

# Theory of Everything by illusion

Kimmo Rouvari \*

April 13, 2013

## Abstract

The Theory of Everything is The Holy Grail of Science. Scientists all over the world are searching for it. Today only three out of four known forces are somewhat unified. Gravitation is a freak without adequate explanation. This theory shows that there is adequate theory for gravitation. As a bonus, this theory presents The Theory of Everything. This paper is only overview of the new theory of everything. Most important information is included. The theory itself is very simple and testable.

# Theory of Everything by illusion

Theory of Everything by illusion (**ToEbi**) demonstrates that gravitation, strong interaction and electromagnetic interactions are generated from the same phenomenon and they are distributed by tiny force transfer ether particles (**FTEPs**). ToEbi gives equations for force calculations which apply in scale from atomic to astronomical. Theory of Everything by illusion is based on two hypothesis:

- Big Bang created very tiny spiked sphere-like objects (physical particles) which vary in sizes.
- Gravitation, strong interactions and electromagnetic interactions between particles or system of particles are purely mechanical (particle collisions and/or particle rotation).

Early Universe formatted particles as we know today. Only tiniest force transfer ether particles (FTEPs) are not detected. These tiniest particles create force transfer ether (**FTE**) into the universe. All particles rotate (due to Big Bang) and therefore generate movement into FTE.

Both stated hypothesis together implies that there must be **rotational component** in force delivery. In ToEbi, rotational component is stated as **G** (capital g). There is a link to the current gravitation constant  $G$ . The rotational component applies directly only to sphere shaped or nearly sphere shaped (like Earth, nuclei and so on) objects which are roughly homogeneously layered inside. Roughly homogeneously layered object's rotation axis position is stable or nearly stable.

Rotating sphere creates maximal movement into FTE. Reason for this is obvious, speed on surface of rotating sphere depends on radius. On equator, surface speed is at greatest while on poles it's minimal. Speed difference generates movement into FTE. Rotation is the key concept in order to generate movement within FTE but it's not necessary to experience FTE. Moving object experiences surrounding FTE and reacts with it.

## Force transfer ether particles

The first hypothesis stated that Big Bang created a very tiny spiked objects (physical particles) which vary in sizes. Current physics can detect many of these particles, like electrons and quarks. Exact shape is not known and that's why we need the first hypothesis. Every particle has tiny spikes. One may think that these spikes are actually the raw material from Big Bang. Because high pressure spikes got entangled with each other and thus created various spiked particles.

At first the smallest particles (FTEPs) survived the pressure. After a while, other particles emerged, like "gluons", quarks and so on.

From the first hypothesis we can explain for example phenomenon like faster than light breakdown of interference pattern in the double slit experiment. Moving photon generates waves propagated through FTE. Because of the spikes, FTEPs are connected to each other. This pure physical connection causes interference pattern to disappear instantly in case of blocking or in some other way observing slits in the experiment.

There is also a phenomenon named as particle entanglement. Entanglement is a direct consequence of physical shape of particles involved (like photons and FTEPs).

## Energy

What particle attributes contribute to particle's energy at rest (in our reference frame)? Current answer comes from Einstein, rest mass and speed of light. Mass is totally understandable but the speed of light sounds a bit strange. From ToEbi hypothesis only reasonable definition for a particle's energy is

**First Law of ToEbi**

$$\vec{E} = J \frac{s}{kg} m \vec{n}$$

where  $m$  is a rest mass and  $n$  is a rotation frequency ( $1/s$ ) of particle.

Based on First law of ToEbi we can make relation between particle's energy and its kinetic energy

$$mn = \frac{1}{2}mv^2$$

so in our reference frame a particle's velocity changes distribute to particle's rotation frequency.

**ToEbi energy relation**

$$\Delta n = \frac{1}{2}\Delta v^2$$

Derived relation is actually quite obvious. What other options a particle has in order to store or release kinetic energy? More on this mechanism in the source of inertia chapter.

## Force

Rotating particle causes a movement of FTEPs around it. In case of two rotating particles there is an interaction between them through FTE. Number of interacting FTEPs depends on the distance between particles. Particle's relative amount of FTEPs in an interacting cross-section diminishes in relation of  $1/\pi r^2$  where  $r$  is the distance between particles.

Because every FTEP ("in the line of fire") between the two particles is involved we can integrate the relative amount of interacting FTEPs per particle. We can also discard the number  $\pi$  because we don't know the exact amount of FTEPs. We can define interactive energy in relation to a distance between particles as

**Interactive energy**

$$\vec{E}_{interactive} = \frac{\vec{E}}{r}$$

where  $E$  is a particle's energy and  $r$  is a distance to another particle.

In case of two particles, combined interactive energy is

$$\vec{E}\vec{E} = \vec{n}^2 \frac{m^2}{r^2}$$

Hence experienced combined interactive energy per particle is

$$\vec{E}_{combined} = \frac{1}{2} \vec{n}^2 \frac{m^2}{r^2}.$$

Because this is the only reasonable way to describe a particle interaction intensity towards another particle, we should define

**Force**

$$F = N \left( \frac{ms}{kg} \right)^2 \frac{1}{2} n^2 \frac{m^2}{r^2} \cos \alpha$$

where  $\alpha$  is the angle between particles rotation axes.

## Gravitation

Physical mechanism behind the gravitation is created by FTPE collisions. Two objects always create bigger ether density between themselves. But in case, where objects have the same rotating direction, FTPE collisions generate pulling force. Objects get a better mechanical grip from denser, slowing down, FTE between themselves and mechanically move towards each other.

Rotational component of force  $G$  can be defined as

**Second Law of ToEbi**

$$G = N \left( \frac{ms}{kg} \right)^2 \frac{1}{2} n^2 \cos \alpha$$

where  $n$  is a rotation frequency (1/s) of object. Acceleration generated from a mass and rotation is

$$\vec{a} = G \frac{M}{r^2}$$

where  $M$  is a mass and  $r$  is a distance from object's mass point. Acceleration vector points to the mass point of object. In case of two rotating, horizontally stationary (no prior orbiting in relation to each other), objects 1 and 2, where object 1 generates bigger acceleration, combined acceleration experienced by object 2 can be calculated with

**Third Law of ToEbi**

$$\vec{a}_{2 \rightarrow 1} = (\vec{a}_1 - \vec{a}_2) \cos(\alpha) + \vec{e}_3 n_1^2 n_2^2 \frac{M_1 M_2}{4r^4} \sin(\alpha)$$

where  $\alpha$  is an angle between rotation axes of objects and  $\vec{e}_3$  is unit vector perpendicular to the plane containing  $\vec{e}_1$  and  $\vec{e}_2$  (rotation unit vectors of objects) in the direction given by the right-hand rule. The acceleration into direction of unit vector  $\vec{e}_3$  can be considered rotation frequency altering acceleration of object (**RFAA**). RFAA effects mainly the area closest between objects. That's because distance weakens acceleration with factor  $\frac{1}{r^4}$ . RFAA has a very important implications for example in energy conversation and in stellar orbiting.

If objects have different spin directions (90 degrees < angle between rotation vectors < 180 degrees) then combined acceleration pushes objects away from each other. Force generated by two rotating objects, experienced by object 2 is

$$\vec{F}_2 = M_2 \vec{a}_{2 \rightarrow 1}$$

Naturally object 1 experiences the exact same force but into a opposite direction.

Rotational component of force is easily observed with modified Cavendish experiment [1]. Larger ball is put near smaller ball, then by rotating larger ball there will be measurable gravitational effect. Experiment on larger mass, like on Earth, effects greatly experiment's results. But still the effect is measurable. The Forth Law of ToEbi will handle the suppressing effect caused by Earth.

Measured gravitation constant is a little less than calculated G on Earth. Difference is due to other masses outside Earth (like Moon, Sun and our galaxy center). Also possible slower rotation frequency of Earth's core is a factor. With high precision measurements there is detected small differences in gravitation constant.

Object's orbital speed effects generated pulling force. This is due to increased ether interactions between objects. In general case where object moves to any direction in relation to other object (like a comet in relation to Earth), movement should be divided into horizontal and vertical component. Horizontal component generates additional pulling force between objects.

Based on Third Law of ToEbi it's possible to calculate for example decreasing rate of rotation frequency of Venus. See calculation examples section.

## Strong interaction

Strong interaction can be calculated with the laws of ToEbi. In case of Helium-(3,4) we can ignore angle, because protons and neutrons are in position where rotation axes are parallel. Based on First Law of ToEbi proton's rotation frequency ( $8.98755e16$  1/s on Earth) and distance in nucleus ( $2.4e-15$  m, particles center-to-center distance), we can calculate force between two protons with calculated G and Newton's gravitation force equation. Strong interaction force (in case of two protons) is roughly  $3.9e9$  N, which is sum of both particle's generated force towards each other.

At the same time there is repulsion between rotating particles. Repulsion prevents particles in nucleus to collide. Repulsion emerges from colliding FTETPs between two nuclei. At ground state force of repulsion is equal to pulling force. Strong interaction force inside Helium-4 nucleus can be calculated by adding up all individual forces between every particle pairs, for Helium-4 strong interaction force is roughly  $23.4e9$  N.

Larger atoms nucleus can be created from simpler nucleus (Hydrogen and Helium isotopes). Some isotopes are stable by themselves but some are just unstable when they are out of larger nucleus (due to radioactive decay or collision). Size and physical particle positions in a nucleus (rotation axes parallel) explains why Universe contains mostly Hydrogen and Helium.

Strongest binding energy by nuclei count has Fe-56. It can be build from 12 He-4 atoms and one He-8 atom. He-4 atoms are in three layers, four He-4 atoms per layer. He-8 is in the middle of the stack. Each layer is positioned so that proton in layer below is next to neutron in layer above. Also proton in He-4 is next to neutron in another He-4 at the same layer. Per nuclei releasable force is roughly  $9.26e9$  N.

# Electromagnetism

Electromagnetic force can be calculated with ToEbi laws. In non-excited state an electron has the same spin direction when compared to nucleus's spin. Opposite spin direction (positron) means pushing force between electron and nucleus (III Law). It is possible to change electron's orbiting direction but the change will cause bigger repulsion force between electron and nucleus. Bigger repulsion force means larger orbit for electron. Also after awhile, electron orbiting velocity decreases and it changes the orbiting direction back to the normal.

High FTEP flux from a nucleus prevents electrons (in normal conditions) to collide with nucleus. Because electrons move along with nucleus generated FTEP flux there won't be a synchrotron like radiation phenomenon.

One interesting phenomenon is a proton-electron parity. Normally in an atom there is a same amount of electrons and protons. Obviously proton's ability to pull electron is optimal in one-to-one situation. More than one electron per proton is weaker construction because amount of FTEPs around one proton is limited. Every extra electron per proton experiences smaller pulling force. Weaker pulling force is very important in case of electric current. In electric current extra electrons move on atom's surface. Electrons from electric current cause valence electron's orbit to bend a bit sideways (amount is related to current strength).

Described bending is the key element in order to create pulling or pushing force with electric current. See the calculation examples section.

Changes between different electron orbits (towards nucleus) in atom causes photon emission. The reason for a photon emission is purely physical. When electron returns to it's ground state, it will cause shock wave of FTEPs toward nucleus. Shock wave of FTEPs towards nucleus compresses FTEPs together and creates a photon particle.

Light's wavelength is actually presentation from photon's rotation frequency. Frequency depends on how near created a photon can get to a nucleus during the compression process and that depends on electrons released potential energy.

Photon emission happens also when heavier particles collide nucleus. With large enough energy, heavier particles can be created from photons. This phenomenon is actually created with high energy lasers. In case of Hydrogen, there is one proton and one electron. Pulling force between particles is roughly (based on ToEbi laws)  $2.2e-3$  N at Bohr radius.

## Magnetism

Orbiting electron creates FTEP waves around an atom. In case when material crystal is magnetized, its electrons are orbiting at parallel position and therefore FTEP waves experience interference. Movement of FTEP near magnetized material can be demonstrated with iron powder.

The reason why for example iron, cobalt and nickel are ferromagnetic is the shape of their nucleus. In all those cases nucleus is a box like. With smoother shaped nucleus, electrons can orbit more freely around nucleus. Box like shape keeps electron orbits more easily parallel. Magnetization orders

these ferromagnetic atoms electrons into an uniform direction inside a crystal. Direction of orbiting electrons rules magnetic pole. Based on Third Law of ToEbi same spin (in this case valence electron orbiting) directions causes pulling force and different spin directions pushing force.

Direct consequence from this interpretation of magnetism is that there can't be so called magnetic monopoles.

Krypton nucleus is also a box like. In normal conditions Krypton is present in a gas form. When Krypton is brought to magnetic field there won't be pulling force, so Krypton is diamagnetic. The reason why Krypton is not generating pulling force towards magnet is because of the freedom of Krypton atom. Instead of pulling, Krypton starts to rotate in magnetic field (used in MRI). Solid form of Krypton (in crystals) can be magnetized.

## FTE

Repulsive capability of FTE is only significant in an atomic scale. Because neutron's (compared to proton) different structure there won't be big enough ether repulsion force between two neutrons. Because of that two neutrons can't create nucleus by themselves (at least on Earth).

Denser FTE means bigger repulsion between objects. Even our own planet experiences this for example in case of Sun's effects on radioactive decay rate on Earth. While orbiting Sun, Earth experiences different densities of FTE around Sun (distance varies). In case when Earth is at nearest to Sun, combined FTE between Earth and Sun is most dense. This puts atom nucleus under increased destructive force induced by electrons. Increased destructive force happens because denser FTE keeps weak spots of nucleus in longer distance than normally. Orbiting electrons get lever from this new nuclei distances which increases odds for a radioactive decay.

Also solar flares create FTE shock waves and denser FTE on Earth. Incoming FTE shock wave can be measured and protective measures can be made against following electromagnetic radiation.

Radioactive decay rate can be accelerated artificially by rotating radioactive material [2]. The reason for this phenomenon is acceleration generated by rotation. Rotating material generates acceleration and particles of rotating material experience force (III Law of ToEbi). Weak spots of a nucleus increase their nuclei distance which gives electrons more destructive lever.

## Force calculations

Rotating object generates acceleration. When rotating object is located on larger mass compared to object itself, the acceleration is experienced mainly by the object itself. In case we want to calculate force between two relatively small spherical objects on Earth we have to consider Earth ether's absorbing effect.

Acceleration between rotating object A and stationary object B on same level on large rotating mass C can be calculated by using multiplier of

## Forth Law of ToEbi

$$T_{A,C} = s^{-2}kg \frac{x_{A,C}^2}{n_C^2 M_C r_{A,B}^2}$$

where  $x_{A,C}$  is object's A mass point distance from the surface of object C in meters and  $n_C$  is rotation frequency and  $M_C$  is mass of object C. Variable  $r_{A,B}$  is distance between mass points of objects A and B in meters. In future version, objects on different levels are covered.

On surface of Earth ( 1 m above) Forth Law of ToEbi is valid down to 3.5e-8 m. Below that atom's own ether density movement overrules Earth's ether movement. Given value 3.5e-8 m is derived from Forth Law of ToEbi when  $T_{A,C} = 1$  applies. 10 000 m above the surface of Earth, Forth Law of ToEbi is valid down to 3.5e-4 m. 1 cm above the surface of Earth, Forth Law of ToEbi is valid down to 3.5e-10 m. Modified Cavendish experiment is one easy way to verify ToEbi force equations.

## Planck constant

Modern physics states Planck constant  $h$  and it's relation on photon's energy and frequency

$$E = hn$$

where  $n$  is (rotation) frequency of photon. Direct consequence from The First Law of ToEbi is that Planck constant presents in reality mass of photon! Photon's energy is increased for example when photon enters denser FTE. In that case photon encounters more and more FTEPs in it's path. This induces higher rotation frequency for a photon. This phenomenon is known as (gravitational) blue shifting. Opposite case is when a photon exits denser FTE. Encounters with FTEPs decrease which decreases photon's rotation frequency. This phenomenon is known as (gravitational) red shifting.

## De Broglie relation

The First Law of ToEbi can be stated with mass of photon (= Planck constant)

$$E = hn = \frac{hc}{\lambda} \quad (1)$$

hence

$$\frac{E}{c} = \frac{h}{\lambda} \quad (2)$$

and momentum

$$p = mv = hc. \quad (3)$$

Based on equations (1) and (3)

$$E\lambda = p \quad (4)$$

hence

$$\frac{p}{n} = \frac{E}{c}. \quad (5)$$

By selecting  $n = 1$  and combining equations (2) and (5) we have the de Broglie relation

$$\lambda = \frac{h}{p}. \quad (6)$$

## Speed of light

Why the speed of light is a constant (in vacuum)? Gravitation effects only on wavelength of light and bends its path. The reason is actually quite obvious. During creation of a photon new particle experiences strong rotation frequency of proton. Proton induced FTE movement gives photon rotational movement opposite to protons rotational movement, in other words, different spin direction.

Based on Second Law of ToEbi this opposite rotation direction causes pushing force between proton and photon. Generated acceleration is massive and very quickly photon achieves velocity where its interactions between incoming FTETs causes it to change orientation of its rotation axis aligned with its trajectory. At that point proton and photon doesn't generate pushing force anymore and photon has reached its maximum constant velocity.

## Neutron

Neutron is made of proton, electron and electron anti-neutrino. The unique feature which differentiates neutron from proton is very close proximity between electron and proton. There is two ways for the neutron production.

- Electron is penetrated repulsive wall of rotating proton and created an electron neutrino and anti-neutrino in pair production (like in electron capture).
- Anti-neutrino (with suitable energy) approaches proton's core through increasingly denser FTE. Dense FTE causes anti-neutrino rotate faster and gain energy to the point of electron-positron pair production. Because of different rotation direction positron is pushed away from proton and electron is captured with slowed down anti-neutrino.

Inside proton three rotating quarks generate repulsive wall and the space inside the wall is big enough to contain electron and its anti-neutrino. Repulsive wall is made of continuous flux of FTETs from between the quarks. Electron and electron anti-neutrino inside this wall causes neutron's ability to connect with proton. These two particles inside repulsive wall decrease greatly neutrons externally observed attractive force (similar but stronger phenomenon than electron shielding). Reduced force enables proton-neutron nucleus because there won't be too powerful initial interaction between proton and neutron.

In case when proton approaches another proton they generate very strong pulling force (both rotating fast). Generated acceleration causes these protons just repulsive bounce and flyby each other. In high temperatures connection between two protons without neutrons can happen.

# Neutrino

Neutrino creation process is quite similar to photon creation process. In case of electron neutrino, the difference is how close to nucleus these particles are created at. Neutrinos are created at very close to repulsive wall hence experiencing greater FTEP flux from nucleus. This causes neutrino pair production like in case of neutron creation. Greater FTEP flux makes neutrinos much smaller and denser than photons. The reason why neutrinos are so hard to detect is the size of neutrino. Most of the time they just fly through the atoms.

Neutrino oscillation is similar to red or blue shifting of light. When neutrino enters more dense FTE it will experience more interactions with FTEPs and rotate faster. Faster rotation frequency generates bigger energy for the neutrino. When neutrino enters less dense FTE it will experience less interactions with FTEPs and rotate slower. Slower rotation frequency decreases the energy of neutrino.

# Spin

Quote from Wikipedia:

Spin is an intrinsic form of angular momentum carried by elementary particles, composite particles (hadrons), and atomic nuclei. Spin is a solely quantum-mechanical phenomenon; it does not have a counterpart in classical mechanics (despite the term spin being reminiscent of classical phenomena such as a planet spinning on its axis).

Actually it does have a counterpart in classical mechanics. Spin is indeed particle spinning on its axis! That is the core of ToEbi. With that interpretation theory of everything is possible.

# Nuclear spin

Nuclear spin is generally determined by calculating protons and neutrons. If both sums pair up it is said that nuclear spin is zero. If only one of them pairs up it is said that spin is half and if both sums are uneven it said that spin is one. There is natural explanation for the nuclear spin and it's very much classical. It also explains the calculus of nuclear spin. In trivial case of hydrogen spin is labeled as half, in case of deuterium it is one and in case of tritium it is half.

Protons and neutrons have different external rotation frequency which explains why spin calculation works separately for protons and neutrons in other words only proton can eliminate other protons spin totally. In tritium there is two neutrons in nucleus and they eliminates each others spin.

With third neutron created hydrogen isotope decays very quickly but based on measurements neutrons around proton are evenly distributed. In that setup neutrons won't eliminate each others spin due to distance and small external rotation frequency (compared to proton) that's why spin is 2.

Elimination of spin means that when two same kind of particles with same spin (different spin means antiparticle) are at very close proximity generated repulsion causes turbulence in FTE between those two particles. Turbulence prevents nucleus ability to resonate with external waves in FTE (like with waves of magnetic field). Turbulence generated between proton and neutron also effects resonating ability but not as totally as in case proton-proton.

Figure 1: Oxygen-17

Other often observed atom isotope in MRI is oxygen-17 (8 protons, 9 neutrons) and its spin is  $5/2$ . Why  $5/2$ ? There is three alpha-particles which have combined spin zero. Two proton-neutron pairs (total spin 2) and one standalone neutron (spin half). So total nuclear spin is  $2\frac{1}{2} = \frac{5}{2}$ .

## Electron spin

Electrons are no exceptions. When two electrons are close enough in dense enough FTE they will generate turbulence into the FTE. Usually this happen when two electrons orbit a nucleus. Close distance to nucleus provides dense enough FTE for two electrons to experience needed repulsion. Without adequate repulsion electrons would collide and propel each other away. Turbulence masks these electrons incapable of participating in covalent bonding or experience resonance with waves around. Electrons are said to have a half spin ( $-1/2, 1/2$ ).

Actually minus sign stands for an antiparticle (in this case positron). The origin of electron spin numbers is in Stern-Gerlach experiment. The real reason why silver atoms create the observed pattern is valence electron's rotation pole orientation in magnetic field. Used magnetic field causes valence electron to choose rotation pole orientation while orbiting around silver nucleus. Different rotation pole orientations causes electron to generate pulling force against either S or N magnetic pole as described by Third Law of ToEbi.

Based on ToEbi electrons tend to orbit nucleus in pairs. Three or more electrons can't orbit nucleus in group. This is due to repulsion induced lack of FTEPs from the first electron pair which prevents other electrons to join the electron group. On larger orbit there can be multiple electron pairs at the same time.

Above classical description of electron spin behavior explains why materials made of atoms which have only one valence electron are the best conductors.

## Synchrotron radiation

Electromagnetic radiation emitted from synchrotron is very misleading phenomenon. It might be the biggest reason why modern particle physics considers classical interpretation of atom structure impossible. Ultra-relativistic (charged) particle emits photons therefore orbiting classical billiard ball electrons must lose energy and crash into atom nucleus. What a shame.

In reality situation is very much different in an atom scale and in a synchrotron. FTE movement in atom is totally effected by nucleus (see Forth Law of ToEbi and examples). On the other hand FTE in synchrotron is effected by rotating (mass) Earth and to certain extend by magnetic field used in synchrotron. Orbiting electron inside atom won't experience incoming FTEPs from the direction of its movement. Electron is moving along with the ejected force transfer ether particles.

The reason for electromagnetic radiation from synchrotron is photon creation (compressed FTEPs) due to collision of ultra-relativistic spinning electron (or proton) and FTEPs provided by Earth. These two are not moving along!

## Source of inertia

Elementary matter particles have same rotation direction (spin). All particles are aligned on/in large mass, like on Earth. Particle's rotation axis is parallel to large object's surface and axis projection onto rotation axis of large mass. Alignment is caused by pulling force generated by particles rotation. None-aligned particles in relaxation will precess (Third Law of ToEbi) and eventually achieve alignment. Recent particle physics research has found this phenomenon also.

Free particle with opposite spin creates pushing force towards other particles. Only in special case when two different spin direction particles with same mass is brought together rotation axis poles head on, there will be pulling force experienced ending to particle annihilation. Same spin direction particles will generate pushing force when brought together axis poles head on. In other cases same spin direction particles generate pulling force but at certain distance repulsion prevents a contact. In nuclear fusion repulsive force is overcome. On larger scale, a single atom nucleus or many nucleus in matter crystal or in molecule, spin to the same direction in an aligned fashion.

So, what causes inertia? In a situation where an object is at rest its all particles are in described alignment with Earth. If we have a two objects, A and B. Object A hits object B (exert force) resulting object B particles alignment breaks away.

Emerged inertia is actually a work against pulling force between Earth and object B (gravity). Object A has its energy stored in higher rotation

frequency of its particles. During impact stored energy causes object B non-alignment in relation to Earth. Bigger the energy bigger the none-alignment.

In next phase pushing force between object A and B overcomes used force and object B starts to precess. Precession is caused by interaction between object B and Earth (Third Law of ToEbi applies). Result of precession is bigger rotation frequency of object B. Momentum and energy are conserved.

Some part of energy is released in form of photon emissions when electrons find their ground states after impact. Electrons also experience non-alignment and precession. Because close distances between atoms in matter crystals or molecules used force is experienced in every particle involved through FTE. Rotation axis directions in picture are irrelevant, same pushing force and precession is generated regardless of impact direction.

One interesting phenomenon because of higher rotation frequency is weight gain of mass. Higher rotation frequency of particles generate bigger pulling force against other masses in this case towards Earth.

Very similar idea on energy conservation and inertia is presented by physicist Vesselin Petkov [3].

## Superconductivity

In order to understand superconductivity we must understand what happens when (thermal) energy is very low in an atom or in a system of atoms. One part is the low kinetic energy of atoms which enables them to be at very close approximate and in ordered position to each other. This is achieved with laser cooling.

Other part is that as we know, based on , removing kinetic energy from a particle equals reducing it's rotation frequency. There is immediately two obvious consequences from reduced rotation frequency.

- Particle (or system of particles) interacts less with Earth's FTE. In other words it experiences less gravitational interaction.
- Orbiting electrons (in material capable of superconductivity) experience less pulling force and repulsion due to slow rotating nucleus (system of all nuclei). This is the key to superconductivity. Outer electrons already in the system are very easily put into motion (into direction of current) by externally put electrons. After that initial push externally put electrons won't experience resistance.

Meissner Effect is easily explained with ToEbi. After critical point in terms of atom energy reduction (reduced rotation frequency) magnetic flux (flow of FTEPs) starts to control spinning orientation and rotation frequency of electrons on surface (and below surface) of object. Magnetic flux induces electrons to spin opposite direction compared to magnetic flux. Phenomenon is exactly the same as in case of photon creation in atom. Based on Third Law of ToEbi magnetic source and outer electrons of the object starts to experience pushing force.

## Helium II phase

One of the most exciting phenomenon in low energy experiments is helium II phase. First of all, helium is the only atom which won't experience solid state in normal pressure no matter how low the temperature (energy) is. The reason for this is atom structure of helium-3,4.

There is three or four nuclei orbited by one pair of electrons. Because those paired electrons helium composes a very inert gas. Helium nucleus is however quite exposed compared to other atoms nucleus. Atoms containing more than one protective electron or electron pair can protect their nucleus much more efficiently. When two atoms are put together there is always generated denser FTE between them. Denser FTE attracts orbiting electrons due to increased interactions between FTE and electron. Because that nucleus exposure helium gas won't experience solid state. Rotating nucleus can always hit another nucleus due to lack of electron protection. With high pressure (25 bar) it is possible to bring helium atoms so close to each other that helium appears to be in solid state.

The difference between helium-4 and helium-3 is one neutron. Because a single neutron in helium-3 its nucleus is more interactive (see nucleus spin chapter) at nucleus level compared to helium-4 nucleus (nuclear spin = 0). This explains why it takes even lower energy to achieve helium II phase with helium-3.

With combination of being liquid and having low energy (rotation frequency of particles is small) helium II phase is an excellent heat conductor. Heat in form of particle motion just go through as a sound in the air. Other atoms are at this temperatures in solid form. Solid form absorbs much more effectively externally given particle motion (kinetic energy) than liquid.

## Creeping effect

So what causes the creeping effect? Obviously gravity causes liquid level equalizing. But why that liquid does the creeping at the first place? The reason is gravity and low energy of container and liquid helium. Even thou container has low energy it certainly has more atom mass in it compared to that helium inside it. This mass provides denser local FTE for helium to interact with. Because of low energy, container and helium can get very close to each other and therefore helium nucleus changes its orientation towards container walls.

The change in orientation causes gravitational interaction between helium and Earth to vanish completely or partially depending on container wall orientation towards Earth (Third Law of ToEbi). Rotation axis orientation explains also why helium can creep on containers roof. But the starter for creeping is gravity which pulls helium towards Earth.

## Future development

Modern physics is too broad for one man to take over and explain through ToEbi. Here is a few action points for future development. Items are not in any priority order.

- Enhancing Forth Law of ToEbi
- Connect ToEbi and quantum mechanics entirely
- Photon entanglement limits and possibilities through ToEbi

This list holds only first actions points by author. Every scientist can come up with a bigger list. Purpose of this list is to encourage other people to develop ToEbi further.

## Consequences

Main consequence (at least to the author) of this new theory is ability to understand, modify and utilize FTE. Also proper understanding of antimatter opens new possibilities. There is already pending patents on these matters. Because patent legislation it's not reasonable to reveal those yet. However, main distribution of these inventions is in energy production area.

Naturally modern physics feel the impact of this theory. Both relativity theories and quantum mechanics need some rethinking. Also EM gets a new insight into it's phenomena. And finally, we do have a proper explanation for gravitation.

## Examples

This section contains few calculation examples with ToEbi equations.

### Parallel wires

Two parallel copper wires, diameter 2.05e-3 m, length 1 m each. Copper crystal size  $a=3.615e-10$  m. Each copper wire surface contains roughly 2.466e16 copper crystals, so roughly 6.2e16 outer electrons. Outer electrons per wire weight roughly 5.6e-14 kg.

Valence electrons (without current) rotate around nucleus axis parallel to wires. Phenomenon is caused by different FTE density inside and outside of wires. Therefore we can handle those outer electrons of the copper wire as a single rotating mass.

Force created between wires at rest at distance of 1 m is

$$F_{rest} = T_{wire,Earth} n_{valence}^2 5.6 \cdot 10^{-14} \approx 3.9 \cdot 10^{-42} n_{valence}^2$$

where  $n_{valence}$  is orbiting frequency of copper's outer electron. Based on

$$F = \frac{mv^2}{r} = 3.78 \cdot 10^{-4} N$$

where 3.78e-4 N is force needed to keep valence electron in it's orbit. Velocity of copper atom's valence electron is roughly 2.3e8 m/s and so rotation frequency  $n_{valence} \approx 2.87e17$ .

So wires generate approximately force of 3.2e-7N. Because wires are not spheres there won't be needed ether flow pattern to actually deliver calculated force. Calculated force is really close to the 1 Ampere definition. With a little bit thinner wire calculated result would be exactly 2.0e-7N.

In order to actually deliver calculated force there is a need for electron movement parallel to wires. Movement is achieved by conducting current through the wires. If we feed the same current but from the different ends of wires then based on Third Law of ToEbi experienced force is pushing the wires apart.

## Mass of Sun

Earth orbits Sun roughly 30 km/s. Force holding Earth in its orbit is

$$F = \frac{mv^2}{r} \approx 3.6 \cdot 10^{22} N.$$

We can imagine that Earth stands still and Sun rotates faster in order to create the same ether interaction amount which Earth is experiencing while orbiting Sun.

Therefore total rotation frequency of Sun is

$$\frac{1}{25.38 \cdot 24 \cdot 60 \cdot 60} 1/s + \frac{2\pi \cdot 30000 m/s}{149597870700 m} \approx 1.7 \cdot 10^{-6} 1/s$$

Total acceleration generated by Earth and Sun is based on Third Law of ToEbi (excluding RFAA)

$$a_{tot} = (a_{Earth} + a_{Sun}) \cos(7.155) = (1.8 \cdot 10^{-8} m/s^2 + \frac{1.7 \cdot 10^{-6} x}{2 \cdot 149597870700^2} m/s^2) 0.9922$$

where  $x$  is the mass of Sun. Resolving  $x$  from

$$F = m_{earth} a_{tot} \approx 3.6 \cdot 10^{22} N$$

gives the mass of Sun, which is roughly 8.9e31 kg. Current calculated value is 1.9891e30 kg.

## Rotation frequency of Venus

Planet Venus orbits Sun, but it's spin direction is different than any other planet in our Solar system. Originally Venus had the same spin direction, but a collision with an other object made it to flip upside down. Because of Venus's orbiting speed, Venus generates pulling force between Sun and itself. Therefore we can imagine that rotation axis of Venus points to North.

But there is one measurable effect because of Venus's different rotation direction, slowing rotation frequency! Based on Third Law of ToEbi, RFAA is breaking Venus's rotation frequency down. During 16 years Venus has slowed down about 20 km [4].

By approximating mass of Venus as 4e26 kg (current estimation is 4.86732e24 kg) we can calculate the braking acceleration for Venus's rotation frequency. Braking acceleration is roughly 1.5e-13  $m/s^2$ . During 16 years that acceleration would cause offset as large as observed 20 km.
