scale of 10-20 GeV? Could the pion-like state generating the signal besides ground state also excitations with excitation energy scale of order 20 GeV? Could these excitation assigned with the color magnetic flux tube structures associated associated with scaled up u and d quarks.

A rough guess for the p-adic prime of scaled up u and d quark in  $M_{89}$  hadron is  $k = 113 - 18 = 95$  ( $k = 113$  corresponds to Gaussian Mersenne and nuclear p-adic length scale). This corresponds to the p-adic mass scale the estimate 16 GeV from electron's p-adic mass scale about .25 MeV. It however turns out that the actual mass must be by a factor two higher so that one would have 32 GeV mass scale.

Could stringy excitations with string tension determined by 32 GeV scale be in question? If so then also ordinary pion should have similar fine structure in mass spectrum with energy scale of 31 MeV assignable with  $u$  and  $d$  quarks with  $k = 113$ . I have a vague memory that Tommaso Dorigo had reported something about low energy excitations of pion but I failed to find anything about this in web and concluded that I must have been hallucinating.

2. Shnoll effect is something which main stream colleagues certainly refuse to take seriously. In TGD framework one can develop a p-adic model for Shnoll effect, [?], which can be justified in terms of quantum arithmetics [?] giving a first principle justification for the canonical identification playing a key role in p-adic mass calculations. The model predicts a number theoretic deformation of probability distributions characterized p-adic prime  $p$ . The modification replaces the rational valued parameters of distribution by quantum rationals. Typically a probability distribution with single bump decomposes to several ones and the phenomenon occurs also in nuclear physics.

Could this deformation be at work even in particle physics? If so, it could cause the splitting of single very wide resonance bump around 125 GeV to several sharper bumps. Even the bump like structure at 113 GeV could correspond to this wide resonance bump. The original resonance bump could be rather wide: something like 30-40 GeV. Very naive guess would be that the width of leptopion obeys able to decay to ordinary quarks  $\Gamma \sim \alpha_s(89)m(\pi_{89})$ . Already for  $\alpha_s = .1$  one could have a bump with width of about 15 GeV. For ordinary pion the impossibility of strong decays would not allow Shnoll effect. The splitting into sub-bumps by Shnoll effect would make this wide bump visible.

After a painful web search I managed to find an article [?] titled *Search for low-mass exotic mesonic structures: II. Attempts to understand the experimental results* reporting that there is experimental support for narrow excited states of pion at masses 62, 80, 100, 140, 181, 198, 215, 227.7, and 235 MeV (authors mention that the last might be uncertain). The states at 100, 140, and 198 MeV are half octaves of the lightest state. The article fits the states to Regge trajectories but it is not possible to use single slope for all states. The mass differences vary between 10 and 40 GeV so that the scale is what one would expect from the above string argument. Also Shnoll effect might explain the existence of the bumps and if the explanations are consistent the spectrum of the pion states is dictated by number theoretical arguments to a high degree.

### 3. Combination of signals from all channels

CMS has also a preprint about the combination of signals from all decay channels of Higgs.

1. CMS gives also a figure combination of all CMS searches ( $\gamma\gamma$ ,  $bb, \tau\tau$ ,  $WW$ ,  $ZZ$ ) [?].
2. Figure 1 of CMS article [?] shows a clear structure around 124 GeV. There is another structure around about 145 GeV. In standard model Higgs scenario the structure at 145 GeV would not be taken seriously since the cross section need to produce the bump would be much below the predicted one but if one accepts super-symmetric  $M_{89}$  hadron physics, the situation changes. There is also structure around 325 GeV and in the range 260-285 GeV.  $M_{89}$  hadron physics would assign these structures to vector mesons  $\rho$  and  $\omega_{89}$  and corresponding smesons consisting of squark and anti-squark.

3. CMS gives a plot comparing the ratio of best fit for signal cross section to the predicted cross section for Higgs to  $b\bar{b}$ ,  $\tau\bar{\tau}$ ,  $\gamma\gamma$ , ZZ, WW. The fit is rather satisfactory for Higgs to  $\gamma\gamma$  the signal cross section is about 1.7 times higher than predicted. One cannot deny that this can be seen as a strong support for standard model Higgs.

The original idea behind  $M_{89}$  hadron physics was that it effectively replaces Higgs. If one takes the CMS result seriously this idea must be realized rather concretely: the predicted signal cross sections must be rather near to those predicted by standard model Higgs. The crucial tests are decay rates to fermion pairs and the possibly existing other resonances.

#### 4. *Higgsy character of 126 GeV bump is not proven!*

Lubos has written a new post [?, ?] where he makes the strange assumption that if there is a signal it must be Higgs. Lubos also uses as a "proof" of Higgsyness the fit of Phil for which the gamma-gamma signal cross section at maximum equals to the prediction. This holds true because the fit forces it to hold true! For some reason Lubos "forgets" this!

By inspecting the figure more closely one finds that the observed cross section has a long tail unlike the predicted cross section. This long tail could correspond to the large width of resonance splitting into sub-bumps if Shnoll effect is present. If Higgs option is correct, this tail should disappear as statistics improves. Also the other structures which are present, should disappear.

What is of course remarkable that CMS paper shows that  $H \rightarrow \gamma\gamma$  cross section is of the same order of magnitude and only about 1.7 times higher than the predicted cross section. This gives a constraint on  $M_{89}$  hadron physics, which it of course might fail to satisfy unless the idea about replacement of Higgs with  $M_{89}$  hadron physics is true at a rather quantitative level.

One should also keep in mind that the value of Higgs mass is at the lower bound for the range with stable Higgs vacuum. This is not a good sign. An interesting question is whether the mass for pion-like state of  $M_{89}$  hadron physics is in some sense also minimal and what this minimality could mean physically: some kind of criticality - maybe on instance of quantum criticality of TGD Universe-but not criticality against the decay of Higgs vacuum?

To sum up, one can agree with the official statement: the situation remains open. What is nice that there very probably is a signal and from TGD point view the nice thing is that this signal is still consistent with  $M_{89}$  hadron physics. To sum up, one can agree with the official statement: the situation remains open. What is nice that there very probably is a signal and from TGD point view the nice thing is that this signal could be still consistent with  $M_{89}$  hadron physics.

### 7.4.2 Higgs or $M_{89}$ hadron physics?

The comments of Lubos and Andrew Oh-Willeke to the blog posting about LHC data release inspired some comments on my side. These hastily typed comments were imprecise and I decided to write an improved version collecting the main points to a more organized structure. I want also to write about these topics to clarify myself some important open issues in my own approach and I will do my best to debunk myself in the following. I will very probably make imprecise and even wrong statements. This is work in progress. Apologies.

#### 1. *The basic issues*

1. The basic issue is whether the signal at LHC is a compelling evidence for Higgs or not. My claim is that it tells only that there is scalar or pseudo-scalar producing the signal and that under rather general assumptions this signal can be even quantitatively equivalent with the Higgs signal for the recently studied signatures.
2. Enthusiasts also forget that the signal cross section has features which do not favor its interpretation in terms of Higgs. Exclusion of Higgs does not mean the exclusion of signal! The clear structures around 135 and 145 GeV have not disappeared, there is a wide bump like structure in the entire region 110-150 GeV, and there is structure at both sides of 300 GeV. All these structures should disappear with increased statistics if Higgs interpretation is correct. We do not know whether this will happen and the natural question is whether one could interpret these structures by replacing Higgs paradigm with something else.

3. Higgs is also disfavored by profound theoretical reasons. It is just around the border of instability against the decay of vacuum. Could this criticality be a signal about the need to replace Higgs with something else? Presumably a microscopic description of particle massivation (provided by TGD already 15 years ago in terms of p-adic thermodynamics). Or are we happy with Higgs phenomenology which only reproduces instead of predicting?

## 2. Brief summary of the main results

The main results hitherto - preliminary of course - are following.

1. Various decay rates of pion like states of  $M_{89}$  hadron physics [K43] can be estimated using the generalization of partially conserved axial vector hypothesis (PCAC) stating that the divergence of the axial vector current is proportional to pion field. The proportionality constant is  $f_\pi m_\pi^2$ . The divergence of axial current equals to the sum of instanton densities for electro-weak gauge fields and color gauge field plus the divergence of axial vector currents for  $u$  and  $d$  type quarks assuming that they are massive: this divergence is by Dirac equation proportional to the mass of the quark.

The contribution of more massive quarks is absent, which is quite a remarkable difference as compared to the standard model Higgs for which the decay amplitudes to massive quark pairs are the most important ones by the proportionality of Higgs-fermion coupling to quark mass. This holds true in  $M^4$  effective QFT picture: one can hope that it is a good approximation. It is indeed known to work in ordinary low energy hadron physics and p-adic fractality suggests that the same holds true for  $M_{89}$  hadron physics.

2. If the generalization of hadronic sigma model involving  $u$  and  $d$  type is accepted then  $f_\pi$  can be identified as the negative of the vacuum expectation value of sigma field:  $f_\pi = -v$ . The inspection of the decay rates of Higgs in standard model [?] and those predicted by PCAC (Iztykson-Zuber [?] is my source) shows that their structure is identical. This strongly suggests that by replacing Higgs vacuum expectation value by a suitable multiple of sigma field vacuum expectation it might be possible to reproduce all decay rates of standard model Higgs. This would apply also at the level of amplitudes.

This kind of duality like relation would not be terribly surprising since the structure of these two models is very similar. This would allow to estimate the decay rates of pionlike state to various channels and have very similar results for the decay rates to weak gauge bosons and also to the states produced via the decay to virtual gauge boson pair decaying to quarks or leptons. The direct decays to other than  $u$  and  $d$  quark pairs do not appear in the lowest order.

3. Assuming  $X = f_\pi/m_\pi = 91/140 = .65$  as for ordinary pion, the decay of pion-like state to gamma pair implied by PCAC is under very natural assumptions by a factor 1.54 times larger than the decay rate of Higgs. The observed signal cross section for gamma pair production by 125 GeV state is by the same factor about 1.5 higher than that predicted by the standard model! The value of  $f_\pi = -v = -81.3$  GeV to be compared with W boson mass 80.4 GeV.  $f_\pi = -m_W$  would give  $m(\pi_{89}) = 123.6$  GeV which is second favored value for the mass of the resonance.

This does not yet allow to shout *Heureka!* and claim that  $M_{89}$  pion hypothesis beats Higgs hypothesis. The production rates for Higgs and pion like state need not be the same. If however the production by fusion of electroweak bosons and gluons dominates and is described by PCAC (action would be just then one has excellent hopes that the production rates could indeed be identical for a propose choice of the parameter  $X$ ! There is also associated production in which W or Z boson emitted by a scattered quark in either proton emits Higgs boson. Also this vertex would be governed by PCAC, when Higgs is replaced by  $M_{89}$ .

4. The experimental data suggests that Higgs signal is much smaller than the predicted signal above 127 GeV but has bump like structure and at bumps larger than the effective signal from the standard model background. Also the  $p$ -value telling the probability that standard model background is able to explain the signal cross section has sharp downwards peaks at two other masses about 127 GeV. TGD interpretation would be in terms of pion like states. This interpretation makes sense only if the proportionality coefficient  $X$  in  $f_\pi = X m_\pi$  is considerably

large than its value for ordinary pion and lowest pion like state given by  $X = 91/140 \sim 1.54$ . This reduces the various couplings of pion like state by a factor  $1/X^2$ . This is of course possible but one should have a good explanation for why  $X$  increases with the mass of pseudo-scalar state.

One can clearly say that sigma model for low-lying  $M_{89}$  hadrons replaces Higgs mechanism as an approximate QFT description in TGD framework and a duality like relation between sigma model description of the meson decay amplitudes and those of standard model Higgs is highly suggestive.

In the following I will also criticize various aspects of the TGD vision about both ordinary and  $M_{89}$  hadron physics for the simple reason that this is the best manner to make progress if one is on the right track.

1. TGD SUSY is also in central role if one believes that higher pion like states are there and have explanation in terms of SUSY. 125 GeV pion like state would be apart from mixing effects spion consisting of squark pair. The assumption is that SUSY is essentially unbroken and that mixing of the quarks implies that mass squared matrix is non-diagonal having element between meson and smeson states.
  - (a) The first possibility is that the second eigenstate is tachyonic due to very strong mixing proportional to  $\alpha_s$  and must be excluded from the spectrum.
  - (b) Second - aesthetically more attractive - option is that second eigenstate indeed is there and quite recently I indeed found evidence for narrow resonances with quantum numbers of pion [?] with mass differences between states typically in the range 10-40 MeV. Some of these might be SUSY states.
2. The experimental evidence suggests that pion has satellites but that their number is much larger than SUSY alone predicts. The bumpy structure of Higgs-like signal cross section suggests the same for  $M_{89}$  hadron physics. There are two alternative but not mutually exclusive explanations. The color magnetic flux tubes for light quarks have length of the order of Compton length and one could assign to them a string tension and IR Regge trajectories. Another explanation would be in terms of Shnoll effect implying that probability distributions with single peak decompose to distribution with several peaks. The TGD based explanation of Shnoll effect suggests that it is universal and could take place even at the level of particle physics.
3. A strong objection against TGD SUSY is that there is no missing energy signal which should result from the decays of squarks to quark and  $\tilde{W}$  decaying in turn to lepton and sneutrino. This objection forces to consider a possible modification of the recent belief system. The covariantly constant right handed neutrino could act as super gauge symmetry annihilating physical states. This reduction of SUSY is standard mechanism of SUSY breaking. The color octet  $CP_2$  partial wave of right handed neutrino would generate superpartners. Color confinement would eliminate the decays producing right handed sneutrinos as missing energy. What would be nice is that leptohadrons could be interpreted in terms of color octet sleptons (dark in TGD sense) and TGD SUSY would be realized in a similar manner both for leptons and quarks and would have been discovered for decades ago. This is of course a speculation and p-adic mass calculations should be carried out to check whether this proposal really works.

### 7.4.3 Similarities and differences between Higgs and pion like state

The original - now 15 year old - vision was that  $M_{89}$  hadron physics or more precisely (pseudo-scalar) mesons of  $M_{89}$  hadron physics replace Higgs. Technicolor could be seen analogous proposal but extending the gauge group.

The first argument in favor of Higgs instead of a pion-like state is that the signal cross section is of the same order of magnitude as the predicted signal cross section.  $\gamma\gamma$  cross section is only by a factor about 1.5 larger than the predicted one. This argument need not however bite.

#### 1. PCAC implies similarity of Higgs and $M_{89}$ pion

The key observation is that the generalization of PCAC from ordinary hadron physics to  $M_{89}$  hadron physics implies what might be seen as duality like relation at the level of decay amplitudes of

Higgs and pionlike states of  $M_{89}$  hadron physics. If one is ready to take seriously the sigma model description of hadron physics this duality like relation becomes even more concrete since the vacuum expectation of Higgs field corresponds to the vacuum expectation of sigma field for  $M_{89}$  hadron physics. The vacuum expectation would now determine the mass of the  $M_{89}$  proton and would not say anything about the masses of fermions predicted by p-adic mass calculations.

1. Gauge symmetry alone implies that the couplings of charged pion like states regarded as particle fields (approximation) to weak gauge bosons are same as in the case of Higgs.
2. For the decays of Higgs to  $\gamma\gamma$  the fermion and charged gauge boson loops involve direct couplings of Higgs to fermions and W boson. Also for WW and ZZ decays there is direct coupling for Higgs.
3. For neutral pseudo-scalars the generalization of PCAC [?] from ordinary low energy hadron physics suggests a universal mechanism allowing to describe all couplings of the pion like state boson and fermion pairs. These three particle couplings would replace corresponding couplings for Higgs. Note that in the case of Higgs the couplings gluons and photon are radiative and thus involve loops. Therefore the descriptions would be very similar structurally.
4. This description could apply also to the decays of other mesons than pion. This mechanism should have also a supersymmetric generalization. The basic assumption is that pion like state is proportional to the divergence of the axial current constructed from  $u$  and  $d$  type quarks and the instanton densities assignable to gauge boson:  $\pi = \partial_\mu j_5^\mu / f_\pi m_\pi^2$ . This hypothesis taken in the sense of effective action allows to describe both the decays of pion like states and their production amplitudes. The basic parameter characterizing the pion like state is the proportionality coefficient  $X$  in  $f_\pi = X m_\pi$ . The assumption that  $X$  is for 125 GeV same as for ordinary pion implies  $X = 1.54$  and  $f_\pi = -m_W$  for for  $m(\pi) = 123.6$  GeV. The emergence of  $m_W$  as vacuum expectation value is highly encouraging since the number of parameters would be reduced by one.
5. PCAC implies that all couplings of pionlike state are proportional to  $1/f_\pi m_\pi^2 = 1/X m_\pi^3$ . The divergence of the axial current is essentially  $\partial_\mu j_5^\mu = 2m\bar{\psi}\gamma_5\psi$  and has the same mass proportionality as the coupling of Higgs if one requires that Higgs mechanism produces Higgs masses. In TGD framework Higgs mechanism is replaced by massivation based on p-adic thermodynamics. Only  $u$  and  $d$  quarks (and squarks) contribute to the axial current in the case of pion like states. The generalization for higher  $M_{89}$  pseudoscalar mesons would allow only couplings to fermion pairs appearing in the the decomposition of the meson to quark pairs. This is an important distinction between TGD and ordinary Higgs mechanism. For instance, the decays of pion like states to lepton pairs are forbidden in the lowest order unlike in the case of Higgs. A good guess is that allow a description in terms of PCAC coupling and loops involving gauge boson exchange or decay to virtual gauge boson pair annihilating to fermion pair.

## 2. Could Higgs mechanism have $M_{89}$ sigma model as counterpart?

Sigma model for nucleon, pion and sigma meson involves the analog of Higgs mechanism [?] so that it might be possible to develop rather close analogies. What is intriguing is the connection between strong and weak interactions expressed by conserved vector current hypothesis and partially conserved axial current hypothesis. The question is whether this connection could generalize to all electroweak axial currents and be useful in understanding of  $M_{89}$  hadron physics?

1. Could sigma model description make sense as an approximation in  $M_{89}$  hadron physics at low energies? If so this model would give generalization of the familiar relations used in low energy hadron physics. For instance, the mass of  $M_{89}$  nucleon would satisfy  $m_N = gv$ , where  $g$  is pion-nucleon coupling. The interpretation of sigma field and its vacuum expectation is interesting of course. The status of sigma in ordinary hadron physics has remained unclear and could be used as an objection against this kind of approach.
2. Could sigma model as  $M^4$  QFT approximation bring in non-perturbative aspects such as the non-analytical dependence of the decay rate to gamma pair? Non-perturbative aspects for weak

interactions would reduce to non-perturbative aspect of strong interactions understandable in terms of parton-string duality of generalized Feynman diagrams. The vacuum expectation  $v$  of sigma field equals to  $v = -f_\pi$  and the decay width of pion to two-gamma and presumably also to other final states is proportional to  $1/v^2$  just like the decay rates of Higgs boson are.

3. Could sigma model description of  $M_{89}$  hadron physics replace the description in terms of standard model Higgs mechanism which fails because Higgs mass has the critical value at which vacuum ceases to be stable? What it means that the vacuum expectation value for sigma field equals to W boson mass within experimental uncertainties?

### 3. Comparison of the decay width to gamma pairs for pion like state and Higgs

As an example one can consider the decay rate of pion like state to gamma pairs using PCAC. Axial current anomaly tells that the divergence of the axial current is  $f_\pi m_\pi^2$  times pion field. Axial current divergence contains a part proportional to the instanton density for electromagnetic field and this defines the effective action allowing to calculate the production amplitude and rate for gamma pairs.

1. From Iztykson-Zuber the decay width of pion to two-gamma would be given as

$$\Gamma(\pi) = \frac{\alpha^2 m_\pi^2}{64\pi^2 f_\pi^2}.$$

$f_\pi$  is expected to be of order  $m_{pi}$ . Let us write  $f_\pi = X m_\pi$ .

2. The decay rates of Higgs can be found here. For the decay of Higgs to two photons the rate is

$$\Gamma(h) = \alpha^2 g_W^2 2^{-10} \pi^{-3} m_h^3 m_W^{-2}.$$

3. The ratio of these rates is for  $m(\pi) = m(h)$

$$r \equiv \frac{\Gamma(h)}{\Gamma(\pi)} = X^2 [\alpha \times \sin^2(\theta_W)]^{-1}.$$

For  $X = 91/140$  and  $m(h) = m(\pi) = 123.6$  GeV this gives  $r = 1.54$  and  $f(\pi) = m_W$ . The rate associated with the anomaly is about 2/3 of the prediction for Higgs. Taking this at face value would suggest that there is second contribution to the decay rate. It took time to realize that this must be the case: this was due to a human error: I confused  $r$  with its inverse value leading to the expectation that anomaly alone could be enough. In the next subsection the correct model will be discussed.

The decays to other gauge bosons can be treated in the similar manner. In the case of ZZ and WW only virtual states decaying to fermion pairs are possible but also in this case PCAC gives the vertex for the decay to virtual ZZ or WW pair and standard model vertices describe the decays of gauge bosons to lepton or quark pairs.

### 4. Comparison of the decay widths of Higgs and pion like states to fermions

The decays to fermion pairs would be mediated by two mechanisms.

1. Neutral  $M_{89}$  pion (spion) consists of superposition of p-adically scaled variant of  $u\bar{u}$  and  $d\bar{d}$  pair or a pair consisting of their spartners and by PCAC can be said to contain also a contribution expressible proportional to the sum of instanton densities of various gauge fields. In the lowest order the decays are expected to take mostly to  $u\bar{u}$  and  $d\bar{d}$  quark jet pairs and gamma pairs since the decay to WW and ZZ pairs is kinematically forbidden. Also the decays to gluon pairs are possible and produce hadronic jets. In Higgs scenario  $b\bar{b}$  and  $\tau\bar{\tau}$  are favored since direct decays to these are possible.

2. One can consider also higher order contributions to the decays. The pseudo-scalar couples democratically to all fermion pairs via the annihilation to virtual gauge boson ( $Z, W, \gamma$ , gluon) pair decaying to fermion pair. The couplings to gauge boson pairs are dictated by  $M_{89}$  generalization of PCAC and given by the instanton terms for gauge boson fields. This gives  $1/v^2$  proportionality with  $v = -f_\pi = X m_\pi$ . Similar factors appear also in Higgs decay rates as a consequence of Higgs mechanism and one expects the kinematical factors depending on mass to be essentially the same. The divergence of the fermionic contribution to the axial current is proportional to the mass of fermion so that the coupling to fermion pairs is proportional to fermion mass as in the case of Higgs boson.
3. The killer prediction is that for lepton pairs and also for quark pairs other than  $u\bar{u}$  and  $d\bar{d}$  the production is possible only in higher order. This should allow to distinguish between TGD and standard model. Reliable estimates for the decay rates of pion like states to all channels would be needed and should be compared with those for Higgs. At this moment most of the data is about  $\gamma\gamma$  decay mode. About  $ZZ$  there are only some events and fermion pairs the data is meager.

*Remark:* It must be warned that in TGD framework one has  $M^4 \times CP_2$  spinors and  $M^4$  scalars/pseudoscalars are necessarily  $CP_2$  vectors/axial vectors. This might mean some technical problems for  $M^4$  QFT limit.

#### 5. How to test the differences?

One can test this picture against Higgs hypothesis.

1. The presence of charged companions of Higgs like states is something new and a test for the scenario.
2. Signal cross sections have structure around 140 GeV and at both sides of 300 GeV. There are very clearly visible as peaks also in the probability  $p_0$  that the signal cross section can be understood in terms of background only. The believer on Higgs can only hope that these structures disappear with bigger statistics. The interpretation in terms of  $M_{89}$  mesons would be natural in TGD framework. For the higher pion like states the parameter  $X(\pi)$  must be smaller since the signal cross section is considerably below that predicted by standard model.

#### 6. Exotic pion like states: "infra-red" Regge trajectories or Shnoll effect?

The experimental claim is that pion is accompanied by pion like states with mass 60, 80, 100, 140, 181, 198, 215, 227.5, and 235 MeV means that besides pion also other pion like states should be there. Similar satellites have been observed for nucleons with ground state mass 934 MeV: the masses of the satellites are 1004, 1044, 1094 MeV. Also the signal cross sections for Higgs to gamma pairs at LHC suggest the existence of several pion and spion like states, and this was the reason why I decided to again search for data about this kind of states (I remembered vaguely that Tommaso Dorigo had talked about them but I failed to find the posting). What is their interpretation? One can imagine two explanations which could be also equivalent.

1. The states could be "infrared" Regge trajectories assignable to magnetic flux tubes of order Compton length of  $u$  and  $d$  quark (very long and with small string tension) could be the explanation. Hadron mass spectrum would have microstructure. This is something very natural in many-sheeted space-time with the predicted p-adic fractal hierarchy of physics. This conforms with the proposal that all baryons have the satellite states and that they correspond to stringy excitations of magnetic flux tubes assignable to quarks. Similar fine structure for nuclei is predicted for nuclei in nuclear string model [L3]. In fact, the first excited state for  ${}^4\text{He}$  has energy equal to 20 MeV not far from the average energy difference 17.5 MeV for the excited states of pion with energies 198, 215, and 227.5 MeV so that this state might correspond to an excitation of a color magnetic flux tube connecting two nucleons.
2. The p-adic model for Shnoll effect [?] relies on universal modification of the notion of probability distribution based on the replacement of ordinary arithmetics with quantum arithmetics. Both the rational valued parameters characterizing the distribution and the integer or rational valued arguments of the distribution are replaced with quantum rationals. Quantum arithmetics

is characterized by quantum phase  $q = \exp(i2\pi/p)$  defined by the p-adic prime  $p$ . The primes in the decomposition of integer are replaced with quantum primes except  $p$  which remains as such. In canonical identification powers of  $p$  are mapped to their inverses. Quite generally, distributions with single peak are replaced with many peaked ones with sub-peak structure having number theoretic origin. A good example is Poisson distribution for which one has  $P(n) = \lambda^n/n!$ . The quantum Poisson distribution is obtained by replacing  $\lambda$  and  $n!$  with their quantum counterparts. Quantum Poisson distribution could apply in the case of resonance bump for which the number of count in a given mass squared interval is integer valued variable.

There are objections against Shnoll effect based explanation.

- (a) If the p-adic prime assignable to quark or hadron characterizes quantum arithmetics it is not distinguishable from ordinary arithmetics since the integers involved are certainly much smaller than say  $M_{107} = 2^{107} - 1$ . In the case of nuclear physics Shnoll effect involves small primes so that this argument is not water tight. For instance, if  $p = 107$  defines the quantum arithmetics, the effects would be visible in good enough resolution and one might even expect variations in the bump structure in the time scale of year.
- (b) The effect is present also for nucleons but the idea about a state with large width splitting into narrower bumps does not fit nicely with the stability of proton.

For Higgs like signals "infra-red" Regge trajectories/Shnoll effect would be visible as a splitting of wide bumps for pion and pion of  $M_{89}$  physics to sub-bumps. This oscillatory bumpy structure is certainly there but is regarded as a statistical artifact. It would be really fascinating to see this quantum deformation of the basic arithmetics at work even in elementary particle physics.

The prediction of the additional pion-like states is one of the predictions of TGD about hadron physics at low energies and one of the first tasks is to look quantitatively possible realizations of Shnoll effect in the case of resonances.

## 7.5 Is it really Higgs?

The discovery of the new spinless particle at LHC [?, ?] is believed to be a turning point in physics, and for a full reason. Before discussing TGD based view about the discovery it is appropriate to discuss briefly the historical background to demonstrate that the answer to the question "Higgs or not Higgs?" indeed determines the path followed in future particle physics.

### 7.5.1 Background

#### GUT paradigm

The leading thread in the story of particle physics is GUT paradigm, which emerged for four decades ago. It however has its problems besides the fact that not a single thread of evidence has accumulated to support it.

1. The basic idea of GUTs is to put all fermions and bosons to multiplets of some big gauge group extending the standard model gauge group. This idea is applied also in the generalization of gauge theories to supersymmetric gauge theories and in superstring models. Scalar fields developing vacuum expectations define a key element of this approach and give hopes of obtaining a realistic mass spectrum. This rather simple minded approach would make unification an easy job. There are however difficulties.
2. One of the basic implications is that baryon and lepton numbers are not conserved separately. Proton decays would make this non-conservation manifest. These decays have not been however observed, and one of the challenges of the GUT based models is fine-tuning of couplings so that proton is long-lived enough. This raises the question whether one could somehow understand the separate conservation of  $B$  and  $L$  from basic principles.

- Putting all fermions in the same multiplet would suggest that the mass ratios for fermions should be simple algebraic numbers not too far from unity. Fermion families have however widely differing mass scales and the ratio of top quark mass scale to neutrino mass scale is gigantic. This suggests that fermion generations and even different charge states of fermions of single generation are characterized by inherent mass scales and do not belong to a multiplet of a big gauge group. Standard model gauge group would be the fundamental gauge group and the challenge would be to deduce it from some fundamental principles. In TGD framework number theoretical vision indeed leads to an explanation for standard model gauge group [K72].

It is also an empirical fact that fermion generations are identical copies of each other apart from widely different masses. This suggests some non-group theoretic explanation for family replication phenomenon. In TGD framework 2-D wormhole throats characterized topological by their genus in orientable category are the fundamental particle like objects. This provides a possible explanation for the family replication phenomenon. One must of course explain why genera higher than  $g = 2$  are heavy or absent from the spectrum, and one can indeed develop an argument for this based on the fact that  $g \leq 2$  2-surfaces allow always  $Z_2$  as conformal symmetries unlike  $g > 2$  2-surfaces [K16].

- Particle massivation in GUT framework is described by coupling the fermions and gauge bosons to a scalar field. The vacuum expectation values of the scalar fields define the mass scales. In the case of standard model one has only single scalar/Higgs field and by choosing the couplings to Higgs field to be proportional to fermion mass one can reproduce particle masses. Only a reproduction is in question and theory is certainly not microscopic. Vacuum expectation value (VEV) paradigm is central also for the inflationary cosmology - in fact for the entire theoretical particle physics developed during last decades. The no-existence of Higgs would force to return to the roots to the situation four decades ago. Therefore the new spinless particle could be a turning point in the history of physics, and it is easy to understand why the attitudes against or on behalf of Higgs interpretation are so passionate and why facts tend to be forgotten.

### How to achieve separate conservation of $B$ and $L$ ?

A possible manner to understand the separate conservation of both  $B$  and  $L$  would be via the identification of spinors as different chiralities of higher-dimensional spinors.

- This would however require the identification of color quantum numbers as angular momentum like quantum numbers assignable to partial waves in internal space. This is indeed the identification performed in TGD framework and  $H = M^4 \times CP_2$  is the unique choice of imbedding space coding for the standard model quantum numbers. In TGD approach quarks and leptons correspond to different imbedding space chiralities, and this excludes Higgs as a genuine imbedding space scalar since it would couple to quark-lepton pairs. To get the couplings correctly Higgs should correspond to imbedding space vector having components only the direction of  $CP_2$  but it is rather difficult to imagine how gauge bosons could "eat" components of Higgs in this case. As a matter fact, Higgs components should be characterized by same charge matrices as weak bosons and would be a TGD counterpart for a mixture of scalar and pseudoscalar.
- Chiral invariance is indeed essential for the renormalizability of 4-D gauge theories. The absence of 8-D scalars would allow also a generalization of chiral invariance from 4-D to 8-D context implying separate conservation of  $B$  and  $L$ . This is the case even in string model framework if separate conservation of  $B$  and  $L$  is assumed. It is worth of mentioning that the separate conservation of  $B$  and  $L$  is not consistent with the standard  $\mathcal{N} = 1$  SUSY realized in terms of Majorana spinors. This is not a catastrophe since LHC has already excluded quite a considerable portion of parameter space for  $\mathcal{N} = 1$  SUSY.  $\mathcal{N} = 2$  SUSY however is and is generated in TGD framework by right-handed neutrino and its antiparticle.

There are however quite intricate delicacies involved discussed in detail in [?]. For instance, the modes of covariantly constant right-handed neutrino spinor of  $CP_2$  generates 4-D generalization of super-conformal symmetry as modes delocalized into entire space-time surfaces whereas other modes are localized to 2-D surfaces and generate badly broken SUSY with very large value of  $\mathcal{N}$ . An open question is whether the  $\nu_R$  covariantly constant also in  $M^4$  degrees of freedom

could generate  $\mathcal{N} = 1$  SUSY analogous to the standard SUSY. In any case, TGD seems to be inconsistent with both scalar VEV paradigm and standard  $\mathcal{N} = 1$  SUSY.

3. p-Adic physics and p-adic length scale hypothesis allow to understand the widely different mass scales of fermions and various gauge bosons since p-adic prime and the primary p-adic length scale defined by it become the characterizers of elementary particle. Also the secondary p-adic length and time scales are important: for electron secondary p-adic time scale is .1 seconds and quite intriguingly the fundamental time scale of biology. p-Adic thermodynamics provides the microscopic theory of particle massivation leading to highly successful predictions not only for particle mass scale ratios but also for the particle masses. p-Adic primes near powers of two - in particular Mersenne primes - pop up naturally and define positive integer characterizing given particle. Number theory becomes the tool of understanding the mystery number  $10^{38}$  defined by the ratio of Planck mass and proton mass (this number is essentially the ratio of  $CP_2$  mass to electron mass) [K39].

If Higgs is needed in TGD framework at all, it might provide gauge bosons with longitudinal polarizations. Even this function seems to be un-necessary. Here so called zero energy ontology (ZEO) comes in rescue.

### Particle massivation from p-adic thermodynamics

p-Adic thermodynamics defines a core element of p-adic mass calculations [K16, K39, K46]. p-Adic thermodynamics is thermodynamics for the conformal scaling generator  $L_0$  in the tensor product representation of super-conformal algebra and the masses are fixed one the p-adic prime characterizing the particle is fixed. p-Adic length scale hypothesis  $p \simeq 2^k$ ,  $k$  integer, implies an exponential sensitivity of the particle mass scale on  $k$  so that a fitting of particle masses is not possible.

1. The first thing that one can get worried about relates to the extension of conformal symmetries. If the conformal symmetries for light-like surfaces and  $\delta M_{\pm}^4 \times CP_2$  generalize to  $D = 4$ , how can one take seriously the results of p-adic mass calculations based on 2-D conformal invariance? There is actually no reason to worry. The reduction of the conformal invariance to 2-D one for the solutions of modified Dirac equation takes care of this problem [?] This however requires that the fermionic contributions assignable to string world sheets and/or partonic 2-surfaces - Super- Kac-Moody contributions - dictate the elementary particle masses. For hadrons also super-symplectic contributions would be present and would give the dominating contribution to baryon masses.

The modes of right handed neutrino are delocalized to a 4-D region of space-time surface and characterized by two integers. The absence of all standard model interactions suggests that no thermalization takes place for them. These modes are de-localized either to a region of Euclidian signature identifiable as 4-D line of generalized Feynman graph or to a region of Minkowskian signature. Since modified gamma matrices vanish identically for  $CP_2$  type vacuum extremals one can ask whether the 4-D neutrino modes are associated only with Minkowskian regions. In this case the counterpart of  $\mathcal{N} = 1$  SUSY would assign spartner to a many-particle state rather than to elementary particle. This could explain for why LHC has not seen the analog of standard SUSY.

2. ZEO suggests that the wormhole throats carrying many-fermion states with parallel momenta are massless: this applies even to virtual wormhole throats [?]. As a consequence, the twistor approach would work and the on mass shell kinematical constraints to the vertices would allow the cancellation of UV divergences. The 2-D Kac-Moody generators assignable to the boundaries of string world sheets would generate Yangian algebra [?]. IR divergences would cancel because incoming and outgoing particles would be massive on mass shell particles as states involving several wormhole throats. The p-adic thermal expectation value is for the longitudinal  $M^2$  momentum squared rather than for the four-momentum squared (the definition of  $CD$  selects  $M^1 \subset M^2 \subset M^4$  as also does number theoretic vision). Also propagator would be determined by  $M^2$  momentum. Lorentz invariance would be achieved by averaging over the moduli for  $CD$  including also Lorentz boosts of  $CD$ .

3. In the original approach states with arbitrary large values of  $L_0^{tot}$  were allowed as physical states. Usually one would require that the generator  $L_0^{tot}$  of conformal scaling annihilates the states. In the calculations however mass squared was assumed to be proportional  $L_0^{tot}$  apart from vacuum contribution. This is a questionable assumption. ZEO suggests that total mass squared vanishes and that one can decompose mass squared to a sum of longitudinal and transversal parts. If one can do the same decomposition for the longitudinal and transverse parts also for the Super Virasoro algebra, one can calculate longitudinal mass squared as a p-adic thermal expectation of  $L_0^{tr}$  in the transversal Super-Virasoro algebra and only states with  $L_0^{tot} = 0$  would contribute and one would have conformal invariance in the standard sense. The decomposition is indeed possible since longitudinal parts correspond to pure gauge degrees of freedom.

Thermodynamics - or rather, its square root - would become part of quantum theory in ZEO.  $M$ -matrix is indeed product of hermitian square root of density matrix multiplied by unitary  $S$ -matrix and defines the entanglement coefficients between positive and negative energy parts of zero energy state. Different  $M$ -matrices orthogonal to each other with respect to trace become rows of the unitary  $U$ -matrix.

4. The crucial constraint is that the number of super-conformal tensor factors is  $N = 5$ : this suggests that thermodynamics applied in Super-Kac-Moody degrees of freedom assignable to string world sheets is enough if one is interested in the masses of fermions and gauge bosons. Super-symplectic degrees of freedom can also contribute and determine the dominant contribution to baryon masses. Should also this contribution obey p-adic thermodynamics in the case when it is present? Or does the very fact that this contribution need not be present mean that it is not thermal? The symplectic contribution should correspond to hadronic p-adic length scale rather the much longer (!) p-adic length scale assignable to say u quark (this paradoxical looking result can be understood in terms of uncertainty principle and the assignment of quarks to the color magnetic body of hadron). Hadronic p-adic mass squared and partonic p-adic mass squared cannot be summed since primes are different. If one accepts the basic rules [K46], longitudinal energy and momentum are additive as indeed assumed in perturbative QCD.
5. Calculations work if the vacuum expectation value of the mass squared must be assumed to be tachyonic. There are two options depending on whether one whether p-adic thermodynamics gives total mass squared or longitudinal mass squared.
  - (a) One could argue that the total mass squared has naturally tachyonic ground state expectation since for massless extremals (MEs, topological light rays [K9]) longitudinal momentum is light-like and transversal momentum squared is necessary present and non-vanishing by the localization to topological light ray of finite thickness of order p-adic length scale. Transversal degrees of freedom would be modeled with a particle in a box.
  - (b) If longitudinal mass squared is what is calculated, the condition would require that transversal momentum squared is negative so that instead of plane wave like behavior exponential damping would be required. This would conform with the localization in transversal degrees of freedom.

This is the general picture. One crucially important implication is that gauge conditions in Lorentz gauge must be modified. Only longitudinal  $M^2$  momentum appears in the propagators (recall that total mass squared vanishes and cannot appear in the propagator if virtual particles are massless). Therefore only  $M^2$  momentum appears in gauge conditions:  $p_L \cdot \epsilon = 0$  holds true and implies that also longitudinal polarization is allowed. Massivation is also unavoidable. The first guess for gauge boson state is as a wormhole contact containing fermion and anti-fermion at 3-D light-like wormhole throats. One must have spin 1 but since fermion and anti-fermion are massless they must have non-parallel 3-momenta in order to have parallel spins. For instance, they could have parallel and massive longitudinal momenta but non-parallel transverse momenta. The longitudinal mass squared would be in general non-vanishing and hence mass squared as the average over moduli of  $CD$  involving also integration over Lorentz boosts of  $CD$ . Higgs is not needed in TGD framework and its possible TGD counterpart seems also incapable of fulfilling its functions.

### Could a TGD counterpart of scalar boson have useful functions in TGD Universe?

The social pressures tending to force the interpretation of the new resonance as Higgs are rather strong and most bloggers seem to take this interpretation as granted. In this kind of situation theoretician with visions deviating from the mainstream thinking of course feels excitement and stress. I am not an exception to this rule. What if the production rate and branching ratios are those predicted by standard model? Is my vision wrong in this case? How it could be wrong? Can I modify it without losing something essential?

Recall that standard model Higgs has two functions. Higgs VEV gives masses for fermions and weak gauge bosons and Higgs gives longitudinal components for massive gauge bosons. Could one have Higgs like states performing only one or none of these functions?

1. In TGD framework fermion massivation by Higgs vacuum expectation is replaced by p-adic thermodynamics giving the dominant contribution to the longitudinal mass squared  $p_L^2$  (all particle states are massless at fundamental level). One cannot however exclude scalar vacuum expectations giving a small corrections to fermion masses. p-Adic thermodynamics as a microscopic mechanism of fermion massivation is so beautiful and predictive that it beats massivation based on Higgs expectation, which in TGD framework can be seen as a phenomenological parametrization at best.
2. In the case of weak gauge bosons p-adic temperature  $T = 1/n$  would be probably smaller ( $T \leq 1/2$  instead of  $T = 1$  for fermions) and the analog of Higgs expectation could give a significant or even dominating contribution to weak gauge boson masses. There are however conceptual problems. What is the TGD counterpart of Higgs VEV? Does it characterize coherent state? Does this expectation have classical space-time correlate as gauge bosons have?

What about the second function of Higgs as a provider of longitudinal polarizations for massive gauge bosons?

1. TGD allows to imagine the existence of analogs of Higgs like states [K43] (see the previous posting). They generalize the notions of scalar and pseudo-scalar in Minkowski space to vector and pseudo-vector in 8-D imbedding space with components only in  $CP_2$  directions defining the analogs of polarizations. These states appear always as singlet and charged triplet and are very much analogous to 1+3 formed by electroweak gauge bosons.
2. In standard model the three components of standard model Higgs also provide the longitudinal components of weak bosons W and Z. ZEO allows to understand the massivation of spin 1 bosons as something unavoidable without the need for Higgs like particle and I do not have any elegant proposal how the possible scalar 1+3 could transform to longitudinal components of weak bosons and single neutral Higgs. Thus there is a tendency to conclude that if Higgs like states exist in TGD Universe they appear as full multiplets 1+3 containing also charged states as physical particles.

I could of course be wrong! Maybe Higgs could after all manage to serve as a provider of longitudinal polarizations. Could one imagine the classical counterparts of gauge bosons eating Higgs components in classical TGD? To get some perspective, consider modified Dirac equation for induced spinors at preferred extremals of Kähler action.

1. For the TGD counterparts of induced Dirac equation both gamma matrices and gauge potentials appearing in the modified Dirac equation are induced from those of imbedding space by simply projecting them to the space-time surface. This implies that induced gamma matrices contain also  $CP_2$  part. This gives rise to new kind of couplings proportional to the contraction of gauge potential with  $CP_2$  part of induced gamma matrices.

Induced gamma matrices are actually replaced by modified gamma matrices defined by Kähler action to obtain supersymmetry and internal consistency of the theory but the conclusion remains the same. Modified gamma matrices are proportional to Maxwell energy momentum tensor expressible in terms of Einstein equations using Einstein tensor and metric for the proposed ansatz for preferred extremals. Could these couplings involving energy momentum tensor and thus mass mimic Higgs couplings? I do not regard this interpretation as plausible.

- Quantum classical correspondence requires the existence of classical counterparts of quanta, also Higgs. My inability to imagine any convincing candidate has been one of the reasons for my skepticism concerning Higgs like states. While writing this I however decided to try once again. I failed but learned that em charge as isospin like quantum number for fermions should be conserved in TGD classically - something very non-trivial that I have taken as granted and shown to be true only for the octonionic representation of imbedding space gamma matrices [?].

Therefore it seems that the possibility to realize the longitudinal polarizations of weak gauge bosons using Higgs like states are rather meager.

### Could the conservation of em charge allow to identify unitary gauge and from this classical Higgs field?

An important aspect of the standard model Higgs mechanism is that it respects em charge leaving photons massless. In standard model the conservation of em charge defined as isospin like quantum number is non-trivial since the presence of classical gauge fields induces transitions between different charge states of fermions. In second quantization this problem is circumvented by replacing classical gauge fields with quantized ones. The so called unitary gauge defined by a gauge transformation depending on Higgs fields allows to express the action in terms of physical (in general massive) fields and makes charge conservation explicit. How the conservation of em charge is obtained in TGD?

- Doesn't one have the same problem but as a much worse variant since classical long range electro-weak gauge fields are unavoidable in TGD and there is no path integral but preferred extremals? Could it make sense to speak about unitary gauge also in TGD framework? Could one turn around this idea to derive classical Higgs from the possibly existing gauge transformation to unitary gauge? The answer is negative. There is actually no need for the unitary gauge.

As a matter fact, the conservation for em charge in spinorial sense leads to the earlier conjecture that the solutions of the modified Dirac equations are localized at 2-D surfaces whose ends define braid strands at space-like 3-surfaces at the ends of causal diamonds and at the light-like 3-surfaces connecting them and defining lines for generalized Feynman diagrams. This picture was earlier derived from the notion of finite measurement resolution implying discretization at the level of partonic 2-surfaces and also from number theoretical vision suggesting that basic objects correspond to 2-D commutative and co-commutative identifiable as sub-manifolds of 4-D associative and co-associated surfaces.

- The point is that the Kähler form of  $CP_2$  is covariantly constant and one can identify covariantly constant em charge as a matrix of form  $Q = aI + bJ_{kl}\Sigma^{kl}$ : the coefficients  $a$  and  $B$  are different for quarks and leptons (different chiralities of H-spinors). This matrix is covariantly constant also with respect to the induced spinor structure and commutes with Dirac operator (be it the TGD counterpart of the ordinary massless Dirac operator or modified Dirac operator). Therefore one should be able to choose the modes of induced spinor field to have a well-defined em charge at each point of space-time surface. The covariantly constant Kähler form of  $CP_2$  is an important element in making possible the conservation of em charge and derives from the supersymmetry generated by covariantly constant right-handed neutrino. This is however not enough as it became clear.
- Rather unexpectedly, the challenge of understanding the charge conservation in the spinorial sense led to a breakthrough in understanding of the modes of the modified Dirac equation. The condition for conservation leads to three separate analogs of Dirac equations and the two additional ones are satisfied if em charged projections of the generalized energy momentum currents defining components of modified gamma matrices vanish. If these components define Beltrami fields expressible as products  $j = \Psi\nabla\Phi$  the conditions can be satisfied for  $\Psi = 0$ . Since  $\Psi$  is complex or hyper-complex, the conditions are satisfied for 2-dimensional surfaces of space-time surfaces identifiable as string world sheets and partonic 2-surfaces. This picture was earlier derived from various arguments. Em charge conservation does not there give rise to a counterpart of unitary gauge but leads to a bridge between modified Dirac equation and general view about quantum TGD based on generalization of super-conformal invariance.

Higgsteria had therefore at least one very positive impact in TGD framework! Note that only slightly earlier emerged the construction recipe for preferred extremals of Kähler action based on a generalization of minimal surface equations of string models to 4-D context and generalizing the 2-D conformal invariance to its four-dimensional analog. This had also a surprising and very pleasant outcome: Einstein's equations with cosmological term follow as consistency conditions for the reduction of field equations to purely algebraic conditions solved by assuming that Euclidian space-time region has hermitian structure and Minkowskian region its counterpart that I have christened Hamilton-Jacobi structure. This simplified considerably the vision about the representations of super-conformal symmetries [?].

### 7.5.2 $M_{89}$ hadron physics instead of Higgs?

The original interpretation for 125 GeV state was as a pion-like state of scaled up copy of hadron physics. Two-photon decay and also the decays to other weak bosons and perhaps even gluons would be due to axial anomaly and involve only gauge boson loops. It however turned out that this does not work: the group theoretic properties of pion ( $3 + 1$  under weak  $u(2)$ ) are not correct, and the assumption of  $M^4$  QFT limit leads to the analog of Higgs mechanism in which some components of pion are eaten. Therefore one must modify the hypothesis by replacing  $M_{89}$  pion with something pion-like, which turned out to be its Euclidian counterpart transforming as  $2 + \bar{2}$  under weak  $u(2)$ . In the following the development of the idea is described in more detail.

#### Scaled copies of hadron physics as a basic prediction of TGD

One of the most surprising "almost-predictions" of TGD is the possibility of scaled variants of hadron physics.

1. Ordinary hadron physics is characterized by Mersenne prime  $M_n = 2^n - 1$ ,  $n = 107$ . There are also other physically interesting Mersenne primes.  $M_{127}$  corresponds to electron and has been tentatively assigned to electro-hadron physics for which color octet states of electron replace color triplet of quarks. Muon corresponds to Gaussian Mersenne  $M_{G,n} = (1 + i)^n - 1$ ,  $n = 113$ , and  $\tau$  to the hadronic Mersenne prime  $M_n$ ,  $n = 107$ .
2. There is evidence for lepto-hadron physics associated with these charged leptons too [?].
3. The masses of current quarks are from QCD estimates in 10 MeV scale and there exists some evidence for Regge trajectories in 20 MeV string tension. The interpretation would be in terms of magnetic flux tubes associated with the "magnetic body" of the hadron and the question. It however seems that  $M_{127}$  variant of hadron physics with characteristic mass scale of order .5 MeV cannot be in question.
4. In biologically relevant length scale range ranging from cell membrane thickness (10 nm) to the size scale of cell nucleus about  $5 \mu\text{m}$  there are as many as four Gaussian Mersennes  $M_{G,n}$  corresponding to  $n = 151, 157, 163, 167$ . Dark matter identified as phases with non-standard value of effective Planck constant coming as integer multiple of ordinary Planck constant is essential for what it is to be living in TGD Universe. The dark matter residing at magnetic flux quanta could correspond to quarks and gluons free in the size scale involved.

$M_{89}$  corresponds to a candidate for a hadron physics with mass scale of hadron physics scaled up by a factor 512: this corresponds to TeV range. For instance, proton mass of order .94 GeV would be scaled up to about 500 GeV. General arguments suggests that some new physics must emerge at TeV energy scale. Could it be that  $M_{89}$  hadron physics is this new physics? If so then the identification of 125 GeV resonance as a pion-like state of the new hadron physics would be natural. It should be easy to kill this hypothesis at LHC since entire spectroscopy of hadron like states is predicted and the experience from QCD allows to predict the dynamics of these states. p-Adic mass calculations in turn allow to estimate the mass spectrum using simple scaling arguments.

### Is it really Higgs?

After the first wave of Higgsteria the attitudes to the discovery at LHC have become more realistic and i "Higgs discovery" is indeed transforming to "discovery". I of course feel empathy for those who have spent their professional career by doing calculations with Higgs: it is not pleasant to find that something totally different might be in question. In the latest New Scientist [?] the problems are acknowledged and summarized.

For most decay channels the rates differ from standard model predictions considerably [?]. In particular, gamma gamma decay rate is about three times too high and tau lepton pairs are not produced at all. This is very alarming since Higgs should couple to leptons with coupling proportional to its mass. It is becoming clear that it is not standard model Higgs. People have begun to talk about "Higgs like" state since nothing else they do not have because technicolor scenario is experimentally excluded. The surplus of gamma pairs is an important hint and suggests an additional decay channel to gamma pairs. The recent data from ATLAS (see figure 10 [?]) support the Higgs like behavior for the decays to Z and W pairs. The decay rates to tau pairs and to b pairs in associated production together with W are lower than predict.

Statistical fluctuations could be in question but the spokesperson Fabiola Gianotti says that "It could well be that it's not the standard model Higgs boson" and later continues "When the uncertainties become even smaller, when we have even more data and more studies, we'll be able to understand better the properties of this particle, if it's a Higgs boson or a more exotic object". So we still do not know if it is Higgs, Higgs like particle, or something else.

The most natural - albeit not the only possible - TGD identification is as a pion-like state. This would mean that it is pseudo-scalar: also SUSY predicts pseudo-scalar as one of the several Higgses.

The basic predictions of TGD scenario deserve to be summarized.

1. Also two charged and one neutral companion of the effective pseudo-scalar should exist. This is because pseudo-scalar must be replaced by imbedding space axial vector having only  $CP_2$  components (4) forming electroweak triplet and singled just as ew gauge bosons do. The identification as  $CP_2$  tangent space vector looks promising at first but it is difficult to imagine how charged components of Higgs could be eaten by weak bosons.
2. ATLAS and CMS see their Higgs candidates at slightly different masses: mass difference is about 1 GeV. Could this mean that the predicted two neutral states contribute and have been already observed? Could this also explain the too large decay rate to two gammas.

One can however counter-argue that ordinary pion has no neutral companion of same mass. In hadronic sigma model it has scalar companion with which it forms 1+3 multiplet of  $SO(4)$ , the tangent space group of  $CP_2$  reducing to  $SU(2)_L \times U(1)$  identifiable as  $U(2) \subset SU(3)$  in the concrete representation of pion states. Could one think that this is the case also now and sigma develops vacuum expectation analogous to that of Higgs determining most of the couplings just as in sigma model for ordinary hadrons? The problem is that the neutral component should be scalar.

Could one get rid of the additional sigma state?  $CP_2$  allows two geodesic spheres and the homologically trivial one allows  $SO(3)$  as isometries instead of  $U(2)$ . In this case one would have naturally  $SO(3)$  triplet instead of 3+1 and no sigma boson. For the four kaon like states one would have 3+1 naturally. This could distinguish between pion-like and kaon-like multiplets also in the ordinary hadron physics [K43]. What is genuinely new that strong isospin groups  $U(2)$  and  $SO(3)$  would reduce to subgroups of color group in spinor representation.

3. If there is pion-like state there, it is pseudo-scalar: this might become clear during this year. SUSY people would identify it as one of the SUSY Higgses.
4. Pion-like states consist of "scaled up" quarks of  $M_{89}$  hadron physics and they prefer to decay to hadrons. Lepton pairs are produced only in higher order via box diagrams with weak boson pair as vertical edges and quark line and lepton line as horizontal edges. This explains why tau pairs are not observed. The fastest decays could take place to two gluons of  $M_{89}$  hadron physics transforming to ordinary gluons in turn decaying to quarks and producing jets.
5. The simplest option is that effective action for decays to weak gauge bosons is instanton action assignable to axial current anomaly. WW production rate is consistent with standard Higgs and

this fixes the coefficient of the instanton term if one assumes that electroweak symmetry is not broken so that  $\gamma$ ,  $Z$ , and  $W$  would have different coefficients.

6. Associated production of  $b\bar{b} + W$  has been observed as predicted. In TGD  $b\bar{b}$  would correspond to decay to two gluons annihilating to quark pair. Light quark pairs would be produced much more than in Higgs decays where Higgs-quark coupling is proportional to quark mass.
7. What is intriguing that the plots for the ratio of observed cross section divided by standard model prediction as a function of Higgs mass show periodically occurring peaks as a function of Higgs mass with period of order 20 GeV. This might be of course a mere artifact related to the size of data bin and probably is and also to the character of the plot. There is however intriguing similarity with the reported existence of satellites of ordinary pion with period of order 20-40 MeV. By scaling 40 MeV by a factor 512 one obtains 20 GeV. Could the 145 GeV state reported earlier by CDF collaboration [?] correspond to this kind of state?

What experimenters have to say about these predictions after year is interesting. The discovery of charged partners, too low rate for the decays to lepton pairs, and too fast decays to light quark pairs would destroy the Higgs interpretation.

### Minkowskian pion as Higgs like state?

The original idea for the identification of Higgs like particle as Euclidian pion came from the model for the model of leptopions via a formation of coherent state of leptopions generated by the electromagnetic instanton term assignable to the strong electric and magnetic field of colliding hea by nuclei near the Coulomb wall [?]. In this model the instanton term was inspired by the basic PCAC giving rise to axial anomaly stating that pion field is proportional to the instanton density. This simple argument can be refined so that it allows to have a linear coupling between pion like state and instanton density.

1. One should realize the linear coupling of Higgs like pion to instanton density. The problem is that  $Tr(F \wedge F \pi)$  since  $\pi$  does not make sense as such since  $\pi$  is defined in terms of gamma matrices of  $CP_2$  and  $F$  in terms of sigma matrices. The gamma matrices of the imbedding space allow octonionic representation as tensor products of 2-D Pauli sigma matrices and octonion units [?]; this provides one manner to define the notion of quaternionicity for the space-time surface. In this representation  $CP_2$  gamma matrices span naturally the complement of quaternionic sub-space and their commutators define sigma matrices proportional to octonion units in quaternionic sub-space assignable to  $M^4$ .  $F$  and  $*F$  are proportional to octonion units in the complement of quaternionic sub-space and the cross product  $F \times *F$  defined as quaternionic commutator and  $H$  are proportional to quaternionic gamma matrices. Hence the quaternionic inner product  $\pi \cdot (F \times *F)$  is well-defined and non-vanishing and defines a generalization of the action term linear in pion. Note that it is necessary to use instanton term since  $F \times F$  not only vanishes but is also excluded by parity conservation.
2. The construction of preferred extremals [?] however suggests that the cross product  $F \times *F$  is identically vanishing for a given Minkowskian space-time sheet. At  $M^4$  QFT limit one can however assume that the effects of parallel space-time sheets superpose for a particle topologically condensed on both space-time sheets. The superposition of fields expresses this at QFT limit. In the recent case  $F$  and  $*F$  could be interpreted as the fields at space-time sheets associated with the colliding hadrons or quarks.
3. This interaction term could appear in the analog of Higgs potential for  $3 + 1$  decomposition but would give a vanishing coupling of Higgs like particle to both  $\gamma$  and  $Z^0$  boson which would therefore remain massless. Hence only  $2 + \bar{2}$  pion like state defined as a vector in the the complement of  $u(2) \subset su(3)$  can define Euclidian pion serving as a candidate for a Higgs like state whereas  $3 + 1$  defines naturally the Minkowskian pion.
4. If the action density contains only the mass term  $m^2\pi^2/2$  plus instanton term  $\frac{1}{32\pi^2 f_\pi} \pi I$ , where  $I$  is the instanton density, one obtains the standard PCAC relation between the vacuum expectation of the pion field and instanton density.

$$\pi_0 = \frac{1}{32\pi^2 f_{pi} m_\pi^2} I .$$

This relation appears also in the model for leptopion production [?]

5. What about the identification of kaon? Ordinary strong interaction physics would suggest identification as a Minkowskian counterpart of  $2 + \bar{2}$  with a small CP breaking so that  $3 + 1$  cannot be excluded. If the  $CP_2$  projection of Minkowskian regions is indeed 3-dimensional as the construction of preferred extremals suggests then only 3  $CP_2$  polarizations are realized for same particle. Could this relate to the fact that  $K^0$  and  $\bar{K}^0$  have slightly different masses?

### Decay rate of Minkowskian pion to gamma pairs

A pion-like state transforming as  $3 + 1$  cannot correspond to Higgs since the it would leave  $Z$  boson massless. One can however ask whether this kind of vacua with massless  $Z$  and photon field could be realized and I have indeed proposed that in TGD inspired quantum biology a vacuum allowin massless  $Z$  is realized (model for the cell membrane [K21]).

Just for fun one can check if the decay rate to gamma pairs is realistic in this case. This exercise also gives idea about what kind of expression one can expect for the decay rate in  $2 + \bar{2}$  case: one actually expects that the decay rate is modified by some numerical factors only.

Consider the decay rate of pion like state to gamma pairs using PCAC. Axial current anomaly tells that the divergence  $\partial_\mu A^\mu$  of the axial current equals to  $f_\pi m_\pi^2 \pi_0$ , where  $\pi_0$  is the neutral pion field. Axial current divergence contains a part proportional to the instanton density for electromagnetic field and this defines the effective action allowing to calculate the production amplitude and rate for gamma pairs.

1. From Iztykson-Zuber [?] the decay width of pion to two-gamma would be given as

$$\Gamma(\pi) = \frac{\alpha^2 m_\pi^2}{64\pi^2 f_\pi^2} .$$

$f_\pi$  is expected to be of order  $m_{pi}$ . Let us write  $f_\pi = X m_\pi$ .

2. The decay rates of Higgs can be found here [?]. For the decay of Higgs to two photons the rate is

$$\Gamma(h) = \alpha^2 g_W^2 2^{-10} \pi^{-3} m_h^3 m_W^{-2} .$$

The prediction is exactly the same in the case of  $M_{89}$  pion. One only replaces scalar with pseudoscalar and Higgs vacuum expectation with that for pseudoscalar and given by PCAC anomaly expressible in terms of instanton density for classical induced em field  $F_{em}$  associated with the space-time sheet assignable to colliding quarks and defining the hadronic space-time sheet for  $M_{89}$  hadron physics (note that this space-time sheet could be also associated with colliding protons).

$$\pi_0(vac) = -\frac{1}{32\pi^2 m_\pi^2 f_\pi} \times I , \quad I = \epsilon_{\alpha\beta\gamma\delta} F_{em}^{\alpha\beta} F_{em}^{\gamma\delta} = 2E \cdot B .$$

Here  $F_{em}$  is defined by identifying gauge potential as  $eA_{mu}$ , which corresponds to the classical gauge potentials in TGD. It is essential that the induced electric and magnetic fields are non-orthogonal: this is true if  $CP_2$  projection of space-time sheet has dimension larger than  $d = 2$ : this is actually always the case for preferred extremals so that the generation of the analog of Higgs expectation is basic phenomenon in TGD Universe but does not give rise to massivation. Instanton density  $I$  appears as a parameter which is in the first approximation constant.

3. The ratio of these rates is for  $m(\pi) = m(h)$

$$r \equiv \frac{\Gamma(h)}{\Gamma(\pi)} = X^2[\alpha \times \sin^2(\theta_W)]^{-1} .$$

Some comments about the result are in order.

- (a) For  $X = 93/135$  holding true for the ordinary neutral pion  $\pi_0$  and  $m(h) = m(\pi) = 125$  GeV this gives  $r = 1.63$  and  $f(\pi) = 1.07m_W$ . Therefore the contribution from the axial anomaly is .61 times the contribution of the gauge kinetic term to the decay rate assuming that the contributions of the amplitudes do not interfere. Interference effects can change the situation. Therefore PCAC anomaly alone is not enough and the prediction for the ratio  $r \equiv \frac{\Gamma(h)+\Gamma(\pi)}{\Gamma(h)}$  is 1.61 times higher than predicted by Higgs. Constructive interference can give rise to 3.17 times larger rate and destructive interference to rate which is only .05 of the rate predicted by Higgs alone.

The relative phase of the amplitudes from anomaly and kinetic term is expected to vary and the first guess is that the interference term gives a vanishing contribution average contribution. Local constructive interference in phase space would allow to understand the local values of  $r$  above 1.61. The ratio of the observed Higgs to gamma pair signal cross section to the predicted one is certainly consistent with this picture! Note that the anomalous contribution is present also for W and Z since instanton term is non-Abelian and only its vacuum expectation value is Abelian. This means that also the rates to W and Z pairs are enhanced as indeed observed by ATLAS.

- (b) The value of  $I$  characterizing the hadronic space-time sheet appears in the kinetic term responsible for the decays and also in the model for the production rate. The expression for the decay rate to gamma pairs involves a relation between Higgs vacuum expectation and Higgs mass provided by standard model. This relationship need not be same for the pion like state.

One cannot predict absolute production rates without a detailed model for the electric and magnetic fields of colliding quarks or protons predicting the instanton density  $I$ . This kind of model has been proposed in [?].

### Windows to $M_{89}$ hadron physics?

Concerning the experimental testing of the theory one should have a clear answer to the question concerning the window to  $M_{89}$  hadron physics. One can imagine several alternative windows.

1. The production  $M_{89}$  pions in strong non-orthogonal electric and magnetic fields of colliding charged particles provides a possible window to  $M_{89}$  hadron physics. In this case one must consider  $M^4$  QFT limit since the electric and magnetic fields are associated with the space-time sheets assignable to the colliding charged particles. If pions are the only window to the new hadron physics, the production of other  $M_{89}$  hadrons should take place via the reactions of the pions of  $M_{89}$  pion condensate producing other  $M_{89}$  hadrons.
2. If the instanton density is non-vanishing at microscopic level one has a portal to what might be regarded as weak physics via production of Higgs like states.
3. I have also considered a window which involves transformation of ordinary gluons to those of  $M_{89}$  physics and also direct transformation of ordinary hadronic space-time sheet to that of  $M_{89}$  physics. Two gluon states transforming to  $M_{89}$  gluons could be one possibility proposed earlier. The model contains a dimensional parameter with dimensions of mass squared characterizing the amplitude for the transformation of  $M_{107}$  gluon to  $M_{89}$  gluon. Both these p-adic length scales are natural parameters defining the dimensional parameter: the product of corresponding p-adic mass scales is the most natural guess.
4. Electroweak gauge bosons correspond to closed flux tubes decomposing to long and short parts. Two short flux tubes associated with the two wormhole contacts connecting the opposite throats define the "Higgsy" pions. Two long flux tubes connect two wormhole contacts at distance of

order weak length scale and define  $M_{89}$  pions and mesons in the more general case. This allows an interpretation as electroweak "de-confinement" transition producing  $M_{89}$  mesons and possibly also baryons. This kind of transition would be rather natural and would not require any specific mechanisms. Maybe the interpretation as a portal to  $M_{89}$  hadron physics makes sense.

### Connection with dark matter searches?

An additional fascinating thread to the story comes from the attempts to detect dark matter. The prediction of TGD approach is that dark matter resides at magnetic flux tubes as phases with large value of Planck constant and that dark energy corresponds to the magnetic energy of the flux tubes and is characterized by a gigantic value of (effective) Planck constant [K25]. This leads to a rather detailed vision about cosmic evolution with magnetic energy replacing the vacuum energy assigned with inflaton fields. The decay of the magnetic flux tubes rather than vacuum expectation of inflaton field would create ordinary matter and dark matter [K66].

The results of the dark matter searches are inconclusive. Some groups claim the detection of what they identify as dark matter [?, ?], some groups see nothing [?, ?]. The analysis is sensitive to the assumptions made and if the assumption that dark matter corresponds to WIMPs - say neutralino of standard SUSY- the analysis might fail. Second source of failure relates to the distribution of dark matter. For instance, the standard assumption about spherical halos around galaxies might be wrong and TGD indeed suggests that this particular form of dark matter is concentrate string like magnetic flux tubes containing galaxies around it like pearls in a necklace.

It has been reported that the nearby space around Earth does not contain dark matter [?]. On the other hand, evidence for string like magnetic flux tubes containing dark matter and connecting galactic clusters has been reported [?]. Even if dark matter candidates are detected, they could be fake since the particles in question could be created in atmosphere in the collisions of highly energetic cosmic rays creating hadrons of  $M_{89}$  hadron physics: certain mysterious cosmic ray events with ultra high energies could be indeed due to  $M_{89}$  hadron physics [?].

Independent positive reports come from groups studying the data from Fermi satellite in the hope of identifying particles of galactic dark matter. 3 sigma evidence has been represented for the claim that there is signal for dark particle with mass around 130 GeV [?]. Gamma pairs would be produced in the annihilation of particles with this mass. Another group [?] reports a signal at the same energy but argues that due to kinematical effects this signal actually corresponds to a particle with a mass of about 145 GeV: similar signal was earlier reported earlier by CDF at Fermilab [?]. Also some indications for a signal at 110 GeV is proposed by the latter group: direct extrapolation to take into account the kinematical effects would suggest a particle at 125 GeV. It has been also claimed that the signal is too strong to be interpreted as neutralino, the main candidate for a WIMP defining dark matter in the standard sense [?]. This is a further blow against standard SUSY. If the Higgs candidate is actually a pionlike state of scaled up variant of hadron physics, one can ask whether  $M_{89}$  hadron physics could be active in the extreme conditions of the galactic center and lead to a copious production of pionlike state of  $M_{89}$  physics annihilating and decaying to gamma pairs.

### 7.5.3 Pseudo-scalar Higgs as Euclidian pion?

The preceding observations and earlier work suggest that pionlike states in TGD framework could be analogous to Higgs like particles. This raises questions. Assuming that QFT in  $M^4$  is a reasonable approximation, does a modification of standard model Higgs mechanism allow to approximate TGD description? What aspects of Higgs mechanism remain intact when Higgs is replaced with pseudo-scalar? Could these aspects be assignable to the massivation of weak gauge bosons?

The key idea allowing to answer these questions is that "Higgsy" pion and ordinary  $M_{89}$  pion are not one and the same thing: the first one corresponds to Euclidian flux tube and the latter one to Minkowskian flux tube and they transform according to  $2+\bar{2}$  and  $3+1$  under  $u(2) \subset su(3)$  respectively.

Hegel would say that one begins with thesis about Higgs, represents anti-thesis replacing Higgs with pion, and ends up with a synthesis in which Higgs is transformed to pseudo-scalar Higgs, "Higgsy" pion, or Higgs like state if you wish! Higgs certainly loses its key role in the massivation of fermions.

### Can one assume that $M^4$ QFT limit exists?

The above approach assumes implicitly - as all comparisons of TGD with experiment - that  $M^4$  QFT limit of TGD exists. The analysis of the assumptions involved with this limit helps also to understand what happens in the generation of "Higgsy" pions.

1. QFT limit involves the assumption that quantum fields and also classical fields superpose in linear approximation. This is certainly not true at given space-time sheet since the number of field like is only four by General Coordinate Invariance. The resolution of the problem is simple: only the effects of fields carried by space-time sheets superpose and this takes place in multiple topological condensation of the particle on several space-time sheets simultaneously. Therefore  $M^4$  QFT limit can make sense only for many-sheeted space-time.
2. The light-like 3-surfaces representing lines of Feynman graphs effectively reduce to braid strands and are just at the light-like boundary between Minkowskian and Euclidian regions so that the fermions at braid strands can experience the presence of the instanton density also in the more fundamental description. The constancy of the instanton density can hold true in a good approximation at braid strands. Certainly the  $M^4$  QFT limit treats Euclidian regions as 1-dimensional lines so that instanton density is replaced with its average.
3. In particular, the instanton density can be non-vanishing for  $M^4$  limit since  $E$  and  $B$  at different space-time sheets can superpose at QFT limit although only their effects superpose in the microscopic theory. At given space-time sheet  $I$  can be non-vanishing only in Euclidian regions representing lines of generalized Feynman graphs.
4. The mechanism leading to the creation of pion like states is assumed to be the presence of strong non-orthogonal electric and magnetic fields accompanying colliding charged particles [?]: this of course in  $M^4$  QFT approximation. Microscopically this corresponds to the presence of separate space-time sheets for the colliding particles. The generation of "Higgsy" pion condensate or pion like states must involve formation of wormhole contacts representing the "Higgsy" pions. These wormhole contacts must connect the space-time sheets containing strong electric and magnetic fields.

### Higgs like pseudo-scalar as Euclidian pion?

The recent view about the construction of preferred extremals predicts that in Minkowskian space-time regions the  $CP_2$  projection is at most 3-D. In Euclidian regions  $M^4$  projection satisfies similar condition. As a consequence, the instanton density vanishes in Minkowskian regions and pion can generate vacuum expectation only in Euclidian regions. Long Minkowskian flux tubes connecting wormhole contacts would correspond to pion like states and short Euclidian flux tubes connecting opposite wormhole throats to "Higgsy" pions.

1. If pseudo-scalar pion like state develops a vacuum expectation value the QFT limit, it provides weak gauge bosons with longitudinal components just as in the case of ordinary Higgs mechanism. Pseudo-scalar boson vacuum expectation contributes to the masses of weak bosons and predicts correctly the ratio of W and Z masses. If p-adic thermodynamics gives a contribution to weak boson masses it must be small as observed already earlier. Higgs like pion cannot give dominant contributions to fermion masses but small radiative correction to fermion masses are possible.

Photon would be massless in 4-D sense unlike weak bosons. If ZEO picture is correct, photon would have small longitudinal mass and should have a third polarization. One must of course remain critical concerning the proposal that longitudinal  $M^2$  momentum replaces momentum in gauge conditions. Certainly only longitudinal momentum can appear in propagators.

2. If three components of Euclidian pion are eaten by weak gauge bosons, only single neutral pion-like state remains. This is not a problem if ordinary pion corresponds to Minkowskian flux tube. Accordingly, the 126 GeV boson would correspond to the remaining component Higgs like Euclidian pion and the boson with mass around 140 GeV for which CDF has provided some evidence to the Minkowskian  $M_{89}$  pion [?] and which might have also shown itself in dark matter searches [?, ?].

3. One can consider two candidates for pion like pseudo-scalars as states whose form apart from parallel translation factor is  $\Psi_1 j^{Ak} \gamma_k \Psi_2$  (see Appendix). Here  $j^A$  is generator of color isometry either in  $U(2)$  sub-algebra or its complement. The state in  $U(2)$  algebra transforms as  $3+1$  under  $U(2)$  and the state in its complement like  $2 + \bar{2}$  under  $U(2)$ .

These states are analogous of  $CP_2$  polarizations, whose number can be at most four. One must select either of these polarization basis.  $2 + \bar{2}$  is an unique candidate for the Higgs like pion and can be naturally assigned with the Euclidian regions having Hermitian structure.  $3+1$  in turn can be assigned naturally to Minkowskian regions having Hamilton-Jacobi structure.

Ordinary pion has however only three components. If one takes seriously the construction of preferred extremals the solution of the problem is simple:  $CP_2$  projection is at most 3-dimensional so that only 3 polarizations in  $CP_2$  direction are possible and only the triplet remains. This corresponds exactly to what happens in sigma model combining describing pion field as field having values at 3-sphere.

4. Minkowskian and Euclidian signatures correspond naturally to the decompositions  $3+1$  and  $2+\bar{2}$ , which could be assigned to quaternionic and co-quaternionic subspaces of  $SU(3)$  Lie algebra or imbedding space with tangent vectors realized in terms of the octonionic representation of gamma matrices.

One can proceed further by making objections.

1. What about kaon, which has a natural  $2 + \bar{2}$  composition but can be also understood as  $3 + 1$  state? Is kaon is Euclidian pion which has not suffered Higgs mechanism? Kaons consists of  $u\bar{s}$   $d\bar{s}$  and their antiparticles. Could this non-diagonal character of kaon states explain why all four states are possible? Or could kaon corresponds to Minkowskian triplet plus singlet remaining from the Euclidian variant of kaon? If so, then neutral kaons having very nearly the same mass - so called short lived and long lived kaons - would correspond to Minkowskian and Euclidian variants of kaon. Why the masses if these states should be so near each other? Could this relate closely to  $CP$  breaking for non-diagonal mesons involving mixing of Euclidian and Minkowskian neutral kaons? Why  $CP$  symmetry requires mass degeneracy?
2. Are also  $M_{107}$  electroweak gauge bosons? Could they correspond to dark variant of electroweak bosons with non-standard value of Planck constant? This would predict the existence of additional - possibly dark - pion-like state lighter than ordinary pion. The Euclidian neutral pion would have mass about  $(125/140) \times 135 \sim 125$  MeV from scaling argument. Interestingly, there is evidence for satellites of pion: they include also a states which are lighter than pion [?]. The reported masses of these states would be  $M = 62, 80, 100, 181, 198, 215, 227.5,$  and  $235$  MeV. 125 MeV state is not included. The interpretation of these states is as IR Regge trajectories in TGD framework.

### How the vacuum expectation of the pseudo-scalar pion is generated?

There are two options to choose concerning the identification of the Euclidian pion.  $2 + \bar{2}$  defining the complement of  $u(2) \subset su(3)$  defines the analog of kaon and antikaon for old-fashioned flavor  $SU(3)$ .  $3 + 1$  in  $u(2)$  is second option but it is easy to see that this option fails.

Euclidian regions have 4-D  $CP_2$  projection so that the instanton density is non-vanishing and Euclidian pion can generate vacuum expectation for both options. In the following an attempt to understand details of this process is made using the unique Higgs potential consistent with conformal invariance.

1. The first observation is that in the case of  $2 + \bar{2}$  the standard form of the Higgs potential gives rise to massivation and the formulas are exactly same as in the standard model. In the standard model the mass term must be tachyonic. This leads to the so called hierarchy problem [?] The source of the problem are the couplings of Higgs to fermions proportional to the mass of fermion. The radiative corrections to Higgs mass squared are positive and proportional to fermion mass so that top quark gives the dominating contribution. This implies that the sign of the mass squared can become positive and the state with vanishing vacuum expectation value of Higgs field becomes the ground state. In the recent case this is not a problem since fermions couple to the  $2 + \bar{2}$  pion like state only radiatively.

2. If the Higgs mass is of order  $O(p)$  p-adically, the lowest order contribution to Higgs mass is  $m_{min}^2 = m^2(CP_2)/p$ . This mass is obtained by scaling the p-adic mass scale  $m_{127}$  assignable to electron having upper bound  $m_{127} \leq m_e/\sqrt{5}$  with the factor  $\sqrt{M_{127}/M_{89}} \simeq 2^{(127-89)/2}$ . This gives  $m_{min} \leq 119.8$  GeV, which is about 4 per cent smaller than the actual mass estimate 125 GeV. This suggests that p-adic mass squared of Euclidian pion is given by  $m_\pi^2 = p + O(p^2)$  mapping to  $m_{\pi,R}^2 = 1/p + O(p^{-2})$  by canonical identification  $\sum x_n p^n \rightarrow \sum x_n p^{-n}$ . The correction could be due to radiative corrections or second order contributions from p-adic thermodynamics. Note that the vacuum expectation value of Higgs is  $v = 246$  GeV, which is slightly larger than  $v = 2m_{min}$ .

The most important result is a solution of the hierarchy problem and one could stop here. One should however have an explanation for the anomalous production of gamma pairs and also a microscopic theory for the tachyonic mass term.

### The microscopic origin of the tachyonic mass term

In the proposed model predicts p-adic thermodynamics does not give rise to the physical Higgs mass. As a matter fact, there are also other arguments forbidding this. 125 GeV is very near to minimal one in p-adic thermodynamics for  $T_p = 1$  for single fermion. Now Higgs like particle consists of a superposition of fermion and antifermion pairs with non-minimal p-adic masses so that the lower bound for minimal mass is two times larger and the mass would be thermodynamical. Hence the physical mass cannot be due to p-adic thermodynamics with  $T_p = 1$  for  $p = M_{89}$ . Of course, the tachyonic mass term cannot be due to p-adic thermodynamics since it gives rise to positive mass squared.

The problem is to understand the origin of the tachyonic mass term.

1. The original erratic ideas was that Higgs like boson has a linear coupling to the instanton density for weak fields: this indeed gives Higgs a mass assuming only that besides the instanton term there is a non-tachyonic mass term in the Higgs potential. In Euclidian regions classical instanton term defined by the induced gauge fields develops a vacuum expectation value and would give rise to mass term. This works if Higgs has the structure  $3+1$  under electroweak  $U(2)$  but not for  $2+\bar{2}$ . Linear coupling is favored by anomaly considerations in the case of ordinary pion transforming as  $3+1$  under  $u(2)$  and also in the case of  $M_{89}$  pion one can expect this kind of term.
2. It is easy to modify the instanton term so that it gives rise to an effective mass term. This term is just the expectation value for the product  $F \wedge *F$  (YM action density) or  $F \wedge F$  (instanton term) in the "state" defined by the 2-spinor representing Higgs like field. Since Higgs like field and its conjugate appear in a bilinear manner in the interaction term, one obtains net scalar contribution from Higgs like fields irrespective of whether the Higgs like field is scalar or pseudoscalar or something between them. In ordinary QFT CP and P invariance would require therefore  $F \wedge *F$  in order to get a scalar.
3. One can wonder whether all electroweak gauge boson fields can appear in the interaction terms. The assumption that only the induced Kähler form is present is very natural one and might be forced by mathematical consistency. In this case only  $Z^0$  and  $\gamma$  would appear in the interaction term: the reason is that their charge matrices contain electro-weak hyper-charge  $Y$ . Therefore only  $Z$  and  $\gamma$  pairs would be produced anomalously in the decays of the Higgs like particle.

The instanton density  $F \wedge F$  is non-vanishing in the Euclidian regions for single space-time sheet. If one restricts  $F$  to be the induced Kähler form,  $F \wedge *F$  and  $F \wedge F$  are identical for  $CP_2$  type vacuum extremals by their self duality. Hence one might hope that the resulting CP breaking effects are small and could relate to the CP breaking occurring in hadron physics and having no explanation in terms of a microscopic theory. One must be however very cautious with interpretations: the point is that CP and P are defined at the level of imbedding space and P and CP for instanton term at space-time level. It is not clear whether these notions of CP and P are equivalent.

4. If one accepts this picture, the mass term in Higgs potential is replaced by effective mass term and one would have

$$\frac{m^2}{2}\overline{H}H \rightarrow K\overline{H}(aF \wedge *F + bF \wedge F)H . \quad (7.5.1)$$

The condition that the mass squared term is tachyonic, dictates the sign of the factor  $K$  if one assumes that the Euclidian region can be approximated by  $CP_2$  type vacuum extremal in the lowest approximation. The value of the Euclidian YM action is always negative so that  $K$  must be positive. This mass term gives at braid strands a constant term of the Higgs potential. The two extreme options corresponding to  $(a = 1, b = 0)$  and  $(a = 0, b = 1)$ .

5. What can one say about the value of the parameter  $K$ ?  $K$  has dimensions of length squared, and the first guess is that  $K$  is proportional to  $m_p^2/m_{CP_2}^2 \propto 1/p$  with  $p = M_{89}$  in the recent case. The values of the action terms are identical for  $CP_2$  type vacuum extremals and do not depend on  $p$ . This option however predicts extremely small value of  $K$  and therefore extremely low anomalous decay rate to gamma pairs. Therefore the reasonable option is that both  $F \wedge *F$  and  $F \wedge F$  are of order  $1/L_p^4$  and  $K \sim L_p^2$  holds true. The interpretation could be that the  $CP_2$  type vacuum extremal is deformed to  $M^4$  directions and its  $M^4$  projection has size of order  $L_p$ .
6. The model avoids the hierarchy problem and explains massivation and the emergence of longitudinal polarizations of weak bosons in standard manner. Higgs like particle could be either scalar or pseudoscalar. The model explains also the two-gamma anomaly. The reason is that the effective mass squared term gives in linearization a term, which makes possible the decays of Higgs to gauge boson pairs.

$$K [\overline{\delta H}(aF \wedge *F + bF \wedge F)H_0 + \overline{H}_0(aF \wedge *F + bF \wedge F)\delta H] . \quad (7.5.2)$$

This term could explain the anomalous production of gamma pairs and predicts also anomalous production of Z pairs and for the most general YM terms also that of W boson pairs. There are 4 unknown real parameters corresponding to  $K$ ,  $a/b$ , and the average values of  $F \wedge *F$  and  $F \wedge F$ . Higgs expectation  $\mu$  and tachyonic Higgs mass squared combined with the p-adic length scale hypothesis give constraints on the parameters. Interesting special cases correspond to  $a = 0$  resp.  $b = 0$  suggesting maximal/minimal CP breaking. The parity of the Euclidian pion does not pose constraints on the action term.

7. The relative phase between the instanton term and kinetic term of pion like state is highly relevant to the decay rate. If the relative phase corresponds to imaginary unit then the rate is just the sum of the anomalous and non-anomalous rates since interference is absent.

### An estimate for the magnitude of the parameter $K$

One can evaluate the magnitude of the anomalous contribution to the decay rate by using standard Feynman rules and the proposed interaction term. Interference with the standard contribution is not excluded so that one should not draw too far reaching conclusions from the estimate. The differential of the decay rate is obtained by using a general expression for the decay rate of a massive particle to two-boson final state given in the Appendix of [?]:

$$\begin{aligned} d\Gamma &= \frac{1}{2m_H}|T|^2 d\mu , \\ d\mu &= (2\pi)^{-2} \frac{d\Omega}{4} . \end{aligned} \quad (7.5.2)$$

For  $|T|^2$  one has in the case of gamma pair

$$\begin{aligned} |T|^2 &= K^2(4\pi\alpha)^2\mu^2|af \circ f + b\tilde{f} \circ f|^2 , \\ f \circ f &= f^{\mu\nu}f_{\mu\nu} , \quad \tilde{f} \circ f = \frac{1}{2}\epsilon^{\mu\nu\gamma\delta}f_{\mu\nu}f_{\gamma\delta} , \quad f_{\mu\nu} = \epsilon_\mu k_\nu - \epsilon_\nu k_\mu . \end{aligned} \quad (7.5.2)$$

Here  $\mu$  denotes Higgs vacuum expectation ( $\mu \simeq 246$  GeV). The factor  $(4\pi\alpha)^2 = (e^2/\hbar)^2$  comes from the  $e^2/\hbar$  factors associated with  $F \circ F$  and  $\bar{F} \circ F$ .

The trivial integration over final state momenta and the averaging over the angle between polarization directions gives the expression for the magnitude of the anomalous contribution to the decay rate

$$\begin{aligned}\Gamma_{ano} &= \frac{X^2}{2\pi} \frac{\mu^2}{m_H} (4\pi\alpha)^2 (a^2 + b^2) , \\ X &\equiv K m_H^2\end{aligned}\tag{7.5.2}$$

The standard model prediction  $\Gamma_{stand}$  for the decay rate to gamma pairs [?] is given by the expression

$$\Gamma_{stand} = (\alpha)^2 g_W^2 2^{-10} \pi^{-3} m_h^3 m_W^{-2} .\tag{7.5.3}$$

If the two contributions to the decay rate sum up incoherently, and if one estimates the ratio of the anomalous rate to the standard model rate to be  $x = .6$  (the observed rate would be 1.6 times higher than predicted), one obtains for the parameter  $X^2(a^2 + b^2)$  the estimate

$$X^2(a^2 + b^2) = 2\pi \times 2^{-10} \times (4\pi)^2 \times (m_H/m_W)^2 \times x \simeq 1.41 .\tag{7.5.4}$$

The value of  $r \equiv K\sqrt{a^2 + b^2}/m_H \simeq 1.19$  looks rather natural taking into account that  $m_H$  is slightly larger than the primary p-adic mass scale squared associated with  $M_{89}$ .  $K\sqrt{a^2 + b^2} = 1/m(M_{89})^2 = L_{89}^2$  is a reasonable first guess.

#### 7.5.4 About the microscopic description of gauge boson massivation

The conjectured QFT limit allows to estimate the quantitative predictions of the theory. This is not however enough. One should identify the microscopic counterparts for various aspects of gauge boson massivation relying on Euclidian pion - something radically new in the space-time ontology. There is also the question about the consistency of the gauge theory limit with the ZEO inspired view about massivation and suggesting gauge conditions differing dramatically from the conventional ones. The basic challenge are obvious: one should translate notions like Higgs vacuum expectation, massivation of gauge bosons, and finite range of weak interactions to the language of wormhole throats, Kähler magnetic flux tubes, and string world sheets.

#### Elementary particles in ZEO

Let us first summarize what kind of picture ZEO suggests about elementary particles.

1. Kähler magnetically charged wormhole throats are the basic building bricks of elementary particles. The lines of generalized Feynman diagrams are identified as the Euclidian regions of space-time surface. The weak form of electric magnetic duality forces magnetic monopoles and gives classical quantization of the Kähler electric charge. Wormhole throat is a carrier of many-fermion state with parallel momenta and the fermionic oscillator algebra gives rise to a badly broken large  $\mathcal{N}$  SUSY [?].
2. The first guess would be that elementary fermions correspond to wormhole throats with unit fermion number and bosons to wormhole contacts carrying fermion and antifermion at opposite throats. The magnetic charges of wormhole throats do not however allow this option. The reason is that the field lines of Kähler magnetic monopole field must close. Both in the case of fermions and bosons one must have a pair of wormhole contacts connected by flux tubes. The most general option is that net quantum numbers are distributed amongst the four wormhole throats. A simpler option is that quantum numbers are carried by the second wormhole: fermion quantum numbers would be carried by its second throat and bosonic quantum numbers by fermion and antifermion at the opposite throats. All elementary particles would therefore be accompanied by parallel flux tubes and string world sheets.

3. A cautious proposal in its original form was that the throats of the other wormhole contact could carry weak isospin represented in terms of neutrinos and neutralizing the weak isospin of the fermion at second end. This would imply weak neutrality and weak confinement above length scales longer than the length of the flux tube. This condition might be un-necessarily strong.

The realization of the weak neutrality using pair of left handed neutrino and right handed antineutrino or a conjugate of this state is possible if one allows right-handed neutrino to have also unphysical helicity. The weak screening of a fermion at wormhole throat is possible if  $\nu_R$  is a constant spinor since in this case Dirac equation trivializes and allows both helicities as solutions. The new element from the solution of the modified Dirac equation is that  $\nu_R$  would be interior mode delocalized either to the other wormhole contact or to the Minkowskian flux tube. The state at the other end of the flux tube is spartner of left-handed neutrino.

It must be emphasized that weak confinement is just a proposal and looks somewhat complex: Nature is perhaps not so complex at the basic level. To understand this better, one can think about how  $M_{89}$  mesons having quark and antiquark at the ends of long flux tube returning back along second space-time sheet could decay to ordinary quark and antiquark.

### ZEO and gauge conditions

ZEO suggests a new approach to gauge conditions. The proposal is of course something which must be taken with extreme cautiousness.

1. In ZEO all wormhole throats - also those associated with virtual particles - are massless. Fermionic propagators identified as 4-D massless propagators would diverge identically. The first guess is that only the longitudinal momentum  $p_L$  defined as  $M^2$  projection of four-momentum appears in propagators. The construction of the functional integral however implies that the propagator defined by the modified Dirac operator appears naturally in the fermion part of perturbation theory. For the light-like braid strands the perturbation theory for fermion  $n$ -point function is conjectured to reduce from stringy perturbation theory to 1-D theory involving only the fermion propagators assigned with the braid strands. The propagator defined by the modified Dirac operator need not of course reduce to  $M^2$  propagator even in this case but this is possible in principle. The momentum in the propagator brings in mind the region momentum of the twistor approach.
2. In the light of 2-D fermionic propagation it would not be terribly surprising if  $p_L$  would appear in the gauge conditions for the physical states so that one would have  $p_L \cdot \epsilon = 0$ .  $M^2$  would be the counterpart of string world sheet at imbedding space level and its presence is strongly suggested both by number theoretical vision and by ZEO. For  $M^2$  option also the third polarization is possible for states massless in 4-D sense - a clear signal about longitudinal massivation (at least this) of gauge bosons. The simplest interpretation of the p-adic mass calculations for fermions would be that p-adic thermodynamics gives longitudinal momentum squared as a thermal expectation value in a state satisfying Virasoro conditions and having massless state as the ground state. One must be however very cautious in introducing completely new elements to the theory.
3. The introduction of  $M^2$  does not Lorentz invariance since one has integral over all  $CDs$  characterized by the choice of  $M^2 \subset M^4$  defining the energy quantization axis (rest system) and spin quantization axis. One should demonstrate that this integration yields sensible scattering amplitudes.

To sum up, for states consisting of several wormhole throats longitudinal massivation allows state to be massless in 4-D sense but does not require this. At least weak bosons could be massive also in 4-D sense, maybe also photon.

### Gauge bosons and pseudoscalars must be massive in 4-D sense

What Higgs mechanism for gauge bosons really means? Is it a QFT counterpart for the  $M^2$  massivation or for a massivation in 4-D sense? The wormhole contacts could have non-parallel massless momenta without giving up the idea about on mass shell massless propagation essential for the twistor approach so that the answer to the question is not obvious. For fermions p-adic thermodynamics suggests

strongly longitudinal massivation and masslessness in 4-D sense. Internal consistency would favor  $M^2$  massivation also in the case of bosons.

The construction of massless states for bosons assuming that second wormhole contact carries the momentum however yields a surprise: spin 1 bosons are necessarily massive in 4-D sense whereas spin 0 bosons can be massless. The Higgs mechanism based on instanton anomaly however implies the massivation of also pseudoscalar bosons. Scalar boson states are the only ones that can remain massless. 4-D form of gauge conditions is therefore possible and obviously the safest option also in ZEO.

Consider now the argument in detail.

1. If one assumes that both fermions are not only massless but also have only physical polarization (in other words satisfy massless Dirac equation with the same sign of energy) one finds that fermion-antifermion state with parallel four-momenta must have vanishing net spin since fermion and antifermion with same  $M^4$  chirality have opposite helicities. Thus it would seem that spin 0 states can be massless but that all spin 1 particles, including photon and gluon, are inherently massive in 4-D sense since the momenta of fermions cannot be exactly parallel. What is important is that this holds true irrespective of gauge conditions.
2. Indeed, if fermions are massless on mass shell states satisfying therefore also massless Dirac equation in  $M^4$ , wormhole throats must carry slightly non-parallel light-like momenta in order to have helicity one states. Massivation of spin one states is unavoidable. Situation changes if one requires masslessness but gives up massless Dirac equation for second fermion so that it can have opposite energy or 3-momentum implying non-physical polarization. The value of either fermion or antifermion energy can dominate and corresponding momentum defines the direction of helicity for the non-vanishing helicity. This being the case one could use also  $M^4$  momentum in gauge conditions since one would obtain three polarizations in any case.
3. If only  $M^2$  momentum appears in the gauge conditions, also the longitudinal polarization is possible for states which remain massless in 4-D sense (note however that this requires unphysical polarization state). This is possible because  $M^2$  momentum is in general massive: wormhole throats can carry parallel massless 4-momenta with massive  $M^2$  momentum.
4. Spinless states exactly massless states with on mass shell fermions with physical helicities are possible since the spins of the parallel on mass shell massless fermion and antifermion sum up to zero. The analog of Higgs mechanism would however make this state massive making the momenta slightly un-parallel. If also the wormhole throat at the second end of flux tube carries momentum, the massivation mechanism is more complex.

It must be noticed that the massivation of gauge bosons is obtained without any reference to Higgs like particle. In gauge theory context the choice of gauge transfers part of Higgsy degrees of freedom to gauge bosons.

### The role of string world sheets and magnetic flux tubes in massivation

What is the role of string world sheets and flux tubes in the massivation? At the fundamental level one studies correlation functions for particles and finite correlation length means massivation.

1. String world sheets define as essential element in 4-D description. All particles are basically bi-local objects: pairs of string at parallel space-time sheets extremely near to each other and connected by wormhole contacts at ends. String world sheets are expected to represent correlations between wormhole throats.
2. Correlation length for the propagator of the gauge boson characterizes its mass. Correlation length can be estimated by calculating the correlation function. For bosons this reduces to the calculation of fermionic correlations functions assignable to string world sheets connecting the upper and lower boundaries of  $CD$  and having four external fermions at the ends of  $CD$ . The perturbation theory reduces to functional integral over space-time sheets and deformation of the space-time sheet inducing the deformation of the induced spinor field expressible as convolution of the propagator associated with the modified Dirac operator with vertex factor defined by the

deformation multiplying the spinor field. The external vertices are braid ends at partonic 2-surfaces and internal vertices are in the interior of string world sheet. Recall that the conjecture is that the restriction to the wormhole throat orbits implies the reduction to diagrams involving only propagators connecting braid ends. The challenge is to understand how the coherent state assigned to the Euclidian pion field induces the finite correlation length in the case of gauge bosons other than photon.

3. The non-vanishing commutator of the gauge boson charge matrix with the vacuum expectation assigned to the Euclidian pion must play a key role. The study of the modified Dirac operator suggests that the braid strands contain the Abelianized variant of non-integrable phase factor defined as  $\exp(i \int A dx)$ . If  $A$  is identified as string world sheet Hodge dual of Kac-Moody charge the opposite edges of string world sheet with geometry of square given contributions which compensate each other by conservation of Kac-Moody charge if  $A$  commutes with the operators building the coherent Higgs state. For photon this would be true. For weak gauge bosons this would not be the case and this gives hopes about obtaining destructive interference leading to a finite correlation length.

One can also consider try to build more concrete manners to understand the finite correlation length.

1. Quantum classical correspondence suggests that string with length of order  $L \sim \hbar/E$ ,  $E = \sqrt{p^2 + m^2}$  serves as a correlate for particle defined by a pair of wormhole contacts. For massive particle wave length satisfies  $L \leq \hbar/m$ . Here  $(p, m)$  must be replaced with  $(p_L, m_L)$  if one takes the notion of longitudinal mass seriously. For photon standard option gives  $L = \lambda$  or  $L = \lambda_L$  and photon can be a bi-local object connecting arbitrarily distant objects. For the second option small longitudinal mass of photon gives an upper bound for the range of the interaction. Also gluon would have longitudinal mass: this makes sense in QCD where the decomposition  $M^4 = M^2 \times E^2$  is basic element of the theory.
2. The magnetic flux tube associated with the particle carries magnetic energy. Magnetic energy grows as the length of flux tube increases. If the flux is quantized magnetic field behaves like  $1/S$ , where  $S$  is the area of the cross section of the flux tube, the total magnetic energy behaves like  $L/S$ . The dependence of  $S$  on  $L$  determines how the magnetic energy depends on  $L$ . If the magnetic energy increases as function of  $L$  the probability of long flux tubes is small and the particle cannot have large size and therefore mediates short range interactions. For  $S \propto L^\alpha \sim \lambda^\alpha$ ,  $\alpha > 1$ , the magnetic energy behaves like  $\lambda^{-\alpha+1}$  and the thickness of the flux tube scales like  $\sqrt{\lambda^\alpha}$ . In case of photon one might expect this option to be true. Note that for photon string world sheet one can argue that the natural choice of string is as light-like string so that its length vanishes.

What kind of string world sheets are possible? One can imagine two options.

1. All strings could connect only the wormhole contacts defining a particle as a bi-local object so that particle would be literally the geometric correlate for the interaction between two objects. The notion of free particle would be figment of imagination. This would lead to a rather stringy picture about gauge interactions. The gauge interaction between systems  $S_1$  and  $S_2$  would mean the emission of gauge bosons as flux tubes with charge carrying end at  $S_1$  and neutral end. Absorption of the gauge boson would mean that the neutral end of boson and neutral end of charge particle fuse together line the lines of Feynman diagram at 3-vertex.
2. Second option allows also string world sheets connecting wormhole contacts of different particles so that there is no flux tube accompanying the string world sheet. In this case particles would be independent entities interacting via string world sheets. In this case one could consider the possibility that photon corresponds to string world sheet (or actually parallel pair of them) not accompanied by a magnetic flux tube and that this makes the photon massless at least in excellent approximation

The first option represents the ontological minimum.

### The counterpart of Higgs vacuum expectation in microscopic language

The challenge is to translate the QFT description of gauge boson massivation to microscopic description. One can say that gauge bosons "eat" the components of Higgs. In unitary gauge one gauge rotates Higgs field to electromagnetically neutral direction defined by the vacuum expectation value of Higgs. The rotation matrix codes for the degrees of freedom assignable to non-neutral part of Higgs and they are transferred to the longitudinal components of Higgs in gauge transformation. This gives rise to the third polarization direction for gauge boson.

1. In path integral formulation the description of the situation is straightforward: unfortunately the mathematical status of path integral formalism is not established. This formulation does not have any obvious connection with its microscopic counterpart in TGD framework.
2. In QFT language the generation of vacuum expectation value could correspond to a formation of coherent state defined as eigenstate for the negative frequency part of Higgs field and obtained by acting with the exponential of positive frequency part of Higgs field to vacuum. Formally can regard the state as a continuous tensor product of states associated with point of 3-space with coherent state with same coherence parameter at each point. Also this notion is mathematically questionable. The parameter in the exponential would be a parameter with dimensions of mass and define the vacuum expectation value of Higgs like field. Note that the Higgs expectation can be constant although the coherent state contains many particle states associated with all possible frequencies and momenta.

One might hope that the latter description has a microscopic counterpart. Higgs like state is a wormhole contact with fermion and antifermion at the throats. This state is different from its Hermitian conjugate since the permutation of the wormhole throats takes place in Hermitian conjugation. One might hope that this pair of operators defines a pair of bosonic operators analogous to a pair formed by bosonic annihilation and creation operator, and that the exponential of the creation operator like part acting on vacuum would define the counterpart of coherent state now. More general coherent state  $|coh\rangle$  could be defined by a series in monomials  $P_{m_1, \dots, m_n}^{N\dagger} = a^{\dagger, m_1} \dots a^{\dagger, m_n}$  of fermionic creation operators with some coefficients  $C_{m_1, \dots, m_n}$ . One can also assume some canonical ordering of the oscillator operators.

The counterpart  $A$  of the bosonic annihilation operator would be defined by the Higgs like state as a sum  $\sum_{mn} A_{mn} P_{mn}^2$  of monomials  $P_{mn}^2 = a_m a_n$  of two fermionic annihilation operators with some coefficients.

The action of a pair  $a_m a_n$  of annihilation operators in  $A$  on  $P_{m_1, \dots, m_N}^N$  produces zero if either of the operators is not contained in  $P^{N\dagger}$  and otherwise cancels the  $a_m^\dagger$  and  $a_n^\dagger$  from it. There is also a sign factor from anticommutators. In the lowest order term one would have  $\sum_{mn} A_{mn} C_{mn} P_{mn}^{2\dagger} = h$ . General conditions would read

$$\begin{aligned} & \sum_{n_1 n_2} A_{n_1 n_2} C_{m_1, \dots, m_N} P_{m_1, \dots, \hat{m}_r, \dots, \hat{m}_s, \dots, m_N}^{N\dagger} \delta_{n_1, m_r} \delta_{n_2, m_s} (-1)^{r+s+\epsilon(r,s)} \\ &= h \times C_{m_1, \dots, m_N} P_{m_1, \dots, m_N}^{N-2\dagger} . \\ & \epsilon(r, s) = 0 \text{ for } r < s \text{ , } \epsilon(r, s) = 1 \text{ for } r > s \text{ .} \end{aligned} \tag{7.5.5}$$

Apart from  $n_1$  and  $n_2$  all indices appearing  $P^{N\dagger}$  appear in  $P^{N-2\dagger}$  in the same order. The equations have a solution only if the number of the oscillator operators is infinite since if  $N_{max}$  is finite, the action produces a polynomial of degree  $N_{max} - 2$ . One can of course consider the weakening of the coherence conditions so that it need not hold for the highest monomials. Finite measurement resolution indeed suggest that the number of oscillator operators is finite and proportional to the number braid strands.

The parameter  $h$  defining the vacuum expectation value should be proportional to the electromagnetic part of instanton density at the end of braid strand. Each component of the Euclidian pion is pseudoscalar so that  $h$  must be pseudoscalar and proportionality to instanton density is the only possible option. The value of the parameter characterizing the instanton density should be characterized by p-adic length scale. Since one needs the Higgs expectation only at the ends of braid strands, the coherent state is well defined since everything is discrete.

### 7.5.5 Could Higgs mechanism provide a description of p-adic particle massivation at QFT limit?

The most recent TGD based explanation of the observed Higgs like state with 125 GeV mass is as "half-Higgs" identified as "Euclidian pion". Euclidian pion would give a dominating contribution to the masses of gauge bosons but the contribution to fermion masses would be negligible and come from p-adic thermodynamics. This scenario saves from the hierarchy problem resulting from fermionic loops giving large contribution from heavy fermion masses and destabilizes Higgs mechanism. It is also known that for the observed mass of the Higgs like state Higgs vacuum is unstable.

What if the Higgs like state decays to fermions pairs with the rate predicted by standard form of Higgs mechanism? This is unpleasant question from TGD point of view. Could it mean that TGD is deadly wrong? Unpleasant questions are often the most useful ones so that it is perhaps time to boldly articulate also this question.

Is the recent TGD based view about Higgs like state as "Euclidian pion" as source of gauge boson masses and p-adic thermodynamics as a source of fermion masses exactly correct? Could Higgs description be only an effective description necessary at QFT limit? p-Adic thermodynamics is based on very general assumptions like super-conformal invariance, the existence of string like objects of length of order  $CP_2$  length predicted by the modified Dirac equation, and the powerful number theoretic constraints coming from p-adic thermodynamics and p-adic length scale hypothesis. Could Higgs mechanism be only a QFT approximation for a microscopic description of massivation based on p-adic thermodynamics so that the two approaches would not be actually competitors?

#### Microscopic description of massivation

Consider first the microscopic description in more detail.

1. In TGD description elementary particles correspond to loops carrying Kähler magnetic monopole flux and having two wormhole contacts with Euclidian signature of induced metric as ends at which magnetic flux flows between opposite light-like 3-D wormhole throats at different space-time sheets. In the case of fermions fermion number resides at wormhole throat at the either end of the loop. In the case of bosons fermion and antifermion number reside at the opposite throats of either wormhole contact. One can imagine variants of this picture since two wormhole contacts are involved: fermion number could be delocalized to both wormhole contacts and both wormhole throats, and bosons could have fermion and antifermion at the throats of different wormhole contacts. p-Adic mass calculations do not allow to distinguish between these options. The solutions of the modified Dirac equation assign to the flux loop closed string and this leads to a rich spectrum of topological quantum numbers and implies that elementary particles are also knots: unfortunately the predicted effects are extremely small [?].
2. What does one actually mean with the expectation value of mass squared in p-adic thermodynamics (as a matter of fact, ZEO suggests that p-adic thermodynamics is replaced with its "complex square root". This has some non-trivial number theoretical implications in the case of fermions discussed in [K71])? There are two options.
  - (a) Genuine mass squared is in question. The simplest possibility is that both throats of the wormhole carry light-like momentum. If the momenta are not parallel, this can give rise to stringy mass squared spectrum with string tension determined by  $CP_2$  length. The role of string is connects the opposite throats of the wormhole contact. In the case of bosons the ends of the short string connecting the throats would carry fermion and antifermion. In the case of fermions second throat would carry purely bosonic excitations generated by the symplectic algebra of  $\delta M_{\pm}^4 \times CP_2$ . One could also assign mass squared to the string but holography suggests that this mass squared is identifiable as total mass squared assignable to the ends.
  - (b) Longitudinal mass squared is in question. The other option favored by ZEO and number theoretical arguments is that p-adic thermodynamics gives only longitudinal mass squared, that this the square of  $M^2$ -projection of light-like fermion momentum, where  $M^2 \subset M^4$  characterizes given  $CD$ .

What happens in the case of contact? Could the transversal momenta of the throats cancel and give rise to a purely longitudinal contribution equal to the entire momentum so that longitudinal option would be equivalent with the first one?

Or could it be that the second wormhole throat does not contribute to the mass squared. The physical mass squared would be the average of longitudinal mass squared over various choices of  $M^2 \subset M^4$  so that Lorentz invariance would be achieved.

Note that the propagators associated with massless twistor lines would be defined by the  $M^2$  projections of fermionic or bosonic momenta and would therefore be finite. Also gauge conditions would involve only the longitudinal projection. I have not been able to develop any killer argument against this option.

3. According to the most recent view, the dominating contribution to gauge boson masses would be due to their coupling to Higgs like Euclidian pion developing vacuum expectation associated with coherent state. But is this fundamental description or only effective description obtained at 8-D QFT limit? An alternative view discussed for a year or two ago is that gauge boson masses correspond to "stringy" contribution from the *long* portion of the closed flux tube pair connecting the two wormhole contacts with a distance of order weak length scale associated with the gauge boson - the analog of Minkowskian meson. The contribution from the *short* part of the closed flux tube - the wormhole contact defining Euclidian pion - would dominate fermionic masses. In this case Higgs vacuum expectation could provide only a convenient effective description at QFT limit.
4. This picture leads naturally to generalized Feynman diagrams suggesting strongly twistor Grassmannian description since even the virtual wormhole throats are light-like. This description in turn would lead to QFT description when wormhole contacts are approximated by points of  $M^4 \times CP_2$  or even  $M^4$ .

p-Adic mass calculations give universal results but the drawback clearly is that they cannot fix the details of the model of elementary particles.

### Does Higgs mechanism emerge in the QFT limit as effective description?

The above description is definitely not QFT description. Does QFT description exist at all - say as a limit of twistorial description? If the QFT limit exists in some sense, what can one conclude about it? In the possibly existing QFT description one must idealize flux loops with point-like particles. Even if p-adic thermodynamics predicts fermion masses by assigning them to short Euclidian strings and gauge boson masses by assigning them to long Minkowskian strings in the closed flux tube, the only manner to describe this at QFT limit might be based on the use of vacuum expectation of Higgs like field and coupling to Higgs field. One could even argue that p-adic thermodynamics is equivalent to Higgs mechanism at QFT limit.

Even if both fermionic and bosonic particle massivation were due to p-adic thermodynamics at the fundamental level, one is forced to describe it at QFT limit by taking mass as given thermal mass. This could be achieved by using coupling to the vacuum expectation of the Higgs like state (Euclidian pion) and by choosing the dimensionless coupling so that a correct value of mass results.

If the fermions couple also to the quantum part of Higgs field as bosons would certainly do, one obtains standard model prediction but encounters the hierarchy problem and vacuum stability problem.  $M_{89}$  hadron physics for which the bump at mass about 130 GeV suggested by the results of Fermi laboratory serves as evidence, might solve these problems. A more plausible option is that the badly broken supersymmetry generated by the second quantized modes of induced spinor field labelled by conformal weight - essentially conformal supersymmetry - guarantees the cancellation of loop contributions at high energies. Note that the modes associated with right-handed neutrino are delocalized at the entire 4-surface, and do not seem plausible candidates for the needed SUSY [?]. One would end up with a description in which Higgs effectively gives rise to the masses of fermions. The outcome would be however an artifact of the QFT approximation.

One can consider QFT limits in  $H = M^4 \times CP_2$  and  $M^4$  respectively.

1. The 8-dimensional QFT limit treats fermions using  $H$ -spinors with quarks and leptons having different  $H$ -chiralities. In this case it is impossible to describe mass as in  $M^4$  since it would

give rise to a coupling between quarks and leptons and break separate conservation of baryon and lepton numbers. One must introduce instead of scalar mass a vector in  $CP_2$  tangent space analogous to polarization vector.

- (a) At quantum level Higgs vacuum expectation value defines a vector in  $CP_2$  tangent space expressible in terms of complexified gamma matrices having dimension 1/length so that is natural for the phenomenological description of mass generated by p-adic thermodynamics. In this description the counterpart of Higgs vacuum expectation would be the quantity  $H^k \gamma_k = H^A \gamma_A$ , where  $H^A$  is a vector in  $CP_2$  tangent space assignable to braid end at the partonic 2-surface (end or wormhole throat orbit at the boundary of  $CD$ ).  $H^A$  has dimensions of 1/length just as Higgs like field. The length squared of this vector would define the mass squared.
  - (b) Can one identify  $H^A$  in terms of induced geometry? The  $CP_2$  part of second fundamental form vanishing for minimal surfaces (analogous to massless particles) is such a vector field. Only the value of  $H^A$  at braid end is needed so that  $H^A$  would be effectively constant. Quantum classical correspondence suggests that  $H^A$  corresponds to vacuum expectation of Higgs field.
2.  $M^4$  QFT limit would define even stronger approximation, which must be however consistent with 8-D QFT limit. Now one must use 4-D spinors and describe the coupling in terms of scalar mass coupling different  $M^4$  chiralities. There are two options for the coupling  $g\bar{\Psi}\Psi\Phi$  and  $(g/m_0)\bar{\Psi}\gamma^\mu\Psi D_\mu\Phi$ . The latter option gives automatically effective coupling  $gm/m_0$  and Higgs couplings are therefore proportional to fermion masses. Fermion masses can be reproduced by the standard form of Higgs mechanism and also now the illusion that Higgs gives rise to fermion masses is created.

To sum up, it is possible that p-adic thermodynamics giving a dominating contribution to fermion and perhaps even boson masses from short/long flux tubes could have Higgs mechanism as the unique description at QFT limit so that the hopes of killing TGD or Higgs mechanism at one blow of experimentalist might be too optimistic. This could give a lesson in the art of ontology: wrong ontology can demand the existence of something that does not exist in more advanced ontology.

### 7.5.6 Low mass exotic mesonic structures as evidence for dark scaled down variants of weak bosons?

During last years reports about low mass exotic mesonic structures have appeared. It is interesting to combine these bits of data with the recent view about TGD analog of Higgs mechanism and find whether new predictions become possible. The basic idea is to derive understanding of the low mass exotic structures from LHC data by scaling and understanding of LHC data from data about mesonic structures by scaling back.

1. The article *Search for low-mass exotic mesonic structures: II. attempts to understand the experimental results* by Tatischeff and Tomasi-Gustafsson [?] mentions evidence for exotic mesonic structures. The motivation came from the observation of a narrow range of dimuon masses in  $\Sigma^+ \rightarrow pP^0, P^0 \rightarrow \mu^- \mu^+$  in the decays of  $P^0$  with mass of  $214.3 \pm .5$  MeV: muon mass is 105.7 MeV giving  $2m_\mu = 211.4$  MeV. Mesonlike exotic states with masses  $M = 62, 80, 100, 181, 198, 215, 227.5,$  and  $235$  MeV are reported. This fine structure of states with mass difference 20-40 MeV between nearby states is reported for also for some baryons.
2. The preprint *Observation of the E(38) boson* by Kh.U. Abraamyan et al [?, ?, ?] reports the observation of what they call E(38) boson decaying to gamma pair observed in  $d(2.0 \text{ GeV/n})+C, d(3.0 \text{ GeV/n})+Cu$  and  $p(4.6 \text{ GeV})+C$  reactions in experiments carried in JINR Nuclotron.

If these results can be replicated they mean a revolution in nuclear and hadron physics. What strongly suggests itself is a fine structure for ordinary hadron states in much smaller energy scale than characterizing hadronic states. Unfortunately the main stream, in particular the theoreticians

interested in beyond standard model physics, regard the physics of strong interactions and weak interactions as closed chapters of physics, and are not interested on results obtained in nuclear collisions.

In TGD framework situation is different. The basic characteristic of TGD Universe is fractality. This predicts new physics in all scales although standard model symmetries are fundamental unlike in GUTs and are reduced to number theory. p-Adic length scale hypothesis characterizes the fractality.

1. In TGD Universe p-adic length scale hypothesis predicts the possibility of scaled versions of both strong and weak interactions. The basic objection against new light bosons is that the decay widths of weak bosons do not allow them. A possible manner to circumvent the objection is that the new light states correspond to dark matter in the sense that the value of Planck constant is not the standard one but its integer multiple [K25].

The assumption that only particles with the same value of Planck constant can appear in the vertex, would explain why weak bosons do not decay directly to light dark particles. One must however allow the transformation of gauge bosons to their dark counterparts. The 2-particle vertex is characterized by a coupling having dimensions of mass squared in the case of bosons, and p-adic length scale hypothesis suggests that the primary p-adic mass scale characterizes the parameter (the secondary p-adic mass scale is lower by factor  $1/\sqrt{p}$  and would give extremely small transformation rate).

2. Ordinary strong interactions correspond to Mersenne prime  $M_n$ ,  $n = 2^{107} - 1$ , in the sense that hadronic space-time sheets correspond to this p-adic prime. Light quarks correspond to space-time sheets identifiable as color magnetic flux tubes, which are much larger than hadron itself.  $M_{89}$  hadron physics has hadronic mass scale 512 times higher than ordinary hadron physics and should be observed at LHC. There exist some pieces of evidence for the mesons of this hadron physics but masked by the Higgsteria.

The original proposal that 125 GeV state could correspond to pion of  $M_{89}$  physics was wrong. The modified proposal replaces the Minkowskian pion (that is ordinary pion) with its Euclidian variant assignable to a flux tube connecting opposite throats of wormhole contact. Euclidian pion would provide masses for intermediate gauge bosons via the analog of Higgs mechanism involving instanton density non-vanishing only in Euclidian regions but giving a negligible contribution to fermion masses: this would solve the hierarchy problem motivating space-time  $\mathcal{N} = 1$  SUSY not possible in TGD Universe. The expectation is that Minkowskian  $M_{89}$  pion (the real one!) has mass around 140 GeV assigned to CDF bump [?].

3. In the leptonic sector there is evidence for lepto-hadron physics for all charged leptons labelled by Mersenne primes  $M_{127}$ ,  $M_{G,113}$  (Gaussian Mersenne), and  $M_{107}$  [?]. One can ask whether the above mentioned resonance  $P^0$  decaying to  $\mu^- \mu^+$  pair motivating the work described in [?] could correspond to pion of muon-hadron physics consisting of a pair of color octet excitations of muon. Its production would presumably take place via production of virtual gluon pair decaying to a pair of color octet muons.
4. The meson-like exotic states seem to be arranged along Regge trajectories but with string tension lower than that for the ordinary Regge trajectories with string tension  $T = .9 \text{ GeV}^2$ . String tension increases slowly with mass of meson like state and has three values  $T/\text{GeV}^2 \in \{1/390, 1/149.7, 1/32.5\}$  in the piecewise linear fit discussed in the article. The TGD inspired proposal has been that IR Regge trajectories assignable to the color magnetic flux tubes accompanying quarks are in question. For instance, in hadrons  $u$  and  $d$  quarks - understood as constituent quarks - would have  $k = 113$  quarks and string tension would be by naive scaling by a factor  $2^{107-113} = 1/64$  lower: as a matter of fact, the largest value of the string tension is twice this value. For current quark with mass scale around 5 MeV the string tension would be by a factor of order  $2^{107-121} = 2^{-16}$  lower.

If one accepts the proposal that the 125 GeV Higgs like state discovered at LHC corresponds to Euclidian pion, one can ask whether the new states could contain a scaled down counterpart of Euclidian pion and whether even scaled down dark counterparts of weak bosons might be involved. These "weak" interaction would be actually of same strength as em interactions below the hadronic length and even above that faster than weak interactions by a factor of  $2^{36}$  coming from the scaling of the factor  $1/m_W^4$  in the simplest scattering involving weak boson exchange.

1. The naive estimate for the mass of  $M_{107}$  Euclidian pion is  $r \times 125$  GeV,  $r = 2^{(89-107)/2} = 2^{-9}$ ; this would give  $m(\pi_{E,107})=244$  MeV. The highest state in the IR Regge trajectory mentioned in [?] has mass 235 MeV. The weak bosons of  $M_{107}$  weak physics would have masses obtained by using the same scaling factor. This would give 156 MeV for  $W_{107}$  and 176 MeV for  $Z_{107}$ . It seems that these states with these masses do not belong to the reported list  $M = 62, 80, 100, 181, 198, 215, 227.5,$  and 235 MeV of masses. For  $k = 109$ , which is also prime, one obtains states with  $m(\pi_{E,109})=122$  MeV,  $m(W_{109}) = m(Z_{109}) = 88$  MeV for vanishing value of Weinberg angle. Also these states seem to be absent from the spectrum listed above.
2. In the original version of dark matter hierarchy the scalings  $\hbar \rightarrow r\hbar$  of Planck constant were restricted to  $r = 2^{11}$ , which is in a reasonable approximation equal to proton/electron mass ratio. If one replaces the  $k = 107$  with  $k = 111$ , which corresponds to a scaling of  $M_{89}$  masses by a factor  $2^{-11}$ , one obtains scaling of  $M_{107}$  masses downwards by a factor  $1/4$ .

Euclidian pion  $\pi_{E,111}$  would have mass 61 MeV: this is near to the mass 62 MeV reported as the mass of the lowest lying mesonlike state at IR Regge trajectory.  $W_{111}$  and  $Z_{111}$  would have masses 39 MeV and 44 MeV for the standard value of Weinberg angle.  $Z$  decays to gamma pairs radiatively via intermediate  $W$  pair: could  $Z_{111}$  correspond to  $E(38)$  with mass 39 MeV? If the Weinberg angle is near to zero, the masses of  $W_{111}$  and  $Z_{111}$  are degenerate, and one would have 39 MeV mass for both. The accuracy of the mass determination for  $E(38)$  is 3 MeV so that the mass would be consistent with the identification as  $Z_{111}$ . Note that small Weinberg angle means that the ratio  $g'/g$  for  $U(1)$  and  $SU(2)$  couplings is small ( $U(1)$  part of ew gauge potential corresponds to Kähler potential for  $CP_2$  in TGD framework).

One can estimate the weak string tension from the mass squared difference for the states with masses 60 MeV and 80 MeV as  $\Delta M^2 = T_{111}$  giving  $2.8 \times 10^{-3}$  GeV<sup>2</sup>. The lowest value for the experimental estimate is  $2.6 \times 10^{-3}$  GeV<sup>2</sup>: the two values are consistent with each other.

3. These observations inspire the question whether  $k = 111 = 3 \times 37$  scaled variant of weak physics could be involved. One can of course ask why the Gaussian Mersenne  $M_{G,k}$ ,  $k = 113$ , assigned to nuclear space-time sheet, would not be realized in dark nuclear physics too. For this option masses would be scaled down a further factor of  $1/2$  to 19.5 MeV for weak bosons and to 30.5 MeV for Euclidian pion. Could it be that dark nuclear physics must correspond to different p-adic length scale differing by a factor 2 from that associated with ordinary nuclear physics? What is interesting is that one of the most long standing interpretational problems of quantum TGD was the fact that the classical theory predicts long ranged classical weak fields: the proposed solution of the problem was that the space-time sheets carrying these fields correspond to a non-standard value of Planck constant.

What does one obtain if one scales back the indications for scaled down variant of weak physics?

1. Scaling back to  $M_{89}$  would give string tension  $T_{89} = 2^{22}T_{111} = 10.8 \times 10^{-3}$  TeV<sup>2</sup>. This predicts that first excited state of Euclidian pion has mass about 168 GeV: a bump with this mass corresponds to one of the many wrong alarms in Higgs hunting. There are indications for an oscillatory bump like structure in LHC data giving the ratio of the observed to predicted production cross section as a function of Higgs mass. This bump structure could reflect the actual presence of IR Regge trajectory for Euclidian pion inducing oscillatory behavior to the production cross section.
2. The obvious question is whether also the intermediate gauge bosons should have Regge trajectories so that the TGD counterpart Higgs mechanism would take place for each state in Regge trajectory separately. The flux tube structure made unavoidable by Kähler magnetic charges of wormhole throats indeed suggests Regge trajectories. For  $M_{89}$  weak physics the first excited state of  $W$  boson would be 144.5 GeV if one assumes the value of  $T_{89}$  given above.

Clearly, a lot of new physics is predicted and it begins to look that fractality - one of the key predictions of TGD - might be realized both in the sense of hierarchy of Planck constants (scaled variants with same mass) and p-adic length scale hypothesis (scaled variants with varying masses). Both hierarchies would represent dark matter if one assumes that the values of Planck constant and p-adic length scale are same in given vertex. The testing of predictions is not however expected to

be easy since one must understand how ordinary matter transforms to dark matter and vice versa. Consider only the fact, that only recently the exotic meson like states have been observed and modern nuclear physics regarded often as more or less trivial low energy phenomenology was born about 80 years ago when Chadwick discovered neutron.

### 7.5.7 Cautious conclusions

The discussion of TGD counterpart of Higgs mechanism gives support for the following general picture.

1. p-Adic thermodynamics for wormhole contacts contributes to the masses of all particles including photon and gluons: in these cases the contributions are however small. For fermions they dominate. For weak bosons the contribution from Euclidian Higgs is dominating as the correct group theoretical prediction for the  $W/Z$  mass ratio demonstrates. The mere spin 1 character for gauge bosons implies that they are massive in 4-D sense. The mass term for Euclidian pion in the analog of Higgs potential is not tachyonic, and the absence of linear couplings to fermions proportional to their masses saves from radiative instability which standard  $\mathcal{N} = 1$  SUSY was hoped to solve. Therefore the usual space-time SUSY associated with imbedding space in TGD framework is not needed, and there are strong arguments suggesting that it is not present [?] For space-time regarded as 4-surfaces one obtains 2-D super-conformal invariance for fermions localized at 2-surfaces and for right-handed neutrino it extends to 4-D superconformal symmetry generalizing ordinary SUSY to infinite-D symmetry.
2. The basic predictions to LHC are following. Euclidian pion will be found to decay to fermion pairs in a manner inconsistent with Higgs interpretation and its pseudoscalar nature will be established. There is an anomalous contribution to the decays to weak gauge boson pairs which for the simplest option is present only for photon and  $Z^0$ .  $M_{89}$  hadron physics will be discovered. Fermi satellite has produced evidence for a particle with mass around 140 GeV and this particle could correspond to the pion of  $M_{89}$  physics. This particle should be observed also at LHC and CDF reported already earlier evidence for it. There has been also indications for other mesons of  $M_{89}$  physics from LHC discussed in [K43].
3. Fermion and boson massivation could emerge unavoidably as a theoretical artifact if one requires the existence of QFT limit leading unavoidably to a description in terms of Higgs mechanism. In the real microscopic theory p-adic thermodynamics for wormhole contacts would describe fermion massivation, and might describe even boson massivation in terms of long parts of flux tubes. Situation remains open in this respect. Therefore the observation of decays of Higgs at expected rate to fermion pairs cannot kill TGD based vision.
4. The new view about Higgs allows to see several conjectures related to ZEO in new light.
  - (a) The basic conjecture related to the perturbation theory is that wormhole throats are massless on mass shell states in imbedding space sense: this would hold true also for virtual particles and brings in mind what happens in twistor program. The recent progress [?] in the construction of n-point functions leads to explicit general formulas for them expressing them in terms of a functional integral over four-surfaces. The deformation of the space-time surface fixes the deformation of basis for induced spinor fields and one obtains a perturbation theory in which correlation functions for imbedding space coordinates and fermionic propagator defined by the inverse of the modified Dirac operator appear as building bricks and the electroweak gauge coupling of the modified Dirac operator define the basic vertex. This operator is indeed 2-D for all other fermions than right-handed neutrino.
  - (b) The functional integral gives some expressions for amplitudes which resemble twistor amplitudes in the sense that the vertices define polygons and external fermions are massless although gauge bosons as their bound states are massive. This suggests perturbation at imbedding space level such that fermionic propagator is defined by longitudinal part of  $M^4$  momentum. Integration over possible choices  $M^2 \subset M^4$  for  $CD$  would give Lorentz invariance and transform propagator terms to something else. As a matter of fact, Yangian invariance suggests general expressions very similar to those obtained in  $\mathcal{N} = 4$  SUSY for amplitudes in Grassmannian approach.

- (c) Another conjecture is that gauge conditions for gauge bosons hold true for longitudinal ( $M^2$ -) momentum and automatically allow 3 polarization states. This allows to consider the possibility that all gauge bosons are massless in 4-D sense. By above argument this conjecture must be wrong. Could one do without  $M^2$  altogether? A strong argument favoring longitudinal massivation is from p-adic thermodynamics for fermions. If p-adic thermodynamics determines longitudinal mass squared as a thermal expectation value such that 4-D momentum always light-like (this is important for twistor approach) one can assume that Super Virasoro conditions hold true for the fermion states. There are also number theoretic arguments and supporting the role of preferred  $M^2$ . Also the condition that the choice of quantization axes has WCW correlates favors  $M^2$  as also the construction of the generalized Feynman graphs analogous to non-planar diagrams as generalization of knot diagrams [?]. Longitudinal scenario is equivalent with more standard one if the transversal momenta at opposite wormhole throats cancel each other.

The ZEO conjectures involving  $M^2$  remain open. If the conjecture that Yangian invariance realized in terms of Grassmannians makes sense it could allow to deduce the outcome of the functional integral over four-surfaces and one could hope that TGD can be transformed to a calculable theory.

## 7.6 Two options for Higgs like states in TGD framework

HCP2012 conference (Hadron Collider Physics Symposium) at Kyoto will provide new data about Higgs candidate at next Wednesday. Resonaances has summarized the basic problem related to the interpretation as standard model Higgs: too high yield of gamma pairs and too low yield of  $\tau\bar{\tau}$  and  $b\bar{b}$  pairs. It is of course possible that higher statistics changes the situation.

### 7.6.1 Two options concerning the interpretation of Higgs like particle in TGD framework

Theoretically the situation quite intricate. The basic starting point is that the original p-adic mass calculations provided excellent predictions for fermion masses. For the gauge bosons the situation was different: a natural prediction for the W/Z mass ratio in terms of Weinberg angle is the fundamental prediction of Higgs mechanism and this prediction did not follow automatically from the p-adic mass calculation in the original form. Classical Higgs field does not seem to have any natural counterpart in the geometry of space-time surface (the trace of the second fundamental form does not work since it vanishes for preferred extremals which are also minimal surfaces). This raised the question whether there is any Higgs boson in TGD Universe and for some time I took seriously the interpretation of the Higgs like state observed by LHC as a pion of  $M_{89}$ . To sum up, the evolution of ideas about TGD counterpart of Higgs mechanism has been full of twists and turns. This summary is warmly recommended for a seriously interested reader.

p-Adic mass calculations and the results from LHC leave two options under consideration.

1. Option I (see also this): Only fermions get the dominating contribution to their masses from p-adic thermodynamics and in the case of gauge bosons the dominating contribution is due to the standard Higgs mechanism. p-Adic thermodynamics would contribute also to the boson masses, in particular photon mass but the contribution would be extremely small and correspond to p-adic temperature  $T = 1/n$ ,  $n > 2$ . For this option only gauge bosons would have standard model couplings to Higgs whereas fermionic couplings could be small. Of course, standard model couplings proportional to fermion mass are also possible. One can criticize this option because fermions and bosons are in an asymmetric position. The beautiful feature is that one could get rid of the hierarchy problem due to the couplings of Higgs to heavy fermions.
2. Option II (see also this and this): p-Adic mass calculations explain also the masses of gauge bosons and Higgs like particle. If Higgs like state develops a coherent state describable in terms of vacuum expectation value as  $M^4$  QFT limit, this expectation value is determined by the mass spectrum determined by the p-adic mass calculations. The mass spectrum of particles determines Higgs expectation and the couplings of Higgs rather than vice versa! For this option Weinberg

angle would be *defined* by the ratio of W and Z boson mass as  $\cos^2(\theta_W) = m_W^2/m_Z^2$  and these masses should be given by p-adic mass calculations.

The recent view about particles as Kähler magnetic loops carrying monopole flux is forced by the assumption that the corresponding partonic 2-surfaces are Kähler magnetic monopoles (implied by the weak form of electric-magnetic duality). The loop proceeds from wormhole throat to another one, then traverses along wormhole contact to another space-time sheet and returns back and eventually is transferred to the first sheet via wormhole contact. The mass squared assignable to this flux loop could give the contribution usually assigned to Higgs vacuum expectation. If this picture is correct, then the reduction of the W/Z mass ratio to Weinberg angle might be much easier to understand. As a matter fact, I have proposed that the flux loop gives rise to a stringy spectrum of states with string tension determined by p-adic length scale associated with  $M_{89}$ .

This option is attractive because fermions and bosons are in an exactly same position. Hierarchy problem is possible problem of this approach: note however that the considerations in the sequel imply that standard model action is predicted to be an effective action giving only tree diagrams so that there are no radiative corrections at  $M^4$  QFT limit.

The original interpretation of Higgs like state was as  $M_{89}$  pion. The recent observations from Fermi telescope suggest the existence of a boson with mass 135 GeV. It would be a good candidate for  $M_{89}$  pion. One can test the hypothesis by scaling the mass of ordinary neutral pion, which corresponds to  $M_{107}$ . The scaling gives mass 69.11 GeV. p-Adic length scale however allows also octaves of the minimum mass (they appear for leptopions) and scaling by two gives mass equal to 138.22 GeV not too far from 135 GeV.

There is also second encouraging numerical co-incidence. It is probably not an accident that Higgs vacuum expectation value corresponds to the minimum mass for  $p = M_{89}$  if the p-adic counterpart of Higgs expectation squared is of order  $O(p)$  in other words one has  $\mu^2/m_{CP_2}^2 = p = M_{89}$ .

My sincere hope is that the results of HCP2012 would allow to distinguish between these two options.

### 7.6.2 Microscopic description of gauge bosons and Higgs like and meson like states

Under the pressures from LHC (and rather harsh social pressures from Helsinki University;-)) it has become gradually clear that the understanding of whether TGD has  $M^4$  QFT limit or not, and how this limit can be defined, is essential for the understanding also the role of Higgs. In the following a first attempt to understand this limit is made. I find it somewhat surprising that I am making this attempt only now but the understanding of the proper role of the classical gauge potentials has been quite a challenge.

1. If one believes that  $M^4$  QFT is a good approximation to TGD at low energy limit then the standard description of Higgs mechanism seems to be the only possibility: this just on purely mathematical grounds. The interpretation would however be that the masses of the particles determine Higgs vacuum expectation value and Higgs couplings rather than vice versa. This would of course be nothing unheard in the history of physics: the emergence of a microscopic theory - in the recent case p-adic thermodynamics - would force to change the direction of the causal arrow in "Higgs makes particles massive" to that in "Higgs expectation is determined by particle masses".
2. The existence of  $M^4$  QFT limit is an intricate issue. In TGD Universe baryon and lepton number correspond to different chiralities of  $H = M^4 \times CP_2$  spinors and this means that Higgs like state cannot be  $H$  scalar (it would be lepto-quark in this case). Rather, Higgs like state must be a vector in  $CP_2$  tangent space degrees of freedom. One can indeed construct a candidate for a Higgs like state as an Euclidian pion or its scalar counterpart: both are possible and one can even consider the mixture of them. The  $H$ -counterpart of Higgs like state is therefore  $CP_2$  axial vector or  $CP_2$  vector or mixture of them.

Euclidian pion or scalar carries fermion and anti-fermion at opposite throat of the wormhole contact. It is easy to imagine that a coherent state of Euclidian pseudo-scalars or scalars or

their mixture having Higgs expectation as  $M^4$  QFT correlate is formed. This state transforms as  $2 \oplus 2$  under  $U(2 \subset SU(3))$  identifiable as weak gauge group. This representation is natural in Euclidian regions Higgs as a tangent space vector of  $CP_2$  has naturally  $2 \oplus 2$  decomposition in tangent space of  $CP_2$  allowing an interpretation as Lie algebra complement of  $u(2) \subset su(3)$ .

In Minkowskian regions  $CP_2$  projection is 3-D and a natural counterpart of Higgs would be pseudo-scalar (or scalar) transforming as  $3 \oplus 1$  and  $U(2 \subset SU(3))$  identifiable now as strong  $U(2)$ . The 3-dimensionality of the  $M^4$  projection suggests that one obtains only the triplet state.

3. By bosonic emergence also gauge bosons correspond at microscopic level to fermion and anti-fermion at opposite throats of wormhole contacts. Meson like states in turn correspond to fermion and anti-fermion at the ends of a flux tube connecting throats of two different wormhole contacts so that both Higgs, gauge bosons, and meson-like states are obtained using similar construction recipe.
4. The popular statement "gauge bosons eat almost all Higgs components" makes sense at the  $M^4$  QFT limit.: just a transition to the unitary gauge effectively eliminates all but one of the components of the Higgs like state and gauge bosons get third polarization. This means gauge boson massivation but for option II it would take place already in p-adic thermodynamics in ZEO (zero energy ontology).

### 7.6.3 Trying to understand the QFT limit of TGD

The counterparts of gauge potentials and Higgs field are not needed in the microscopic description if p-adic thermodynamics gives the masses so that the gauge potentials and Higgs field should emerge only at  $M^4$  QFT limit. It is not even necessary to speak about Higgs and YM parts of the action at the microscopic level. The functional integral defined by the vacuum function expressed as exponent of Kähler action for preferred extremals to which couplings of microscopic expressions of particles in terms of fermions coupled to the effective fields describing them at QFT limit should define the effective action at QFT limit.

The basic recipe is simple.

1. Start from the vacuum functional which is exponent of Kähler action for preferred extremals with Euclidian regions giving real exponent and Minkowskian regions imaginary exponent.
2. Add to this action terms which are bilinear in the microscopic expression for the particle state and the corresponding effective field appearing in the effective action.
3. Perform the functional integration over WCW ("world of classical worlds") and take vacuum expectation value in fermionic degrees of freedom.
4. This gives an effective field theory in  $M^4 \times CP_2$ . To get  $M^4$  QFT integrate over  $CP_2$  degrees of freedom in the action. This dimensional reduction is similar to what occurs in Kaluza-Klein theories.

The functional integration of WCW induces also integration of induced spinor fields which apart from right-handed neutrino are restricted to the string world sheets. In principle induced spinor fields could be non-vanishing also at partonic 2-surfaces but simple physical considerations suggest that they are restricted to the intersection points of partonic 2-surfaces and string world sheets defining the ends of braid strands. Therefore the effective spinor fields  $\Psi_{eff}$  would appear only at braid ends in the integration over WCW and one has good hopes of performing the functional integral.

1. One can assign to the induced spinor fields  $\Psi$  imbedding space spinor fields  $\Psi_{eff}$  appearing in the effective action. The dimensions of  $\Psi$  and  $\Psi_{eff}$  are  $1/L^{3/2}$ . A dimensionally correct guess is the term  $\int d^2x \sqrt{g_2} \bar{\Psi}_{eff}(P) D^{-1} \Psi + h.c.$ , where  $\Gamma^\alpha$  denotes the induced gamma matrices,  $P$  denotes the end point of a braid strand at the wormhole throat, and  $D$  denotes the "ordinary" massless Dirac operator  $\Gamma^\alpha D_\alpha$  for the induced gamma matrices. Propagator contributes dimension  $L$  and is well-defined since  $\Psi$  is not annihilated by  $D$  but by the modified Dirac operator in which modified gamma matrices defined by the modified Dirac action appear. Note that internal

consistency does not allow the replacement of Kähler action with four-volume. Integral over the second wormhole throat contributes dimension  $L^2$ . Therefore the outcome is a dimensionless finite quantity, which reduces to the value of integrand at the intersection of partonic 2-surface and string world sheet - that is at ends of braid strand since induced spinors are localized at string world sheets unless right-handed neutrinos are in question. The fact that induced spinor fields are proportional to a delta function restricting them to string world sheets does not lead to problems since the modified Dirac action itself vanishes by modified Dirac equation.

2. Both Higgs and gauge bosons correspond to bi-local objects consisting of fermion and anti-fermion at opposite throats of wormhole contact and restricted to braid ends. They are connected by the analog of non-integrable phase factor defined by classical gauge potentials. These bilinear fermionic objects should correspond to Higgs and gauge potentials at QFT limit. The two integrations over the partonic 2-surfaces contribute  $L^2$  both, whereas the dimension of the quantity defining the gauge boson or Higgs like state is  $1/L^3$  from the dimensions of spinor fields and from the dimension of generalized polarization vector compensated by that of gamma matrices. Hence the dimensions of the bi-local quantities are  $L$  for both gauge bosons and Higgs like particles. They must be coupled to their effective QFT counterparts so that a dimensionless term in action results. Note that delta functions associated with the induced spinor fields reduce them to the end points of braid strand connecting wormhole throats and finite result is obtained.
3. How to identify these dimensional bilinear terms defining the QFT limit? The basic problem is that the microscopic representation of the particle is bi-local and the effective field at QFT limit should be local. The only possibility is to consider an average of the effective field over the stringy curve connecting the points at two throats. The resulting quantities must have dimensions  $1/L$  in accordance with naive scaling dimensions of gauge bosons and Higgs to compensate the dimension  $L$  of the microscopic representation of bosons. For gauge bosons having zero dimension as 1-forms the average  $\int A_\mu dx^\mu/l$  along a unique stringy curve of length  $l$  connecting wormhole throats defines a quantity with dimension  $1/L$ . For Higgs components having dimension  $1/L$  the quantities  $\int H_A \sqrt{g_1} dx/l$ , where  $g_1$  corresponds to the induced metric at the stringy curve, has also dimension  $1/L$ . The presence of the induced metric depending on  $CP_2$  metric guarantees that the effective action contains dimensional parameters so that the breaking of scale invariance results.

To sum up, for option II the parameters for the counterpart of Higgs action emerging at QFT limit must be determined by the p-adic mass calculations in TGD framework and the flux tube structure of particles would in the case of gauge bosons should give the standard contribution to gauge boson masses. For option I fermionic masses would emerge as mass parameters of the effective action. The presence of Euclidian regions of space-time having interpretation as lines of generalized Feynman diagrams is absolutely crucial in making possible Higgs like states. One must however emphasize that at this stage both option I and II must be considered.

#### 7.6.4 To deeper waters

Higgs issue seems to divide theoreticians to two classes: the simple-minded pragmatists and real thinkers.

For pragmatists the existence of Higgs and Higgs mechanism is something absolute: Higgs exists or not and one can make a bet about it. Most bloggers and most phenomenologists applying numerical models belong to this group. In particular, bloggers have had heated discussions and have made bets pro and con, mostly pro.

Thinkers see the situation in a wider perspective. The real issue is the status of quantum field theory as a description of fundamental forces. Is QFT something fundamental or is it only a low energy limit of a more fundamental microscopic theory? Could it even happen that QFT limit fails in some respects and could the description of particle massivation represent such an aspect?

Already string models taught (or at least should have taught) to see quantum field theory as an effective description of a microscopic theory working at low energy limit. Since string theorists have not been able to cook up any convincing answer to the layman's innocent question "How would you describe an atom using these tiny strings which are so awe inspiring?", QFT limits have become what string models actually are at the phenomenological level. AdS-CFT correspondence actually equates

string theory with a conformal quantum field theory in Minkowski space so that hopes about genuine microscopic theory are lost. This is disappointing but not surprising since strings are still too simple: they are either open or closed, there is no interesting internal topology.

In TGD framework string world sheets are replaced with 4-D space-time surfaces. One ends up with a very concrete vision about matter based on the notion of many-sheeted space-time and the implications are highly non-trivial in all scales. For instance, blackhole interior is replaced with a space-time region with Euclidian signature of the induced metric characterizing any physical system be it elementary particle, condensed matter system, or astrophysical object. Therefore the key question becomes the following. Does TGD have QFT in  $M^4$  as low energy limit or rather - as a limit holding true in a given scale in the infinite length scale hierarchies predicted by theory (p-adic length scale hierarchy and hierarchy of effective Planck constants and hierarchy of causal diamonds)?

### Deeper question: Does QFT limit of the fundamental theory exist?

Could the QFT limit defined as QFT in  $M^4$  fail to exist? After this question one cannot avoid questions about the character of Higgs and Higgs mechanism.

1. It is quite possible that in QFT framework Higgs mechanism is the only description of particle massivation. But this is just a mimicry, not a predictive description. QFT limit can only reproduce the spectrum of elementary particles masses or rather - mass ratios. The ratio of Planck mass (also an ad hoc concept) to proton mass remains a complete mystery.

This failure has been convincingly demonstrated by a huge amount of work in particle phenomenology. First came the GUT theorists. They applied every imaginable gauge group with elementary particles put in all imaginable group representations to reproduce the known part of the particle spectrum. They have reproduced standard model gauge symmetries at low energy limit. They have also done the necessary fine-tuning to make proton long-lived enough, to give large enough masses for the exotics, and to make beta functions sensical.

The same procedures have been repeated in SUSY framework and finally super string phenomenology has produced QFT limits with Higgs mechanism, and are now doing intense fine tuning to save poor SUSY from the aggressive attacks by LHC. During these 40 years of busy modeling practically nothing has been achieved but the work goes on since theoreticians have their methods and they must produce highly technical papers to preserve the illusion of hard science.

2. Higgs mechanism is also plagued by profound problems. The hierarchy problem means that the Higgs mechanism with mass of about 125 GeV is just at the border of stability. The problem is that the sign of mass squared term in Higgs potential can change by radiative corrections so that the vacuum with a vanishing Higgs expectation value becomes stable. SUSY was hoped to solve the hierarchy problem but LHC has made SUSY in standard sense implausible. Even if it exists cannot help in this issue. Another problem is that the coefficients of the fourth power in the Higgs potential can become negative so that vacuum becomes unstable: the bottom of a valley becomes top of a hill. The value of Higgs mass is such that also this seems to happen! (see the posting of Resonaances).

Quite generally, fine tuning problems are the characteristic issues of the QFT limit. Proton must be long-lived enough, baryon and lepton number violating decay rates cannot be too high, the predicted exotic particles implied by the extension of the standard model gauge group must be massive enough, and so on... This requires a lot of fine tuning. Theory has transformed from a healer to a patient: the efforts of theoreticians reduce to attempts to resuscitate the patient. All this becomes understandable as one realizes that QFT is just a mimicry, not the fundamental theory.

One could also see these two problems of the Higgs mechanism as the last attempt of the frustrated Nature to signal to the busy mainstream career builders something very profound about reality by using paradox as its last means. From TGD vantage point the intended message of Nature looks quite obvious.

### Shut up and calculate

The problem in the recent theoretical physics is that thinking has not been allowed for more than half century. Thinking is seen as "philosophy" - something very very bad. The fathers of quantum theory were philosophers: they realized the deep problems of quantum measurement theory and considered possible conclusions for the world view. For instance, Bohr - whose view became orthodoxy - concluded that objective reality cannot exist at all and that quantum theory is just a collection of calculational recipes with  $\Psi$  having no real existence. Einstein had totally different view. He believed that quantum theory is somehow fundamentally wrong.

Neither of them was yet mature to see that the problem involves the conscious observer in a very intimate manner: in particular, how the subjective time and the geometric time of physicist - certainly not one and the same thing - relate to each other. Both were also unable to see that objective reality could be replaced by objective realities identified as "solutions of field equations" and that quantum jumps would take between them and give rise to conscious experience. This would resolve both the problem of time and the basic problem of quantum measurement theory.

Later theoreticians followed the advice which has been put to the mouth of Feynman, and decided to just shut up and calculate. This long silence has lasted more than half a century now. I belong to those few who refused to follow the advice with the consequence that the decision makers of Helsinki University gave me officially a label of a madman and besides intensive blackmailing did their best to prevent any support for my work (see previous posting motivated by a warning of young readers about the dangers of reading my blog - sent by presumably finnish physics authority calling himself Anonymous).

LHC has now demonstrated how catastrophic consequences can be when the profession of the theoretician reduces to mindless calculation. We have got lost generations of theoreticians who continue to fill hep-th and hep-ph with preprints with a minimal connection to physical reality and mostly trying to solve the problems created by the theory itself rather than those provided by physics. This is however what they are able to do: collective silence has lasted too long. Even string model gurus have lost their beliefs on The Only Possible Theory of Everything. Some of them have suffered a regression to surprisingly childish models of gravitation (entropic gravity). Some have begun to see everything as black-holes without realizing that blackholes as a mathematical failure of general relativity should have been the starting point rather than the end. Some are making bets and having learned debates about paradoxes related to blackholes (firewall paradox is the latest newcomer (see the blog posting).

### Or could thinking be a rewarding activity after all?

There are also some theoreticians who have followed their own star and have not been able to resist the temptation to think and imagine. I have used to call my own star TGD. As described in previous posting, p-adic thermodynamics can be seen as a- or even *the* - microscopic mechanism of massivation in TGD framework. There are two options to consider. According to Option I p-adic thermodynamics alone explains only fermion masses and the microscopic counterpart of Higgs mechanism would give the dominant contribution to gauge boson masses. For Option II p-adic thermodynamics would produce both gauge boson and Higgs masses and Higgs mechanism could appear at QFT limit as a mere phenomenological description of the massivation.

Option II is the most conservative option and apparently conforms with the standard model view. It also treats all particles in the same position. Note that in standard model Higgs itself like eye which cannot see itself since its tachyonic bare mass is put in by hand. Option II is also aesthetically more satisfactory if one believes that QFT limit of TGD indeed exists. For Option I one should invent new QFT mechanism describing fermion massivation in QFT framework or give up the idea about QFT limit altogether. Option I or Option II? This question might find an answer within few days!

The existence of  $M^4$  QFT limit is not obvious in TGD framework (what this limit could be if it exists has been discussed in the previous posting). This is due to a dramatic simplification in the microscopic description of particles. The only fundamental fields are spinors of  $H = M^4 \times CP_2$  having just spin and electroweak quantum numbers and conserved carrying quark or lepton number depending on H-chirality. Color emerges and corresponds to color partial waves in  $H$ . Also bosons emerge meaning that gauge bosons, Higgs, and graviton have pairs of fermion and anti-fermion at the opposite throats of wormhole contacts as building bricks. Gauge fields, Higgs field, gravitational field and also Higgs mechanism can emerge in this approach only as a phenomenological description

at  $M^4$  QFT limit assuming that it exists. Fermionic families emerge from topology and also bosons are expected the analog of family replication phenomenon induced from the fermionic one.

Higgs like bosons exist as Euclidian pions or scalar particles and they might also develop coherent states characterized by the vacuum expectation value of Higgs but already this possibility must be taken critically since coherent states is a QFT based notion and it is not quite clear whether it generalizes to microscopic level (see this).

What is important that Higgs does not make fermions massive. For Option II this is true also for bosons. Rather, the couplings and vacuum expectation of Higgs are such that Higgs can pretend of achieving this feat. Higgs mechanism reproduces: p-adic thermodynamics predicts.

Standard model action is only an effective action providing tree diagrams so that the loop corrections leading to the hierarchy problem are not present unless the counterpart of fatal radiative corrections appear in the effective action which must depend on p-adic length scale (in TGD the discrete p-adic length scale evolution replaces the continuous renormalization group evolution of quantum field theories). Zero energy ontology however dramatically modifies the view about Feynman diagrams, and can save the situation since standard SUSY generalizes to super-conformal invariance.

There are of course lot of critical questions to be answered. I have written an entire book motivated by the challenge of understanding why p-adic thermodynamics should be needed in real number based physics. p-Adic physics for single prime is definitely not enough: one must fuse p-adic physics for various primes  $p$  and real physics to single coherent whole and this requires a lot of not yet existing mathematics such as generalization of number concept. The connections of p-adic physics to the description of cognition and intention in quantum consciousness theory are also obvious and p-adic space-time sheet would correspond to the "mind stuff" of Descartes. These few examples show how profound and totally unexpected new visions a more philosophical and imaginative attitude to physics generates.

Another book is devoted to the physical implications of p-adic physics and of the hierarchy of effective Planck constants, a notion implied by the very special properties of the basic variational principle dictating the space-time dynamics in TGD framework.

### 7.6.5 Higgs-like state according to TGD after HCP2012

As both Phil Gibbs and Tommaso Dorigo have already told, ATLAS and CMS reported new Higgs results at LHC in Kyoto. From TGD perspective these results are of special interest since - as explained in previous postings (see this and this), they could allow to distinguish between two options suggested by TGD for the interpretation of the Higgs like particle. Before continuing it must be made clear that the road to these options has been long and with many twists and turns (see this). Rather imaginatively, I have christened the basic options as Option I and II.

#### The two options

I have described these options here. In follow up posting I have described how Option II can be understood in TGD framework, where both gauge fields, Higgs field, and also graviton field are only constructs emerging at the QFT limit of the theory rather than having a fundamental ontological status.

1. Option I assumes that Higgs like state cannot explain fermion masses so that the couplings of Higgs to fermions can even vanish. Gauge boson masses are however assumed to result by the counterpart of Higgs mechanism which would be formation of a coherent state assignable to the Higgs like particle identified a  $M^4$  scalar formed from fermion and antifermion at opposite throats of wormhole contacts (just like gauge bosons). Note that Higgs like state is actually  $CP_2$  vector.
  - (a) One can wonder why not allow coherent states of Higgs like particle also for option II at the microscopic level. p-Adic thermodynamics does not tolerate this. The conclusion that these coherent states explain also fermion masses is difficult to avoid. For me it would mean return 17 years back to the times before p-adic mass calculations without a slightest idea why fermion masses are what they are.

- (b) Both scalar and pseudoscalar identification is possible for Higgs like state in TGD as it is now. Somewhat misleadingly I have referred to the Higgs like state as Euclidian pion. "Pion" is a misleading terminological mammoth bone from my original identification of 125 GeV state as pion of  $M_{89}$  hadron physics.  $M_{89}$  hadrons is one of the most important new physics (almost)-predictions of TGD. The 135 GeV particle for which Fermi telescope has provided considerable evidence could correspond to  $M_{89}$  pion. It is a pity that the experimentalist are testing only the mainstream theories such as standard SUSY, whose state after HCP2012 is so critical that journalists have rumored that SUSY is now at hospital.

The reason for "Euclidian" is that the space-time regions assignable to the (thickened) lines of generalized Feynman diagrams have Euclidian signature of induced metric. The Minkowskian parts of the flux tubes would be much longer, of the order of Compton length of particle, and could be identified as counterparts of hadronic strings if both ends carry fermion number. This means a unification of elementary particles and hadron like states: they are both string like objects but with widely differing typical lengths and string tensions. The string tension assignable to the long strings/flux tubes would give the dominant contribution to hadron masses.

2. Option II is conservative in the sense that apparently Higgs would make both bosons and fermions massive: aesthetically this is of course very nice feature. This conservative character is only apparent since p-adic thermodynamics would determine both fermion and boson masses - also the mass of Higgs.

- (a) Both gauge boson fields and Higgs field would be constructs of QFT limit for the microscopic physical objects not describable as fields and obtained by making 3-surfaces assigned with particles to point like objects. In the earlier posting I described how standard model like theory would result as a QFT limit of TGD by using a modification of a standard construction for the effective action.
- (b) "Apparent" would mean that Higgs vacuum expectation value is a purely fictive notion for this option. It would apparently explain masses for gauge bosons and fermions if the coupling of fermions to the scalar state mapped to Higgs field corresponds to gradient coupling  $\bar{\Psi}\gamma^\mu\partial_\mu\Phi\Psi/\mu$ ,  $\mu$  the Higgs vacuum expectation value reproducing the fermion mass from this coupling. In the case of gauge bosons the standard gauge coupling to Higgs would reproduce the gauge boson mass in same manner. This is however only a mimicry of the mass spectrum, not its prediction. QFT limit cannot do better. The crucial ratio of W and Z boson masses expressible in terms of Weinberg angle would become a definition of Weinberg angle.

- (c) The identification of elementary particles in terms of monopole flux loops allows also to consider gauge boson masses as contributions to the conformal weight of the gauge boson ground state so that it would not result from the p-adic thermodynamics proper. Is this contribution present also in fermionic ground states and does it give only a small shift to fermion mass squared from the value determined by p-adic thermodynamics?

For gauge bosons this contribution is of order  $O(p^2)$ : the coefficient would be large so that the contribution would not be much below the smallest possible  $O(p)$  contribution. Assuming this for fermions this contribution would induce only a small upwards shift of fermion masses whose relative size would be largest for lowest fermion families. For this option the parameter  $\mu \simeq 246$  GeV, which actually corresponds to the smallest possible value of p-adic mass squared of order  $O(p)$ : clearly W and Z boson masses are below this but not much and this would require p-adic temperature  $T = 1/2$  in p-adic thermodynamics. The proportionality of the mass of long string to the square of appropriate gauge coupling constant appearing in the gauge boson masses would be also natural and predict W/Z mass ratio correctly.

### Option I or Option II?

What do the results of the data released by ATLAS and CMS groups allow to conclude? Option I or Option II?

1. Perhaps the most important piece of data is the production rate for  $\tau^+\tau^-$  pairs by Higgs decays. CMS reports excess of  $.72 \pm .52$  and ATLAS  $.72 \pm .64$ . Earlier Tevatron reported evidence excess in bb channel. Together these results are quite strong and if taken at face value (note however the large error margins) then Option II survives in TGD framework.
2. The crucial diphoton channels, where gamma pair excess has been reported hitherto have not been updated by either group. This is a pity since for Option I the development of coherent state of Euclidian scalar serving as a counterpart for the Higgs expectation would be due to a coupling of pseudoscalar (scalar) to instanton density (YM action density) - call it just  $X$  - slashed between Higgs like state and its conjugate in QFT description. The addition of a quantized piece to  $X$  would give rise to a term giving rise to anomalous decays to photon pairs/gauge boson pairs.

For the pseudoscalar Higgs the coefficient of the interaction term would be dictated by anomaly considerations. For a scalar Higgs the ad hoc guess would be that the coefficient is same.  $CP_2$  type vacuum extremal represents the extreme case of Euclidian space-time region and for this induced Kähler form is self dual. Could this be used to justify this adhoc assumption?

Many explanations for diphoton excess have been proposed and I cannot avoid the temptation to add an additional contribution to the soup. There have been rumors that the state around 125 GeV splits into two: ATLAS and CMS have indeed reported slightly different masses. Could this be a real effect and explain the diphoton excess - and also why nothing was reported in Kyoto? The believer on  $M_{89}$  physics could argue as follows.

- (a) The pion like state corresponds to  $3 \oplus 1$  representation for strong isospin group  $U(2)$  realized using sub-algebra  $SU(2)$  of  $SU(3)$  playing the role of strong isospin group in TGD. Pion realizes only "3". Could "1" correspond to the sigma meson of  $M_{89}$  hadron physics and have mass around 125 GeV and thus explain two-photon anomaly? Unfortunately, the status of sigma even in ordinary hadron physics has turned out to be very problematic.
  - (b) One can also play with a second idea. There is recent evidence that ordinary pion has what might be called an infrared Regge trajectory with the mass splitting about 20 MeV or 40 MeV between different states (see this). This pion would satellites also below its usual mass: the first reported one around 100 MeV. If also  $M_{89}$  pion has similar IR Regge trajectory then by scaling by a factor 512 the splitting of 20 (40) MeV would scale up to a splitting of 10 (20) GeV. This would map 100 MeV pion to a copy of 135 GeV  $M_{89}$  pion with mass around 115 GeV (for which ATLAS found evidence for a couple of years ago!). This state is unfortunately 10 GeV too low! 20 MeV splitting would suggest a satellite of pion around 120 MeV, and its  $M_{89}$  variant would be around 125 GeV! In this case the different parities of Euclidian scalar and scaled down copy of Euclidian pion would allow to distinguish between them. This copy of pion would have also charged companions. There have been also rumors about charged companions of Higgs.
3. Tommaso Dorigo tells that also the first determination of the spin parity of the state has been made.  $0_+$  is slightly favored so that scalar Higgs would be in question. TGD indeed allows both options but for the scalar option the coupling of Higgs like state to YM action density remains the ad hoc guess mentioned above.

To sum up, the challenge of understanding Higgs like states in TGD framework seems to be now to be accomplished to high extent. The outcome is a formulation for the QFT limit of TGD which allows to understand how TGD implies standard model like theory as its QFT limit and rather precise view about limitations of QFT approximation.

### 7.6.6 About the basic assumptions behind p-adic mass calculations

The motivation for this piece of text was the basic horror experience of theoretician waking him up at early morning hours. Is there something wrong with basic assumptions of some particular piece of theory? At this time it was p-adic thermodynamics. Theoretician tries to figure this out in a drowsy state between wake-up and sleep, fails repeatedly, and blames the mighties of the Universe for his miserable fate as eternal doubter. Eventually merciful sleep arrives and theoretician wakes up in the

morning, recalls the problem and feels that nothing is wrong. But theoretician knows that it is better to check everything once again.

So that this is what I am doing in the sequel: listing and challenging the basic assumptions and philosophy behind p-adic mass calculations. As always in this kind of situation, I prefer to think it all over again rather than finding what I have written earlier: reader can check whether the recent me agrees with the earlier me. This list is not the only one that I have made during these years and other, possibly different, lists can be found in the chapters of various books. Although the results of calculations are unique and involve only very general assumptions, the guessing of the detailed physical picture behind them is difficult.

I hope that this piece of text would also help to understand better how p-adic mass calculations as a microscopic theory and the standard description of Higgs mechanism as a phenomenological low energy parameterization relate to each other.

### Why p-adic thermodynamics?

p-Adic thermodynamics is a fundamental assumption behind the p-adic mass calculations: p-adic mass squared is identified as a thermal average of mass squared for super-conformal representation with p-adic mass squared given essentially by the conformal weight.

Zero energy ontology (ZEO) has gradually gained a status of second fundamental assumption. In fact, ZEO strongly suggests the replacement of p-adic thermodynamics with its "complex square root" so that one would be actually considering genuine quantum states squaring to thermodynamical states. This idea looks highly satisfactory for anyone used to think that elementary particles cannot be thermodynamical objects. The square root of p-adic thermodynamics raises delicate number theoretical issues [K71] since the p-adic square root of the conformal weight having value  $p$  does not exist without a proper algebraic extension of p-adic numbers leading to algebraic integers and generalized notion of primeness.

**Q:** Why p-adic thermodynamics, which predicts the thermal expectation of p-adic mass squared and requires the mapping of p-adic valued mass squared to real mass squared by some variant of canonical identification?

**A:** Number theoretical universality requires fusion of real and p-adic number based physics for various primes so that p-adic thermodynamics becomes natural.

1. The answer inspired by TGD inspired theory of consciousness would be that the interaction of p-adic space-time sheets serving as correlates of cognition with real space-time sheets representing matter makes p-adic topology effective topology in some length scale range also for real space-time sheets (as an effective topology for discretization). One could even speak about cognitive representations of elementary particles using the rational or algebraic intersections of real and p-adic space-time sheets. These cognitive representations are very simple in p-adic topology and it is easy to calculate the masses of the particles using p-adic thermodynamics. Since representation is in question, the result should characterize also real particle.
2. The pragmatic answer would be that p-adic thermodynamics gives extremely powerful number theoretical constraints leading to the quantization of mass scales and masses with p-adic temperature  $T = 1/n$  and p-adic prime appearing as free parameters. Also conformal invariance is strongly favored since the counterpart of Hamiltonian must be integer valued as the super-conformal scaling generator indeed is.
3. By number theoretical universality one can require that the p-adic mass thermodynamics is equivalent with real thermodynamics for real mass squared. This is the case if partition function has cutoff so that conformal weights only up to some maximum value  $N$  are allowed. This has no practical consequences since the real-valued contribution from the conformal weight  $n$  is proportional to  $p^{-n+1/2}$  and for  $n > 2$  is completely negligible since the primes involved are so large ( $p = M_{127} = 2^{127} - 1$  for electron for instance).

**Q:** Is the canonical identification mapping the p-adic mass squared to real mass squared unique? This is not the case. One can imagine a family of identification for which integers  $n < p^N$ ,  $N = 1, 2, \dots$  are mapped to itself. This however has no practical implications for the calculations since the values of primes involved are so large.

The calculations themselves assume only p-adic thermodynamics and super-conformal invariance. The most important thing that matters is the number of tensor factors in the tensor product of representations of conformal algebra, which must be *five*.

**Q:** What are the fundamental conformal algebras giving rise to the super conformal symmetries?

**A:** There are two conformal algebras involved.

1. The symplectic algebra of  $\delta M_{\pm}^4 \times CP_2$  has the formal structure of Kac-Moody algebra with the light-like radial coordinate  $r$  of the light-cone boundary  $\delta M_{\pm}^4$  taking the role of complex coordinate  $z$ . It has symplectic algebras of  $CP_2$  and sphere  $S^2$  of light-cone boundary as building blocks taking the role of the finite-dimensional Lie group defining Kac-Moody algebra. This algebra has not in string models.
2. There is also the Kac-Moody algebra assignable to the light-like wormhole throats and assignable to the isometries of the imbedding space having  $M^4$  and  $CP_2$  isometries as factors. There are also electroweak symmetries acting on spinor fields. In fact, the construction of the solutions of the modified Dirac equation [?] suggests that electroweak and color gauge symmetries become Kac-Moody symmetries in TGD framework. In practice this means that only the generators with positive conformal weight annihilate the physical states. For gauge symmetry also those with negative conformal weight annihilate the physical states.

One can of course ask whether also  $SU(2)$  sub-algebra of  $SL(2,C)$  acting on spinors should be counted. One could argue that this is not the case since spin does correspond to gauge or Kac-Moody symmetry as electroweak quantum numbers do.

**Q:** One must have five tensor factors. How should one count the number of tensor factors, in other words what is the basic building brick to which one identifies as a tensor factor of Super-Virasoro algebra?

**A:** One can imagine two options.

1. The most general option is that one takes the  $CP_2$  and  $S^2$  symplectic algebras as factors in the symplectic sector. In Kac-Moody sector one has  $E^2 \subset M^4$  isometries (longitudinal degrees of freedom of string world sheet carrying induce spinors fields are not physical) and  $SU(3)$ . Besides this one has electroweak algebra  $U(2)$ , which almost but quite not decomposes to  $SU(2)_L \times U(1)$  (there are correlations between  $SU(2)_L$  and  $U(1)$  quantum numbers and the existence of spinor structure of  $CP_2$  makes also these correlations manifest). This would give 5 tensor factors as required.
2. I have also considered Cartan algebras as separate tensor factors. I must confess, that at this moment I am unable to rediscover what my motivation for this actually has been. This would give a larger number of tensor factors: 1+2 factors in symplectic sector from Cartan algebras of  $SO(3) \times SU(3)$  defining subgroup of symplectic group, 2+2 for isometries in Kac-Moody sector from  $E^2$  and  $SU(3)$ , and 1+1 in the electroweak sector with spin giving a possible further factor. This means 9 (or possibly 10) factors so that thermalization is not possible for all Cartan algebra factors. Symplectic sectors are certainly a natural candidate in this respect so that one would have 5 as required (or 6 if spin is allowed to have Kac-Moody structure) sectors.

The first option looks more convincing to me.

### How to understand the conformal weight of the ground state?

Ground state conformal weight which is non-positive can receives various contributions. One contribution is negative and therefore corresponds to a tachyonic mass squared, second contribution corresponds to  $CP_2$  cm degrees of freedom and together with the momentum squared boils down to an eigenvalue of the square of spinor d'Alembertian for  $H = M^4 \times CP_2$  (by bosonic emergence). Third one comes from the conformal moduli of the partonic 2-surface at the end of the space-time sheet at light-like boundary of causal diamond and distinguishes between different fermion families.

**Q:** Tachyonic ground state mass does not look physical and is quite generally seen as a serious - if not lethal - problem also in string models. What is the origin of the tachyonic contribution to the mass squared in TGD framework?

**A:** The recent picture about elementary particles is as lines of generalized Feynman diagram identified as space-time regions with Euclidian signature of the induced metric. In this regions mass squared is naturally negative and it is natural to think that ground state mass squared receives contributions from both Euclidian and Minkowskian regions. If so, the necessary tachyonic contribution would be a direct signal for the presence of the Euclidian regions, which have actually turned out to define a generalization of blackhole interior and be assignable to any system as a space-time sheet characterizing the system geometrically [?]. For instance, my own body as I experience it would correspond to my personal Euclidian space-time sheet as a line of generalized Feynman diagram.

**Q:** Where does the  $H = M^4 \times CP_2$  contribution to the scaling generator  $L_0$  assignable to spinor partial waves in  $H$  come from?

**A:** Zero energy ontology (ZEO) allows to assign to each particle a causal diamond  $CD$  and according to the recent view emerging from the analysis of the relationship between subjective (experienced) time and geometric time, particle is characterized by a quantum superposition of  $CD$ s. Every state function reduction means localization of the upper or lower tip of all  $CD$ s in the superposition and delocalization of the other tip. The position of the upper tip has wave function in  $H_{\pm} = M_{\pm}^4 \times CP_2$  and there is a great temptation to identify the wave function as being induced from a partial wave in  $H = M^4 \times CP_2$ . As a matter of fact, number theoretic arguments and arguments related to finite measurement resolution strongly suggest discretization of  $H_{\pm}$ .  $M_{\pm}^4$  would be replaced with a union of hyperboloids with a distance from the tip of  $M_{\pm}^4$  which is quantized as a multiple of  $CP_2$  radius. Furthermore at each hyperboloid the allowed points would correspond to the orbit of some discrete subgroup of  $SL(2, C)$ .  $CP_2$  would be also discretized.

### What about Lorentz invariance?

The square root of p-adic thermodynamics implies quantum superposition of states with different values of mass squared and hence four-momenta. In ZEO this does not mean obvious breaking of Lorentz invariance since physical states have vanishing total energy. Note that coherent states of Cooper pairs, which in ordinary ontology would have both ill-defined energy and fermion number, have a natural interpretation in ZEO.

1. A natural assumption is that the state in the rest system involves only a superposition of states with vanishing three-momentum. For Lorentz boosts the state would be a superposition of states with different three-momenta but same velocity. Classically the assumption about same 3-velocity is natural.

**Q:** Could Lorentz invariance break down by the presence of the superposition of different momenta?

**A:** This is not the case if only the average four-momentum is observable. The reason is that average four-momentum transforms linearly under Lorentz boosts. I have earlier considered the possibility of replacing momentum squared with conformal weight but this option looks somewhat artificial and even wrong to me now.

2. The decomposition  $M^4 = M^2 \times E^2$  is fundamental in the formulation of quantum TGD, in the number theoretical vision about TGD, in the construction of preferred extremals, and for the vision about generalized Feynman diagrams. It is also fundamental in the decomposition of the degrees of string to longitudinal and transversal ones. An additional item to the list is that also the states appearing in thermodynamical ensemble in p-adic thermodynamics correspond to four-momenta in  $M^2$  fixed by the direction of the Lorentz boost.

**Q:** In parton model of hadrons it is assumed that the partons have a distribution with respect to longitudinal momentum, which means that the velocities of partons are same along the direction of motion of hadron. Could one have p-adic thermodynamics for hadrons?

**A:** For hadronic p-adic thermodynamics the value of the string tension parameter would be much smaller and the thermal contributions from  $n > 0$  states would be completely negligible so that the idea does not look good. In p-adic thermodynamics for elementary particles one would have distribution coming from different values of p-adic mass squared which is integer valued apart from ground state configuration.

### What are the fundamental dynamical objects?

The original assumption was that elementary particles correspond to wormhole throats. With the discovery of the weak form of electric-magnetic duality came the realization that wormhole throat is homological magnetic monopole (rather than Dirac monopole) and must therefore have (Kähler) magnetic charge. Magnetic flux lines must be however closed so that the wormhole throat must be associated with closed flux loop.

The most natural assumption is that this loop connects two wormhole throats at the first space-time sheet, that the flux goes through a second wormhole contact to another sheet, returns back along second flux tube, and eventually is transferred to the original throat along the first wormhole contact.

The solutions of the Modified Dirac equation [?] assign to this flux tube string like curve as a boundary of string world sheet carrying the induced fermion field. This closed string has "short" portions assignable to wormhole contacts and "long" portions corresponding to the flux tubes connecting the two wormhole contacts. One can assign a string tension defined by  $CP_2$  scale with the "short" portions of the string and string tension defined by the primary or perhaps secondary p-adic length scale to the "long" portions of the closed string.

Also the "long" portion of the string can contribute to the mass of the elementary particle as a contribution to the vacuum conformal weight. In the case of weak gauge bosons this would be the case and since the contribution is naturally proportional to gauge couplings strength of W/Z boson one could understand Q/Z mass ratio if the p-adic thermodynamics gives a very small contribution from the "short" piece of string (also photon would receive this small contribution in ZEO): this is the case if one must have  $T = 1/2$  for gauge bosons. Note that "long" portion of string can contribute also to fermion masses a small shift. Hence no Higgs vacuum expectation value or coherent state of Higgs would be needed. There are two options for the interpretation of recent results about Higgs and Option II in which Higgs mechanism emerges as an effective description of particle massivation at QFT limit of the theory and both gauge fields and Higgs fields and its vacuum expectation exist only as constructs making sense at QFT limit. Higgs like particles do of course exist. At WCW limit they are replaced by WCW spinor fields as fundamental object.

**Q:** One can consider several identifications of the fundamental dynamical object of p-adic mass calculations. Either as a wormhole throat (in the case of fermions for which either wormhole throat carries the fermion quantum number this looks natural), as entire wormhole contact, or as the entire flux tube having two wormhole contacts. Which one of these options is correct?

**A:** The strong analogy with string model implied by the presence of fermionic string world sheet would support that the identification as entire flux tube in which case the large masses for higher conformal excitations could be interpreted in terms of string tension. Note that this is the only possibility in case of gauge bosons.

**Q:** What about p-adic thermodynamics or its square root in hadronic scale?

**A:** As noticed the contributions from  $n > 0$  conformal excitations would be extremely small in p-adic thermodynamics for "long" portions. It would seem that this contribution is non-thermal and comes from each value of  $n$  labelling states in Regge trajectory separately just as in old-fashioned string model. Even weak bosons would have Regge trajectories. The dominant contribution to the hadron mass can be assigned to the magnetic body of the hadron consisting of Kähler magnetic flux tubes. The Kähler-magnetic (or equivalently color-magnetic) flux tubes connecting valence quarks can contribute to the mass squared of hadron. I have also considered the possibility that symplectic conformal symmetries distinguishing between TGD and superstring models could be responsible for a contribution identifiable as color magnetic energy of hadron classically.

## 7.7 Appendix: The particle spectrum predicted by TGD

The detailed model of elementary particles has evolved slowly during more than 15 years and is still in progress. What SUSY means in TGD framework is second difficult question. In this problem text books provide no help since the SUSY differs in several respects from the standard SUSY. It must be admitted that there are open questions and several competing candidates for interpretations at the level of details and following just summarizes various competing approaches.

### 7.7.1 The general TGD based view about elementary particles

A rough overall view about the particle spectrum predicted by TGD has remained rather stable since 1995 when I performed first p-adic mass calculations but several important ideas have emerged allowing to make the vision more detailed.

1. The discovery of bosonic emergence [?] had far reaching implications for both the formulation and interpretation of TGD. Bosonic emergence means that the basic building bricks of bosons are identifiable as wormhole contacts with throats carrying fermion and anti-fermion quantum numbers.
2. A big step was the realization wormhole throats carry Kähler magnetic charge [?]. This forces to assume that observed elementary particles are string like objects carrying opposite magnetic charges at the wormhole ends of magnetic flux tubes. The obvious idea is that weak massivation corresponds to the screening of weak charges by neutrino pairs at the second end of the flux tube.

At least for weak gauge bosons this would fix the length of the flux tube to be given by weak length scale. For fermions and gluons the length of flux tube could also correspond to Compton length: the second end would be invisible since it would contain only neutrino pair. In the case of quarks an attractive idea is that flux tubes carry color magnetic fluxes and connect valence quarks and have hadronic size scale.

There are thus several stringy length scales present. The most fundamental corresponds to wormhole contacts and to  $CP_2$  length scale appearing in p-adic mass calculations and is analogous to the Planck scale characterizing string models. String like objects indeed appear at all levels in TGD Universe: one can say that strings emerge. The assumption that strings are fundamental objects would be a fatal error.

3. p-Adic massivation does not involve Higgs mechanism [K39]. The idea that Higgs provides longitudinal polarizations for gauge bosons is attractive, and its TGD based variant was that *all* Higgs components become longitudinal polarizations so that also photon has a small mass. The recent formulation of gauge conditions as  $p_{M^2} \cdot \epsilon = 0$ , where  $p_{M^2}$  is a projection of the momentum to a preferred plane  $M^2 \subset M^4$  assignable to a given  $CD$  and defining rest system and spin quantization axis, allows three polarizations automatically. Also the construction of gauge bosons as wormhole contacts with fermion and anti-fermion at the ends of throat massless on mass-shell states implies that all gauge bosons must be massive. Therefore Higgs does not seem to serve its original purposes in TGD.
4. This does not however mean that Higgs like states - or more generally spin 0 particles, could not exist. Here one encounters the problem of formulating what the notions like "scalar" and "pseudo-scalar" defined in  $M^4$  field theory mean when  $M^4$  is replaced with  $M^4 \times CP_2$ . The reason is that genuine scalars and pseudo-scalars in  $M^4 \times CP_2$  would correspond to lepto-quark states and chiral invariance implying separate conservation of quark and lepton numbers denies their existence.

These problems are highly non-trivial, and depending on what one is willing to assume, one can have spin 0 particles which however need not have anything to do with Higgs.

- (a) For a subset of these spin 0 particles the interpretation as 4 polarizations of gauge bosons in  $CP_2$  direction is highly suggestive: the polarizations can be regarded as doublets  $2 \oplus \bar{2}$  defining representations of  $u(2) \subset su(3)$  in its complement and therefore being rather "Higgsy". Another subset consists of triplet and singlet representations for  $u(2) \subset u(3)$  allowing interpretation as the analog of strong isospin symmetry in  $CP_2$  scale for the analogs of hadrons defined by wormhole contacts.
- (b)  $3 \oplus 1$  representation of  $u(2) \subset su(3)$  acting on  $u(2)$  is highly analogous to  $(\pi, \eta)$  system and  $2 \oplus \bar{2}$  representation assignable naturally to the complement of  $u(2)$  is analogous to kaon system. Exactly the same representations are obtained from the model of hadrons as string like objects and the two representations explain the difference between  $(\pi, \eta)$  like and  $(K, \bar{K})$  systems in terms of  $SU(3)$  Lie-algebra. Also the vector bosons associated

with pseudo-scalar mesons identified as string like objects have counterparts at the level of wormhole contacts. A surprisingly precise analogy between hadronic spectrum and the spectrum of elementary particle states emerges and could help to understand the details of elementary particle spectrum in TGD Universe.

In both cases charge matrices are expressible in terms of Killing vector fields of color isometries and gamma matrices or sigma matrices acting however on electroweak spin degrees of freedom so that a close connection between color and strong isospin is suggestive. This connection is empirically suggested also by the conserved vector current hypothesis and and partially conserved vector current hypothesis allowing to express strong interaction observables in terms of weak currents. In TGD framework color and electro-weak quantum numbers are therefore not totally unrelated as they are in standard model and it would be interesting to see whether this could allow to distinguish between TGD and standard model.

The detailed model for elementary particles involves still many un-certainties and in the following some suggestions allowing more detailed view are considered.

### 7.7.2 Construction of single fermion states

The general prediction of TGD is that particles correspond to partonic 2-surfaces, which can carry arbitrary high fermion number. The question is why only wormhole throats seem to carry fermion number 1 or 0 and why higher fermion numbers can be only assigned to the possibly existing super-partners.

1. p-Adic calculations assume that fermions correspond at imbedding space level to color partial waves assignable to the  $CP_2$  cm degrees of freedom of partonic 2-surface. The challenge is to give a precise mathematical content to the statement that partonic 2-surface moves in color partial wave. Color partial wave for the generic partonic 2-surface in general varies along the surface. One must either identify a special point of the surface as cm or assume that color partial wave is constant at the partonic 2-surface.
2. The first option looks artificial. Constancy condition is however very attractive since it would correlate the geometry of partonic 2-surface with the geometry of color partial wave and therefore code color quantum numbers to the geometry of space-time surface. This quantum classical correlation cannot hold true generally but could be true for the maxima of Kähler function.
3. Similar condition can be posed in  $M^4$  degrees of freedom and would state that the plane wave representing momentum eigenstate is constant at the partonic 2-surface.

For momentum eigenstates one obtains only one condition stating

$$p_{M^4} \cdot m = \text{constant} = C$$

at the partonic 2-surface located at the light-like boundary of  $CD$ . Here  $p_{M^4}$  denotes the  $M^2$  projection of the four-momentum.  $CD$  projection is at most 2-dimensional and at the surface of ellipsoid of form

$$x^2 + y^2 + k^2(z - z_0)^2 = R^2 \quad ,$$

where the parameters are expressible in terms of the momentum components  $p_0, p_3$  parameter  $C$ . In this case, the assumption that fermions have collinear  $M^2$  momentum projection allows to add several fermions to the state provided the conditions in  $CP_2$  degrees of freedom allow this. In particular, covariantly constant right-handed neutrino must be collinear with the other fermions possibly present in the state.

For color partial waves the condition says that color partial wave is complex constant at partonic 2-surface  $\Psi = C$ .

1. The condition implies that the  $CP_2$  projection of the color partial wave is 2-dimensional so that one obtains a family of 2-surfaces  $Y^2$  labelled by complex parameter  $C$ . Color transformations act in this space of 2-surfaces. In general  $Y^2$  is not holomorphic since only the lowest representations (1,0) and (0,1) of  $SU(3)$  correspond to holomorphic color partial waves. What is highly satisfying is that the condition allows  $CP_2$  projection with maximal possible dimension.

2. If one requires covariant constancy of fermionic spinors, only vanishing induced spinor curvature is possible and  $CP_2$  projection is 1-dimensional, which does not conform with the assumption that elementary particles correspond to Kähler magnetic monopoles.
3. There is an objection against this picture. The topology of  $CP_2$  projection must be consistent with the genus of the partonic 2-surface [K16]. The conditions that plane waves and color partial waves are constant at the partonic 2-surface means that one can regard partonic 2-surfaces as sub-manifolds in 4-dimensional sub-manifold of  $A \times B \subset \delta CD \times CP_2$ . The topologies of  $A$  and  $B$  pose no conditions on the genus of partonic 2-surface locally. Therefore the objection does not bite.

One can consider also partonic 2-surfaces containing several fermions. In the case of covariantly constant right-handed neutrino this gives no additional conditions in  $CP_2$  degrees of freedom if the right handed neutrino has  $M^2$  momentum projection collinear with the already existing fermion. Therefore  $\Psi = C$  constraint is consistent with SUSY in TGD sense. For other fermions  $N$ -fermion state gives  $2N$  conditions in  $CP_2$  degrees of freedom. Already for  $N = 2$  the solutions consist of discrete points of  $CP_2$ . Physical intuition suggests that the states with higher fermion number are not realized as maxima of Kähler function and are effectively absent unlike the observed states and their partners.

### 7.7.3 About the construction of mesons and elementary bosons in TGD Universe

It looks somewhat strange to talk about the construction of mesons and elementary bosons in the same sentence. The construction recipes are however structurally identical so that it is perhaps sensible to proceed from mesons to elementary bosons. Therefore I will first consider the construction of meson like states relevant for the TGD based model of hadrons, in particular for the model of the pion of  $M_{89}$  hadron physics possibly explaining the 125 GeV state for which LHC finds evidence. The more standard interpretation is as elementary spin 0 boson, which need not however have anything to do with Higgs. Amusingly, the two alternatives obey very similar mathematics.

#### Construction of meson like states in TGD framework

The challenge is how translate attributes like scalar and pseudo-scalar making sense at  $M^4$  level to statements making sense at the level of  $M^4 \times CP_2$ .

In QCD the view about construction of pseudo-scalar mesons is roughly that one has string like object having quark and antiquark at its ends, call them  $A$  and  $B$ . The parallel translation of the antiquark spinor from  $A$  to  $B$  is needed in order to construct gauge invariant object of type  $\bar{\Psi}O\Psi$ , where  $O$  characterizes the meson. The parallel translation implies stringy non-locality. In lattice QCD this string correspond to the edge of lattice cell. For a general meson  $O$  is "charge matrix" obtained as a combination of gamma matrices ( $\gamma_5$  matrix for pseudo-scalar), polarization vectors, and isospin matrices.

This procedure must be generalized to TGD context. In fact a similar procedure applies also in the construction of gauge bosons possible Higgs like states since also in this case one must have general coordinate invariance and gauge invariance. Consider as an example pseudo-scalars.

1. Pseudo-scalars in  $M^4$  are replaced with axial vectors in  $M^4 \times CP_2$  with components in  $CP_2$  direction. One can say that these pseudo-scalars have  $CP_2$  polarization representing the charge of the pseudo-scalar meson. One replaces  $\gamma_5$  with  $\gamma_5 \times O_a$  where  $O_a = O_a^k \gamma_k$  is the analog of  $\epsilon^k \gamma_k$  for gauge boson. Now however the gamma matrices are  $CP_2$  gamma matrices and  $O_a^k$  is some vector field in  $CP_2$ . The index  $a$  labels the isospin components of the meson.
2. What can one assume about  $O_a$  at the partonic 2-surfaces? In the case of pseudo-scalars pion and  $\eta$  (or vector mesons  $\rho$  and  $\omega$  with nearly the same masses) one should have four such fields forming isospin triplet and singlet with large mass splitting. In the case of kaon would should have also 4 such fields but with almost degenerate masses. Why such a large difference between kaon and  $(\pi, \eta)$  system? A plausible explanation is in terms of mixing of neutral pseudo-scalar mesons with vanishing weak isospin mesons raising the mass of  $\eta$  but one might dream of alternative explanations too.

- (a) Obviously  $O_a$ 's should form strong isospin triplets and singlets in case of  $(\pi, \eta)$  system. In the case of kaon system they should form strong isospin doublets. The group in question should be identifiable as strong isospin group. One can formally identify the subgroup  $U(2) \subset SU(3)$  as a counterpart of strong isospin group. The group  $SO(3) \subset SU(3)$  defines second candidate of this kind. These subgroups correspond to two different geodesic spheres of  $S^2$ . The first gives rise to vacuum extremals of Kähler action and second one to non-vacuum extremals carrying magnetic charge at the partonic 2-surface. Cosmic strings as vacuum extremals and cosmic strings as magnetically charged objects are basic examples of what one obtains. The fact that partonic 2-surfaces carry Kähler magnetic charge strongly suggests that  $U(2)$  option is the only sensible one but one must avoid too strong conclusions.
- (b) Could one identify  $O_a$  as Killing vector fields for  $u(2) \subset su(3)$  or for its complement and in this manner obtain two kinds of meson states directly from the basic Lie algebra structure of color algebra? For  $u(2)$  one would obtain 3+1 vector fields forming a representation of  $u(2)$  decomposing to a direct sum of representations 3 and 1 of  $U(2)$  having interpretation in terms of  $\pi$  and  $\eta$  the symmetry breaking is expected to be small between these representations. For the complement of  $u(2)$  one would obtain doublet and its conjugate corresponding to kaon like states. Mesons states are constructed from the four states  $U_i \bar{D}_j$ ,  $\bar{U}_i D_j$ ,  $U_i \bar{U}_j$ ,  $D_i \bar{D}_j$ . For  $i = j$  one would have  $u(2)$  and for  $i \neq j$  its complement.
- (c) One would obtain a connection between color group and strong isospin group at the level of meson states and one could say that mesons states are not color invariants in the strict sense of the world since color would act on electroweak spin degrees of freedom non-trivially. This could relate naturally to the possibility to characterize hadrons at the low energy limit of theory in terms of electroweak quantum numbers. Strong force at low energies could be described as color force but acting only on the electroweak spin degrees of freedom. This is certainly something new not predicted by the standard model.
3. Covariant constancy of  $O_a$  at the entire partonic 2-surface is perhaps too strong a constraint. One can however assume this condition only at the the braid ends.
- (a) The holonomy algebra of the partonic 2-surface is Abelian and reduces to a direct sum of left and right handed parts. For both left- and right-handed parts it reduces to a direct sum of two algebras. Covariant constancy requires that the induced spinor curvature defining classical electroweak gauge field commutes with  $O_a$ . The physical interpretation is that electroweak symmetries commute with strong symmetries defined by  $O_a$ . There would be at least two conditions depending only on the  $CP_2$  projection of the partonic 2-surface.
- (b) The conditions have the form

$$F^{AB} j_B^a = 0 \quad ,$$

where  $a$  is color index for the sub-algebra in question and  $A, B$  are electroweak indices. The conditions are quadratic in the gradients of  $CP_2$  coordinates. One can interpret  $F^{AB}$  as components of gauge field in  $CP_2$  with Abelian holonomy and  $j^a$  as electroweak current. The condition would say that the electroweak Lorentz force acting on  $j^a$  vanishes at the partonic 2-surface projected to  $CP_2$ . This interpretation looks natural classically. The conditions are trivially satisfied at points, where one has  $j_B^a = 0$ , that is at the fixed points of the one-parameter subgroups of isometries in question.  $O_a$  would however vanish identically in this case.

- (c) The condition  $F^{AB} j_B^a = 0$  at all points of the partonic 2-surface looks un-necessary strong and might fail to have solution. The reason is that quantum classical correspondence strongly suggests that the color partial waves of fermions and planewaves associated with 4-momentum are constant along the partonic surface. The additional condition  $F^{AB} j_B^a = 0$  allows only a discrete set of solutions.

A weaker form of these conditions would hold true for the braid ends only and could be used to identify them. This conforms with the notion of finite measurement resolution and looks rather natural from the point of view of quantum classical correspondence. Both forms of the conditions allows SUSY in the sense that one can add to the fermionic state

at partonic 2-surface a covariantly constant right-handed neutrino spinor with opposite fermionic helicity.

- (d) These conditions would be satisfied only for the operators  $O_a$  characterizing the meson state and this would give rise to symmetry breaking relating to the mass splittings. Physical intuition suggests that the constraint on the partonic 2-surface should select or at least pose constraints on the maximum of Kähler function. This would give the desired quantum classical correlation between the quantum numbers of meson and space-time surface.
4. The parallel translation between the ends connecting the partonic 2-surfaces at which quark and antiquark reside at braid ends is along braid strand defining the state of string like object at the boundary of  $CD$ . These stringy world sheets are fundamental structures in quantum TGD and a possible interpretation is as singularity of the effective covering of the imbedding space associated with the hierarchy of Planck constants and due to the vacuum degeneracy of Kähler action implying that canonical momentum densities correspond to several values for the gradients of imbedding space coordinates. The parallel translation is therefore unique once the partonic 2-surface is fixed. This is of outmost importance for the well-definedness of quantum states. Obviously this state of affairs gives an additional "must" for braids.

The construction recipe generalizes trivially to scalars. There is however a delicate issue associated with the construction of spin 1 partners of the pseudo-scalar mesons. One must assign to a spin 1 meson polarization vector using  $\epsilon^k \gamma_k$  as an additional factor in the "charge matrix" slashed between fermion and antifermion. If the charge matrix is taken to be  $Q_a = \epsilon^k \gamma_k j_k^a \Gamma^k$ , it has matrix elements only between quark and lepton spinors. The solution of the problem is simple. The triplet of charge matrices defined as  $Q_a = \epsilon^k \gamma_k D_k j_l^a \Sigma^{kl}$  transforms in the same manner as the original triplet under  $U(2)$  rotations and can be used in the construction of spin 1 vector mesons.

### Generalization to the construction of gauge bosons and spin 0 bosons

The above developed argument generalizes with trivial modifications to the construction of the gauge bosons and possible Higgs like states as well as their super-partners.

1. Now one must form bi-linears from fermion and anti-fermion at the opposite throats of the wormhole contact rather than at the ends of magnetic flux tube. This requires braid strands along the wormhole contact and parallel translation of the spinors along them. Hadronic strings are replaced with the TGD counterparts of fundamental strings.
2. For electro-weak gauge bosons  $O$  corresponds to the product  $\epsilon_k \gamma^k Q_i$ , where  $Q_i$  is the charge matrix associated with gauge bosons contracted between both leptonic and quark like states. For gluons the charge matrix is of form  $Q_A = \epsilon_k \gamma^k H_A$ , where  $H_A$  is the Hamiltonian of the corresponding color isometry.
3. One can also consider the possibility of charge matrices of form  $Q_A = \epsilon^k \gamma_k D_k j_l^A \Sigma^{kl}$ , where  $j^A$  is the Killing vector field of color isometry. These states would compose to representations of  $u(2) \subset u(3)$  to form the analogs of  $(\rho, \omega)$  and  $(K^*, \bar{K}^*)$  system in  $CP_2$  scale. This is definitely something new.
4. In the case of spin zero states polarization vector is replaced with polarization in  $CP_2$  degrees of freedom represented by one of the operators  $O_a$  already discussed. One would obtain the analogs of  $(\pi, \eta)$  and  $(K, \bar{K})$  systems at the level of wormhole contacts. Higgs mechanism for these does not explain fermionic masses since p-adic thermodynamics gives the dominant contributions to them. It is also difficult to imagine how gauge bosons could eat these states and what the generation of vacuum expectation value could mean mathematically. Higgs mechanism is essentially 4-D concept and now the situation is 8-dimensional.
5. At least part of spin zero states corresponds to polarizations in  $CP_2$  directions for the electroweak gauge bosons. This would mean that one replaces  $\epsilon_k \gamma^k$  with  $j_a^k \Gamma^k$ , where  $j_a$  is Killing vector field of color isometry in the complement of  $u(2) \subset su(3)$ . This would give four additional polarization states. One would have 4+2=6 polarization just as one for a gauge field in 8-D Minkowski space. What about the polarization directions defined by  $u(2)$  itself? For the Kähler

part of electroweak gauge field this part would give just the  $(\rho, \omega)$  like states already mentioned. Internal consistency might force to drop these states from consideration.

The nice aspect of p-adic mass calculations is that they are so general: only super-conformal invariance and p-adic thermodynamics and p-adic length scale hypothesis are assumed. The drawback is that this leaves a lot of room for the detailed modeling of elementary particles.

1. Lightest mesons are lowest states at Regge trajectories and also p-adic mass calculations assign Regge trajectories in  $CP_2$  scale to both fermions and bosons.
2. It would be natural to assign the string tension with the wormhole contact in the case of bosons and identifiable in terms of the Kähler action assignable to the wormhole contact modelable as piece of  $CP_2$  type vacuum extremal and having interpretation in terms of the action of Kähler magnetic fields.
3. Free fermion has only single wormhole throat. The action of the piece of  $CP_2$  type vacuum extremal could give rise to the string tension also now. One would have something analogous to a string with only one end, and one can worry whether this is enough. The magnetic flux of the fermion however enters to the Minkowskian region and ends up eventually to a wormhole throat with opposite magnetic charge. This contribution to the string tension is however expected to be small being proportional to  $1/S$ , where  $S$  is the thickness of the magnetic flux tube connecting the throats. Only if the magnetic flux tube remains narrow, does one obtain the needed string tension from the Minkowskian contribution. This is the case if the flux tube is very short. It seem that the dominant contribution to the string tension must come from the wormhole throat.
4. The explanation of family replication phenomenon [K16] based on the genus of wormhole throat works for fermions if the the genus is same for the two throats associated with the fermion. In case of bosons the possibility of different genera leads to a prediction of dynamical SU(3) group assignable to genus degree of freedom and gauge bosons should appear also in octets besides singlets corresponding to ordinary elementary particles. For the option assuming identical genera also for bosons only the singlets are possible.
5. Regge trajectories in  $CP_2$  scale indeed absolutely essential in p-adic thermodynamics in which massless states generate thermal mass in p-adic sense. This makes sense in zero energy ontology without breaking of Poincare invariance if  $CD$  corresponds to the rest system of the massive particle. An alternative way to achieve Lorentz invariance is to assume that observed mass squared equals to the thermal expectation value of thermal weight rather than being thermal expectation for mass squared.

It must be emphasized that spin 0 states and exotic spin 1 states togetherwith their super-partners might be excluded by some general arguments. Induced gauge fields have only two polarization states, and one might argue that that same reduction takes place at the quantum level for the number of polarization states which would mean the elimination of  $F_L \overline{F}_R$  type states having interpretation as  $CP_2$  type polarizations for gauge bosons. One could also argue that only gauge bosons with charge matrices corresponding to induced spinor connection and gluons are realized. The situation remains open in this respect.

#### 7.7.4 What SUSY could mean in TGD framework?

What SUSY means in TGD framework is second long-standing problem. In TGD framework SUSY is inherited from super-conformal symmetry at the level of WCW [?, ?]. The SUSY differs from  $\mathcal{N} = 1$  SUSY of the MSSM and from the SUSY predicted by its generalization and by string models. One obtains the analog of the  $\mathcal{N} = 4$  SUSY in bosonic sector but there are profound differences in the physical interpretation.

1. One could understand SUSY in very general sense as an algebra of fermionic oscillator operators acting on vacuum states at partonic 2-surfaces. Oscillator operators are assignable to braids ends and generate fermionic many particle states. SUSY in this sense is badly broken and the algebra corresponds to rather large  $\mathcal{N}$ . The restriction to covariantly constant right-handed neutrinos (in  $CP_2$  degrees of freedom) gives rise to the counterpart of ordinary SUSY, which is more physically interesting at this moment.

2. Right handed neutrino and antineutrino are not Majorana fermions. This is necessary for separate conservation of lepton and baryon numbers. For fermions one obtains the analog  $\mathcal{N} = 2$  SUSY.
3. Bosonic emergence [?] means the construction of bosons as bound states of fermions and anti-fermions at opposite throats of wormhole contact. This reduces TGD SUSY to that for fermions. This difference is fundamental and means deviation from the SUSY of  $\mathcal{N} = 4$  SUSY, where SUSY acts on gauge boson states. Bosonic representations are obtained as tensor products of representation assigned to the opposite throats of wormhole contacts. Further tensor products with representations associated with the wormhole ends of magnetic flux tubes are needed to construct physical particles. This represents a crucial difference with respect to standard approach, where one introduces at the fundamental level both fermions and bosons or gauge bosons as in  $\mathcal{N} = 4$  SUSY. Fermionic  $\mathcal{N} = 2$  representations are analogous to "short"  $\mathcal{N} = 4$  representations for which one half of super-generators annihilates the states.
4. The introduction of both fermions and gauge bosons as fundamental particles leads in quantum gravity theories and string models to  $d = 10$  condition for the target space, spontaneous compactification, and eventually to the landscape catastrophe.

For a supersymmetric gauge theory (SYM) in  $d$ -dimensional Minkowski space the condition that the number of transversal polarization for gauge bosons given by  $d - 2$  equals to the number of fermionic states made of Majorana fermions gives  $d - 2 = 2^k$ , since the the number of fermionic spinor components is always power of 2.

This allows only  $d = 3, 4, 6, 10, 16, \dots$ . Also the dimensions  $d + 1$  are actually possible since the number of spinor components for  $d$  and  $d + 1$  is same for  $d$  even. This is the standard argument leading to super-string models and M-theory. It is lost - or better to say, one gets rid of it - if the basic fields include only fermion fields and bosonic states are constructed as the tensor products of fermionic states. This is indeed the case in TGD, where spontaneous compactification plays no role and bosons are emergent.

5. Spontaneous compactification leads in string model picture from  $\mathcal{N} = 1$  SUSY in say  $d = 10$  to  $\mathcal{N} > 1$  SUSY in  $d = 4$  since the fermionic multiplet reduces to a direct sum of fermionic multiplets in  $d = 4$ . In TGD imbedding space is not dynamical but fixed by internal consistency requirements, and also by the condition that the theory is consistent with the standard model symmetries. The identification of space-time as 4-surface makes the induced spinor field dynamical and the notion of many-sheeted space-time allows to circumvent the objections related to the fact that only 4 field like degrees of freedom are present.

The missing energy predicted standard SUSY is absent at LHC. The easy explanation would be that the mass scale of SUSY is unexpectedly high, of order 1 TeV. This would however destroy the original motivations for SUSY.

In TGD framework the natural first guess was that the missing energy corresponds to covariantly constant right-handed neutrinos carrying four-momentum. The objection is that covariantly constant right-handed neutrinos cannot appear in asymptotic states because one cannot assign a super-multiplet to right-handed neutrinos consistently. Covariantly constant right-handed neutrinos can however generate SUSY.

This alone would explain the missing missing momentum at LHC predicted by standard SUSY. The assumption that fermions correspond to color partial waves in  $H$  implies that color excitations of the right handed neutrino that would appear in asymptotic states are necessarily colored. It could happen that these excitations are color neutralized by super-conformal generators. If this is not the case, these neutrinos would be like quarks and color confinement would explain why they cannot be observed as asymptotic states in macroscopic scales. So called leptohadrons could correspond to bound states of colored sleptons and have same p-adic mass scale as leptons have [?]. Even in the case of quarks the situation could be the same.

Second possibility considered earlier is that SUSY itself is generated by color partial waves of right-handed neutrino, octet most naturally. This option is not however consistent with the above model for one-fermion states and their super-partners.

The breakthrough in the understanding of the preferred extremals of Kähler action and solutions of the modified Dirac equation led to a radical reconsideration of the existing picture. The most

natural conclusion is that the TGD counterpart of standard SUSY is most naturally absent. The arguments in favor of this conclusion discussed in the last section are rather strong. The breakthrough in understanding of TGD counterpart for Higgs like particle - Euclidian  $M_{89}$  pion - led to a model for the generation of weak gauge bosons masses free of the problem of the standard Higgs mechanism caused by the fact that tachyonic mass term is not stable under radiative corrections. In TGD framework this kind of term is absent. Therefore also the basic motivation for standard SUSY as stabilizer of radiative corrections disappears. Standard space-time SUSY would be replaced with 4-D generalization of 2-D super-conformal invariance but restricted to the modes of right-handed neutrino. For other fermion states the modes would be restricted to 2-D string world sheets and partonic 2-surfaces and super-conformal symmetry would reduce to 2-D one. The 2-D super-conformal symmetry is mathematically analogous to badly broken SUSY with very large value of  $\mathcal{N}$  and massive neutrino would represent the least broken aspect of this symmetry. The masses of sparticles are expected to be higher than particles for this SUSY.

## Chapter 8

# SUSY in TGD Universe

### 8.1 Introduction

TGD based vision about supersymmetry has developed rather slowly.

1. From the beginning it was clear that super-conformal symmetry is realized in TGD but differs in many respects from the more standard realizations such as  $\mathcal{N} = \infty$  SUSY realized in MSSM [?] involving Majorana spinors in an essential manner. The covariantly constant right-handed neutrino generates the super-symmetry at the level of  $CP_2$  geometry and the construction of super-partners would be more or less equivalent with the addition of right-handed covariantly constant right-handed neutrino and antineutrinos. It was however not clear whether space-time supersymmetry is realized at all since one could argue that that these states are just gauge degrees of freedom.
2. A more general general SUSY algebra is generated by the generalized eigen modes of the modified Dirac operator at partonic 2-surface. The value of  $\mathcal{N}$  can be very large-even infinite- for this algebra and the SUSY is badly broken: this picture leads to a construction of QFT limit of TGD [?], which seems to be crucial also for the understanding of TGD itself. Right-handed neutrinos represent the sub-SUSY with minimal breaking induced by the mixing of right- and left handed neutrinos caused by the properties of the modified gamma matrices for which mixing between  $M^4$  and  $CP_2$  gamma matrices takes place induced breaking of  $M^4$  chirality serving as a signature for massivation.
3. R-parity conservation leading to strong predictions in the case of MSSM is broken and since super-particles can decay to neutrino and particles the life-times of super-partners are finite and there is no lightest sparticle. The decay to neutrinos would however produce missing energy and the problem of missing missing energy, which is the basic difficulty of the standard SUSY, might be encountered also in TGD framework. One proposal avoiding this difficulty relies on the assumption that the right-handed neutrino generating supersymmetry is colored and color confinement forces spartners to combine to non-colored state transforming to ordinary hadrons.
4. Quite recent developments in the understanding of the modified Dirac equation [?] (I am writing this 2012) have led to a considerable understanding of the special role of right-handed neutrino. Whereas all other fermions are localized to 2-D string world sheets and partonic 2-surfaces by the condition that electromagnetic charge defined in spinorial sense is conserved, right-handed neutrino is delocalized at entire space-time surface and there is unbroken 4-dimensional counterpart of 2-D super-conformal symmetry associated with it. One has also 2-D badly broken SUSY generated by all fermion modes of the modified Dirac equation and labelled by conformal weight. This SUSY could be also interpreted super-conformal symmetry. One has also the unbroken  $\mathcal{N} = 2$  space-time SUSY generated by right-handed neutrino and antineutrino. The rapid experimental progress at LHC during 2011-2012 has more or less eliminated standard SUSY and this gives a powerful constraint in the attempts to understand what TGD SUSY could be.

What remains to be understood is the role of the covariantly constant right-handed neutrino spinor carrying no momentum: it behaves like Majorana spinor and its helicity is not constrained by Dirac equation. It is not clear whether the states defined by 2-D parton and by parton plus 4-D delocalized right-handed neutrino can be distinguished experimentally if right-handed neutrino does not carry four-momentum. This would be a trivial explanation for the failure to find evidence for SUSY at LHC. In fact, this argument can be developed to a more precise one: both fermions and sfermions exist and form representations of SUSY with second state having zero norm. Therefore fermion and sfermion candidates exist but belong to different representations of SUSY, and right-handed neutrinos remain invisible in the dynamics and the characteristic spin and momentum dependent vertex factors distinguishing between particle and sparticle are absent. The loss of space-time SUSY is not a catastrophe since it is not needed to stabilize Higgs in TGD framework since the variant of Higgs mechanism based on Higgs like pseudo-scalar is based conformally covariant Higgs potential containing no tachyonic Higgs mass term and is free of the problems related to radiative instability of the tachyonic Higgs mass term.

Personally I have a strong temptation to take the argument for the absence of space-time SUSY - space-time understood here as  $M^4$  or  $M^4 \times CP_1$  - seriously. This would conform with the failure of LHC to find space-time SUSY. At first one might see the absence of space-time SUSY as disappointing. Space-time SUSY however extends to the 4D analog of super-conformal invariance (not the usual super-conformal invariance but an infinite-dimensional symmetry) when space-time is understood as space-time surface.

If this argument - described later in more detail in the section "What is the role of the right-handed neutrino?" - one can conclude that most of the chapter is more or less obsolete! It is however better to be very cautious: some-one has said that our theories are much more intelligent than their builders, and from my personal experience I can fully agree with this statement! Therefore I dare not take the recent view as the final one: only the experimental input allows to fill in the details correctly. It is however clear that TGD based SUSY differs dramatically from the SUSY as it is usually understood and that LHC could allow to decide which of these views is nearer to truth.

In the following I will describe the evolution of ideas related to SUSY in TGD framework. There is no attempt to build a coherent final view and arguments in different sections represent how the views have developed.

## 8.2 A concise view about SUSY phenomenology in TGD inspired Universe

The results from SUSY have been very inspiring and forced me to learn the basics of MSSM phenomenology and abstract what it shares with TGD view. As always this kind of process has been very useful. In the following I summarize the big ideas which distinguish TGD SUSY from MSSM and try to formulate the resulting general phenomenological picture. Of course, one can argue that this kind of approach assuming that QFT calculations can be interpreted in TGD framework is ad hoc since twistor approach applied in TGD means deviation from QFT at the fundamental level. I just assume that QFT approach is a good approximation to TGD and look for consequences. Also the experimental constraints on SUSY parameters deduced in the framework of MSSM model with R-symmetry are discussed in TGD framework and shown to be relaxed considerably so that it is possible to avoid problems plaguing MSSM approach: mention only little hierarchy problem and conflicting demands from  $g-2$  anomaly of muon and from squark mass limits.

### 8.2.1 Super-conformal invariance and generalized space-time supersymmetry

Super-conformal symmetry is behind the space-time supersymmetry in TGD framework. It took long time to get convinced that one obtains space-time supersymmetry in some sense.

1. The basic new idea is that the fermionic oscillator operators assignable to partonic 2-surfaces defined the SUSY algebra analogous to space-time SUSY algebra. Without length scale cutoff

the number of oscillator operators is infinite and one would have  $\mathcal{N} = \infty$  SUSY. Finite measurement resolution realized automatically by the dynamics of the modified Dirac action however effectively replaces the partonic two-surface with a discrete set of points which is expected to be finite and one obtains reduction finite value of  $\mathcal{N}$ . Braids become basic objects in finite measurement resolution at light-like 3-D wormhole throats. String world sheets become the basic objects at the level of 4-D space-time surfaces and it is now possible to identify them uniquely and a connection with the theory of 1-knots, their cobordisms and 2-knots emerges.

The supersymmetry involves several algebras for which the fermionic oscillator operator algebra serves as a building block. Also the gamma matrices of the world of classical worlds (WCW) are expressible in terms of the fermionic oscillator operators so that fermionic anticommutations have purely geometric interpretation. The presence of SUSY in the sense of conservation of fermionic supra currents requires a consistency condition. For induced gamma matrices the surface must be minimal surfaces (extremal of volume action). For Kähler action and Chern-Simons action one must replace induced gammas by modified ones defined by the contractions of canonical momentum densities with the imbedding space gamma matrices.

The super-symmetry in TGD framework differs from that in standard approach in that Majorana spinors are not involved. One has 8-D imbedding space spinors with interpretation as quark and lepton spinors. This makes sense because color corresponds to color partial waves and quarks move in triality  $t = \pm 1$  and leptons in  $t = 0$  waves. Baryon and lepton number are conserved exactly.

2. A highly non-trivial aspect of TGD based SUSY is bosonic emergence meaning that bosons can be constructed from fermions. Zero energy ontology makes this construction extremely elegant since both massive states and virtual states are composites of massless states. The mass shell constraints on vertices reduce dramatically the momentum space for virtual momenta and resolves UV divergences. General arguments support the existence of pseudoscalar Higgs but it is not quite clear whether its existence is somehow forbidden by symmetries. Scalar and pseudoscalar Higgs transforming according to 3+1 decomposition under weak  $SU(2)$  replace two complex doublets of MSSM if this is not the case. This difference is essentially due to the fact that spinors are not  $M^4$  spinors but  $M^4 \times CP_2$  spinors. A proper notation would be  $B, h_B$  for the gauge bosons and corresponding Higgs particles and one expects that electroweak mixing characterized by Weinberg angle takes place for neutral Higgs particles and also their super-counterparts.

The sfermions associated with left and right handed fermions should couple to fermions via  $P_{\pm} = 1 \pm \gamma_5$  so that one can speak about left- and right-handed scalars. Maximal mixing between them leads to scalar and pseudoscalar. This observation raises a question about Higgs and its pseudoscalar variant. Could one also assume that the initial states are right and left handed Higgs and that maximal mixing leads to scalar and pseudoscalar with scalar eaten by gauge bosons?

3. Also spin one particles regarded usually as massless must have small mass and this means that Higgs scalar is completely eaten by gauge bosons. Also scalar gluons are predicted and would be eaten by gluons to develop a small mass. This resolves the IR difficulties of massless gauge theories and conjecture to make possible exact Yangian symmetry in the twistor approach to TGD. The disappearance of Higgs means that corresponding limits on the parameters of SUSY are lost. For instance the limits in  $(\tan(\beta), M_{SUSY})$  coming from Higgs mass do not hold anymore. The disappearance of Higgs means also the disappearance of the little hierarchy problem, which is one of the worst headaches of MSSM SUSY: no Higgs- no Higgs mass to be stabilized.

### 8.2.2 Induced spinor structure and purely geometric breaking of SUSY

Particle massivation and the breaking of SUSY and R-symmetry are the basic problems of both QFT and stringy approach to SUSY. Just by looking the arguments related to how MSSM could emerge from string models make clear how hopelessly ad hoc the constructions are. The notion of modified gamma matrix provides a purely geometric approach to these symmetric breakings involving no free

parameters. To my view the failure to realize partially explains the recent situation in the forefront of theoretical physics and LHC findings are now making clear that something is badly wrong.

1. The space-time supersymmetry is broken. The reason is that the modified gamma matrices are superpositions of  $M^4$  and  $CP_2$  gamma matrices. This implies mixing of  $M^4$  chiralities, which is a direct symptom of massivation and is responsible for Higgs like aspects of massivation: p-adic thermodynamics is second and completely new aspect. There is hierarchy of supersymmetries according to the strength of breaking. Right handed neutrino generates supersymmetry which is broken only by the mixing of right handed neutrino with left handed one and induced by the mixing of gamma matrices. This corresponds to the supersymmetry analogous to that of MSSM. The supersymmetries generated by other fermionic oscillator operators with electroweak quantum numbers break the super-symmetry in much more dramatic manner but the basic algebra remains and should allow an elegant formulation of TGD in terms of generalized super fields [?] .
2. One important implication is R-parity breaking due to the transformation of right handed neutrino of superpartner to left-handed neutrino. If this takes place fast enough, the process  $\tilde{P} \rightarrow P + \nu$  becomes possible. The universal decay signature would be lonely neutrino representing missing energy without accompanying charged lepton. This means that the experimental limits on sparticle masses deduced assuming R-symmetry do not hold anymore. For instance, the masses of charginos and neutralinos can be considerably lower than weak mass scale as suggested by strange 1995 event [?] . The recent very high lower bounds of squark masses putting them above 800 GeV assume also R-symmetry and therefore need not hold true if the decays  $\tilde{h} \rightarrow q + \nu$  and  $\tilde{g} \rightarrow g + \nu$  take place fast enough. A further implication is that the scale of SUSY can be weak mass scale- say the p-adic mass scale of 105 GeV corresponding to Mersenne prime  $M_{89}$ .

### 8.2.3 p-Adic length scale hypothesis and breaking of SUSY by a selection of p-adic length scale

p-Adic length scale symmetry leads to a completely new view about SUSY breaking which leads to extremely strong prediction. The basic conjecture is that if the p-adic length scales associated with particles and sparticle are same, their masses are identical. The basic aspect of SUSY breaking is therefore different p-adic mass scales of particle and sparticle. By p-adic length scale hypothesis the masses of particle and superpartner therefore differ by a power of  $\sqrt{2}$ . This is extremely powerful prediction and given only minimal kinematical constraints on the event suggesting super-symmetry allows to deduce the mass of super-partner. Some examples give an idea about what is involved.

1. The idea about  $M_{89}$  as the prime characterizing both electroweak scale and SUSY mass scale leads to the proposal that all superpartners correspond to the same p-adic mass scale characterized by  $k = 89$ . For instance, the masses of sfermions would be given in first order p-adic thermodynamics calculation by

$$\begin{aligned}
 \frac{m_{\tilde{L}}}{GeV} &= (262, 439, 945) , \\
 \frac{m_{\tilde{e}}}{GeV} &= (235, 423, 938) , \\
 \frac{m_{\tilde{U}}}{GeV} &= (262, 287, 893) , \\
 \frac{m_{\tilde{D}}}{GeV} &= (235, 287, 900) .
 \end{aligned}
 \tag{8.2.-3}$$

The recent results from LHC force imply that in absence of R-parity breaking the masses of squarks must be in the region 800-1000 GeV, which forces to conclude that neutrino mixing must be fast enough to allow direct decays  $\tilde{P} \rightarrow P + \nu$ .

2. In case of the mixing of gaugino and corresponding Higgsino the hypothesis means that the mass matrix is of such form that its eigenvalues have same magnitude but opposite sign. For instance, for the mixing of wino and  $h_W$  one would have

$$M = \begin{pmatrix} M_2 & \sqrt{2}M_W \cos(\beta) \\ \sqrt{2}M_W \cos(\beta) & \mu \end{pmatrix}$$

so that the hypothesis implies

$$M_2 = -\mu .$$

The masses of the resulting two states would be same but they could correspond to different p-adic primes so that mass scales would differ by a power of  $\sqrt{2}$ . This formula applies also zino and  $\tilde{h}_Z$  and photino and  $\tilde{h}_\gamma$ . One possibility is that heavier weak gaugino corresponds to intermediate gauge boson mass scale and light gaugino to 1/2 of this scale: lighter mass scales are forbidden by the decay widths of weak gauge bosons. The exotic event of 1995 suggest that heavier zino has very nearly the same mass as  $Z^0$  and the lighter one mass which in good approximation equal to one half of  $Z^0$  mass. This would mean  $M_2 = -\mu \ll M_Z$ .

3. If one accepts the SUSY formula

$$m_{\tilde{\nu}}^2 = m_{\tilde{L}}^2 + \frac{1}{2}M_Z^2 \cos(2\beta)$$

relating neutrino and sneutrino masses, one can conclude that  $\cos(\beta) = 1/\sqrt{2}$  is the only possible option so that  $\tan(\beta) = 1$  is obtained. This value is excluded by R-parity conserving MSSM but could be consistent with the explanation of g-2 anomaly of muon in terms of loops involving weak gauginos and corresponding higgsinos. One can however argue that this formula can hold only if the particles involved correspond to same value of p-adic prime. This formula relates to the standard view about massivation and might well be a mere nuisance in the scenario based on p-adic thermodynamics.

4. One must distinguish between right- and left handed sfermions  $\tilde{F}_R$  and  $\tilde{F}_L$ . These states couple via  $1 \pm \gamma_5$  to fermions and are not therefore either pure scalars or pure pseudoscalars. One expects that a maximal mixing of left and right handed sfermions occurs and leads to scalar and pseudoscalar. Mass formula is naturally same for the states for the same value of p-adic prime and also same value of p-adic prime is suggestive. It might however happen that a p-adic mass scales are different for scalars and pseudoscalars. This would allow to have light and heavy variants of squarks and sleptons with scalars probably being the lighter ones.

To sum up, TGD leads to a very predictive model for SUSY and its breaking.

1. Since there is no Higgs, there are no bounds to parameters from Higgs mass and little hierarchy problem is avoided.
2. The basic element is R-parity breaking reflected in the possibility of decays of sparticles to particle and lonely neutrino not balanced by charge lepton. This together with the absence of Higgs would allow to circumvent various mass limits deduced from LHC and its predecessors and only the limits from the decay width of intermediate gauge bosons on charginos and neutralinos would remain.
3. The assumption that the masses of particles and sparticles are same for same p-adic length scale and that the choice of p-adic length scale breaks SUSY means that sparticle masses can be deduce from those of particles apart from a scaling by a power of  $\sqrt{2}$ . This is a powerful and directly testable prediction and predicts the  $2 \times 2$  mixing matrices for charginos and neutralinos completely apart from the parameter  $M = -\mu$ . One must however take it very cautiously in TGD framework since in TGD framework higgsino might disappear from the spectrum just like Higgs and the situation becomes degenerate. An attractive idea is that  $m_{SUSY}$  corresponds to p-adic mass scale associated with Mersenne prime  $M_{89}$  characterizing electro-weak length scale

and that Mesrenne hypothesis poses conditions on sfermion masses so that all sparticles so that the only light particles are selectron and sneutrinos and other sfermions have masses about 13 TeV.

4. Muon g-2 anomaly could be understood from the predictions  $\tan(\beta) = 1$ ,  $m_{SUSY} \simeq 105$  GeV if one assumes that sneutrinos are light. Scalar and pseudoscalar sfermions could in principle have different mass scales but there seems to be no recently accepted anomalies requiring this.

### 8.3 What do experiments say about the situation?

#### Do also Higgsinos disappear from the spectrum?

In the following still some comments about TGD based view about symmetry breaking, Higgs, electroweak symmetry breaking, and SUSY. There are several unclear issues at the level of details. This is thanks to my unforgivable laziness in writing down the details. The results from LHC are however so fascinating that they force me to win my laziness. In the following I try to clarify my thoughts.

##### 1. *Is the earlier conjectured pseudoscalar Higgs there at all?*

Spin 1 gauge bosons and Higgs differ only by different spin direction of fermions at opposite wormhole throats. For spin 1 gauge bosons the 3-momenta at two wormhole throats cannot be parallel if one wants non-vanishing spin component in the direction of moment. 3-momenta are most naturally opposite for the massless states at throats. This forces massivation for all gauge bosons and even graviton and this in turn requires Higgs even in the case of gluons.

The question is whether the parity properties of the couplings of gauge boson and corresponding Higgs transforming like 3+1 under SU(2) (this is due to the special character of imbedding space spinors) be exactly the same? Higgs would couple like a mixture of scalar and pseudoscalar to fermions just as weak gauge bosons couple and the mixture would be just the same. If there are no axial variants of vector gauge bosons there should exist no pseudoscalar Higgs. The nonexistence of axial variants of vector gauge bosons is suggested by quantum classical correspondence: only gauge bosons having classical space-time correlates as induced gauge potentials should be allowed, nothing else. Note that color variant of Higgs would exist and would be eaten by gluons to get mass.

##### 2. *Could Higgs mechanism lead to the disappearance of also Higgsinos?*

The similarity of the construction of gauge bosons and Higgsinos as pairs of wormhole throats containing fermion and antifermion encourages to think that Higgs mechanism is invariant under supersymmetries. If so, also Higgsinos would be eaten and one would have massive super-symmetric gauge theory with fermions with photon and other massless particle possessing a tiny mass. This looks very simple. The testable implication would be that only weak gauginos should contribute to muon g-2 anomaly.

##### 3. *Electroweak symmetry breaking*

The recent view about electroweak symmetry breaking is less than year old. The basic realization was that wormhole throats carrying elementary particle quantum numbers possess Kähler magnetic charge (in homological sense-  $CP_2$  has non-trivial second homology). This magnetic charge must be compensated and this is achieved if the particle wormhole throat is connected to a second wormhole throat by a magnetic flux tube. The second wormhole would carry a weak charge of neutrino pair compensating the weak isospin of the particle so that weak interactions would be screened above the weak length scale. For colored states the compensation could also occur in longer length scale and corresponds to color confinement.

This does not actually require the length scale of flux tubes associated with all elementary particles to be the weak length scale as I have thought. Rather, the flux tube length for a particle at rest could correspond to the Compton length of the particle. For instance, for electron the maximal flux tube length would be about  $10^{-13}$  meters. For particles not at rest the length would get shorter by length contraction. For very light but massive particles such as photon and graviton the maximum length of flux tube would be very long. The interaction of very low energy photons and gravitons would be essentially classical and induced by the classical oscillations of induced gauge fields induced by a long flux tube connecting the interacting systems. For high energy quanta this interaction would be

essentially quantal and realized as absorption of quanta with flux tube length -essentially wave length of quantum- much shorter than the distance between the interacting systems. Gravitational waves would interact essentially classically even when absorbed since absorption would mean that the flux tube would connect two parts of the measurement apparatus. For large  $\hbar$  gravitons the length of flux tube could correspond to the distance between interaction systems.

A fascinating possibility is that electronic Cooper pairs of superconductors with large value of  $\hbar$ , could correspond to long flux tubes with electron's quantum numbers at both ends. Maybe this takes place in high  $T_c$  super conductors.

#### 4. Some details of the SUSY predictions

TGD SUSY differs from the standard SUSY in many respects.

1. All fermionic oscillator operators assignable to the wormhole throats generate supersymmetries. These oscillator operators differ from ordinary ones in that they do not have momentum label and momentum can be only assigned to the entire state. Therefore the interpretation of all states assignable to wormhole throats as large SUSY multiplet is possible. This SUSY is badly broken and there is hierarchy of breakings defined by the interactions inducing the breaking in turn define by the quantum numbers of SUSY generators. For quark generators the breaking is largest and the smallest breaking is associated with the oscillator operators assignable to right-handed neutrinos since they have only gravitational interactions.
2. The symmetry generators are not Majorana spinors and this does not lead to any difficulties as has been found. Only if one would try stringy quantization trying to define stringy diagrams in terms of stringy propagators defined by stringy form of super-conformal algebra, one would end up with difficulties. Majorana property is also excluded by the separate conservation of baryon and lepton number.

For single wormhole throat one can see the situation in terms of N=2 SUSY with right handed neutrino and its antiparticle appearing as SUSY generators carrying conserved fermion number. One can classify the superpartners by their right-handed neutrino number which is  $\pm 1$ . For instance, for single wormhole throat one obtains fermion and its partner containing  $\nu_R$  pair, and fermion number 0 and fermion number 2 sfermions. In the case of gauge bosons and Higgs similar degeneracy is obtained for both wormhole throats.

3. Since induced gamma matrices and modified gamma matrices are mixtures of  $M^4$  and  $CP_2$  gamma matrices right handed neutrino is mixed with the left handed neutrino meaning breaking of R-parity. The simplest decays of sparticles are of form  $P \rightarrow P + \nu$  and can be said to be gravitationally induced since the mixing of gamma matrices is indeed a characteristic phenomenon of induced spinor structure. Also more complex decays with neutrino replaced with charge lepton are possible. The basic signature is lonely lepton not possible in decays of weak bosons.
4. The basic outcome of SUSY QFT limit of TGD [?] is that wormhole throat can carry only spin 0, 1/2, 1 corresponding to fermion and fermion pair if one wants to obtain standard propagator: otherwise one obtains  $1/p^n$ ,  $n > 2$  and this is not an ordinary particle pole. The reason is that one cannot assign to fermionic oscillator operators independent momenta but only common momentum so they propagate effectively collinearly.

One can criticize this argument as being inconsistent with the twistorial approach combined with zero energy ontology implying that wormhole throats are massless even for on mass shell states. In this approach one in principle avoids completely the use of propagators which would of course diverge for on shell wormhole throats. Also for twistor diagrams the counterparts of virtual particles are massless and off shell. The so called region momentum replaces momentum in Grassmannian twistor approach and has a direct counterpart as eigenvalue of the modified Dirac operator so that the analog of propagator exists in TGD framework. Since QFT limit must be a reasonable approximation to the full theory, one might hope that the QFT based argument makes sense when one replaces momentum with region momentum (or pseudo momentum as I have called it in TGD framework).

5. Should one allow both  $\nu_R$  and its antiparticle as SUSY generators? This would mean more states as in standard SUSY for which only  $\bar{\nu}_R$  would be allowed for fermion. This would assign to a given wormhole throat with fermion number 1 spin 1 and spin 0 super partner and companion of fermion containing  $\nu_R - \bar{\nu}_R$  pair. For this state however propagator would behave like  $1/p^3$  should that again strong SUSY breaking would occur for this extended SUSY. Only one half of SUSY would be broken weakly by the mixing of  $M^4$  and  $CP_2$  gamma matrices appearing in modified gamma matrices: the mixing would not involve weak or color interactions but could be said to be gravitational but not in the sense of abstract for geometry but induced geometry.

The breaking of symmetries by this mechanism would be a beautiful demonstration that it is sub-manifold geometry rather than abstract manifold geometry that matters. Again string theorists managed to miss the point by effectively eliminating induced geometry from the original string model by inducing the metric of space-time sheet as an independent variable. The motivation was that it became easy to calculate! The price paid was symmetry breaking mechanisms involving hundreds of three parameters.

6. Single wormhole contact could carry spin  $J=2$  and give rise to graviton like state. If one constructs from this gravitino by adding right-handed neutrinos, and if SUSY QFT limit makes sense, one obtains particle with propagator decreasing faster at either throat so that gravitino in standard sense would not exist. This would represent strong SUSY breaking in gravitational sector. These results are of utmost importance since the basic argument in favor dimension  $D=10$  or  $D=11$  for the target space of superstring models is that higher dimensions would give fundamental massless particles with higher spin.

Note that the replacement of wormhole throats by flux tubes having neutrino pair at the second end of the flux tube complicates the situation since one can add right handed neutrino also to the neutrino end. The SUSY QFT criterion would however suggest that these states are not particle like.

### Super-symplectic bosons

TGD predicts also exotic bosons which are analogous to fermion in the sense that they correspond to single wormhole throat associated with  $CP_2$  type vacuum extremal whereas ordinary gauge bosons corresponds to a pair of wormhole contacts assignable to wormhole contact connecting positive and negative energy space-time sheets. These bosons have super-conformal partners with quantum numbers of right handed neutrino and thus having no electro-weak couplings. The bosons are created by the purely bosonic part of super-symplectic algebra [?, K15], whose generators belong to the representations of the color group and 3-D rotation group but have vanishing electro-weak quantum numbers. Their spin is analogous to orbital angular momentum whereas the spin of ordinary gauge bosons reduces to fermionic spin. Recall that super-symplectic algebra is crucial for the construction of configuration space Kähler geometry. If one assumes that super-symplectic gluons suffer topological mixing identical with that suffered by say  $U$  type quarks, the conformal weights would be (5,6,58) for the three lowest generations. The application of super-symplectic bosons in TGD based model of hadron masses is discussed in [K46] and here only a brief summary is given.

As explained in [K46], the assignment of these bosons to hadronic space-time sheet is an attractive idea.

1. Quarks explain only a small fraction of the baryon mass and that there is an additional contribution which in a good approximation does not depend on baryon. This contribution should correspond to the non-perturbative aspects of QCD. A possible identification of this contribution is in terms of super-symplectic gluons. Baryonic space-time sheet with  $k = 107$  would contain a many-particle state of super-symplectic gluons with net conformal weight of 16 units. This leads to a model of baryon masses in which masses are predicted with an accuracy better than 1 per cent.
2. Hadronic string model provides a phenomenological description of non-perturbative aspects of QCD and a connection with the hadronic string model indeed emerges. Hadronic string tension is predicted correctly from the additivity of mass squared for  $J = 2$  bound states of super-symplectic quanta. If the topological mixing for super-symplectic bosons is equal to that for  $U$

type quarks then a 3-particle state formed by 2 super-symplectic quanta from the first generation and 1 quantum from the second generation would define baryonic ground state with 16 units of conformal weight. A very precise prediction for hadron masses results by assuming that the spin of hadron correlates with its super-symplectic particle content.

3. Also the baryonic spin puzzle caused by the fact that quarks give only a small contribution to the spin of baryons, could find a natural solution since these bosons could give to the spin of baryon an angular momentum like contribution having nothing to do with the angular momentum of quarks.
4. Super-symplectic bosons suggest a solution to several other anomalies related to hadron physics. The events observed for a couple of years ago in RHIC [?] suggest a creation of a black-hole like state in the collision of heavy nuclei and inspire the notion of color glass condensate of gluons, whose natural identification in TGD framework would be in terms of a fusion of hadronic space-time sheets containing super-symplectic matter materialized also from the collision energy. In the collision, valence quarks connected together by color bonds to form separate units would evaporate from their hadronic space-time sheets in the collision, and would define TGD counterpart of Pomeron, which experienced a reincarnation for few years ago [?]. The strange features of the events related to the collisions of high energy cosmic rays with hadrons of atmosphere (the particles in question are hadron like but the penetration length is anomalously long and the rate for the production of hadrons increases as one approaches surface of Earth) could be also understood in terms of the same general mechanism.

### 8.3.1 Experimental situation

The experimental situation in the case of SUSY is still open but it there are excellent hopes that the results from LHC will determine the fate of the MSSM SUSY and also constraint more general scenarios. Unfortunately, the research concentrates to the signatures of MSSM and its variants quite different from those of TGD SUSY so that it might happen that TGD SUSY will be discovered accidentally if its there: say by the decays of spartner to partner and neutrino. Already from the recent results it is clear that the allowed parameter space for MSSM SUSY is very small and that superpartners of quarks and also weak gauge bosons must be very heavy if MSSM SUSY is realized. This leads to difficulties with the only known evidence for SUSY coming from the g-2 anomaly of muon. TGD based SUSY allows light masses and also SUSY explanation of g-2 anomaly if sneutrino masses are light.

The representation involves a lot of references to blog postings and this might irritate so called serious scientists. I however feel that since blogs provide my only contact to the particle physics it is only fair to make clear that this communication tool is absolutely essential for a scientist working as out-of-law in academic community. Blogs could indeed bring democracy to science and mean end of the era of secrecy and censorship by the referee system.

#### Experimental indication for space-time super-symmetry

There is experimental indication for super-symmetry dating back to 1995 [?]. The event involves  $e^+e^-\gamma\gamma$  plus missing transverse energy  $\cancel{E}_T$ . The electron-positron pair has transversal energies  $E_T = (36, 59)$  GeV and invariant mass  $M_{ee} = 165$  GeV. The two photons have transversal energies (30,38) GeV. The missing transverse energy is  $\cancel{E}_T = 53$  GeV. The cross sections for these events in standard model are too small to be observed. Statistical fluctuation could be in question but one could also consider the event as an indication for super-symmetry.

In [?] an explanation of the event in terms of minimal super-symmetric standard model (MSSM) was proposed.

1. The collision of proton and antiproton would induce an annihilation of quark and antiquark to selectron pair  $\tilde{e}^-\tilde{e}^+$  via virtual photon or  $Z^0$  boson with the mass of  $\tilde{e}$  in the range (80,130) GeV (the upper bound comes from the total energy of the particles involved).
2.  $\tilde{e}^\pm$  would in turn decay to  $e^\pm$  and neutralino  $\chi_2^0$  and  $\chi_2^0$  in turn to the lightest super-symmetric particle  $\chi_1^0$  and photon. The neutralinos are in principle mixtures of the super partners associated

with  $\gamma$ ,  $Z^0$ , and neutral higgs  $h$  (there are two of them in minimal super-symmetric generalization of standard model). The highest probability for the chain is obtained if  $\chi_2^0$  is zino and  $\chi_1^0$  is higgsino.

3. The kinematics of the event allows to deduce the bounds

$$\begin{aligned} 80 &< m(\tilde{e})/GeV < 130 \quad , \\ 38 &\leq m(\chi_2^0)/GeV \leq \min [1.12m(\tilde{e})/GeV - 37, 95 + 0.17m(\chi_1^0)/GeV] \quad , \\ m(\chi_1^0)/GeV &\leq m(\chi_2^0)/GeV \leq \min [1.4m(\tilde{e})/GeV - 105, 1.6m(\chi_2^0)/GeV - 60] \quad . \end{aligned} \quad (8.3.-2)$$

Note that the bounds give no lower bound for  $m(\chi_1^0)$  so that it could correspond to neutrino.

4. Sfermion production rate depends only on masses of the sfermions, so that slepton production cross section decouples from the analysis of particular scenarios. The cross section is at the level of  $\sigma = 10$  fb and consistent with data (one event!). The parameters of MSSM are super-symmetric soft-breaking parameters, super-potential parameters, and the parameter  $\tan(\beta)$ . This allows to derive more stringent limits on the masses and parameters of MSSM.

Consider now the explanation of the event in TGD framework.

1. For the simplest TGD inspired option both Higgs and higgsino would disappear from the spectrum in the massivation and  $\chi_2^0$  would decay to photon and neutrino so that the missing energy would consist of neutrinos.
2. By the properties of super-partners the production rate for  $\tilde{e}^- \tilde{e}^+$  is predicted to be same as in MSSM for  $\tilde{e} = e_R \bar{\nu}_R$ . Same order of magnitude is predicted also for more exotic super-partners such as  $e_L \bar{\nu}_R$  with spin 1.
3. In TGD framework it is safest to use just the kinematical bounds on the masses and p-adic length scale hypothesis. If super-symmetry breaking means same mass formula from p-adic thermodynamics but in a different p-adic mass scale,  $m(\tilde{e})$  is related by a power of  $\sqrt{2}$  to  $m(e)$ . Using  $m(\tilde{e}) = 2^{(127-k(\tilde{e}))/2} m(e)$  one finds that the mass range [80, 130] GeV allows two possible masses for selectron corresponding to  $p \simeq 2^k$ ,  $k = 91$  with  $m(\tilde{e}) = 131.1$  GeV and  $k = 92$  with  $m(\tilde{e}) = 92.7$  GeV. The bounds on  $m(Z)$  leave only the option  $m(\tilde{Z}) = m(Z) = 91.2$  GeV and  $m(\tilde{e}) = 131.1$  GeV.
4. In the earlier variant of the TGD inspired model the existence of Higgs was considered as a realistic option. The indirect determinations of Higgs masses from experimental data seemed to converge to two different values. The first one seemed to correspond to  $m(h) = 129$  GeV and  $k(h) = 94$  and second one to  $m(h) = 91$  GeV with  $k(h) = 95$  [K39]. The fact that already the TGD counterpart for the Gell-Mann-Okubo mass formula in TGD framework requires quarks to exist at several p-adic mass scales [K46], suggests that Higgs can exist in both of these mass scales depending on the experimental situation. The mass of Higgsino would correspond to some half octave of  $m(h)$ . Note that the model allows to conclude that Higgs indeed exists also in TGD Universe although it does not seem to play the same role in particle massivation as in the standard model. The bounds allow only  $k(\tilde{h}) = k(h) + 3 = 97$  and  $m(\tilde{h}) = 45.6$  GeV for  $m(h) = 129$  GeV. The same mass is obtained for  $m(h) = 91$  GeV. Therefore the kinematic limits plus super-symmetry breaking at the level of p-adic mass scale fix completely the masses of the super-particles involved in absence of mixing effects for sneutralinos.

To sum up, the masses of sparticles involved for the option allowing Higgs are predicted to be

$$m(\tilde{e}) = 131 \text{ GeV} \quad , \quad m(\tilde{Z}^0) = 91.2 \text{ GeV} \quad , \quad m(\tilde{h}) = 45.6 \text{ GeV} \quad . \quad (8.3.-1)$$

If Higgs and Higgsino are both eaten in the massivation, the third condition drops off. The argument to be represented below suggests that also sleptons could correspond to Mersennes and Gaussian Mersennes: this option predictions  $k(\tilde{e}) = 89$  so that the mass would be 250 GeV: this excludes the proposed interpretation of the strange event.

### Goodbye large extra dimensions and MSSM

New results giving strong constraints on large extra dimensions and on the parameters of minimally supersymmetric standard model (MSSM) have come from LHC and one might say that both larger extra dimensions and MSSM are experimentally excluded.

#### 1. *The problems of MSSM*

According to the article *The fine-tuning price of the early LHC* by A. Strumia [?] the results from LHC reduce the parameter space of MSSM dramatically. Recall that the king idea of MSSM is that the presence of super partners tends to cancel the loop corrections from ordinary particles giving to Higgs mass much larger correction than the mass itself. Note that the essential assumption is that R-parity is an exact symmetry so that the lightest superpartner is stable. The signature of SUSY is indeed missing energy resulting in the decay chain beginning with the decay of gluino to chargino and quark pair followed by the decay of chargino to W boson and neutralino representing missing energy.

The article *Search for supersymmetry using final states with onelepton, jets, and missing transverse momentum with the ATLAS detector in  $s^{1/2} = 7$  TeV pp collisions* [?] by ATLAS collaboration at LHC poses strong limits on the parameters of MSSM implying that the mass of gluino is above 700 GeV in the case that gluino mass is same as that of squark. In Europhysics 1011 meeting the lower bounds for squark and gluino masses were raised to about 1 TeV. The experimental lower bounds on masses of superpartners are so high and the upper bound on Higgs mass so low that the superpartners cannot give rise to large enough compensating corrections to stabilize Higgs. This requires fine-tuning even in MSSM known as little hierarchy problem.

In typical models this also means that the bounds on slepton masses are too high to be able to explain the muonic g-2 anomaly, which was one of the original experimental motivations for MSSM. Therefore the simplest candidates for supersymmetric unifications are lost. This strengthens the suspicion that something is badly wrong with the standard view about SUSY forcing among other things to assume unstability of proton due to non-conservation of baryon and lepton numbers separately.

#### 2. *The difficulties of large extra dimensions*

The results from LHC do not leave much about the dream of solving hierarchy problem using SUSY. One must try something else. One example of this something else are large extra dimensions implying massive graviton, which could provide a new mechanism for massivation based on the idea that massive particle in Minkowski space are massless particles in higher dimensional space (also essential element of TGD). This could perhaps the little hierarchy problem if the mass of Kaluza-Klein graviton is in TeV range.

The article *LHC bounds on large extra dimensions* by A. Strumia and collaborators [?] poses very strong constraints on large extra dimensions and mass and effective coupling constant parameter of massive graviton. Kaluza-Klein graviton would appear in exchange diagrams and loop diagrams for 2-jet production and could become visible in higher energy proton-proton collisions at LHC. KK graviton would be also produced as invisible KK-graviton energy in proton-proton collisions. The general conclusion from data gathered hitherto shrinks dramatically the allowed parameter space for the KK-graviton. Does this mean that we are left with the anthropic option?

#### 3. *Also M-theorists admit that there are reasons for the skepticism*

Michael Dine admits in the article *Supersymmetry From the Top Down* [?] that there are strong reasons for skepticism. Dine emphasizes that the hierarchy problem related to the in-stability of Higgs mass due to the radiative corrections is the main experimental motivation for SUSY but that little hierarchy problem remains the greatest challenge of the approach. As noticed, in TGD this problem is absent. The same basic vision based on zero energy ontology and twistors predicts among other things

- the cancellation of UV and IR infinities in generalized Feynman (or more like twistor-) diagrams,

- predicts that in the electroweak scale the stringy character of particles identifiable as magnetically charged wormhole flux tubes should begin to make itself manifest,
- particles regarded usually as massless eat all Higgs like particles accompanying them (here "predict" is perhaps too strong a statement),
- also pseudo-scalar counterparts of Higgs-like particles which avoid the fate of their scalar variants (there already exist indications for pseudo-scalar gluons).

Combined with the powerful predictions of p-adic thermodynamics for particle masses these qualitative successes make TGD a respectable candidate for the follower of string theory.

### Could TGD approach save super-symmetry?

In TGD framework the situation is not at all so desolate. Due to the differences between the induced spinor structure and ordinary spinors, Higgs corresponds to  $SU(2)$  triplet and singlet in TGD framework rather than complex doublet. The recent view about particles as bound states of massless wormhole throats forced by twistorial considerations and emergence of physical particles as bound states of wormhole contacts carrying fermion number and vibrational degrees of freedom strongly suggests- I do not quite dare to say "implies"- that also photon and gluons become massive and eat their Higgs partners to get longitudinal polarization they need. No Higgs- no fine tuning of Higgs mass- no hierarchy problems.

Note that super-symmetry is not given up in TGD but differs in many essential respects from that of MSSM. In particular, super-symmetry breaking and breaking of R-parity are automatically present from the beginning and relate very closely to the massivation.

1. If the gamma matrices were induced gamma matrices, the mixing would be large by the light-likeness of wormhole throats carrying the quantum numbers. Induced gamma matrices are however excluded by internal consistency requiring modified gamma matrices obtained as contractions of canonical momentum densities with imbedding space gamma matrices. Induced gamma matrices would require the replacement of Kähler action with 4-volume and this is unphysical option.
2. In the interior Kähler action defines the canonical momentum densities and near wormhole throats the mixing is large: one should note that the condition that the modified gamma matrices multiplied by square root of metric determinant must be finite. One should show that the weak form of electric-magnetic duality guarantees this: it could even imply the vanishing of the limiting values of these quantities with the interpretation that the space-time surfaces becomes the analog of Abelian instanton with Minkowski signature having vanishing energy momentum tensor near the wormhole throats. If this is the case, Euclidian and Minkowskian regions of space-time surface could provide dual descriptions of physics in terms of generalized Feynman diagrams and fields.
3. At wormhole throats Abelian Chern-Simons-Kähler action with the constraint term guaranteeing the weak form of electric-magnetic duality defines the modified gamma matrices. Without the constraint term Chern-Simons gammas would involve only  $CP_2$  gamma matrices and no mixing of  $M^4$  chiralities would occur. The constraint term transforming TGD from topological QFT to almost topological QFT by bringing in  $M^4$  part to the modified gamma matrices however induces a mixing proportional to Lagrange multiplier. It is difficult to say anything precise about the strength of the constraint force density but one expect that the mixing is large since it is also large in the nearby interior.

If the mixing of the modified gamma matrices is indeed large, the transformation of the right-handed neutrino to its left handed companion should take place rapidly. If this is the case, the decay signatures of spartners are dramatically changed as will be found and the bounds on the masses of squarks and gluinos derived for MSSM do not apply in TGD framework.

#### 1. Proposal for the mass spectrum of sfermions

In TGD framework p-adic length scale hypothesis (stating that preferred p-adic primes come as  $p \simeq 2^k$ ,  $k$  integer) allows to predict the masses of sleptons and squarks modulo scaling by a powers

$\sqrt{2}$  determined by the p-adic length scale by using information coming from CKM mixing induced by topological mixing of particle families in TGD framework. Also natural guesses for the mass scales of ew gauginos and gluinos are obtained.

1. If one assumes that the mass scale of SUSY corresponds to Mersenne prime  $M_{89}$  assigned with intermediate gauge bosons one obtains unique predictions for the various masses apart from uncertainties due to the mixing of quarks and neutrinos [K39] .
2. In first order the p-adic mass formulas for fermions read as

$$\begin{aligned} m_F &= \sqrt{\frac{n_F}{5}} \times 2^{(127-k_F)/2} \times m_e , \\ n_L &= (5, 14, 65) , \quad n_\nu = (4, 24, 64) , \quad n_U = (5, 6, 58) , \quad n_D = (4, 6, 59) . \end{aligned} \quad (8.3.-2)$$

Here  $k_F$  is the integer characterizing p-adic mass scale of fermion via  $p \simeq 2^{k_F}$ . The values of  $k_F$  are not listed here since they are not needed now. Note that electroweak symmetry breaking distinguish U and D type fermions is very small when one uses p-adic length scale as unit.

By taking  $k_F = 89$  for super-partners as a reference mass scale, one obtains in good approximation (the first calculation contained erranous scaling factor)

$$\begin{aligned} \frac{m_{\tilde{L}}}{GeV} &= 2^{(89-k_F)/2} (262, 439, 945) , \\ \frac{m_{\tilde{\nu}}}{GeV} &= 2^{(89-k_F)/2} (235, 423, 938) , \\ \frac{m_{\tilde{U}}}{GeV} &= 2^{(89-k_F)/2} (262, 287, 893) , \\ \frac{m_{\tilde{D}}}{GeV} &= 2^{(89-k_F)/2} (235, 287, 900) . \end{aligned} \quad (8.3.-5)$$

Charged leptons correspond to subsequent Mersennes or Gaussian Mersennes. The first guess is that this holds true also for charged sleptons. This would give  $k_F(\tilde{e}) = 89$ ,  $k_F(\tilde{\mu}) = 79$ , and  $k_F(\tilde{\tau}) = 61$ . For quarks one has  $k_F(q) \geq 113$  ( $k = 113$  corresponds to Gaussian Mersenne). If one generalizes this to  $k_F(\tilde{q}) \leq 79$ , all sfermion masses expect those of selectron and sneutrinos are above 13 TeV. This option might well be consistent with the recent experimental data require that squark masses are above 1 TeV. The possible problem is selectron mass 262 GeV.

3. The simplest possibility is that ew gauginos are characterized by  $k = 89$  and have same masses as  $W$  and  $Z$  in good approximation. Therefore  $\tilde{W}$  could be the lightest super-symmetric particle and could be observed directly if the neutrino mixing is not too fast and allowing the decay  $\tilde{W} + \nu$ . Also gluinos could be characterized by  $M_{89}$  and have mass of order intermediate gauge boson mass. For this option to be discussed below the decay scenario of MSSM changes considerably.
4. It should be noticed that the single strange event reported 1995 [?] discussed in [?]ives for the mass of selectron the estimate 131 GeV, which corresponds to  $M_{91}$  instead of  $M_{89}$  and is thus one half of the selectron mass for Mersenne option. This event allowed also to estimate the masses of Zino and corresponding Higgsino. The results are summarized by the following table:

$$m(\tilde{e}) = 131 \text{ GeV} , \quad m(\tilde{Z}^0) = 91.2 \text{ GeV} , \quad m(\tilde{h}) = 45.6 \text{ GeV} . \quad (8.3.-4)$$

If one takes these results at face value one must conclude either that  $M_{89}$  hypothesis is too strong or  $M_{SUSY}$  corresponds to  $M_{91}$  or that  $M_{89}$  is correct identification but also sfermions can appear in several p-adic mass scales.

The decay cascades searched for in LHC are initiated by the decay  $q \rightarrow \tilde{q} + \tilde{g}$  and  $g \rightarrow \tilde{q} + \tilde{q}_c$ . Consider first R-parity conserving decays. Gluino could decay in R-parity conserving manner via  $\tilde{g} \rightarrow \tilde{q} + q$ . Squark in turn could decay via  $\tilde{q} \rightarrow q_1 + \tilde{W}$  or via  $\tilde{q} \rightarrow q + \tilde{Z}^0$ . For the proposed first guess about masses the decay  $\tilde{W} \rightarrow \nu_e + \tilde{e}$  or  $\tilde{Z}^0 \rightarrow \nu_e + \tilde{\nu}_e$  would not be possible on mass shell.

If the mixing of right-handed and left-handed neutrinos is fast enough, R-parity is not conserved and the decays  $\tilde{g} \rightarrow g + \nu$  and  $\tilde{q} \rightarrow q + \nu$  could take place by the mixing  $\nu_R \rightarrow \nu_L$  following by electroweak interaction between  $\nu_L$  quark or antiquark appearing as composite of gluon. The decay signature in this case would be pair of jets (quark and antiquark or gluon gluon jet both containing a lonely neutrino not accompanied by a charged lepton required by electroweak decays. Also the decays of electroweak gauginos and sleptons could produce similar lonely neutrinos.

The lower bound to quark masses from LHC is about 600 GeV and 800 GeV for gluon masses assuming light neutralino is slightly above the proposed masses of lightest squarks [?]. In Europhysics 2011 lower bounds were raised to 1 TeV for both gluino and squark masses. These bounds are consistent with the above speculative picture. These masses are allowed for R-parity conserving option if the decay rate producing chargino is reduced by the large mass of chargino the bounds become weaker. If the decay via R-parity breaking is fast enough no bounds on masses of squarks and gluinos are obtained in TGD framework but jets with neutrino unbalanced by a charged lepton should be observed.

## 2. How to relate MSSM picture to TGD picture?

In order to utilize MSSM calculation in TGD framework one must relate MSSM picture to TGD picture. The basic constraint is that Higgs is absent. This could apply also to Higgsino. This certainly simplifies the formulas. A further condition is that superpartners obey the same mass formulas as partners for same p-adic length scale.

It has been proposed that the loops involving superpartners could explain the anomaly [?]. In one-loop order one would have the processes  $\mu \rightarrow \tilde{\mu} + \tilde{Z}^0$  and  $\mu \rightarrow \tilde{\nu}_\mu + \tilde{W}^0$ . The situation is complicated by the possible mixing of the gauginos and Higgsinos and in MSSM this mixing is described by the mixing matrices called  $X$  and  $Y$ . The general conclusion is however clear: if muonic sneutrino is light, it is possible to have sizable contribution to the g-2 anomaly.

1. Magnetic moment operator mixes different  $M^4$  chiralities. For simplest one-loop diagrams this corresponds in TGD framework to coupling in the modified Dirac equation mixing different chiralities describable as an effective mass term. The couplings between right and left handed sfermions also contributes to the magnetic moment and these couplings reduce to those of sfermions being basically induced by the fermionic chirality mixing which reduces to the fact that modified gamma matrices are superpositions of  $M^4$  and  $CP_2$  gamma matrices.
2. The basic outcome in the standard SUSY approach is that the mixing is proportional to the factor  $m_\mu^2/m_{SUSY}^2$ . One expects that in the recent situation  $m_{SUSY} = m_W$  is a reasonable first guess so that the mixing is large and could explain the anomaly. Second guess is as  $M_{89}$  p-adic mass scale.
3. MSSM calculations for anomalous g-2 involve the mixing of both  $\tilde{f}_L$  and  $\tilde{f}_R$  and of gauginos and Higgsinos. In MSSM the mixing matrices involve the parameter  $\tan(\beta)$  where the angle  $\beta$  characterizes the ratio of mass scales of U and D type fermions fixed by the ratio of Higgs expectations for the two complex Higgs doublets [?].  $\tan(\beta)$  also characterizes in MSSM the ratio of vacuum expectation values of two Higgses assignable to U and D type quarks and cannot be fixed from this criterion since in TGD framework one has one scalar Higgs and pseudo-scalar Higgs decomposing to triplet and singlet under  $SU(2)$  and the mass ratio is fixed by p-adic mass calculations.

The question is what happens if Higgs and Higgsino are absent and what one can conclude about the value of  $\beta$  in TGD framework where p-adic mass calculations give the dominant contribution to fermion masses and the mass formulas for particles and sparticles should be identical for a fixed p-adic prime.

### 2.1 Mixing of charged gauginos and Higgsinos

Consider first the mixing between charged gauginos and Higgsinos. The angle  $\beta$  characterizes also the mixing of  $\tilde{W}$  and charged Higgsino parametrized by the mass matrix

$$X = \begin{pmatrix} M_2 & M_W \sqrt{2} \sin(\beta) \\ M_W \sqrt{2} \cos(\beta) & \mu \end{pmatrix}. \quad (8.3-3)$$

The  $\tan(\beta)$  gives the ratio of mass scales of U and D type quarks in MSSM. In MSSM  $\tan(\beta)$  reduces to the ratio of Higgs vacuum expectations and it would be better to get rid of the entire parameter in TGD framework. The maximally symmetric situation corresponds to the same mass scale for U and D type quarks and this suggests that one has  $\sin(\beta) = \cos(\beta) = 1/\sqrt{2}$  implying  $\tan(\beta) = 1$ . In MSSM  $\tan(\beta) > 2$  is required and this is due to the large value of the  $m_{SUSY}$ .

Whether this parameterization makes sense in TGD framework depends on whether one allows Higgsino.

1. If also Higgsino is absent the formula does not make sense. A natural condition is that the value of  $\tan(\beta)$  does not appear at all in the limiting formulas for the anomalous g-2. Note that in p-adic mass calculations do not contain this kind of a priori continuous parameter. There the simplest TGD based option is that the Higgsino is just absent and the mass matrix reduces  $1 \times 1$  matrix  $M_2$  giving wino mass. The idea that particle and sparticles have identical masses for the same p-adic mass scale would give  $M_2 = M_W$ . One must however remember that in TGD framework mass operator acts like a preferred combination of gamma matrices in  $CP_2$  degrees of freedom mixing  $M^3$  chiralities.
2. If one allows Higgsinos, the simplest guess is that apart from p-adic mass scale same has  $M_2 = -\mu = m$ : this guarantees identical masses for the mixed states in accordance with the ideas that different masses for particles and sparticles result from the different p-adic length scale. For  $\cos(\beta) = 1/\sqrt{2}$  this would give mass matrix with eigen values  $(M, -M)$ ,  $M = \sqrt{m^2 + m_W^2}$  so that mass squared values of the mixed states would be identical and above  $m_W$  mass for  $p = M_{89}$ . Symmetry breaking by an increase of the p-adic length scale could however reduce the mass of other state by a power of  $\sqrt{2}$ .

If also winos and zinos eat the higgsinos, one can argue that the determinant of  $X$  must vanish so that the eigenstate with vanishing eigen value would correspond to unphysical statete meaning the elimination of second state from the spetrum. This would require  $M_2\mu - M_W^2 \sin(2\beta) = 0$ .  $\sin(\beta) = 1/\sqrt{2}$  and  $M_2 = \mu = M_W$  is the simplest solution to the condition. This looks tricky.

### 2.2 Mixing of neutral gauginos and Higgsinos

In MSSM  $4 \times 4$  matrix is needed to describe the mixing of neutral gauginos and two kinds of neutral Higgsinos. In TGD framework second Higgs (if it exists at all) is pseudo-scalar and does not contribute and the  $2 \times 2$  matrices describe the mixing also now.

$$X = \begin{pmatrix} \begin{pmatrix} M_1 & 0 \\ 0 & M_2 \end{pmatrix} & M_Z \begin{pmatrix} s_W \cos(\beta) & s_W \sin(\beta) \\ c_W \cos(\beta) & c_W \sin(\beta) \end{pmatrix} \\ M_Z \begin{pmatrix} s_W \cos(\beta) & s_W \sin(\beta) \\ c_W \cos(\beta) & c_W \sin(\beta) \end{pmatrix} & -\mu \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \end{pmatrix}. \quad (8.3-2)$$

For  $\sin(\beta) = \cos(\beta) = 0$  the non-diagonal part of the mass matrix is degenerate.

Again there are two options depending on whether Higgsinos are present and if they are absent the dependence on the angle  $\beta$  vanishes. Indeed, if Higgsinos are absent the matrix reduces to a diagonal  $2 \times 2$  mass matrix for U(1) gaugino  $\tilde{B}$  and neutral SU(2) gaugino  $\tilde{W}^3$ . If one takes seriously MSSM, there would be no mixing. On the other hand, TGD suggests that neutral gauginos mix in the same manner as neutral gauge bosons so that Weinberg angle would characterize the mixing with photino and zino appearing as mass eigen states. Again for same value of p-adic prime the values of mass squared for gauge bosons and gauginos should be identical.

One can also consider the option with Higgsino.

1. Since Higgs and Higgsino have representation content 3+1 with respect to electroweak SU(2) in TGD framework, one can speak about  $\tilde{h}_B$ ,  $B = W, Z, \gamma$ . An attractive assumption is that Weinberg angle characterizes also the mixing giving rise to  $\tilde{Z}$  and  $\tilde{\gamma}$  on one hand and  $\tilde{h}_\gamma$  and  $\tilde{h}_Z$  on the other hand if these belong to the spectrum. This would reduce the mixing matrix to two  $2 \times 2$  matrices: the first one for  $\tilde{\gamma}$  and  $\tilde{h}_\gamma$  and the second one for  $\tilde{Z}$  and  $\tilde{h}_Z$ .

2. A further attractive assumption is that the mass matrices describing mixing of gauginos and corresponding Higgsinos are in some sense universal with respect to electroweak interactions. The form of the mixing matrix would be essentially same for all cases. This would suggest that  $M_W$  is replaced in the above formula with the mass of  $Z^0$  and photon in these matrices (recall that it is assumed that photon gets small mass by eating the neutral Higgs). Note that for photino and corresponding Higgsino the mixing would be small. The guess is  $M_2 = -\mu = m_Z$ . For photino one can guess that  $M_2$  corresponds to  $M_{89}$  mass scale.

These assumptions of course define only the first maximally symmetric guess and the simplest modification that one can imagine is due to the different p-adic mass scales. If the above discussed values for zino and neutralino masses deduced from the 1995 event [?] are taken at face value, the eigenvalues would be  $\pm\sqrt{M_Z^2 + m^2}$  with  $m = M_2 = -\mu$  for  $\tilde{Z} - \tilde{h}_Z$ -mixing and the other state would have p-adic length scale  $k = 91$  rather than  $k = 89$ .  $M$  and  $\mu$  would have opposite signs as required by the correct sign for the  $g - 2$  anomaly for muon assuming that smuons correspond to  $p = M_{89}$  as will be found.

### 2.3 The relationship between masses of charged sleptons and sneutrinos

In MSSM approach one has also the formula relating the masses of sneutrinos and charged sleptons [?]:

$$m_{\tilde{\nu}}^2 = m_L^2 + \frac{1}{2}M_Z^2 \cos(2\beta) . \quad (8.3.-1)$$

For  $\beta = \pm\pi/4$  one would have  $\tan(\beta) = 1$  and

$$m_{\tilde{\nu}}^2 = m_L^2 .$$

In p-adic mass calculations this kind of formula is highly questionable and could make sense only if these particles involved correspond to same value of p-adic prime and therefore would not make sense after symmetry breaking.

### 3. The anomalous magnetic moment of muon as a constraint on SUSY

The anomalous magnetic moment  $a_\mu \equiv (g - 2)/2$  of muon has been used as a further constraint on SUSY. The measured value of  $a_\mu$  is  $a_\mu^{exp} = 11659208.0(6.3) \times 10^{10}$ . The theoretical prediction decomposes to a sum of reliably calculable contributions and hadronic contribution for which the low energy photon appearing as vertex correction decays to virtual hadrons. This contribution is not easy to calculate since non-perturbative regime of QCD is involved. The deviation between prediction and experimental value is  $\Delta a_\mu(exp - SM) = 23.9(9.9) \times 10^{-10}$  giving  $\Delta a_\mu(exp - SM)/a_\mu = 2 \times 10^{-6}$ . The hadronic contribution is estimated to be  $692.3 \times 10^{-10}$  so that the anomaly is 3 per cent from the hadronic contribution [?]. One can ask whether the uncertainties due to the non-perturbative effects could explain the anomaly.

The following calculation is a poor man's version of MSSM calculation [?]. Also now SUSY requires that the electroweak couplings between particles dictate those between sparticles. Supersymmetry for massivation suggests that in TGD framework higgsinos do not belong to the spectrum. Light sfermions appear as single copy with vanishing fermion number so that various mixing matrices of MSSM reduce to unit matrices. This leads to a rough recipe: take only the one loop contributions to  $g-2$  and assume trivial mixing matrices and drop off summations. At least a good order of magnitude estimate should result in this manner.

#### 3.1 A rough MSSM inspired estimate $g-2$ anomaly

Consider now a rough estimate for the  $g-2$  anomaly by using the formulas 56-58 of [?]. One obtains for the charged loop the expression

$$\Delta a_\mu^\pm = -\frac{21g_2^2}{32\pi^2} \times \left(\frac{m_\mu}{m_W}\right)^2 \times \text{sign}(\mu M_2) . \quad (8.3.0)$$

This however involves a formula relating sneutrino and charged slepton masses. There is no reason to expect this formula to hold true in TGD framework.

For neutral contribution the expression is more difficult to deduce. As physical intuition suggests, the expression inversely proportional to  $1/m_W^2$  since  $m_W$  corresponds now  $m_{SUSY}$  although this is not obvious on the basis of the general formulas suggesting the proportionality to  $1/m_{\tilde{\nu}_\mu}^2$ . The p-adic mass scale corresponding to  $M_{89}$  is the natural guess for  $M_{SUSY}$  and would give  $M_{SUSY} = 104.9$  GeV. The fact that the correction has positive sign requires that  $\mu$  and  $M_2$  have opposite signs unlike in MSSM. The sign factor is opposite to that in MSSM because sfermion mass scales are assumed to be much higher than weak gaugino mass scale.

The ratio of the correction to the lowest QED estimate  $a_{\mu,0} = \alpha/2\pi$  can be written as

$$\frac{\Delta a_\mu^+}{a_{\mu,0}} = \frac{21}{4\sin^2(\theta_W)} \times \left(\frac{m_\mu}{m_{SUSY}}\right)^2 \simeq 2.73 \times 10^{-5} . \quad (8.3.1)$$

which is roughly 10 times larger than the observed correction. The contribution  $\Delta a_\mu^0$  could reduce this contribution. At this moment I am however not yet able to transform the formula for it to TGD context. Also the scaling up of the  $m_{SUSY}$  by a factor of order  $2^{3/2}$  could reduce the correction.

The parameter values ( $\tan(\beta) = 1, M_{SUSY} = 100$  GeV) corresponds to the boundary of the region allowed by the LHC data and  $g-2$  anomaly is marginally consistent with these parameter values (see figure 16 of [?]). The reason is that in the recent case the mass of lightest Higgs particle does not pose any restrictions (the brown region in the figure). Due to the different mixing pattern of gauginos and higgsinos in neutral sector TGD prediction need not be identical with MSSM prediction.

The contribution from Higgs loop is not present if Higgs is eaten by photon [?]. This contribution by a factor of order  $(m_\mu/h_H)^2$  smaller than the estimate for the SUSY contribution so that the dropping of Higgs contribution does not affect considerably the situation.

$$\Delta a_\mu^H = \frac{2}{2.24^2} \left(\frac{m_\mu}{m_H}\right)^4 \times \left(\log\left(\left(\frac{m_H}{m_\tau}\right)^2\right) - \frac{3}{2}\right) . \quad (8.3.2)$$

The proposed estimate is certainly poor man's estimate since it is not clear how near the proposed twistorial approach relying on zero energy ontology is to QFT approach. It is however encouraging that the simplest possible scenario might work and that this is essentially due to the p-adic length scale hypothesis.

### 3.2 An improved estimate for $g-2$ anomaly

An attractive scenario for sfermion masses marginally consistent with the recent data from LHC generalizes the observation that charged lepton masses correspond to subsequent Mersenne primes of Gaussian Mersennes. The only sfermions lighter than about 13 TeV are selectron with mass 262 GeV ( $k = 89$ ) and sneutrinos, which can have much smaller masses.  $\tilde{W}\tilde{\nu}_\mu$  virtual state would be mostly responsible for the muonic  $g-2$  anomaly since the largest term in the correction is proportional to  $m(\mu)m(\tilde{W})/m^2(\tilde{\nu}_\mu)$  and the anomaly might allow to determine  $m(\tilde{\nu}_\mu)$ . This option should be explain the  $g-2$  anomaly.

The following estimate demonstrates that there are hopes about this. Using the formulas of [?] one can write the one loop contributions to the anomalous contribution  $a(\mu)$  as

$$\begin{aligned} a_\mu^{\chi^0} &= \frac{m(\mu)}{16\pi^2} \sum_{i,m} X_{im} , \\ X_{im} &= -\frac{m(\mu)}{12m^2(\tilde{\mu}_m)} \left[ |n_{im}^L|^2 + |n_{im}^R|^2 \right] F_1^N(x_{im}) + \frac{m(\chi_i^0)}{3m^2(\tilde{\mu}_m)} \text{Re} [n_{im}^L n_{im}^R] F_2^N(x_{im}) , \end{aligned} \quad (8.3.1)$$

and

$$\begin{aligned} a_\mu^{\chi^\pm} &= \frac{m(\mu)}{16\pi^2} \sum_k X_k , \\ X_k &= -\frac{m(\mu)}{12m^2(\tilde{\nu}_\mu)} \left[ |c_k^L|^2 + |c_k^R|^2 \right] F_1^C(x_k) + \frac{2m(\chi_k^\pm)}{3m^2(\tilde{\nu}_\mu)} \text{Re} [c_k^L c_k^R] F_2^C(x_k) . \end{aligned} \quad (8.3.0)$$

Here  $i = 1, \dots, 4$  denotes neutralino indices which should reduce to two if also Higgsinos disappear from the spectrum.  $k = 1, 2$  denotes the neutral and charginos indices reducing to single index now.  $m = 1, 2$  denotes smuon index. Note that TGD suggests strongly that the masses of  $\tilde{\mu}_R$  and  $\tilde{\mu}_L$  are degenerate. The matrices  $n_{im}^L, n_{im}^R$  and  $c_k^L$  and  $c_k^R$  relate to the mixing of mass eigenstates and are given explicitly in MSSM [?].

The kinematic variables are defined as the mass ratios  $x_{im} = m^2(\chi_i^0)/m^2(\tilde{\mu}_m)$  and  $x_k = m^2(\chi_k^\pm)/m^2(\tilde{\nu}_\mu)$  and the loop functions are given by

$$\begin{aligned} F_1^N(x) &= \frac{2}{(1-x)^4} [1 - 6x + 3x^2 + 2x^3 - 6x^2 \log(x)] , \\ F_2^N(x) &= \frac{3}{(1-x)^3} [1 - x^2 + 2x \log(x)] , \\ F_1^C(x) &= \frac{2}{(1-x)^4} [2 + 3x - 6x^2 + x^3 + 6x \log(x)] , \\ F_2^C(x) &= \frac{3}{(1-x)^3} [-3 + 4x - x^2 - 2 \log(x)] . \end{aligned} \quad (8.3.-3)$$

If one does not assume any relationship between sneutrino and charged slepton masses then for  $m(\tilde{\nu}_\mu)/m(\tilde{\mu}) \ll 1$ ,  $m(\mu)/m(\chi^\pm) \ll 1$ , and  $m(\chi_k^0)/m(\tilde{\mu}) \ll 1$  the functions  $F_1^N$  and  $F_2^N(x)$  are in good approximation constant and the corresponding contributions are negligible. One has  $F_1^C(x) \simeq 1/x$  and  $F_2^C(x) \simeq 3/x$ . It turns out that the terms proportional to  $F_1^C(x)$  and  $F_2^C(x_k)$  are of the same order of magnitude. If Higgsinos do not belong to the spectrum one has  $U_{k2} = 0$  giving  $V_{k1}U_{k2} = 0$  leaving only the  $F_1^C$  contribution.

Consider now the mixing matrices for sfermions.

1. One has

$$\begin{aligned} c_k^L &= -g_2 V_{k1} , \quad c_k^R = y_\mu U_{k2} , \\ y_\mu &= \frac{m(\mu)}{m(W)} \frac{g_2}{\sqrt{2} \cos(\beta)} , \quad g_2 = \frac{e}{\sin(\theta_W)} . \end{aligned} \quad (8.3.-3)$$

Here the index  $k$  refers to the mixed states of  $L$  and  $R$  type sfermions. Since they are formed from fermion and right-handed neutrino, one expects that at higher energies the mixing is negligible. Mixing is however present and induced by the mixing of right and left handed fermion so that the mixing matrices are non-trivial at low energies and give relate closely to the massivation of sfermions and fermions.

2. One obtains

$$\begin{aligned} c_k^L c_k^R &= -g_2^2 \frac{m(\mu)}{m(W)} \frac{1}{\sqrt{2} \cos(\beta)} V_{k1} U_{k2} = -\frac{m(\mu)}{m(W)} \times \frac{4\pi\alpha}{\sin^2(\theta_W)} \times \frac{1}{\sqrt{2} \cos(\beta)} V_{k1} U_{k2} , \\ |c_k^L|^2 + |c_k^R|^2 &= g_2^2 \left[ |V_{k1}|^2 + \frac{m^2(\mu)}{m^2(W)} \frac{1}{2 \cos^2(\beta)} |U_{k2}|^2 \right] . \end{aligned} \quad (8.3.-3)$$

Using these results one obtains explicit expressions for the two terms in  $a_\mu$ .

1. The expressions for the term resulting from mixing of right and left handed sfermions is given by

$$\begin{aligned} a_\mu^{mix,k} &= \frac{m(\mu)}{8\pi^2 m(\chi_k^\pm)} \sum_k \text{Re}[c_k^L c_k^R] \\ &= \frac{1}{8\pi^2} \frac{4\pi\alpha}{\sin^2(\theta_W) \sqrt{2} \cos(\beta)} \frac{m^2(\mu)}{m(W) m(\chi_k^\pm)} \text{Re}[V_{k1} U_{k2}] . \end{aligned} \quad (8.3.-3)$$

2. Second term is diagonal and non-vanishing also when Higgsino is absent from the spectrum.

$$a_{\mu}^{diag,k} = \frac{1}{8\pi^2} \frac{m^2(\mu)}{m^2(\chi^{\pm})} [ |c_k^L|^2 + |c_k^R|^2 ] . \quad (8.3-2)$$

Note that  $|c_k^R| \ll |c_k^L|$  holds true unless  $\cos(\beta)$  is very small.

3. The ratio of the contributions is

$$\left| \frac{a_{\mu}^{diag,k}}{a_{\mu}^{mix,k}} \right| = \frac{m(W)}{m(\chi^{\pm})_k} \sqrt{2} \cos(\beta) \times \left| \frac{V_{k1}}{U_{k2}} \right| . \quad (8.3-1)$$

For  $c_k^R = 0$  (no Higgsino) one has

$$a_{\mu} \simeq a_{\mu}^{diag,k} = \frac{1}{8\pi^2} \frac{m^2(\mu)}{m^2(\chi^{\pm})} \sqrt{2} \cos(\beta) \frac{4\pi\alpha}{\sin^2(\theta_W)} |V_{k1}|^2 . \quad (8.3.0)$$

The dependence on the mass of muonic sneutrino disappears so that one cannot conclude anything about its value in this approximation.  $a_{\mu}$  is determined by the mass scale of  $\tilde{W}$ , which should be of the same order of magnitude as  $W$  boson mass. The sign of the diagonal term is positive so that this contribution gives to g-2 a contribution which is of correct sign. This encourages to consider the option for which Higgsinos disappear from the spectrum.

The experimental value of the anomaly is equal to  $\Delta a_{\mu} \simeq 23.9 \times 10^{-10}$ . The order of magnitude estimate obtained by assuming ( $\cos(\beta) = 1/\sqrt{2}, V_{k1} = 1, U_{k2} = 0$ ) one obtains  $a_{\mu} = 82.7 \times 10^{-10} \times (m(W)/m(\chi^{\pm}))^2$ , which for  $m(W)/m(\chi^{\pm}) = 1$  is roughly 3.46 times larger than the anomaly. The p-adic scaling  $k(\tilde{W}) = 89 \rightarrow k(\tilde{W}) - 2 = 87$  would give a value of  $a_{\mu}$  near to the observed one. The mass of  $\tilde{W}$  would be 160.8 GeV. Clearly the TGD inspired view about SUSY leads to a remarkably simple picture explaining the g-2 anomaly.

#### 4. Basic differences between MSSM and TGD

The basic differences between TGD and MSSM [?] and related approaches deserve to be noticed (see also the article about the experimental side [?]). If Higgses and Higgsinos are absent from the spectrum, SUSY in TGD sense does not introduce flavor non-conserving currents (FNCC problem plaguing MSSM type approaches). In MSSM approach the mass spectrum of superpartners can be only guessed using various constraints and in a typical scenario masses of sfermions are assumed to be same in GUT unification scales so that at long length scales the mass spectrum for sfermions is inverted from that for fermions with stop and stau being the lightest superpartners. In TGD framework p-adic thermodynamics and the topological explanation of family replication phenomenon changes the situation completely and the spectrum of sfermions is very naturally qualitatively similar to that of fermions (genus generation correspondence is the SUSY invariant answer to the famous question of Rabi "Who ordered them?" !). This is essential for the explanation of g-2 anomaly for instance. Note that the experimental searches concentrating on finding the production of stop or stau pairs are bound to fail in TGD Universe.

Another key difference is that in TGD the huge number of parameters of MSSM is replaced with a single parameter- the universal coupling characterizing the decay

sparticle  $\rightarrow$  particle+right handed neutrino,

which by its universality is very "gravitational". The gravitational character suggests that it is small so that SUSY would not be badly broken meaning for instance that sparticles are rather longlived and R-parity is a rather good symmetry.

One can try to fix the coupling by requiring that the decay rate of sfermion is proportional to gravitational constant  $G$  or equivalently, to the square of  $CP_2$  radius

$$R \simeq 10^{7+1/2} \left(\frac{G}{\hbar_0}\right)^{1/2} .$$

Sfermion-fermion-neutrino vertex coupling to each other same fermion  $M^4$  chiralities involves the gradient of the sfermion field. Yukawa coupling - call it  $L$  - would have dimension of length. For massive fermions in  $M^4$  it would reduce to dimensionless coupling  $g$  different  $M^4$  chiralities. In equal mass case  $g$  would be proportional to  $L(m_1 + m_2)/\hbar$ , where  $m_i$  are the masses of fermions.

1. For the simplest option  $L$  is expressible in terms of  $CP_2$  geometry alone and corresponds to

$$L = kR .$$

$k$  is a numerical constant of order unity.  $\hbar_0$  denotes the standard value of Planck constant, whose multiple the effective value of Planck constant is in TGD Universe in dark matter sectors. The decay rate of sfermion would be proportional to

$$k^2 R^2 \left(\frac{M}{\hbar_{\text{bar}}}\right)^3 \simeq k^2 \times 10^7 \times \frac{G}{\hbar_0} \times \left(\frac{M}{\hbar}\right)^3 ,$$

where  $M$  is the mass scale characterizing the phase space volume for the decays of sfermion and is given by the mass of sfermion multiplied by a dimensionless factor depending on mass ratios. The decay rate is extremely low so that R-parity conservation would be an excellent approximate symmetry. In cosmology this could mean that zinos and photinos would decay by an exchange of sfermions rather than directly and could give rise to dark matter like phase as in MSSM.

2. Second option carries also information about Kähler action one would have apart from a numerical constant of order unity  $k = \alpha_K$ . The Kähler coupling strength

$$\alpha_K = \frac{g_K^2}{4\pi \times \hbar_0} \simeq 1/137$$

is the fundamental dimensionless coupling of TGD analogous to critical temperature.

3. For the option which "knows" nothing about  $CP_2$  geometry the length scale would be proportional to the Schwartchild radius

$$L = kGM .$$

In this case the decay rate would be proportional to  $k^2 G^2 M^2 (M/\hbar)^3$  and extremely low.

4. The purely kinematic option which one cannot call "gravitational" "knows" only about sfermion mass and  $\hbar$  Planck constant, and one would have

$$L = k \times \frac{\hbar}{M} .$$

The decay rate would be proportional to the naive order of magnitude guess  $k^2 (M/\hbar)$  and fast unlike in all "gravitational cases". R-parity would be badly broken. Again  $k \propto \alpha_K$  option can be considered.

Note that also in mSUGRA gravitatonal sector in short length scales determines MSSM parameters via flavor blind interactions and also breaking of SUSY via breaking of local SUSY in short scales.

### 8.3.2 Do $X$ and $Y$ mesons provide evidence for color excited quarks or squarks?

Now and then come the days when head is completely empty of ideas. One just walks around and gets more and more frustrated. One can of course make authoritative appearances in blog groups and express strong opinions but sooner or later one is forced to look for web if one could find some problem. At this time I had good luck. By some kind of divine guidance I found myself immediately in Quantum Diaries and found a blog posting with title *Who ordered that?! An X-traordinary particle?* [?].

Not too many unified theorists take meson spectroscopy seriously. Although they are now accepting low energy phenomenology (*the physics for the rest of us*) as something to be taken seriously, meson physics is for them a totally uninteresting branch of botany. They could not care less. As a crackpot I am however not well-informed about what good theoretician should do and shouldn't do and got interested. Could this give me a problem that my poor crackpot brain is crying for?

The posting told me that in the spectroscopy of  $c\bar{c}$  type mesons is understood except for some troublesome mesons christened imaginatively with letters  $X$  and  $Y$  plus brackets containing their mass in MeVs.  $X(3872)$  is the firstly discovered troublemaker and what is known about it can be found in the blog posting and also in Particle Data Tables [?]. The problem is that these mesons should not be there. Their decay widths seem to be narrow taking into account their mass and their decay characteristics are strange: in particular the kinematically allow decays to  $D\bar{D}$  dominating the decays of  $\Psi(3770)$  with branching ratio 93 per cent has not been observed whereas the decay to  $D\bar{D}\pi^0$  occurs with a branching fraction  $> 3.2 \times 10^{-3}$ . Why the pion is needed?  $X(3872)$  should decay to photon and charmonium state in a predictable way but it does not.

#### Could these be the good questions?

TGD predicts a lot of exotic physics and I of course started to exclude various alternatives. First one must however try to invent a good question. Maybe the following questions might satisfy the criterion of goodness.

1. Why these exotic states appear only for mesons made of heavy quark and antiquark? Why not for light mesons? Why not for mesons containing one heavy quark and light quark? Could it be that also  $b\bar{b}$  mesons could have exotic partners not yet detected? Could it be that also exotic  $b\bar{c}$  type mesons could be there? Why the presence of light quark would eliminate the exotic partner from the spectrum?
2. Do the decays obey some selection rules? There is indeed this kind of rule: the numbers of  $c$  and  $\bar{c}$  quarks in the final state are equal to one.
  - (a) If  $c$  and  $\bar{c}$  exist in the initial state and the decay involves only strong interactions, the rule holds true.
  - (b) If  $c$  and  $\bar{c}$  are not present in the initial state the only option that one can imagine is the exchange of two  $W$  bosons transforming  $d$  type quarks to  $c$  type quarks must be present. If this were the case the initial state should correspond to  $d\bar{d}$  like state rather than  $c\bar{c}$  and this looks very strange from the standard physics point of view. Also the rate for this kind of decays would be very small and it seems that this option cannot make sense.

#### Both leptons and quarks have color excitations in TGD Universe

TGD predicts that both leptons and quarks have color excitations [?]. For leptons they correspond to color octets and there is a lot of experimental evidence for them. Why we do not have any evidence for color excited quarks? Or do we actually have?! Could these strange  $X$ :s and  $Y$ :s provide this evidence?

Ordinary quarks correspond to triality one color triplet partial waves in  $CP_2$ . The higher color partial waves would also correspond to triality one states but in higher color partial waves in  $CP_2$ . The representations of the color group are labelled by two integers  $(p,q)$  and the dimension of the representation is given by

$$d = \frac{(p+1)(q+1)(p+q+2)}{2} .$$

A given  $t = \pm 1$  representation is accompanied by its conjugate with the same dimension and opposite triality  $t = \mp 1$ .  $t = 1$  representations satisfy  $p - q = 1$  modulo 3 and come as  $(1,0)$ ,  $(0,2)$ ,  $(3,0)$ ,  $(2,1)$ , with dimensions 3, 6, 10, 15,... The simplest candidate for the color excitations would correspond to the representation  $\bar{6}$ . It does not correspond directly to a solution of the Dirac equation in  $CP_2$  since physical states involve also color Kac-Moody generators [K39].

Some remarks are in order:

1. The tensor product of gluon octet with  $t = 1$  with color triplet representation contains  $8 \times 3 = 24$  states and decomposes into  $t = 1$  representations as  $3 \oplus \bar{6} \oplus 15$ . The coupling of gluons by Lie algebra action can couple given representation only with itself. The coupling between triplet and  $\bar{6}$  and 15 is therefore not by Lie algebra action. The coupling constant between quarks and color excited quarks is *assumed* to be proportional to color coupling.
2. The existence of this kind of coupling would explain the selection rules elegantly. If this kind of coupling is not allowed then only the annihilation of exotic quark to gluon decaying to quark pair can transform exotic mesons to ordinary ones and I have not been able to explain selection rules using this option.

The basic constraint applying to all variants based on exotic states of quarks comes from the fact that the decay widths of intermediate gauge bosons do not allow new light particles. This objection is encountered already in the model of lepto-hadrons [?]. The solution is that the light exotic states are possible only if they are dark in TGD sense having therefore non-standard value of Planck constant and behaving as dark matter. The value of Planck constant is only effective and has purely geometric interpretation in TGD framework. This implies that a phase transition transforming quarks and gluons to their dark counterparts is the key element of the model. After this a phase transition a gluon exchange would transform the quark pair to an exotic quark pair.

### Also squarks could explain exotic charmonium states

Supersymmetry provides an alternative mechanism. Right-handed neutrino generates super-symmetries in TGD Universe and quarks are accompanied by squarks consisting in a well-defined sense of quark and right-handed neutrino. Super-symmetry would allow completely standard couplings to gluons by adding to the spectrum squarks and gluinos. Exactly the same selection rules result if these new states are mesonlike states from squark and anti-squark and the exchange of gluino after the  $\hbar$  changing phase transition transforms exotic meson to ordinary one and vice versa.

In the sequel it will be shown that the existence of color excited quarks or of their superpartners could indeed allow to understand the origin of  $X$  and  $Y$  mesons and also the absence of analogous states accompanying mesons containing light quarks or antiquarks.

This picture would lead to a completely new view about detection of squarks and gluinos.

1. In the standard scenario the basic processes are production of squark and gluino pair. The creation of squark-antisquark pair is followed by the decay of squark (anti-squark) to quark (antiquark) and neutralino or chargino. If R-parity is conserved, the decay chain eventually gives rise to at least two hadron jets and lightest neutralinos identifiable as missing energy. Gluinos in turn decay to quark and anti-squark (squark and antiquark) and squark (anti-squark) in turn to quark (anti-quark) and neutralino or chargino. At least four hadron jets and missing energy is produced. In TGD framework neutralinos would decay eventually to zinos or photinos and right-handed neutrino transforming to ordinary neutrino (R-parity is not conserved). This process might be however slow.
2. In the recent case quite different scenario relying on color confinement and "shadronization" suggests itself. By definition smesons consist of squarks and antisquark. Sbaryons could consist of two squarks containing right-handed neutrino and its antineutrino ( $\mathcal{N} = 2$  SUSY) and one quark and thus have same quantum numbers as baryon. Note that the squarks are dark in TGD sense.

Also now dark squark or gluino pair would be produced at the first step and would require  $\hbar$  changing phase transition of gluon. These would shadronize to form a dark shadron. One can indeed argue that the required emission of winos and zinos and photinos is too slow a process

as compared to shadronization. Shadrons (mostly smesons) would in turn decay to hadrons by the exchange of gluinos between squarks. No neutralinos (missing energy) would be produced. This would explain the failure to detect squarks and gluinos at LHC.

This mechanism does not however apply to sleptons so that it seems that the p-adic mass scale of sleptons must be much higher for sleptons than that for squarks as I have indeed proposed.

### Could exotic charmonium states consist of color excited $c$ and $\bar{c}$ or of their partners?

Could one provide answers to the questions presented in the beginning assuming that exotic charmonium states consists of dark color excited  $c$  and  $\bar{c}$ : or more generally, a mixture of ordinary charmonium and exotic charmonium state? The mixing is expected since  $\hbar$  changing phase transition followed by a gluon exchange can transform these meson states to each other. Also annihilation to gluon and back to quark pair can induce this mixing. The mixing is however small for heavy quarks for which  $\alpha_s \simeq .1$  holds true. Exactly the same arguments apply to the meson like bound states of squarks and in the following only the first option will be discussed.

1. In the case of charged leptons colored excitations have have same p-adic mass scale: for  $\tau$  however several p-adic mass scales appear as the model if the two year old CDF anomaly is taken seriously [?]. Assume that p-adic mass scales - but not necessarily masses- are the same also now. This assumption might be non-sensical since also light mesons would have exotic counterparts and somehow they should disappear from the spectrum. To simplify the estimates one could even assume even that the masses are same.
2. In the presence of small mixing the decay amplitude would come solely from the small contribution of the ordinary  $c\bar{c}$  state present in the state dominated by color excited pair. The two manners to see the situation should give essentially the same answer.
3. The decays would take place via strong interactions.

The challenge is to understand why the dominating decays to  $D\bar{D}$  with branching fraction of 93 per cent are not allowed whereas  $D\bar{D}\pi^0$  takes place. Why the pion is needed? The second challenge is to understand why  $X$  does not decay to charmonium and photon.

1. For ordinary charmonium the decay to  $D\bar{D}$  could take place by the emission of gluon from either  $c$  or  $\bar{c}$  which then decays to light quark pair whose members combine with  $c$  and  $\bar{c}$  to form  $D$  and  $\bar{D}$ . Now this mechanism does not work. At least *two* gluons must be emitted to transform colored excited  $c\bar{c}$  to ordinary  $c\bar{c}$ . If these gluons decay to light quark pairs one indeed obtains an additional pion in hadronization. The emission of two gluons instead of only one is expected to reduce the rate roughly by  $\alpha_s^2 \simeq 10^{-2}$  factor.
2. Also ordinary decays are predicted to occur but with a slower rate. The first step would be an exchange of gluon transforming color excited charmed quark pair to an ordinary charmed quark pair. After the transformation to off mass shell  $c\bar{c}$  pair, the only difference to the decays of charmonium states would be due to the fact that charmonium would be replaced with  $c\bar{c}$  pair. The exchange of the gluon preceding this step could reduce the decay rate with respect to charmonium decay rates by a factor of order  $\alpha_s^2 \simeq 10^{-2}$ . Therefore also the ordinary decay modes should be there but with a considerably reduced rate.
3. Why the direct decays to photon and charmonium state do not occur in the manner predicted by the model of charmonium? For ordinary charmonium the decay proceeds by an emission of photon by either quark or antiquark. Same mechanism applies for exotic charmonium states but leads to final state which consists of *exotic* charmonium and photon. In the case of  $X(3872)$  there exists no lighter exotic charmonium state so that the decay is forbidden in this order of perturbation theory. Heavier exotic charmonium states can however decay to photon plus exotic charmonium state in this order of perturbation theory if discrete symmetries favor this.

Essentially identical arguments go through if  $c$  and  $\bar{c}$  are replaced with their dark partners and exchange of gluon by the emission of gluino. The transformation of gluon to its dark variants is an essential element in the process.

### Why the color excitations/spartners of light quarks would be effectively absent?

Can one understand the effective absence of mesons consisting of color excited light quarks or squarks if the excitations have same mass scale and even mass as the light quarks? The following arguments are for color excited quarks but they apply also to squarks.

1. Suppose that the mixing induced by  $\hbar$  changing phase transition followed by a gluon exchange and annihilation is described by mass squared matrix containing besides diagonal components  $M_1^2 = M_2^2$  also non-diagonal component  $M_{12}^2 = \overline{M_{21}^2}$ . The eigenstates of the mass squared matrix correspond to the physical states which are mixtures of states consisting of ordinary quark pair and pair of color excited quarks. The non-diagonal elements of the mass squared matrix corresponds to gluon exchange and since color interactions get very strong at low energy scales, one expects that these elements get very large. In the degenerate case  $M_1^2 = M_2^2$  the mass squared eigen values are given by

$$M_{\pm}^2 = M_0^2 \pm |M_{12}|^2 . \quad (8.3.1)$$

2. Suppose that  $M_0^2 = 0$  holds true in accordance with approximate pseudo Goldstone nature of pion and more generally all light pseudo-scalar mesons. In fact assume that this is the case before color magnetic spin-spin splitting has taken place so that in this approximation pion and  $\rho$  would have same mass  $m_{\pi}^2 = m_{\rho}^2 = M_0^2$ . In TGD based model for color magnetic spin-spin splitting  $M_0^2$  energy is replaced with mass squared [K46] and  $M_0^2$  is obtained in terms of physical masses of  $\pi$  and  $\rho$  from the basic formulas

$$\begin{aligned} m_{\pi}^2 &= M_0^2 - \frac{1}{4}\Delta , & m_{\rho}^2 &= M_0^2 + \frac{3}{4}\Delta , \\ M_0^2 &= \frac{m_{\rho}^2 + 3m_{\pi}^2}{2} , & \Delta &= m_{\rho}^2 - m_{\pi}^2 . \end{aligned} \quad (8.3.0)$$

The exotic  $\pi$  and  $\rho$  would have masses

$$\begin{aligned} m_{\pi_{ex}}^2 &= -M_0^2 - \frac{1}{4}\Delta = m_{\pi}^2 - 2M_0^2 , \\ m_{\rho_{ex}}^2 &= -M_0^2 + \frac{3}{4}\Delta = m_{\rho}^2 - 2M_0^2 . \end{aligned} \quad (8.3.0)$$

For  $m_{\pi} = 140 \text{ MeV}$  and  $m_{\rho} = 770 \text{ MeV}$  the calculation gives  $m_{\pi_{ex}} = i \times 685 \text{ MeV}$  so a tachyon would be in question. For  $\rho$  one would have  $m_{\rho_{ex}} = 323 \text{ MeV}$  so that the mass would not be tachyonic.

One can try to improve the situation by allowing  $M_1^2 \neq M_2^2$  giving additional flexibility and hopes about tachyonicity of the exotic  $\rho$ .

1. In this case one obtains the equations

$$\begin{aligned} m_{\pi}^2 &= M_+^2 - \frac{1}{4}\Delta , & m_{\rho}^2 &= M_+^2 + \frac{3}{4}\Delta \\ m_{\pi_{ex}}^2 &= M_-^2 - \frac{1}{4}\Delta , & m_{\rho_{ex}}^2 &= M_-^2 + \frac{3}{4}\Delta , \\ M_+^2 &= \frac{M_1^2 + M_2^2}{2} + \sqrt{\left(\frac{M_1^2 - M_2^2}{2}\right)^2 + M_{12}^4} = \frac{m_{\rho}^2 + 3m_{\pi}^2}{2} , \\ M_-^2 &= \frac{M_1^2 + M_2^2}{2} - \sqrt{\left(\frac{M_1^2 - M_2^2}{2}\right)^2 + M_{12}^4} = M_+^2 - 2\sqrt{\left(\frac{M_1^2 - M_2^2}{2}\right)^2 + M_{12}^4} \end{aligned} \quad (8.3.-2)$$

2. The condition that  $\rho_{ex}$  is tachyonic gives

$$m_{\rho_{ex}}^2 = M_-^2 + \frac{3}{4}\Delta < 0 , \quad (8.3.-2)$$

giving

$$\begin{aligned} m_\rho^2 &< 2\sqrt{\left(\frac{M_1^2 + M_2^2}{2}\right)^2 + M_{12}^4} , \\ M_+^2 &= \frac{M_1^2 + M_2^2}{2} + \sqrt{\left(\frac{M_1^2 + M_2^2}{2}\right)^2 + M_{12}^4} = \frac{m_\rho^2 + 3m_\pi^2}{2} , \end{aligned} \quad (8.3.-2)$$

3. In the parametrization  $(m_1^2, m_2^2, M_{12}^2) = (x, y, z)m_\rho^2$  one obtains the conditions

$$\begin{aligned} D \equiv \sqrt{(x+y)^2 + z^2} &> 1/2 , \\ \frac{x+y}{2} + D &= \frac{1}{2} + \frac{3}{2} \frac{m_\pi^2}{m_\rho^2} . \end{aligned} \quad (8.3.-2)$$

4. These equations imply the conditions

$$\begin{aligned} x+y &< 3 \frac{m_\pi^2}{m_\rho^2} \simeq .099 , \\ .490 &< z < .599 . \end{aligned} \quad (8.3.-2)$$

The first condition implies  $\sqrt{m_1^2 + m_2^2} < 242.7$  MeV. Second condition gives  $339 < M_{12}/MeV < 595.9$  so that rather stringent bounds on the parameters are obtained. The simplest solution to the conditions corresponds to  $x = y = 0$  and  $z = .599$ . This solution would mean vanishing masses in the absence of mixing and spin-spin splitting and could be defended by the Golstone boson property of pions mass degenerate with  $\rho$  mesons.

This little calculation encourages to consider the possibility that all exotic counterparts of light mesons are tachyonic and that this due the very large mixing induced by gluon exchange (gluino exchange squark option) at low energies. It would be nice if also mesons containing only single heavy quark were tachyonic and this could be the case if the p-adic length scale defining the strength of color interactions corresponds to that of the light quark so that the mass matrix has large enough non-diagonal component. Here one must be however very cautious since experimental situation is far from clear.

The model suggests that ordinary charmonium states and their exotic partners are in 1-1 correspondence. If so then many new exotic states are waiting to be discovered.

### The option based on heavy color excitations/spartners of light quarks

An alternative option is that color excitations/spartners of light quarks have large mass: this mass should not be however larger than the mass of  $c$  quarks if we want to explain  $X$ :s and  $Y$ :s as pairs of color excitations of light quarks. Suppose that the p-adic mass scale is same as that for  $c$  quarks or near it (not that the scales come as powers of  $\sqrt{2}$ ). This raises the question whether exotic  $c\bar{c}$  mesons really consist of exotic  $c$  and  $\bar{c}$ : why not color excitations of  $u, d, s$  and their antiquarks? As a matter fact, we cannot be sure about the quark content of  $X$  and  $Y$  mesons. Could these states be  $d\bar{d}$  and

$u\bar{u}$  states for their color excitations? It however seems that the presence of two  $W$  exchanges makes the decay rate quite too low so that this option seems to be out of question.

One can however consider the option in which the squarks associated with light quarks are heavy. This option is indeed realized in standard SUSY were the mass scales of particles families are inverted so that stop and sbottom are the lightest squarks and super-partners of  $u$  and  $d$  the heaviest ones. This would predict that the smesons associated with  $\bar{t}$  and  $b\bar{b}$  are lighter than  $X$  and  $Y$  (s)mesons. This option does not look at all natural in TGD but of course deserves experimental checking.

### How to test the dark squark option?

The identification of  $X$  and  $Y$  as dark smesons looks like a viable option and explains the failure to find SUSY at LHC if shadronization is a fast process as compared to the selectro-weak decays. The option certainly deserves an experimental testing. One could learn a lot about SUSY in TGD sense (or maybe in some other sense!) by just carefully scanning the existing data at lower energies. For instance, one could try to answer the following questions by analyzing the already existing experimental data.

1. Are  $X$  and  $Y$  type mesons indeed in 1-1 correspondence with charmonium states? One could develop numerical models allowing to predict the precise masses of scharmonium states and their decay rates to various final states and test the predictions experimentally.
2. Do  $b\bar{b}$  mesons have smesonic counterparts with the same mass scale? What about  $B_c$  type mesons containing two heavy squarks?
3. Do the mesons containing one heavy quark and one light quark have smesonic counterparts? My light-hearted guess that this is not the case is based on the assumption that the general mass scale of the mass squared matrix is defined by the p-adic mass scale of the heavy quark and the non-diagonal elements are proportional to the color coupling strength at p-adic length scale associated with the light quark and therefore very large: as a consequence the second mass eigenstate would be tachyonic.
4. What implications the strong mixing of light mesons and smesons would have for CP breaking? CP breaking amplitudes would be superpositions of diagrams representing CP breaking for mesons *resp.* smesons. Could the presence of smesonic contributions perhaps shed light on the poorly understood aspects of CP breaking?

### Objection against covariantly constant neutrinos as SUSY generators

TGD SUSY in its simplest form assumes that covariantly constant right-handed neutrino generates SUSY. The second purely TGD based element is that squarks would correspond to the same p-adic mass scale as partners.

This looks nice but there are objections.

1. The first objection relates to the tachyonicity needed to get rid of double degeneracy of light mesons consisting of  $u$ ,  $d$ , and  $s$  quarks. Mesons and smesons consisting of squark pair mix and for large  $\alpha_s$  the mixing is large and can indeed make second eigenvalue of the mass squared matrix negative. If so, these states disappears from spectrum. At least to me this looks however somewhat unaesthetic.

Luckily, the transformation of second pion-like state to tachyon and disappearance from spectrum is not the only possibility. After a painful search I found experimental work [?] claiming the existence of states analogous to ordinary pion with masses 60, 80, 100, 140,.... MeV. Also nucleons have this kind of satellite states. Could it be that one of these states is spion predicted by TGD SUSY for ordinary hadrons? But what about other states? They are not partners: what are they?

2. The second objection relates to the missing energy. SUSY signatures involving missing energy have not been observed at LHC. This excludes standard SUSY candidates and could do the same in the case of TGD. In TGD framework the missing energy would be eventually right handed neutrinos resulting from the decays of sfermions to fermion and sneutrino in turn decaying to neutrino and right handed neutrino. The naive argument is that shadronization would be much

faster process than the decay of squarks to quarks and spartners of electro-weak gauge bosons and missing energy so that these events would not be observed. Shadrons would in turn decay to hadrons by gluino exchanges. The problem with this argument is that the weak decays of squarks producing right handed neutrinos as missing energy are still there!

This objection forces to consider the possibility that covariantly constant right handed neutrino which generates SUSY is replaced with a color octet. Color excitations of leptons of lepto-hadron hypothesis would be sleptons which are color octets so that SUSY for leptons would have been seen already at seventies in the case of electron. The whole picture would be nicely unified. Sleptons and squark states would contain color octet right handed neutrino the same wormhole throats as their em charge resides. In the case of squarks the tensor product  $3 \otimes 8 = 3 + \bar{6} + 15$  would give several colored exotics. Triplet squark would be like ordinary quark with respect to color.

Covariantly constant right-handed neutrino as such would represent pure gauge symmetry, a super-generator annihilating the physical states. Something very similar can occur in the reduction of ordinary SUSY algebra to sub-algebra familiar in string model context. By color confinement missing energy realized as a color octet right handed neutrino could not be produced and one could overcome the basic objections against SUSY by LHC.

What about the claimed anomalous trilepton events at LHC interpreted in terms of SUSY, which however breaks either the conservation of lepton or baryon number. I have proposed TGD based interpretation [K43] is in terms of the decays of  $W$  to  $\tilde{W}$  and  $\tilde{Z}$ , which in turn decay and produce the three lepton signature. Suppose that  $\tilde{W}$  and  $\tilde{Z}$  are color octets and that sleptons replace the color octet excitations of leptons responsible for lepto-hadron physics [?]. One possible decay chain would involve the decays  $\tilde{W}^+ \rightarrow \tilde{L}^+ + \bar{\nu}_L$  and  $\tilde{Z} \rightarrow L^+ + \tilde{L}^-$ . Color octet sleptons pair combine to form lepton pair which decays to lepton pair. This decay cascade would produce missing energy as neutrino and this seems to be the case for other options too. One could overcome the basic objections against SUSY by LHC.

This view about TGD SUSY clearly represents a hybrid of the two alternative views about X and Y bosons as composites of either color excitations of quarks or of squarks and is just one possibility. The situation is not completely settled and one must keep mind open.

### Does one really obtain pseudo-scalar smesons?

The critical question is whether one obtains pseudo-scalar states as mesonlike bound states of squarks. This depends on what one means with squarks. Also the notion of pseudo-scalar is not the same for  $M^4 \times CP_2$  and  $M^4$ . In TGD framework  $M^4$  (pseudo-)scalars constructed from fermions and anti-fermions are replaced by  $CP_2$  (pseudo-)vectors since the chiral symmetry for  $M^4 \times CP_2$  implying separate conservation of lepton and baryon numbers implies that genuine fermionic H-scalars and pseudo-scalars would have quantum numbers of leptoquark.

1. The first question is what one means with ordinary pseudo-scalar mesons in TGD framework. These mesons should be characterized by a bi-local quantity which behaves like a preferred  $CP_2$  pseudo-vector and therefore like  $M^4$  pseudo-scalar. One should identify a unique direction of  $CP_2$  polarization mathematically analogous to Higgs vacuum expectation value and construct a bilinear in quark wave functions associated with the partonic 2-surfaces assigned to the quarks. The problem is however that  $CP_2$  is not a flat space. Also non-locality is a problem. Somehow one should be able to construct general coordinate invariant quantities with well-defined transformation properties under discrete symmetries.
2. The effective 2-dimensionality implying the notions of partonic 2-surfaces and string world sheets suggests a solution to the non-locality problem. Also the experience with QCD suggests that bilinear expression contains a non-integrable phase factor  $U$  connecting quark and anti-quark and defined by the classical color gauge potentials which are just projections of SU(4) Killing vector fields to the space-time surface. The curve would be analogous to a string connecting the partonic 2-surfaces and fixed uniquely by the strong form of holography in turn reducing to the strong form of general coordinate invariance. TGD indeed predicts the existence of string world sheets and thus strings at the 3-D ends of space-time sheets defined by causal diamond.

3. What about the preferred  $CP_2$  vector?
  - (a) The first candidate is the quantity  $X = I_3 j_3^{Ak} \Gamma_k + Y j_Y^{Ak} \Gamma_k$  where  $I_3$  and  $Y$  denote color isospin and hyper-charge of the quark and  $j_i^{Ak}$  corresponding Killing vectors. The preferred vector would be due to the choice of quantization axes. This option is natural for in the case of quark bilinears but fails for a bilinear constructed from covariantly constant right handed neutrino.
  - (b) Second candidate would be the  $CP_2$  part for the trace of the second fundamental form contracted with  $CP_2$  gamma matrices -denote it by  $X = H^k \Gamma_k$  -at the either end of the string connecting fermion and anti-fermion at partonic 2-surfaces. This option would be natural for the right-handed neutrino. Bi-local super-generators would vanish when the partonic 2-surface is minimal surface. This would be analogous to the representations of SUSY for which  $2^{-k} \mathcal{N}$  generators annihilate the physical states and act as pure gauge symmetries.
4. This would suggest that the basic invariants in the construction is the quantity  $\bar{\Psi}_1 U X O \Psi_2$ . Sub-script  $i = 1, 2$  refers to the partonic 2-surface,  $X$  can occur at both ends and  $\gamma_5$  guarantees pseudo-scalar property.  $O$  is  $1 \pm \gamma_5$  for right- *resp.* left-handed quarks. The recipe would apply also to the bilinears formed right-handed neutrinos: now only the projector  $(1 + \gamma_5)$  to right-handed neutrino appears so that only single state is obtained.

Most of the options that one can imagine give something else than pseudo-scalar meson.

1. Assuming that  $\mathcal{N} = 2$  symmetry is not too badly broken, one can add to the partonic 2-surface carrying quark either right-handed neutrino or anti-neutrino or both so that one obtains a 4-plet containing two quark states, spin zero squark and spin 1 squark. From these states one can construct meson like states.
  - (a) The first implication is degeneracy of quark like states because of the presence of neutrino pair. TGD however predicts large breaking of SUSY. According to the arguments of [?] the state containing right handed neutrino pair has propagator behaving like  $1/p^3$  and does not correspond to ordinary particle. It is not at all clear whether this kind squarks can give rise to meson like states. Also the R-parity of these squarks would be +1 and the model requires negative R-parity.
  - (b) For spin one squarks one obtains pseudo-vector state with spin 1: the meson state would transform like the cross product of the vectors characterizing spin 1 squarks. These states could be also present in the spectrum although they do not correspond to pseudo-scalars.

This suggests that  $\mathcal{N} = 2$  SUSY is badly broken and one must restrict the consideration to  $\mathcal{N} = 1$  option.

2. For  $\mathcal{N} = 1$  option both squarks are scalars (quark plus anti-neutrino option).
  - (a) Forgetting the non-locality and regarding partonic 2-surfaces as basic objects as a whole, one has bound state of scalar squarks and the possible mesonlike state is most naturally a scalar rather than pseudo-scalar.
  - (b) Non-locality brought in by strings however changes the situation. One could construct a pseudo-scalar by starting from pseudo-scalar meson constructed by using the non-local recipe. To add neutrino and anti-neutrino at the partonic 2-surfaces one could use the bilinears  $\bar{\nu}_{R,1} H^k \Gamma_k \nu_{R,2}$  and  $\bar{\nu}_{R,2} H^k \Gamma_k \nu_{R,1}$  to obtain the needed right-handed  $CP_2$  current, which is neither scalar nor pseudo-scalar. The stringy picture (braids as representation of many fermion states) forced by the strong form of general coordinate invariance (or strong form of holography or effective two-dimensionality) would be absolutely essential for this picture to work.

To sum up, it is not completely clear whether the squark option really gives pseudo-scalar mesons. One cannot exclude additional pseudo-vector states and scalars unless  $\mathcal{N} = 2$  SUSY is badly broken. The option based on color excitations in turn predicts only pseudo-scalar mesons but also for this option a non-local state construction is needed.

### What are the implications for $M_{89}$ hadron physics?

Lubos told about the latest information concerning Higgs search. It is not clear how much these data reflect actual situation [?]. Certainly the mass values must correspond to observed bumps. The statistical significances are *expected* statistical significances, not based on real data. Hence a special caution is required. At 4.5/fb of data one has following bumps together with their expected statistical significance:

- 119 GeV: 3 sigma
- 144 GeV: 6 sigma(!)
- 240 GeV: 4.5 sigma
- 500 GeV: 4 sigma

It is interesting to try to interpret these numbers in TGD framework. The first thing to observe is that weak boson decay widths do not pose any constraints on the model and one could assume that  $M_{89}$  squarks are not dark.

#### 1. *The interpretation of 144 GeV bump*

Consider first the 144 GeV state 6 sigma expected significance, which is usually regarded as a criterion for discovery. Of course this is only expected statistical significance, which cannot be taken seriously.

1. 144 GeV is exactly the predicted mass of the pion of  $M_{89}$  hadron physics which was first observed by *CDF* and then decided to be a statistical fluctuation. I found myself rather alone while defending the interpretation as  $M_{89}$  pion in viXra log and trying to warn that one should not throw baby with the bath water.
2. From an earlier posting of Lubos one learns that 244 GeV state must be CP odd -just like neutral pion- and should correspond to  $A_0$  Higgs of SUSY. Probably this conclusion as well as the claimed CP even property of 119 GeV state follow both from the assumption that these states correspond to SUSY Higgses so that one must not take them seriously.
3. The next step before TGD will be accepted is to discover that this state cannot be Higgs of any kind.

#### 2. *Possible identification of the remaining bumps*

Could the other bumps correspond to the pseudoscalar mesons of  $M_{89}$  hadron physics? For only a week ago I would have answered 'Definitely not'! Could the claimed bumps explained by assuming that also  $M_{89}$  quarks have either color excitations or super partners with the same mass scale and the same mechanism is at work for  $M_{89}$  mesons as for ordinary mesons. The same question can be made for the option based on color excitations of quarks in  $\bar{6}$  or 15.

Consider now the possible identification of the remaining Higgs candidates concentrating for definiteness to the squark option.

1. In the earlier framework there was no identification for meson like states below 144 GeV. The discovery of this week was however that squarks could have the same p-adic mass scale as quarks and that one has besides mesons also smesons consisting of squark pair as a consequence. Every meson would be accompanied by a smeson. Gluino exchange however mixes mesons and smesons so that mass eigenstates are mixtures of these states. At low energies however the very large non-diagonal element of mass squared matrix can make second mass eigenstate tachyonic. This must happen for mesons consisting of light quarks. This of course for the  $M_{107}$  hadron physics familiar to us.
2. Does same happen in  $M_{89}$  hadron physics? Or is the non-diagonal element of mass squared matrix so small that both states remain in the spectrum? Could 119 GeV state and 144 GeV state correspond to the mass eigenstates of supersymmetric  $M_{89}$  hadron physics? If this is the case one could understand also this state.

3. What about 240 GeV state? The proposal has been that selectron corresponds to  $M_{89}$ . This would give it the mass 262.14 GeV by direct scaling;  $m(\text{selectron}) = 2^{(127-89)/2}m(\text{electron})$ . This is somewhat larger than 240 GeV.

Could this state correspond to spartner of the  $\rho_{89}$  consisting of  $M_{89}$  squarks. There is already earlier evidence for bumps at 325 GeV interpreted in terms of  $\rho_{89}$  and  $\omega_{89}$ . The mass squared difference should be same for pionic mass eigenstates and  $\rho_{89}$  like mass eigenstates. This would predict that the mass of the second  $\rho$  like eigenstate is 259 GeV, which is not too far from 240 GeV.

Tommaso Dorigo's newest posting The Plot Of The Week - The 327 GeV ZZ Anomaly [?] tells about further support about ZZ anomaly at 327 GeV, which in TGD framework could be interpreted in terms of decays of the neutral member of  $\rho_{89}$  isospin triplet or  $\omega_{89}$ , which is isospin singlet. A small splitting in mass found earlier is expected unless this decay corresponds to  $\omega_{89}$ . Also WZ anomaly is predicted.

4. What about the interpretation of 500 GeV state? The  $\eta'$  meson of  $M_{107}$  hadron physics has mass 957.66 MeV. The scaling by 512 gives 490.3 GeV- not too far from 500 GeV!

The alternative option replaces squarks with their color excitations. The arguments are identical in this case. Many other pseudoscalar mesons states are predicted if either of these options is correct. In the case of squark option one could say that also SUSY in TGD sense has been discovered and has been discovered in ordinary hadron physics for 8 years ago! SUSY would not reveal itself via the usual signatures since shadronization would be faster process than the decay of squarks via emission of selectro-weak bosons.

All these looks too good to be true. I do not know how the *expected* significances are estimated and how precisely the mass values correspond to experimental data. In any case, if these states turn out to be pseudoscalars, one can say that this is a triumph for TGD. Combining this with the neutrino super-luminality which can be explained easily in terms of sub-manifold gravitation, the prospects for TGD to become the next TOE are brighter than ever.

### 8.3.3 Strange trilepton events at CMS

Lubos Motl reports that CMS sees SUSY-like trilepton excesses. Also Matt Strassler tells about indications that something curious has been detected at the Large Hadron Collider [?]. Probably a statistical fluctuation is in questions as so many times earlier. The dream to discover SUSY easily leads to mis-interpretations. Trilepton events however provide an excellent opportunity to learn about SUSY in TGD framework.

#### The recent view about TGD SUSY briefly

Before continuing it is good to say something about what SUSY in TGD Universe might mean and also about expected masses of squarks and sleptons as well as intermediate gauge bosons in TGD Universe. The picture is of course preliminary and developing all the time in strong interaction with experimental input from LHC so that there is no guarantee that I agree with this view for the rest of my life.

1. Super-partner of the particle is obtained by adding a the partonic 2-surface a parallelly moving right-handed neutrino or antineutrino so that one has  $\mathcal{N} = 1$  SUSY. It must be emphasized that one has higher SUSYs but they are badly broken. Allowing both right-handed neutrino and antineutrino one obtains  $\mathcal{N} = 2$  SUSY and interpreting all fermionic oscillator operators as generators of SUSY one obtains badly broken SUSY with rather large  $\mathcal{N}$ , which is however finite by finite measurement resolution inducing a cutoff on the number of fermionic oscillator operators.
2. R-parity is broken in TGD SUSY since sparticle can decay to particle and neutrino. Therefore all neutral sparticles manifesting themselves as missing energy in TGD framework eventually decay and produce neutrinos as the eventual missing energy. The decay rates to particles and neutrinos can however be so slow that photino and sneutrinos leave the reactor volume before decaying.

3. The basic assumption is that particle and sparticle obey the same mass formula apart from p-adic mass scale that can be different. For instance, the masses of sleptons are half-octaves of lepton masses. This breaking of SUSY is extremely elegant and is absolutely essential part of ordinary particle massivation too explaining the enormous mass scale differences between neutrinos and top quark in a natural manner.
4. I have proposed that the super-partners of  $M_{107}$  quarks (ordinary quarks) and gluon could have the same mass scale but be dark in TGD sense, in other words have Planck constant which is integer multiple of the ordinary Planck constant. This is required by the fact that intermediate gauge boson decay widths do not allow light exotic particles. This hypothesis could allow to understand the exotic  $X$  and  $Y$  mesons and also the absence of smesons containing light squarks could be understood. Since shadronization is expected to proceed much faster than selectro-weak decays of squarks, the squarks of  $M_{89}$  hadron physics need not be dark and  $M_{89}$  shadrons might be there. The fruitless search for squarks would be based on wrong signatures if this the case and already now we would have direct evidence for the squarks of  $M_{89}$  hadron physics.
5. Only the decays of electro-weak gauginos and sleptons would produce the standard signatures.
  - (a) Charged sleptons must have large p-adic scales in TGD Universe. Ordinary leptons correspond to Mersenne prime  $M_{127}$ , Gaussian Mersenne  $M_{G,113}$ , and Mersenne prime  $M_{107}$ . If also sleptons obey this rule, they would correspond to the Mersenne primes  $M_{89}$  and Gaussian Mersennes  $M_{G,n}$ ,  $n = 79, 73$ . Assuming that particle and sparticle obey the same mass formula apart from different p-adic mass scale, the masses of selectron, smuon, and stau would be about 267 GeV, 13.9 TeV, and 164.6 TeV. Only selectron is expected to be visible at LHC.
  - (b) About the mass scales of sneutrinos it is difficult to say anything definite. A natural guess is that sneutrinos are relatively light so that they would be produced in the decays of sleptons and electro-weak gauginos. Same applies to photino. These particles are good candidates to missing energy unless their decay to particle plus neutrino is fast enough.
  - (c) There seems to be no strong constraints to the mass scales of  $\tilde{W}$  and  $\tilde{Z}$ . The mass scale could be even  $M_{89}$  characterizing  $W$  and  $Z$ . p-Adic length scale hypothesis predicts that the p-adic mass scale is half octave of intermediate boson mass scale and if the Weinberg angle is same the masses are half octaves of  $W/Z$  masses.
6. The most general option inspired by twistorial considerations (absence of IR divergences) and zero energy ontology is that both Higgs like states and Higgsinos and their higher spin generalizations are eaten so that the outcome is spectrum of massive states. This might have something do with the phenomenon in which some supersymmetry generators annihilate physical states. In any case the fermions at wormhole throats are always massless- even the virtual particles identified in terms of wormhole contacts consist of massless wormhole throats which can have also negative energy.

It is important to notice that trilepton events as signals for SUSY have nothing to do with squarks and gluinos for which I have proposed a non-standard interpretation in the previous postings (see this, this ,this) and in the article [?].

### How to interpret the trilepton events in TGD framework?

Trilepton events [?] represent the simplest SUSY signal and would be created in the decays  $W \rightarrow \tilde{W} + \tilde{Z}$ . The decays  $Z \rightarrow \tilde{W}^+ + \tilde{W}^-$  would give rise to dilepton events. Electro-weak gauginos would in turn decay and yield multi-lepton events. Neither  $W/Z$  boson nor the gauginos need to be on mass shell.

In the following I will discuss these decays taking seriously the above listed conjectures about SUSY a la TGD.

1. Obviously the situation reduces to the study of the decays of  $\tilde{W}$  and  $\tilde{Z}$ .
  - (a) For  $\tilde{W}$  the decay channels are  $\tilde{W} \rightarrow W + \tilde{\gamma}$  and  $\tilde{W} \rightarrow L + \tilde{\nu}_L$ .  $W$  would decay to charged lepton-neutrino pair. One charged lepton would result in both cases.

- (b) For  $\tilde{Z}$  the decay channels are  $\tilde{Z} \rightarrow \nu + \tilde{\nu}_L$ ,  $\tilde{Z} \rightarrow \tilde{W}^+ + W^-$ , and  $\tilde{Z} \rightarrow \tilde{L} + \bar{L}$  and charge conjugates of these. For the second decay mode the decays of  $W^+$  and  $\tilde{W}^-$  produce lepton antilepton pair. For the third decay mode selectron is the most plausible slepton candidate and is expected to have rather large masses in TGD Universe (about 267 GeV and thus off mass-shell).  $\tilde{L} \rightarrow L + \tilde{\gamma}$  is the most natural decay for slepton.
2. The decay cascade beginning with  $Z \rightarrow \tilde{W}^+ + \tilde{W}^-$  would produce 2 charged leptons (more generally even number of charged leptons) plus missing energy. Charged leptons would have opposite charges. No sleptons would be needed as intermediate states and all lepton families would be democratically represented as final states.
  3. The decay cascade beginning with  $W \rightarrow \tilde{W} + \tilde{Z}$  would produce 2 or 3 charged leptons plus missing energy.
    - (a) For  $\tilde{Z} \rightarrow \tilde{W}^+ + W^-$  option 3 charged leptons would result and there would be a complete family democracy. For this option the rate is expected to be largest.
    - (b) For the option having slepton as intermediate state, the large masses for smuon and stau would favor selectron for 3 lepton events. 3-lepton events would have charge signatures  $-+$  or  $++-$  following from charge conservation alone. The suggested large mass for selectron would however reduce also the rate of 3 lepton events considerably. Note that the reported events have total transversal energy larger than 200 GeV.
  4. In MSSM also  $sZ \rightarrow \tilde{\chi}_1^0 + Z$  followed by  $Z \rightarrow L^+ + L^-$  is possible so that trilepton state results. Here  $\tilde{\chi}_1^0$  denotes the lightest neutral sboson and is a mixture of  $\tilde{h}$ ,  $\tilde{Z}$ , and  $\tilde{\gamma}$ . If  $\tilde{h}$  is not in the spectrum, then  $\tilde{\gamma}$  is an excellent candidate for the lightest neutral gaugino. If the Weinberg angle is SUSY invariant the decay producing three charged leptons in this manner is not possible.
  5. Photinos would decay to photons and neutrinos producing photons and missing energy. It is not clear whether this decay is fast enough to take place in the reactor volume.

To sum up, the trilepton events are possible and would be produced in the decays  $\tilde{Z} \rightarrow \tilde{W} + W$  and  $\tilde{W} \rightarrow e + \tilde{\gamma}$ . The trilepton events involving selectron as intermediate state do not look highly plausible in TGD framework if one takes seriously the guess for the slepton mass scales.

### More about strange trilepton events

I already told about indications for strange charged tri-lepton events at CMS. The inspiration came from a posting CMS sees SUSY-like tri-lepton excesses of Lubos.

Only a few days later both Tommaso and Lubos discussed a quite recent paper telling about charged tri-lepton events observed at CMS.

1. From Tommaso's posting one learns that three charged leptons with total mass near to  $Z$  mass have been observed. Charge conservation of course requires fourth charged lepton if the particles originate in the decay of  $Z$  as assumed and Tommaso argues that this lepton has so low energy that it is not detected. This kind of lepton could result in an energy asymmetric decay of photon. The assumption that  $Z$  is the decaying particle might be however un-necessarily strong: it could be quite well  $W$  with almost the same mass. In this case charge conservation allows genuine charged tri-lepton event. The above discussion suggests the decay  $W \rightarrow \tilde{W} + \tilde{Z}$  to be the source of charged tri-lepton events.
2. The authors of the paper propose that the reaction could be initiated by a decay of squark or gluino and necessarily involving R-parity breaking. There are two possible options for R-parity breaking allowed by proton stability depending on whether it conserves lepton or baryon number. For lepton number violating option intermediate particle is neutralino (lightest sparticle which is stable in R-parity breaking scenarios) and for baryon number violating scenario bino or higgsino. The R-parity violating decay of lightest spartner (neutral) would yield slepton-lepton pair and the R-parity violating decay of slepton a lepton pair plus neutrino. This would produce instead single observed lepton charged tri-lepton state. The authors do not give enough details to make possible for a non-professional to deduce what the detailed model for the process really is.

It is interesting to consider the situation in TGD framework in light of the crucial additional data (the three charged leptons have mass rather near to that of  $Z$  and therefore to that of  $W$ ).

1. The decay of  $W \rightarrow \tilde{W} + \tilde{Z}$  with the decays  $\tilde{W}$  and  $\tilde{Z}$  proceeding in either of the two manners discussed above would predict that the *total mass of all particles produced* is near to  $W$  mass (and therefore  $Z$  mass) and also why one obtains genuine charged tri-lepton states. The problem is that missing energy in the form of neutrinos and neutral sparticles is present and it is not at all clear why this energy should be small.
2. An option not discussed above is the decay  $W \rightarrow \tilde{\nu} + L$  followed by the decay  $\tilde{\nu} \rightarrow L + \tilde{W}$  followed by  $\tilde{W} \rightarrow L + \tilde{\nu}$  would not break R-parity and would produce  $\tilde{\nu}$ . Total energy would correspond to  $W$  mass but it is not clear why the missing energy assigned with  $\tilde{\nu}$  should be small.
3. R-parity violation predicted by TGD however allows also to consider the direct decay  $\tilde{\nu} \rightarrow L^+ + L^-$  so that there would be no missing energy. One could say that the decay is the reversal of a process in which  $L^+ + L^-$  annihilates to a  $\tilde{\nu}$  identifiable as a pair of neutrino and right-handed neutrino at microscopic level. All standard model quantum numbers would be conserved.

In TGD framework R-parity violation is a prediction of the theory and it would not violate either baryon or lepton number conservation. There is no need to assume undetected charged lepton since charge conservation allows charged tri-lepton final state as such without any missing energy. Obviously the TGD based model is by several orders of magnitude simpler than the model based on standard SUSY.

### 8.3.4 CMS observes large diphoton excess

LHC has started to produce data indicating that the new physics required by very general arguments indeed is there. Lubos [?] told today about a preprint by CMS collaboration [?] showing a very large excess of di-photons in proto-proton collisions. This excess is so large that only a rough systematic error can threaten its status.

#### What has been observed?

The following two data bits give strong hints about what might be involved.

1. From the figure in the posting of Lubos [?] one learns that the distribution for the difference  $\Delta\phi$  for the difference of the azimuthal angles with respect to the beam direction covers rather evenly the span  $\Delta\phi < 2.80$  and the production rate is considerably higher than predicted by QCD calculations except near  $\pi$  where the production rate is smaller than the prediction. From momentum conservation one would expect  $\Delta\phi \sim \pi$  in a good approximation in the cm frame of photons. Unless the resonance does not move with a very high velocity, the photons  $\Delta\phi \simeq \pi$  should hold true quite generally. This gives hints about the production mechanism.
2. Figure 3 of the CMS preprint [?] gives the differential cross section with respect to diphoton invariant mass  $m_{\gamma\gamma}$  as a function of  $m_{\gamma\gamma}$ . The distribution has a sharp knee between 45-55 GeV. One might be able to see double peak at invariant masses about 50 GeV and 75 GeV and even third peak around 175 GeV. The differential cross section is however anomalous already around 20 GeV which serves as transverse momentum cutoff for photons

The naive question by a non-professional is whether there could be resonance decaying to two photons with mass in this range.  $\Delta\phi \sim \pi$  would be however required if the resonance does not move very fast in the cm frame of colliding protons. The cut on transversal momenta is 20 GeV making 40 GeV transversal energy and I am not absolutely sure whether this could cause the shoulder. The experimenters however speak about shoulder and certainly they would not do this if it were due to the cutoff. Therefore I will assume that the shoulder is genuine.

3. If the shoulder located roughly between 45 GeV and 75 GeV is real, it would seem that the two-photon state must be accompanied by a state with opposite momentum and roughly the same energy and thus moving in opposite direction. This suggests two states with mass(es) in the range [90,150] GeV.

### What could it be?

The speculation of Lubos is that the decay of Higgs like state with mass around 119 GeV might explain the finding but admits that standard model Higgs should not produce any visible effect. Even worse, the so called little Higgs alternative would predict a reduction of diphoton production rate. There are also exotic explanations involving large dimensions and exotic gravitons but to my opinion these alternatives belong to the realm of bad science fiction and can be safely forgotten.

In my naive mind frame the strong knee around 55 GeV is something which I find very difficult to not interpret as a bump suggesting the presence of a meson like state. On the other hand, the distribution for  $\Delta\phi$ ; does not fit with this simplistic picture.

What about the TGD inspired interpretation? The first interpretation that comes into mind relies on the TGD based view about SUSY, which differs considerably from the standard view.

1. As explained in the earlier posting [K43], TGD could allow the realization of SUSY in which quarks and squarks have same p-adic mass scale- perhaps even masses- before the mixing of hadrons and shadrons allowed by R-parity conservation. The mechanism explaining the experimental absence of squarks would be shadronization proceeding faster than the decay of squarks to quark and electroweak gaugino.
  - (a) In this framework the mysterious  $X$  and  $Y$  mesons accompanying charmonium states would be their super partners in a good approximation since the mixing would be small. The mixing of mesons and smesons would be however very large near confinement mass scale and make the other mixed state (identified as eigen state of mass squared matrix) tachyonic and eliminate it from the spectrum. The companion of pion would be tachyonic and excluded from spectrum: this would hold true for all smesons containing light quarks and perhaps also those containing only single light squark if the mass scale of the mass squared matrix is determined by the heavier quark and  $\alpha_s$  by the lighter quark so that mixing is very large.
  - (b) A crucial assumption is that the squarks are dark in the sense of having a non-standard value of Planck constant: otherwise the decay widths of electro-weak gauge bosons would be too large. The phase transition changing the value of  $\hbar$  and having a purely geometric (topological) meaning in TGD framework would accompany also the mixing process being analogous to mass insertions in the lines of Feynman graph.
2. In TGD framework the proposed view about squarks as particles having common p-adic mass scale with quark is suggested to hold true in both the ordinary  $M_{107}$ - and  $M_{89}$  hadron physics. There is however no need to assume that  $M_{89}$  squarks are dark. The pion of  $M_{89}$  hadron physics could identified as the earlier 144 GeV Higgs candidate, forgotten but mentioned again by Lubos [?], would have 119 GeV bump as a lighter companion. The two states would be mixtures of pion and spion. The mass values for the bumps assigned to  $\rho_{89}$  and  $\omega_{89}$  and to their spartner candidates allow to estimate the mass of the partner of  $\pi_{89}$ . The mass would near to 119 GeV for which there are slight indications [K43].

How the shoulder around 45-55 GeV could be created from the decays of the partner of  $\pi_{89}$ - a (probably strong) mixture of pion and spion. Could the two mixtures of  $M_{89}$  pion and its spartner with masses (say) 119 GeV and 144 GeV (one should not take these number too literally) be responsible for the effect as the indications about two peaked structure suggest? Could the spionic parts of the states produce the events diphoton events.

1. The simplest Feynman diagram for the decay of the pion-like state would describe the turn around of squark backwards in time via the emission of two photons. This would produce only  $\Delta\phi \sim \pi$  events and photons with energies around 60 GeV and 72 GeV for the proposed masses 119 GeV and 144 GeV.

**Comment:** 144 GeV is the estimate for the mass of  $\pi_{89}^\pm$ , one obtains 138 GeV for  $\pi_{89}^0$ : I have earlier neglected electromagnetic mass splitting of pions and approximated pion masses with charged pion mass 140 MeV. This scales the second mass to 69 GeV.

2. For a more complex Feynman diagram exchanged squark turning around in time would emit quark and antiquark transforming in this manner to gluino and back to squark. Another possibility is emission of two gluons. This would give photon pair and something which could be just two hadron jets if the emitted quarks and gluons transform to ordinary quarks.

3. The objection is that this model need not explain the strong concentration of diphoton invariant mass to the range 45-75 GeV since in principle 4-particle final states are in question and phase space distribution does not predict anything like this. p-Adic length scale hypothesis however suggests that the resulting quark pairs actually form a p-adically scaled down variant of the pion like state and have therefore mass, which is half of its mass. This would give rise to a resonance like behavior and imply a strong concentration of the events to the invariant masses which are one half of the mass of the mother particle.

The p-adically scaled up quarks appear even in the TGD based model of light hadrons and produce mass formula replacing Gell-Mann-Nishijima mass formula (see this). As a matter fact, the naive prediction for the mass of  $M_{89}$  pion is just 512 times the mass of the ordinary neutral pion and gives 69.1 GeV!

4. One must also worry about overall parity conservation required if only strong and electromagnetic interactions are involved with the decay process. Pion is pseudoscalar and the decay of pion to two pions with scaled down mass requires parity breaking in the effective action involving the pion fields only unless the vertex contains derivatives but one cannot build a Lorentz invariant involving 4-D permutation symbol from three pion fields. Should one assume that the process breaks parity conservation and involves therefore weak interactions? Or should one assume that second scaled down pion is replaced with two pions with mass equal 1/4 the mass of the decaying pion to give parity invariant effective interaction Lagrangian as assumed in the model of CDF anomaly. This would predict also diphoton pairs with invariant masses scaled down to 22.5-40 GeV. The differential cross section is anomalous down to the 20 GeV cutoff. One should be able to resolve this issue before one can take the model seriously.

#### A connection with Aleph anomaly

There is an old anomaly known as Aleph anomaly [?] producing 4-jets states with *jet-jet* invariant mass of 55 GeV. According to the reference, the anomaly did not survive improved statistics. Delphi and L3 also observed 4-jet anomaly with dijet invariant mass about 68 GeV: this not too far from the mass for p-adically scaled down mass of  $\pi_{89}$  equal to 69.1 GeV! Remarkably, according to the above reference L3 observation survived the improvement of the statistics!

1. For more than decade ago I proposed an explanation of Aleph anomaly in terms of a meson-like state formed by p-adically scaled up variants of  $b$  quark and its antiquark (see this ) [K46]. The mass of the resonance was predicted correctly using p-adic length scale hypothesis predicting that the mass of scaled up  $b$  quark is half octave of the mass of  $b$  quark.
2. The model could be generalized by replacing  $b$  quark with its super-partner if one assumes that SUSY breaking means only different p-adic mass scale. There is however an aesthetic problem (I take aesthetic arguments very seriously). The model for  $X$  and  $Y$  mesons assumed that the p-adic mass scale is same: now one should give up this assumption for  $b$  quark. The reader has probably already asked whether Aleph anomaly and the recent CMS anomaly could correspond to the same meson like state. 4-jets could be produced when  $\tilde{b}$  and  $\tilde{b}^*$  decay to  $bb^*$  pair by emission of gluinos which then exchange quark to produce quark pair or gluon pair. In the decays of  $X$  and  $Y$  mesons the resulting quark pair would form pion or some other meson. Now two quark or gluon jets by exchanged gluinos would be produced giving altogether four jets.
3. CMS anomaly suggests a different interpretation. Perhaps the 4-jets with di-jet energies around 55 GeV and 68 GeV are produced by the decays of the mixtures of  $M_{89}$  pion and spion with masses around 110 GeV and 144 GeV producing as intermediate state the 2-adically scaled down pions with half of their original masses.

The same mechanism is assumed also in the model of CDF anomaly discovered for three years ago but already forgotten [?]. Political memory is short! The mechanism would be a modification of that producing the diphoton excess. Squark and anti-squark would transform to quark-antiquark pair giving rise to intermediate scaled down pionlike state decaying to two jets with invariant mass concentrated around the mass of pion-like state. The exchanged gluino emits quark and antiquark or two gluons. Quark antiquark state could also form a scaled down  $M_{89}$  pion before the decay to two jets. The outcome would be four jets with concentration to preferred invariant masses.

## 8.4 Understanding of the role of right-handed neutrino in supersymmetry

From the beginning it was clear that right-handed neutrino should generate super-conformal symmetry of some kind and the natural question was whether it generates also space-time SUSY.  $\mathcal{N} = 1$  SUSY was excluded by separate conservation of  $B$  and  $L$  but  $\mathcal{N} = 2$  variant of this symmetry could be considered. The new element in the picture was the physical realization of the supersymmetry by adding right-handed neutrino to the state: Does this produce in the case of covariantly constant right-handed neutrino space-time SUSY or something else?: this was the question. Only the breakthrough in understanding of the preferred extremals of Kähler action and solutions of the modified Dirac equations allowed to provide reasonably convincing negative answer to the question about existence of space-time SUSY.

### 8.4.1 Basic vision

What SUSY means in TGD framework is second long-standing problem. In TGD framework SUSY is inherited from super-conformal symmetry at the level of WCW [?, ?]. The SUSY differs from  $\mathcal{N} = 1$  SUSY of the MSSM and from the SUSY predicted by its generalization and by string models. One obtains the analog of the  $\mathcal{N} = 4$  SUSY in bosonic sector but there are profound differences in the physical interpretation.

1. One could understand SUSY in very general sense as an algebra of fermionic oscillator operators acting on vacuum states at partonic 2-surfaces. Oscillator operators are assignable to braids ends and generate fermionic many particle states. SUSY in this sense is badly broken and the algebra corresponds to rather large  $\mathcal{N}$ . The restriction to covariantly constant right-handed neutrinos (in  $CP_2$  degrees of freedom) gives rise to the counterpart of ordinary SUSY, which is more physically interesting at this moment.
2. Right handed neutrino and antineutrino are not Majorana fermions. This is necessary for separate conservation of lepton and baryon numbers. For fermions one obtains the analog  $\mathcal{N} = 2$  SUSY.
3. Bosonic emergence [?] means the construction of bosons as bound states of fermions and anti-fermions at opposite throats of wormhole contact. This reduces TGD SUSY to that for fermions. This difference is fundamental and means deviation from the SUSY of  $\mathcal{N} = 4$  SUSY, where SUSY acts on gauge boson states. Bosonic representations are obtained as tensor products of representation assigned to the opposite throats of wormhole contacts. Further tensor products with representations associated with the wormhole ends of magnetic flux tubes are needed to construct physical particles. This represents a crucial difference with respect to standard approach, where one introduces at the fundamental level both fermions and bosons or gauge bosons as in  $\mathcal{N} = 4$  SUSY. Fermionic  $\mathcal{N} = 2$  representations are analogous to "short"  $\mathcal{N} = 4$  representations for which one half of super-generators annihilates the states.
4. The introduction of both fermions and gauge bosons as fundamental particles leads in quantum gravity theories and string models to  $d = 10$  condition for the target space, spontaneous compactification, and eventually to the landscape catastrophe.

For a supersymmetric gauge theory (SYM) in  $d$ -dimensional Minkowski space the condition that the number of transversal polarization for gauge bosons given by  $d - 2$  equals to the number of fermionic states made of Majorana fermions gives  $d - 2 = 2^k$ , since the the number of fermionic spinor components is always power of 2.

This allows only  $d = 3, 4, 6, 10, 16, \dots$ . Also the dimensions  $d + 1$  are actually possible since the number of spinor components for  $d$  and  $d + 1$  is same for  $d$  even. This is the standard argument leading to super-string models and M-theory. It is lost - or better to say, one gets rid of it - if the basic fields include only fermion fields and bosonic states are constructed as the tensor products of fermionic states. This is indeed the case in TGD, where spontaneous compactification plays no role and bosons are emergent.

5. Spontaneous compactification leads in string model picture from  $\mathcal{N} = 1$  SUSY in say  $d = 10$  to  $\mathcal{N} > 1$  SUSY in  $d = 4$  since the fermionic multiplet reduces to a direct sum of fermionic multiplets in  $d = 4$ . In TGD imbedding space is not dynamical but fixed by internal consistency requirements, and also by the condition that the theory is consistent with the standard model symmetries. The identification of space-time as 4-surface makes the induced spinor field dynamical and the notion of many-sheeted space-time allows to circumvent the objections related to the fact that only 4 field like degrees of freedom are present.

### 8.4.2 What is the role of the right-handed neutrino?

The general ansatz for the preferred extremals of Kähler action and application of the conservation of em charge to the modified Dirac equation have led to a rather detailed view about classical and TGD and allowed to build a bridge between general vision about super-conformal symmetries in TGD Universe and field equations. This vision is discussed in detail in [?] and [?] and also in the second chapter of this book. This input represents the newest layer of TGD and I cannot guarantee a full consistency with other pieces of text about SUSY appearing in this chapter.

1. Equivalence Principle realized as Einstein's equations in all scales follows directly from the general ansatz for preferred extremals implying that space-time surface has either hermitian or Hamilton-Jacobi structure (which of them depends on the signature of the induced metric).
2. The general structure of Super Virasoro representations can be understood: super-symplectic algebra is responsible for the non-perturbative aspects of QCD and determines also the ground states of elementary particles determining their quantum numbers.
3. Super-Kac-Moody algebras associated with isometries and holonomies dictate standard model quantum numbers and lead to a massivation by p-adic thermodynamics: the crucial condition that the number of tensor factors in Super-Virasoro representation is 5 is satisfied.
4. One can understand how the Super-Kac-Moody currents assignable to stringy world sheets emerging naturally from the conservation of em charge defined as their string world sheet Hodge duals gauge potentials for standard model gauge group and also their analogs for gravitons. Also the conjecture Yangian algebra generated by Super-Kac-Moody charges emerges naturally.
5. One also finds that right handed neutrino is in a very special role because of its lacking couplings in electroweak sector and its role as a generator of the least broken SUSY. All other modes of induced spinor field are restricted to 2-D string world sheets and partonic 2-surfaces. Right-handed neutrino allows also the mode delocalized to entire space-time surface or perhaps only to the Euclidian regions defined by the 4-D line of the generalized Feynman diagrams.

In fact, in the following the possibility that the resulting sparticles cannot be distinguished from particles since the presence of right handed neutrino is not seen in the interactions and does not manifest itself in different spin structures for the couplings of particle and sparticle. This could explain the failure to detect spartners at LHC. Intermediate gauge boson decay widths however require that sparticles are dark in the sense of having non-standard value of Planck constant. Another variant of the argument assumes that 4-D right handed neutrinos are associated with space-time regions of Minkowskian signature and SUSY is defined for many-particle states rather than single particle states. It should be emphasized that TGD predicts that all fermions act as generators of badly broken supersymmetries at partonic 2-surfaces but these super-symmetries could correspond to much higher mass scale as that associated with the delocalized right-handed neutrino. The following piece of text summarizes the argument.

Right-handed neutrino has a very special role in TGD view about Super-Kac-Moody symmetry and its generalization to 4-D context.

1. Only right handed neutrino allows besides the modes restricted to 2-D surfaces also the 4D modes delocalized to the entire space-time surface. The first ones are holomorphic functions of single coordinate and the latter ones holomorphic functions of two complex/Hamilton-Jacobi coordinates. Only  $\nu_R$  has the full  $D = 4$  counterpart of the conformal symmetry and the localization to 2-surfaces has interpretation as super-conformal symmetry breaking halving the number of super-conformal generators.

2. This forces to ask for the meaning of super-partners. Are super-partners obtained by adding  $\nu_R$  neutrino localized at partonic 2-surface or delocalized to entire space-time surface or its Euclidian or Minkowskian region accompanying particle identified as wormhole throat? Only the Euclidian option allows to assign right handed neutrino to a unique partonic 2-surface. For the Minkowskian regions the assignment is to many particle state defined by the partonic 2-surfaces associated with the 3-surface. Hence for spartners the 4-D right-handed neutrino must be associated with the 4-D Euclidian line of the generalized Feynman diagram.
3. The orthogonality of the localized and de-localized right handed neutrino modes requires that 2-D modes correspond to higher color partial waves at the level of imbedding space. If color octet is in question, the 2-D right handed neutrino as the candidate for the generator of standard SUSY would combine with the left handed neutrino to form a massive neutrino. If 2-D massive neutrino acts as a generator of super-symmetries, it is in the same role as badly broken supersymmetries generated by other 2-D modes of the induced spinor field (SUSY with rather large value of  $\mathcal{N}$ ) and one can argue that the counterpart of standard SUSY cannot correspond to this kind of super-symmetries. The right-handed neutrinos delocalized inside the lines of generalized Feynman diagrams, could generate  $\mathcal{N} = 2$  variant of the standard SUSY.

### How particle and right handed neutrino are bound together?

Ordinary SUSY means that apart from kinematical spin factors sparticles and particles behave identically with respect to standard model interactions. These spin factors would allow to distinguish between particles and sparticles. But is this the case now?

1. One can argue that 2-D particle and 4-D right-handed neutrino behave like independent entities, and because  $\nu_R$  has no standard model couplings this entire structure behaves like a particle rather than sparticle with respect to standard model interactions: the kinematical spin dependent factors would be absent.
2. The question is also about the internal structure of the sparticle. How the four-momentum is divided between the  $\nu_R$  and 2-D fermion. If  $\nu_R$  carries a negligible portion of four-momentum, the four-momentum carried by the particle part of sparticle is same as that carried by particle for given four-momentum so that the distinctions are only kinematical for the ordinary view about sparticle and trivial for the view suggested by the 4-D character of  $\nu_R$ .

Could sparticle character become manifest in the ordinary scattering of sparticle?

1. If  $\nu_R$  behaves as an independent unit not bound to the particle, it would continue in the original direction as particle scatters: sparticle would decay to particle and right-handed neutrino. If  $\nu_R$  carries a non-negligible energy the scattering could be detected via a missing energy. If not, then the decay could be detected by the interactions revealing the presence of  $\nu_R$ .  $\nu_R$  can have only gravitational interactions. What these gravitational interactions are is not however quite clear since the proposed identification of gravitational gauge potentials is as duals of Kac-Moody currents analogous to gauge potentials located at the boundaries of string world sheets. Does this mean that 4-D right-handed neutrino has no quantal gravitational interactions? Does internal consistency require  $\nu_R$  to have a vanishing gravitational and inertial masses and does this mean that this particle carries only spin?
2. The cautious conclusion would be following: if delocalized  $\nu_R$  and parton are un-correlated particle and sparticle cannot be distinguished experimentally and one might perhaps understand the failure to detect standard SUSY at LHC. Note however that the 2-D fermionic oscillator algebra defines badly broken large  $\mathcal{N}$  SUSY containing also massive (longitudinal momentum square is non-vanishing) neutrino modes as generators.

### Taking a closer look on sparticles

It is good to take a closer look at the delocalized right handed neutrino modes.

1. At imbedding space level that is in cm mass degrees of freedom they correspond to covariantly constant  $CP_2$  spinors carrying light-like momentum which for causal diamond could be discretized. For non-vanishing momentum one can speak about helicity having opposite sign for  $\nu_R$  and  $\bar{\nu}_R$ . For vanishing four-momentum the situation is delicate since only spin remains and Majorana like behavior is suggestive. Unless one has momentum continuum, this mode might be important and generate additional SUSY resembling standard  $\mathcal{N} = 1$  SUSY.
2. At space-time level the solutions of modified Dirac equation are holomorphic or anti-holomorphic.
  - (a) For non-constant holomorphic modes these characteristics correlate naturally with fermion number and helicity of  $\nu_R$ . One can assign creation/annihilation operator to these two kinds of modes and the sign of fermion number correlates with the sign of helicity.
  - (b) The covariantly constant mode is naturally assignable to the covariantly constant neutrino spinor of imbedding space. To the two helicities one can assign also oscillator operators  $\{a_{\pm}, a_{\pm}^{\dagger}\}$ . The effective Majorana property is expressed in terms of non-orthogonality of  $\nu_R$  and  $\bar{\nu}_R$  translated to the non-vanishing of the anti-commutator  $\{a_{+}^{\dagger}, a_{-}\} = \{a_{-}^{\dagger}, a_{+}\} = 1$ . The reduction of the rank of the  $4 \times 4$  matrix defined by anti-commutators to two expresses the fact that the number of degrees of freedom has halved.  $a_{+}^{\dagger} = a_{-}$  realizes the conditions and implies that one has only  $\mathcal{N} = 1$  SUSY multiplet since the state containing both  $\nu_R$  and  $\bar{\nu}_R$  is same as that containing no right handed neutrinos.
  - (c) One can wonder whether this SUSY is masked totally by the fact that sparticles with all possible conformal weights  $n$  for induced spinor field are possible and the branching ratio to  $n = 0$  channel is small. If momentum continuum is present, the zero momentum mode might be equivalent to nothing.

What can happen in spin degrees of freedom in super-symmetric interaction vertices if one accepts this interpretation? As already noticed, this depends solely on what one assumes about the correlation of the four-momenta of particle and  $\nu_R$ . One can only imagine alternatives.

1. For SUSY generated by covariantly constant  $\nu_R$  and  $\bar{\nu}_R$  there is no neutrino four-momentum involved so that only spin matters. One cannot speak about the change of direction for  $\nu_R$ . In the scattering of sparticle the direction of particle changes and introduces different spin quantization axes.  $\nu_R$  retains its spin and in new system it is superposition of two spin projections. The presence of both helicities requires that the transformation  $\nu_R \rightarrow \bar{\nu}_R$  happens with an amplitude determined purely kinematically by spin rotation matrices. This is consistent with fermion number conservation modulo 2.  $\mathcal{N} = 1$  SUSY based on Majorana spinors is highly suggestive.
2. For SUSY generated by non-constant holomorphic and anti-holomorphic modes carrying fermion number the behavior in the scattering is different. Suppose that the sparticle does not split to particle moving in the new direction and  $\nu_R$  moving in the original direction so that also  $\nu_R$  or  $\bar{\nu}_R$  carrying some massless fraction of four-momentum changes its direction of motion. One can form the spin projections with respect to the new spin axis but must drop the projection which does not conserve fermion number. Therefore the kinematics at the vertices is different. Hence  $\mathcal{N} = 2$  SUSY with fermion number conservation is suggestive when the momentum directions of particle and  $\nu_R$  are completely correlated.
3. Since right-handed neutrino has no standard model couplings, p-adic thermodynamics for 4-D right-handed neutrino must correspond to a very low p-adic temperature  $T = 1/n$ . This implies that the excitations with non-vanishing conformal weights are effectively absent and one would have  $\mathcal{N} = 1$  SUSY effectively.

The simplest assumption is that particle and sparticle correspond to the same p-adic mass scale and have degenerate masses: it is difficult to imagine any good reason for why the p-adic mass scales should differ. This should have been observed -say in decay widths of weak bosons - unless the spartners correspond to large  $\hbar$  phase and therefore to dark matter. Note that for the badly broken 2-D  $\mathcal{N}=2$  SUSY in fermionic sector this kind of almost degeneracy cannot be excluded and I have considered an explanation for the mysterious X and Y mesons in terms of this degeneracy [K43].

### Why space-time SUSY is not possible in TGD framework?

LHC suggests that one does not have  $\mathcal{N} = 1$  SUSY in standard sense. Why one cannot have standard space-time SUSY in TGD framework. Let us begin by listing all arguments popping in mind.

1. Could covariantly constant  $\nu_R$  represents a gauge degree of freedom? This is plausible since the corresponding fermion current is non-vanishing.
2. The original argument for absence of space-time SUSY years ago was indirect:  $M^4 \times CP_2$  does not allow Majorana spinors so that  $\mathcal{N} = 1$  SUSY is excluded.
3. One can however consider  $\mathcal{N} = 2$  SUSY by including both helicities possible for covariantly constant  $\nu_R$ . For  $\nu_R$  the four-momentum vanishes so that one cannot distinguish the modes assigned to the creation operator and its conjugate via complex conjugation of the spinor. Rather, one oscillator operator and its conjugate correspond to the two different helicities of right-handed neutrino with respect to the direction determined by the momentum of the particle. The spinors can be chosen to be real in this basis. This indeed gives rise to an irreducible representation of spin 1/2 SUSY algebra with right-handed neutrino creation operator acting as a ladder operator. This is however  $\mathcal{N} = 1$  algebra and right-handed neutrino in this particular basis behaves effectively like Majorana spinor. One can argue that the system is mathematically inconsistent. By choosing the spin projection axis differently the spinor basis becomes complex. In the new basis one would have  $\mathcal{N} = 2$ , which however reduces to  $\mathcal{N} = 1$  in the real basis.
4. Or could it be that fermion and sfermion do exist but cannot be related by SUSY? In standard SUSY fermions and sfermions forming irreducible representations of super Poincare algebra are combined to components of superfield very much like finite-dimensional representations of Lorentz group are combined to those of Poincare. In TGD framework  $\nu_R$  generates in space-time interior generalization of 2-D super-conformal symmetry but covariantly constant  $\nu_R$  cannot give rise to space-time SUSY.

This would be very natural since right-handed neutrinos do not have any electroweak interactions and are delocalized into the interior of the space-time surface unlike other particles localized at 2-surfaces. It is difficult to imagine how fermion and  $\nu_R$  could behave as a single coherent unit reflecting itself in the characteristic spin and momentum dependence of vertices implied by SUSY. Rather, it would seem that fermion and sfermion should behave identically with respect to electroweak interactions.

The third argument looks rather convincing and can be developed to a precise argument.

1. If sfermion is to represent elementary bosons, the products of fermionic oscillator operators with the oscillator operators assignable to the covariantly constant right handed neutrinos must define might-be bosonic oscillator operators as  $b_n = a_n a$  and  $b_n^\dagger = a_n^\dagger a^\dagger$ . One can calculate the commutator for the product of operators. If fermionic oscillator operators commute, so do the corresponding bosonic operators. The commutator  $[b_n, b_n^\dagger]$  is however proportional to occupation number for  $\nu_R$  in  $\mathcal{N} = 1$  SUSY representation and vanishes for the second state of the representation. Therefore  $\mathcal{N} = 1$  SUSY is a pure gauge symmetry.
2. One can however have both irreducible representations of SUSY: for them either fermion or sfermion has a non-vanishing norm. One would have both fermions and sfermions but they would not belong to the same SUSY multiplet, and one cannot expect SUSY symmetries of 3-particle vertices.
3. For instance,  $\gamma FF$  vertex is closely related to  $\gamma \tilde{F} \tilde{F}$  in standard SUSY. Now one expects this vertex to decompose to a product of  $\gamma F \tilde{F}$  vertex and amplitude for the creation of  $\nu_R \tilde{\nu}_R$  from vacuum so that the characteristic momentum and spin dependent factors distinguishing between the couplings of photon to scalar and fermion are absent. Both states behave like fermions. The amplitude for the creation of  $\nu_R \tilde{\nu}_R$  from vacuum is naturally equal to unity as an occupation number operator by crossing symmetry. The presence of right-handed neutrinos would be invisible if this picture is correct. Whether this invisible label can have some consequences is not quite clear: one could argue that the decay rates of weak bosons to fermion pairs are doubled unless one introduces  $1/\sqrt{2}$  factors to couplings.

Where the sfermions might make themselves visible are loops. What loops are? Consider boson line first. Boson line is replaced with a sum of two contributions corresponding to ordinary contribution with fermion and antifermion at opposite throats and second contribution with fermion and antifermion accompanied by right-handed neutrino  $\nu_R$  and its antiparticle which now has opposite helicity to  $\nu_R$ . The loop for  $\nu_R$  decomposes to four pieces since also the propagation from wormhole throat to the opposite wormhole throat must be taken into account. Each of the four propagators equals to  $a_{1/2}^\dagger a_{-1/2}^\dagger$  or its hermitian conjugate. The product of these is slashed between vacuum states and anti-commutations give imaginary unit per propagator giving  $i^4 = 1$ . The two contributions are therefore identical and the scaling  $g \rightarrow g/\sqrt{2}$  for coupling constants guarantees that sfermions do not affect the scattering amplitudes at all. The argument is identical for the internal fermion lines.

### 8.4.3 The impact from LHC and evolution of TGD itself

The missing energy predicted standard SUSY is absent at LHC. The easy explanation would be that the mass scale of SUSY is unexpectedly high, of order 1 TeV. This would however destroy the original motivations for SUSY. The arguments developed in the following manner.

1. In TGD framework the natural first guess was that the missing energy corresponds to covariantly constant right-handed neutrinos carrying four-momentum. The objection is that covariantly constant right-handed neutrinos cannot appear in asymptotic states because one cannot assign a super-multiplet to right-handed neutrinos consistently. Covariantly constant right-handed neutrinos could however generate SUSY in some sense.
2. This alone would not explain the missing missing momentum at LHC predicted by standard SUSY. The assumption that fermions correspond to color partial waves in  $H$  implies that color excitations of the right handed neutrino that would appear in asymptotic states are necessarily colored. It could happen that these excitations are color neutralized by super-conformal generators. If this is not the case, these neutrinos would be like quarks and color confinement would explain why they cannot be observed as asymptotic states in macroscopic scales.

Second possibility considered earlier is that SUSY itself is generated by color partial waves of right-handed neutrino, octet most naturally. This option is not however consistent with the above model for one-fermion states and their super-partners.

3. The breakthrough in the understanding of the preferred extremals of Kähler action and solutions of the modified Dirac equation led to a radical reconsideration of the existing picture. The most natural conclusion is that the TGD counterpart of standard SUSY is most naturally absent. The arguments in favor of this conclusion discussed in the last section are rather strong. The breakthrough in understanding of TGD counterpart for Higgs like particle - Euclidian  $M_{89}$  pion - led to a model for the generation of weak gauge bosons masses free of the problem of the standard Higgs mechanism caused by the fact that tachyonic mass term is not stable under radiative corrections. In TGD framework this kind of term is absent. Therefore also the basic motivation for standard SUSY as stabilizer of radiative corrections disappears.

Standard space-time SUSY would be replaced with 4-D generalization of 2-D super-conformal invariance but restricted to the modes of right-handed neutrino. For other fermion states the modes would be restricted to 2-D string world sheets and partonic 2-surfaces and super-conformal symmetry would reduce to 2-D one. The 2-D super-conformal symmetry is mathematically analogous to badly broken SUSY with very large value of  $\mathcal{N}$  and massive neutrino would represent the least broken aspect of this symmetry. The masses of sparticles are expected to be higher than particles for this SUSY and there is no reason to require that they should correspond to the TeV scale required by the radiative stability of the standard model Higgs.

### 8.4.4 Conclusions

The conclusion that the standard SUSY is absent looks very attractive in light of various arguments discussed in this chapter and also conforms with the LHC data. During the attempts to understand SUSY several ideas emerged and the original discussions are retained as such in this chapter. It is interesting to see that their fate is if standard SUSY has no TGD counterpart.

1. One of the craziest ideas was that spartners indeed exists and even with the same p-adic mass scale but might be realized as dark matter. Same mass is indeed natural prediction since right-handed neutrino carries no momentum and has no electroweak interactions with fermions. Therefore even the mesons of ordinary hadron physics would be accompanied by smesons - pairs of squark and antisquark. In fact, this is what the most recent form of the theory predicts: unfortunately there is no manner to experimentally distinguish between fermion and pseudo-fermion if  $\nu_R$  is zero momentum state lacking even gravitational interactions.
2. There are indications that charmonium as exotic states christened as X and Y mesons and the question was that they could correspond to mesons built either from colored excitations of charged quark and antiquark or from squark and antisquark. The recent view leaves only the option based on colored excitations alive. The states in question would be analogous to pairs of color excitations of leptons introduced to explain various anomalies in leptonic sector [?]. The question was whether leptohadrons could correspond to bound states of colored sleptons and have same p-adic mass scale as leptons have [?]. The original form of leptohadron hypothesis remains intact.
3. Evidence that pion and also other hadrons have what could be called infrared Regge trajectories has been reported, and one could ask whether these trajectories could include spion identified as a bound state of squarks. Also this identification is excluded and the proposed identification in terms of stringy states assignable to long color magnetic flux tubes accompanying hadron remains under consideration. IR Regge trajectories would serve as a signature for the non-perturbative aspects of hadron physics.

## Chapter 9

# New Physics Predicted by TGD: Part I

### 9.1 Introduction

TGD predicts a lot of new physics and it is quite possible that this new physics becomes visible at LHC. Although calculational formalism is still lacking, p-adic length scale hypothesis allows to make precise quantitative predictions for particle masses by using simple scaling arguments. Actually there is already now evidence for effects providing further support for TGD based view about QCD and first rumors about super-symmetric particles have appeared.

Before detailed discussion it is good to summarize what elements of quantum TGD are responsible for new physics.

1. The new view about particles relies on their identification as partonic 2-surfaces (plus 4-D tangent space data to be precise). This effective metric 2-dimensionality implies generalization of the notion of Feynman diagram and holography in strong sense. One implication is the notion of field identity or field body making sense also for elementary particles and the Lamb shift anomaly of muonic hydrogen could be explained in terms of field bodies of quarks.
2. The topological explanation for family replication phenomenon implies genus generation correspondence and predicts in principle infinite number of fermion families. One can however develop a rather general argument based on the notion of conformal symmetry known as hyper-ellipticity stating that only the genera  $g = 0, 1, 2$  are light [?] What "light" means is however an open question. If light means something below  $CP_2$  mass there is no hope of observing new fermion families at LHC. If it means weak mass scale situation changes.

For bosons the implications of family replication phenomenon can be understood from the fact that they can be regarded as pairs of fermion and antifermion assignable to the opposite wormhole throats of wormhole throat. This means that bosons formally belong to octet and singlet representations of dynamical SU(3) for which 3 fermion families define 3-D representation. Singlet would correspond to ordinary gauge bosons. Also interacting fermions suffer topological condensation and correspond to wormhole contact. One can either assume that the resulting wormhole throat has the topology of sphere or that the genus is same for both throats.

3. The view about space-time supersymmetry differs from the standard view in many respects. First of all, the super symmetries are not associated with Majorana spinors. Super generators correspond to the fermionic oscillator operators assignable to leptonic and quark-like induced spinors and there is in principle infinite number of them so that formally one would have  $\mathcal{N} = \infty$  SUSY. I have discussed the required modification of the formalism of SUSY theories in [?] and it turns out that effectively one obtains just  $\mathcal{N} = 1$  SUSY required by experimental constraints. The reason is that the fermion states with higher fermion number define only short range interactions analogous to van der Waals forces. Right handed neutrino generates this super-symmetry broken by the mixing of the  $M^4$  chiralities implied by the mixing of  $M^4$  and  $CP_2$  gamma matrices for induced gamma matrices. The simplest assumption is that particles

and their superpartners obey the same mass formula but that the p-adic length scale can be different for them.

4. The new view about particle massivation involves besides p-adic thermodynamics also Higgs but there is no need to assume that Higgs vacuum expectation plays any role. The most natural option favored by the assumption that elementary bosons are bound states of massless elementary fermions, by twistorial considerations, and by the fact that both gauge bosons and Higgs form SU(2) triplet and singlet, predicts that also photon and other massless gauge bosons develop small mass so that all Higgs particles and their colored variants would disappear from spectrum. Also Higgsinos could be eaten by gauginos so that only massive gauginos would be seen at LHC.
5. One of the basic distinctions between TGD and standard model is the new view about color.
  - (a) The first implication is separate conservation of quark and lepton quantum numbers implying the stability of proton against the decay via the channels predicted by GUTs. This does not mean that proton would be absolutely stable. p-Adic and dark length scale hierarchies indeed predict the existence of scale variants of quarks and leptons and proton could decay to hadrons of some zoomed up copy of hadrons physics. These decays should be slow and presumably they would involve phase transition changing the value of Planck constant characterizing proton. It might be that the simultaneous increase of Planck constant for all quarks occurs with very low rate.
  - (b) Also color excitations of leptons and quarks are in principle possible. Detailed calculations would be required to see whether their mass scale is given by  $CP_2$  mass scale. The so called leptohadron physics proposed to explain certain anomalies associated with both electron, muon, and  $\tau$  lepton could be understood in terms of color octet excitations of leptons [?]
6. Fractal hierarchies of weak and hadronic physics labelled by p-adic primes and by the levels of dark matter hierarchy are highly suggestive. Ordinary hadron physics corresponds to  $M_{107} = 2^{107} - 1$ . One especially interesting candidate would be scaled up hadronic physics which would correspond to  $M_{89} = 2^{89} - 1$  defining the p-adic prime of weak bosons. The corresponding string tension is about 512 GeV and it might be possible to see the first signatures of this physics at LHC. Nuclear string model in turn predicts that nuclei correspond to nuclear strings of nucleons connected by colored flux tubes having light quarks at their ends. The interpretation might be in terms of  $M_{127}$  hadron physics. In biologically most interesting length scale range 10 nm-2.5  $\mu\text{m}$  there are four Gaussian Mersennes and the conjecture is that these and other Gaussian Mersennes are associated with zoomed up variants of hadron physics relevant for living matter. Cosmic rays might also reveal copies of hadron physics corresponding to  $M_{61}$  and  $M_{31}$ .
7. Weak form of electric magnetic duality implies that the fermions and antifermions associated with both leptons and bosons are Kähler magnetic monopoles accompanied by monopoles of opposite magnetic charge and with opposite weak isospin. For quarks Kähler magnetic charge need not cancel and cancellation might occur only in hadronic length scale. The magnetic flux tubes behave like string like objects and if the string tension is determined by weak length scale, these string aspects should become visible at LHC. If the string tension is 512 GeV the situation becomes less promising.

In this chapter the predicted new elementary particle physics and possible indications for it are discussed. Second chapter is devoted to new hadron physics and scaled up variants of hadron physics in both quark and lepton sector.

## 9.2 Family replication phenomenon

### 9.2.1 Family replication phenomenon for bosons

TGD predicts that also gauge bosons, with gravitons included, should be characterized by family replication phenomenon but not quite in the expected manner. The first expectation was that these gauge bosons would have at least 3 light generations just like quarks and leptons.

Only within last years it has become clear that there is a deep difference between fermions and gauge bosons. Elementary fermions and particles super-conformally related to elementary fermions correspond to single throat of a wormhole contact assignable to a topologically condensed  $CP_2$  type vacuum extremal whereas gauge bosons would correspond to a wormhole throat pair assignable to wormhole contact connecting two space-time sheets. Wormhole throats correspond to light-like partonic 3-surfaces at which the signature of the induced metric changes.

In the case of 3 generations gauge bosons can be arranged to octet and singlet representations of a dynamical  $SU(3)$  and octet bosons for which wormhole throats have different genus could be massive and effectively absent from the spectrum.

Exotic gauge boson octet would induce particle reactions in which conserved handle number would be exchanged between incoming particles such that total handle number of boson would be difference of the handle numbers of positive and negative energy throat. These gauge bosons would induce flavor changing but genus conserving neutral current. There is no evidence for this kind of currents at low energies which suggests that octet mesons are heavy. Typical reaction would be  $\mu + e \rightarrow e + \mu$  scattering by exchange of  $\Delta g = 1$  exotic photon.

### 9.2.2 Higher gauge boson families

TGD predicts that also gauge bosons, with gravitons included, should be characterized by family replication phenomenon but not quite in the expected manner. The first expectation was that these gauge bosons would have at least 3 light generations just like quarks and leptons.

Only within last two years it has become clear that there is a deep difference between fermions and gauge bosons. Elementary fermions and particles super-conformally related to elementary fermions correspond to single throat of a wormhole contact assignable to a topologically condensed  $CP_2$  type vacuum extremal whereas gauge bosons would correspond to a wormhole throat pair assignable to wormhole contact connecting two space-time sheets. Wormhole throats correspond to light-like partonic 3-surfaces at which the signature of the induced metric changes.

In the case of 3 generations gauge bosons can be arranged to octet and singlet representations of a dynamical  $SU(3)$  and octet bosons for which wormhole throats have different genus could be massive and effectively absent from the spectrum.

Exotic gauge boson octet would induce particle reactions in which conserved handle number would be exchanged between incoming particles such that total handle number of boson would be difference of the handle numbers of positive and negative energy throat. These gauge bosons would induce flavor changing but genus conserving neutral current. There is no evidence for this kind of currents at low energies which suggests that octet mesons are heavy. Typical reaction would be  $\mu + e \rightarrow e + \mu$  scattering by exchange of  $\Delta g = 1$  exotic photon.

#### New view about interaction vertices and bosons

There are two options for the identification of particle vertices as topological vertices.

##### 1. Option a)

The original assumption was that one can assign also to bosons a partonic 2-surface  $X^2$  with more or less well defined genus  $g$ . The hypothesis is consistent with the view that particle reactions are described by smooth 4-surfaces with vertices being singular 3-surfaces intermediate between two three-topologies. The basic objection against this option is that it can induce too high rates for flavor changing currents. In particular  $g > 0$  gluons could induce these currents. Second counter argument is that stable  $n > 4$ -particle vertices are not possible.

##### 2. Option b)

According to the new vision (option 2)), particle decays correspond to branchings of the partonic 2-surfaces in the same sense as the vertices of the ordinary Feynman diagrams do correspond to branchings of lines. The basic mathematical justification for this vision is the enormous simplification caused by the fact that vertices correspond to non-singular 2-manifolds. This option allows also  $n > 3$ -vertices as stable vertices.

A consistency with the experimental facts is achieved if the observed gauge bosons have each value of  $g(X^2)$  with the same probability. Hence the general boson state would correspond to a phase

$\exp(in2\pi g/3)$ ,  $n = 0, 1, 2$ , in the discrete space of 3 lowest topologies  $g = 0, 1, 2$ . The observed bosons would correspond to  $n = 0$  state and exotic higher states to  $n = 1, 2$ .

The nice feature of this option is that no flavor changing neutral electro-weak or color currents are predicted. This conforms with the fact that CKM mixing can be understood as electro-weak phenomenon described most naturally by causal determinants  $X_l^3$  (appearing as lines of generalized Feynman diagram) connecting fermionic 2-surfaces of different genus.

Consider now objections against this scenario.

1. Since the modular contribution does not depend on the gradient of the elementary particle vacuum functional but only on its logarithm, all three boson states should have mass squared which is the average of the mass squared values  $M^2(g)$  associated with three generations. The fact that modular contribution to the mass squared is due to the super-symplectic thermodynamics allows to circumvent this objection. If the super-symplectic p-adic temperature is small, say  $T_p = 1/2$ , then the modular contribution to the mass squared is completely negligible also for  $g > 0$  and photon, graviton, and gluons could remain massless. The wiggling of the elementary particle vacuum functionals at the boundaries of the moduli spaces  $\mathcal{M}_g$  corresponding to 2-surfaces intermediate between different 2-topologies (say pinched torus and self-touching sphere) caused by the change of overall phase might relate to the higher p-adic temperature  $T_p$  for exotic bosons.
2. If photon states had a 3-fold degeneracy, the energy density of black body radiation would be three times higher than it is. This problem is avoided if the the super-symplectic temperature for  $n = 1, 2$  states is higher than for  $n = 0$  states, and same as for fermions, say  $T_p = 1$ . In this case two mass degenerate bosons would be predicted with mass squared being the average over the three genera. In this kind of situation the factor  $1/3$  could make the real mass squared very large, or order  $CP_2$  mass squared, unless the sum of the modular contributions to the mass squared values  $M_{mod}^2(g) \propto n(g)$  is divisible by 3. This would make also photon, graviton, and gluons massive. Fortunately,  $n(g)$  is divisible by 3 as is clear from  $n(0) = 0$ ,  $n(1) = 9$ ,  $n(2) = 60$ .

### Masses of genus-octet bosons

For option 1) ordinary bosons are accompanied by  $g > 0$  massive partners. For option 2) both ordinary gauge bosons and their exotic partners have suffered maximal topological mixing in the case that they are singlets with respect to the dynamical  $SU(3)$ . There are good reasons to expect that Higgs mechanism for ordinary gauge bosons generalizes as such and that  $1/T_p > 1$  means that the contribution of p-adic thermodynamics to the mass is negligible. The scale of Higgs boson expectation would be given by p-adic length scale and mass degeneracy of octet is expected. A good guess is obtained by scaling the masses of electro-weak bosons by the factor  $2^{(k-89)/2}$ . Also the masses of genus-octet of gluons and photon should be non-vanishing and induced by a vacuum expectation of Higgs particle which is electro-weak singlet but genus-octet.

### Indications for genus-generation correspondence for gauge bosons

Tommaso Dorigo is a highly inspiring blogger since he writes from the point of view of experimental physicist without the burden of theoretical dogmas. I share with him also the symptoms of splitting of personality to fluctuation-enthusiast and die-hard skeptic. This makes life interesting but not easy. This time Tommaso told about the evidence for new neutral gauge boson states in  $p\bar{p}$  collisions. The title of the posting was "A New  $Z'$  Boson at 240 GeV? No, Wait, at 720!?" [?].

#### 1. The findings

The title tells that the tentative interpretation of these states are as excited states of  $Z^0$  boson and that the masses of the states are around 240 GeV and 720 GeV. The evidence for the new states comes from electron-positron pairs in relatively narrow energy interval produced by the decays of the might-be-there gauge boson. This kind of decay is an especially clean signature since strong interaction effects are not present and it appears at sharp energy.

240 GeV bump was reported by CDF last year [?] CDF last year in  $p\bar{p}$  collisions at  $\sqrt{s} = 1.96$  TeV. The probability that it is a fluctuation is .6 per cent. What is encouraging that also D0 found the same bump. If the particle in question is analogous to  $Z^0$ , it should decay also to muons. CDF checked this and found a negative result. This made Tommaso rather skeptic.

Also indications for 720 GeV resonance (720 GeV is just a nominal value, the mass could be somewhere between 700-800 GeV) was reported by D0 collaboration: the report is titled as "Search for high-mass narrow resonances in the di-electron channel at D0" [?] . There are just 2 events above 700 GeV but background is small: just three events above 600 GeV. It is easy to guess what skeptic would say.

Before continuing I want to make clear that I refuse to be blind believer or die-hard skeptic and that I am unable to say anything serious about the experimental side. I am just interested to see whether these events might be interpreted in TGD framework. TGD indeed predicts -or should I say strongly suggests- a lot of new physics above intermediate boson length scale.

2. *Are exotic  $Z^0$  bosons p-adically scaled up variants of ordinary  $Z^0$  boson?*

p-Adic length scale hypothesis allows the p-adic length scale characterized by prime  $p \simeq 2^k$  vary since  $k$  can have several integer values. The TGD counterpart of Gell-Mann-Okubo mass formula involves varying value of  $k$  for quark masses. Several anomalies reported by Tommaso during years could be resolved if  $k$  can have several values. Last anomaly was the discovery that  $\Omega_b$  baryon containing two strange quarks and bottom quark seems to appear with two masses differing by about 100 MeV. TGD explains the mass difference correctly by assuming that strange quark can have besides ordinary mass scale mass differing by factor of 2. The prediction is 105 MeV.

One can look whether p-adic length scale hypothesis could explain the masses of exotic  $Z^0$  candidates as multiples of half octaves of  $Z^0$  mass which is 91 GeV.  $k=3$  would give 257 GeV, not too far from 240 GeV.  $k=6$  would give 728 GeV consistent with the nominal value of the mass. Also other masses are predicted and this could serve as a test for the theory. This option does not however explain why muon pairs are not produced in the case of 240 GeV resonance.

3. *Support for topological explanation of family replication phenomenon?*

The improved explanation is based on TGD based view about family replication phenomenon [K16]

1. In TGD the explanation of family replication is in terms of genus of 2-dimensional partonic surface representing fermion. Fermions correspond to SU(3) triplet of a dynamical symmetry assignable to the three lowest genera (sphere, torus, sphere with two handles). Bosons as wormhole contacts have two wormhole throats carrying fermion numbers and correspond to SU(3) singlet and octet. Sooner or later the members of the octet - presumably heavier than singlet- should be observed (maybe this has been done now;-)).
2. The exchange of these particles predicts also charged flavor changing currents respecting conservation of corresponding "isospin" and "hypercharge." For instance, lepton quark scattering  $e + s \rightarrow \mu + d$  would be possible. The most dramatic signature of these states is production of muon-positron pairs (for instance) via decays.
3. Since the  $Z^0$  or photon like boson in question has vanishing "isospin" and "hypercharge", it must be orthogonal to the ordinary  $Z^0$  which couples identically to all families. There are two states of this kind and they correspond to superpositions of fermion pairs of different generations in TGD framework. The two bosons - very optimistically identified as 240 GeV and 720 GeV  $Z^0$ , must be orthogonal to the ordinary  $Z^0$ . This requires that the phase factors in superposition of pairs adjust themselves properly. Also mixing effects breaking color symmetry are possible and expected to occur since the SU(3) in question is not an exact symmetry. Hence the exotic  $Z^0$  bosons *could* couple preferentially to some fermion generation. This kind of mixing might be used to explain the absence of muon pair signal in the case of 240 GeV resonance.
4. The prediction for the masses is same as for the first option if the octet and singlet bosons have identical masses for same p-adic mass scale so that mass splitting between different representations would take place via the choice of the mass scale alone.

4. *Could scaled up copy of hadron physics involved?*

One can also ask whether these particles could come from the decays of hadrons of a scaled up copy of hadron physics strongly suggested by p-Adic length scale hypothesis.

1. Various hadron physics would correspond to Mersenne primes: standard hadron physics to  $M_{107}$  and new hadron physics to Mersenne prime  $M_{89} = 2^{89} - 1$ . The first guess for the mass scale of "light"  $M^{89}$  hadrons would be  $2^{(107-89)/2} = 512$  times that for ordinary hadrons. The electron pairs might result in a decay of scaled up variant of pseudoscalar mesons  $\pi$ ,  $\eta$ , or of  $\eta'$  or spin one  $\rho$  and  $\omega$  mesons with nearly the same mass. Only scaled up  $\rho$  and  $\omega$  mesons remains under consideration if one assumes spin 1.
2. The scaling of pion mass about 140 MeV gives 72 GeV. This is three times smaller than 240 GeV but this is extremely rough estimate. Actually it is the p-adic mass scale of quarks involved which matters rather than that of hadronic space-time sheet characterized by  $M_{89}$ . The naive scaling of the mass of  $\eta$  meson with mass 548 MeV would give about 281 GeV.  $\eta'$  would give 490 GeV.  $\rho$  meson with mass would give 396 GeV. The estimates are just order of magnitude estimates since the mass splitting between pseudoscalar and corresponding vector meson is sensitive to quark mass scale.
3. This option does not provide any explanation for the lack of muon pairs in decays of 240 GeV resonance.

To conclude, family replication phenomenon for gauge bosons is consistent with the claimed masses and also absence of muon pairs might be understood and it remains to be seen whether only statistical fluctuations are in question.

### A slight indication for the exotic octet of gauge bosons from forward-backward asymmetry in top pair production

CDF has reported two anomalies related to the production of top quark pairs. The production rate for the pairs is too high and the forward backward asymmetry is also anomalously high. Both these anomalies could be understood as support for the octet of gauge bosons associated predicted by TGD based explanation of family replication phenomenon [K16]. The exchange of both gauge bosons would induce both charged and neutral flavour changing electroweak and color currents.

#### 1. Two high production rate for top quark pairs

Both Jester and Lubos tell about top quark related anomaly in proton-antiproton collisions at Tevatron reported by CDF collaboration. The anomaly has been actually reported already last summer but has gone un-noticed. For more detailed data see this [?].

What has been found is that the production rate for jet pairs with jet mass around 170 GeV, which happens to correspond to top quark mass, the production cross section is about 3 times higher higher than QCD simulations predict. 3.44 sigma deviation is in question meaning that its probability is same as for the normalized random variable  $x/\sigma$  to be larger than 3.44 for Gaussian distribution  $\exp(-(x/\sigma)^2/2)/(2\pi\sigma^2)^{1/2}$ . Recall that 5 sigma is regarded as so improbable fluctuation that one speaks about discovery. If top pairs are produced by some new particle, this deviation should be seen also when second top decays leptonically meaning a large missing energy of neutrino. There is however a slight deficit rather than excess of these events.

One can consider three interpretations.

1. The effect is a statistical fluke. But why just at the top quark mass?
2. The hadronic signal is real but there is a downwards fluctuation reducing the number of leptonic events slightly from the expected one. In the leptonic sector the measurement resolution is poorer so that this interpretation looks reasonable. In this case the decay of some exotic boson to top quark pair could explain the signal. Below this option will be considered in more detail in TGD framework and the nice thing is that it can be connected to the anomalously high forward backward asymmetry in top quark pair production reported by CDF for few weeks ago [?].
3. Both effects are real and the signal is due to R-parity violating 3-particle decays of gluinos with mass near to top quark mass. This is the explanation proposed in the paper of Perez and collaborators.

2. *Too high forward backward asymmetry in the production rate for top quark pairs*

There is also a second anomaly involved with top pair production. Jester reports new data [?] about the strange top-pair forward-backward asymmetry in top pair production in p-pbar collisions already mentioned [?]. In Europhysics 2011 conference D0 collaboration reported the same result. CMS collaboration found however no evidence for the asymmetry in p-p collisions at LHC [?]. For top pairs with invariant mass above 450 GeV the asymmetry is claimed by CDF to be stunningly large 48+/-11 per cent. 3 times more often top quarks produced in qqbar annihilation prefer to move in the direction of quark. Note that this experiment would have reduced the situation from the level of ppbar collisions to the level of quark-antiquark collisions and the negative result suggests that valence quarks might play an essential role in the anomaly.

The TGD based explanation for the finding would relation on the flavor octet of gluons and the new view about Feynman diagrams.

1. The identification of family replication phenomenon in terms of genus of the wormhole throats (see this) predicts that family replication corresponds to a dynamical SU(3) symmetry (having nothing to do with color SU(3) or Gell-Mann's SU(3)) with gauge bosons belonging to the octet and singlet representations. Ordinary gauge bosons would correspond besides the familiar singlet representation also to exotic octet representation for which the exchanges induce neutral flavor changing currents in the case of gluons and neutral weak bosons and charge changing ones in the case of charged gauge bosons. The exchanges of the octet representation for gluons could explain both the anomalously high production rate of top quark pairs and the anomalously large forward backward asymmetry! Also electroweak octet could of course contribute.
2. This argument requires a more detailed explanation for what happens in the exchange of gauge boson changing the genus. Particles correspond to wormhole contacts. For topologically condensed fermions the genus of the second throat is that of sphere created when the fermionic  $CP_2$  vacuum extremal touches background space sheet. For bosons both wormhole throats are dynamical and the topologies of both throats matter. The exchange diagram corresponds to a situation in which  $g = g_i$  fermionic wormhole throat from past turns back in time spending some time as second throat of virtual boson wormhole contact and  $g = g_f$  from future turns back in time and defines the second throat of virtual boson wormhole contact. The turning corresponds to gauge boson exchange represented by a wormhole contact with  $g = g_i$  and  $g = g_f$  wormhole throats. Ordinary gauge bosons are quantum superpositions of  $(g, g)$  pairs transforming as SU(3) singlets and SU(3) charged octet bosons are of pairs  $(g_1, g_2)$  with  $g_1 \neq g_2$ . In the absence of topological mixing of fermions inducing CKM mixing the exchange is possible only between fermions of same generation. The mixing is however large and changes the situation.
3. One could say that top quark from the geometric future transforms at exchange line to space-like t-quark (genus  $g = 2$ ) and returns to future. The quark from the geometric past does the same and returns back to the past as antiquark of antiproton. In the exchange line this quark combines with t-quark to form a virtual color octet gluon.

This mechanism could also give additional contributions to the mechanism generating CP breaking since new box diagrams involving two exchanges of flavor octet weak boson contribute to the mixings of quark pairs in mesons. The exchanges giving rise to an intermediate state of two top quarks are expected to give the largest contribution to the mixing of the neutral quark pairs making up the meson. This involves exchange of a member W boson flavor octet boson analogous to the usual exchange of the flavor singlet boson. This might relate to the reported anomalous like sign muon asymmetry in BBbar decay [?] suggesting that the CP breaking in this system is roughly 50 times larger than predicted by CKM matrix. The new diagrams would only amplify the CP breaking associated with CKM matrix rather than bringing in any new source of CP breaking. This mechanism increases also the CP breaking in KKbar system known to be also anomalously high.

### 9.2.3 The physics of $M - \bar{M}$ systems forces the identification of vertices as branchings of partonic 2-surfaces

For option 2) gluons are superpositions of  $g = 0, 1, 2$  states with identical probabilities and vertices correspond to branchings of partonic 2-surfaces. Exotic gluons do not induce mixing of quark families

and genus changing transitions correspond to light like 3-surfaces connecting partonic 2-surfaces with different genera. CKM mixing is induced by this topological mixing. The basic testable predictions relate to the physics of  $M\bar{M}$  systems and are due to the contribution of exotic gluons and large direct CP breaking effects in  $K - \bar{K}$  favor this option.

For option 1) vertices correspond to fusions rather than branchings of the partonic 2-surfaces. The prediction that quarks can exchange handle number by exchanging  $g > 0$  gluons (to be denoted by  $G_g$  in the sequel) could be in conflict with the experimental facts.

### 1. CP breaking in $K - \bar{K}$ as a basic test

CP breaking physics in kaon-antikaon and other neutral pseudoscalar meson systems is very sensitive to the new physics. What makes the situation especially interesting, is the recently reported high precision value for the parameter  $\epsilon'/\epsilon$  describing direct CP breaking in kaon-antikaon system [?]. The value is almost by an order of magnitude larger than the standard model expectation.  $K - \bar{K}$  mass difference predicted by perturbative standard model is 30 per cent smaller than the the experimental value and one cannot exclude the possibility that new physics instead of/besides non-perturbative QCD might be involved.

In standard model the low energy effective action is determined by box and penguin diagrams.  $\Delta S = 2$  piece of the effective weak Lagrangian, which describes processes like  $s\bar{d} \rightarrow d\bar{s}$ , determines the value of the  $K - \bar{K}$  mass difference  $\Delta m_K$  and since this piece determines  $K \rightarrow \bar{K}$  amplitude it also contributes to the parameter  $\epsilon$  characterizing indirect CP breaking.  $\Delta S = 2$  part of the weak effective action corresponds to box diagrams involving two  $W$  boson exchanges.

### 2. $\Delta m_K$ kills option a

For option 1) box diagrams involving  $Z$  and  $g > 0$  exchanges are allowed provided exchanges correspond to exchange of both  $Z$  and  $g > 0$  gluon. The most obvious objection is that the exchanges of  $g > 0$  gluons make strong  $\Delta S > 0$  decays of mesons possible:  $K_S \rightarrow \pi\pi$  is a good example of this kind of decay. The enhancement of the decay rate would be of order  $(\alpha_s(g=1)/\alpha_{em})^2(m_W/m_G(g=1))^2 \sim 10^3$ . Also other  $\Delta S = 1$  decay rates would be enhanced by this factor. The real killer prediction is a gigantic value of  $\Delta m_K$  for kaon-antikaon system resulting from the possibility of  $\bar{s}d \rightarrow \bar{d}s$  decay by single  $g = 1$  gluon exchange. This prediction alone excludes option 1).

### 3. Option 2) could explain direct CP breaking

For option 2) box diagrams are not affected in the lowest order by exotic gluons. The standard model contributions to  $\Delta m_K$  and indirect CP breaking are correct for the observed value of the top quark mass which results if top corresponds to a secondary p-adic length scale  $L(2, k)$  associated with  $k = 47$  (Appendix). Higher order gluonic contribution could increase the value of  $\Delta m_K$  predicted to be about 30 per cent too small by the standard model.

In standard model penguin diagrams contribute to  $\Delta S = 1$  piece of the weak Lagrangian, which determines the direct CP breaking characterized by the parameter  $\epsilon'/\epsilon$ . Penguin diagrams, which describe processes like  $s\bar{d} \rightarrow d\bar{d}$ , are characterized by effective vertices  $dsB$ , where  $B$  denotes photon, gluon or  $Z$  boson.  $dsB$  vertices give the dominant contribution to direct CP breaking in standard model. The new penguin diagrams are obtained from ordinary penguin diagrams by replacing ordinary gluons with exotic gluons.

For option 2) the contributions predicted by the standard model are multiplied by a factor 3 in the approximation that exotic gluon mass is negligible in the mass scale of intermediate gauge boson. These diagrams affect the value of the parameter  $\epsilon'/\epsilon$  characterizing direct CP breaking in  $K - \bar{K}$  system found experimentally to be almost order of magnitude larger than standard model expectation [?].

## 9.3 Dark matter in TGD Universe

TGD based explanation of dark matter means one of the strongest departures of TGD from the more standard approaches. In standard approaches dark matter corresponds to some very weakly interaction exotic particles contributing to the mass density of the Universe a fraction considerably larger than the contributions of "visible" matter. In TGD Universe dark matter corresponds to phases with non-standard value of Planck constant and also ordinary particles could be in dark phase.

### 9.3.1 Dark matter and energy in TGD Universe
