The Continuum Hypothesis

In this paper we give a proof of the Continuum Hypothesis.

Theorem "Generalized Continuum Hypothesis": For every transfinite cardinal number α, there is no cardinal number between α and 2^{α}.

Proof: Let **Card** be the class of transfinite cardinal numbers and let **Ord** be class of infinite initial ordinal numbers. We prove the equivalence of these two categories showing that there exist a full and faithfull functor $T\colon$ **Card**$\to$**Ord** such that each $\beta \in$ **Ord** is isomorphic to $T\alpha$ for some $\alpha \in$ **Card**.

Let $T\colon$ **Card**$\to$**Ord** be the well-ordering functor which, by the well-ordering principle, assigns to every transfinite cardinal number α its infinite initial ordinal number, $T\alpha$. The functor T is full because to every pair of transfinite cardinal numbers α and α' and to every arrow $g\colon T\alpha \to T\alpha'$ in **Ord** there is an arrow $f\colon \alpha \to \alpha'$ such that $Tf = g$ because every infinite initial ordinal number is a transfinite cardinal number and, by definition of transfinite cardinal number, both well orders are isomorphic, that is, there exist an order-preserving isomorphism between these two well orders, **Card** $\cong_{\subset}$**Ord**. The functor T is faithful because to every pair of transfinite cardinal numbers α and α' and to every pair of arrows f_1, $f_2\colon \alpha \to \alpha'$ the equality $Tf_1 = Tf_2$ implies $f_1 = f_2$ because every f_i is unique since **Card** is a preorder. And, by definition of transfinite cardinal number, to each infinite ordinal number β there is an order-preserving bijection on it to its well-ordered transfinite cardinal number $T|\beta|$ which, by definition of transfinite cardinal number, is the same infinite ordinal number up to isomorphism, that is, $\beta \cong T|\beta|$. Therefore **Card** $\cong$ **Ord**.

Thus, by the fundamental theorem of cardinal arithmetic, the equivalence between the categories **Card** and **Ord** proves, since there is no initial ordinal number between ω and ω^{ω}, that there is no cardinal number between the transfinite cardinal numbers $\aleph_0$ and $2^{\aleph_0}$, and, in general, that there is no cardinal number between the transfinite cardinal numbers α and 2^{α}. As a consequence, there exist no inaccessible cardinals. In fact, the class of transfinite cardinal numbers is countable.

A theorem of universal algebra

Thus not only does the theorem prove that the class of transfinite cardinal numbers is an infinite countable nondiscrete large category which is a closed complete and cocomplete semiring, with arrows, the polynomial maps and the exponential maps, that is an algebra by the action of the covariant exponential functor semiring e, itself, a functor algebra, but also, by definition of initial limit ordinal number and the well-ordering principle, that the closed complete and cocomplete algebra of initial limit ordinal numbers **Ord** is isomorphic to the closed complete and cocomplete algebra of transfinite cardinals **Card**, that is, **Card** $\cong$ **Ord**.

The theorem in categorical logic

In categorical logic, not only does the theorem prove that all first order theories are infinite linear orders that have transfinite cardinal number $\alpha \leq 2^{\aleph_0}$, but also therefore, that all higuer order theories are continuums for they are partial orders which are countably infinite products of first order theories.

The theorem in topos theory

In topos theory, this theorem proves that the category **Card** of (small) cardinal numbers is a topos, and that its topos of sheaves is the category $\mathbf{Sets}^{\mathbf{Card}^*}$, denoting the dual category of the category **Card** by $\mathbf{Card}^*$, of the set-valued contravariant functors on **Card** to **Sets** which assign to every cardinal number β its set of cardinal functions on β all of which turn out to be the cardinal continuous functions on the topology of the cardinal numbers.
