I. INTRODUCTION

The Smarandache function $S : \mathbb{N}^* \rightarrow \mathbb{N}^*$ is defined [9] by the condition that $S(n)$ is the smallest positive integer $k$ such that $k!$ is divisible by $n$.

If

$$n = p_1^{a_1} \cdot p_2^{a_2} \cdots \cdot p_r^{a_r}$$

is the decomposition of the positive integer $n$ into primes, then it is easy to verify that

$$S(n) = \max \left( S\left( p_i^{a_i} \right) \right)$$

One of the most important properties of this function is that a positive integer $p$ is a fixed point of $S$ if and only if $p$ is a prime or $p = 4$.

This paper is aimed to provide generalizations of the Smarandache function. They will be constructed by means of sequences more general than the sequence of the factorials. Such sequences are monotonously convergent to zero sequences and divisibility sequences (in particular the Fibonacci sequence).

Our main result states that the Smarandache generalized function associated with every strong divisibility sequence (sequence satisfying the condition (15) from below) is a dual strong divisibility sequence (i.e. it satisfies the condition (26), the dual of (15)).

Note that the Smarandache function $S$ is not monotonous. Indeed, $n_1 \sim n_2$ does not imply $S(n_1) \sim S(n_2)$. For instance $5 \sim 12$ and $S(5) = 5$, $S(12) = 4$.

Let us denote by $\vee$ the least common multiple, by $\wedge$ the greatest common divisor and let $\wedge = \min \d$, $\vee = \max \d$. It is known that

$$\mathbb{N}_d = \left( \mathbb{N}^*, \wedge, \vee \right) \quad \text{and} \quad \mathbb{N}_d = \left( \mathbb{N}^*, \wedge, \vee \right)$$

are lattices. The order on $\mathbb{N}^*$ corresponding to the lattice $\mathbb{N}_0$ is the usual order:

$$n_1 \leq n_2 \Leftrightarrow n_1 \wedge n_2 = n_1$$

and it is a total order. On the contrary, the order $\preceq$ corresponding to the lattice $\mathbb{N}_d$, defined as

$$n_1 \preceq n_2 \Leftrightarrow n_1 \wedge n_2 = n_1$$

( the divisibility relation) is only a partial order.

More precisely we have
\( n_1 \leq n_2 \Leftrightarrow n_1 \text{ divides } n_2 \).

For \( n_1 \leq n_2 \) we shall also write \( n_2 \geq n_1 \). We notice that \( N_d \) has zero as the greatest element, \( N_0 \) does not possess a greatest element and both lattices have 1 as the smallest element. Then it is convenient to consider in \( N_0 \) the convergence to infinity and in \( N_d \), the convergence to zero.

Let
\[
\begin{align*}
  n_1 &= \prod p_i^{\alpha_i} \quad \text{and} \\
  n_2 &= \prod p_i^{\beta_i}
\end{align*}
\]

be the decompositions into primes of \( n_1 \) and \( n_2 \). Then we have

\[
\begin{align*}
  n_1 \lor n_2 &= \prod p_i^{\max(\alpha_i, \beta_i)}. \\
  \text{The definition of the Smarandache function implies that} \\
  S\left( n_1 \lor n_2 \right) &= S(n_1) \lor S(n_2) \quad (3)
\end{align*}
\]

Also we have

\[
\begin{align*}
  n_1 \leq n_2 \Rightarrow S(n_1) \leq S(n_2). \\
  \text{(4)}
\end{align*}
\]

In order to make explicit the lattice (so, the order) on the set \( N^* \), we shall write \( N_0 \) instead of \( N^* \), if the order on the set of the positive integers is the usual order and \( N_d \) instead of \( N^* \), if we consider the order \( \leq d \) respectively.

Then (4) shows that the Smarandache function, considered as a function
\[
S : N_d \rightarrow N_0, \quad (5)
\]

is an order preserving map.

From (2) it follows that the determination of \( S(n) \) reduces to the computation of \( S(p^\alpha) \). In addition, it is proved [1] that if the sequence

\[
(p) : 1, p, p^2, \ldots, p^i, \ldots
\]

is the standard \( p \)-scale and the sequence

\[
[p] : a_1(p), a_2(p), \ldots, a_i(p), \ldots
\]

is the generalized numerical scale determined by the sequence

\[
a_i(p) = \frac{p^i - 1}{p - 1}
\]

then

\[
S(p^\alpha) = p(a_{[p]}(\alpha)). \quad (7)
\]

In other words, \( S(p^\alpha) \) can be obtained by multiplying by \( p \) the number obtained writing the exponent \( \alpha \) in the generalized scale \([p]\) and "reading" it in the scale \((p)\).

For instance, in order to calculate \( S(3^{99}) \) let us consider the scale

\[
[3] : 1, 4, 13, 40, 121, \ldots
\]

Then, for \( \alpha = 99 \), we have

\[
a_{[3]} = 2a_4(3) + a_3(3) + a_2(3) + 2a_1(3) = 2112_{[3]}
\]

51
and "reading" this number in the usual scale
\[(3) \quad 1, 3, 3^2, 3^3, \ldots \]
we get \(S(3^{99}) = 3(2 \cdot 3^2 + 3^3 + 3 + 2) = 204\). So, 204 is the smallest positive integer whose factorial is divisible by \(3^{99}\).

We quote also the following formula used to compute \(S(p^a)\):
\[
S(p^a) = (p-1)a + \sigma_{[p]}(\alpha),
\]
where \(\sigma_{[p]}(\alpha)\) stands for the sum of the digits of the integer \(\alpha\) written in the scale \([p]\).

2. GENERALIZED SMARANDACHE FUNCTIONS

A sequence of positive integers is a mapping \(\sigma : N^* \rightarrow N^*\) and it is usually denoted by \((\sigma_n)_{n \in N^*}\) (i.e. the set of its values). Since in the sequel an essential point is to make evident the structure (the lattice) on the domain and on the range of this function respectively, we adopt the notation from (5).

Then
\[
\sigma : N_0 \rightarrow N_d
\]
shows that \(\sigma\) is a sequence of positive integers defined on the set \(N^*\). This set was structured as a lattice by \(\wedge\) and \(\vee\) and its range has also a structure of lattice, induced by \(\wedge_d\) and \(\vee_d\).

**Definition 2.1.** [3] The sequence (9) is a *multiplicatively convergent to zero* sequence \((mcz)\) if
\[
(\forall)n \in N^* \quad (\exists) \quad m_n \in N^* \quad (\forall)m \geq m_n \Rightarrow n \leq \sigma(m).
\]

In other words, a \((mcz)\) sequence is a sequence defined as in (9), which is *convergent to zero*.

These sequences, satisfying in addition the condition
\[
\sigma(n) \leq \sigma(n+1)
\]
(that is \(\sigma(n)\) divides \(\sigma(n+1)\)) were considered by G. Christol [3] in order to obtain a generalization of \(p\)-adic numbers.

As an example of a \((mcz)\) sequence we may consider the sequence defined by \(\sigma(n) = n!\). This sequence also satisfies the condition (11).

**Remark 2.1.** We find that the value \(S(n)\) of the Smarandache function at the point \(n\) is the smallest integer \(m_n\) provided by (10), whenever \(\sigma(n) = n!\). This enables us to define a Smarandache type function for each \((mcz)\) sequence. Indeed, for an arbitrary \((mcz)\) sequence \(\sigma\), we may define \(S_\sigma(n)\) as the smallest integer \(m_n\) given by (10).

The \((mcz)\) sequences satisfying the extra-condition (11) generalize the factorial. Indeed, if
\[ \sigma(n+1) = k_{n+1} \sigma(n) \]

then

\[ \sigma(n) = k_1 \cdot k_2 \cdot \ldots \cdot k_n, \text{ with } k_i = 1 \text{ and } k_i \in \mathbb{N}^* \text{ for } i > 1. \]

Starting with the lattices \( N_0 \) and \( N_d \), we can construct sequences

\[ \sigma : N_d \to N_d. \]  

**Definition 2.2.** A sequence (13) is called a *divisibility sequence (ds)* if

\[ n \leq m \Rightarrow \sigma(n) \leq \sigma(m) \]  

(that is if the mapping \( \sigma \) from (13) is monotonous). The sequence (13) is called a *strong divisibility sequence (sds)* if

\[ \sigma(n \land m) = \sigma(n) \land \sigma(m) \]  

for every \( n, m \in \mathbb{N}^* \).

Strong divisibility sequences are considered, for instance, by N. Jensen in [5].

It is known that the Fibonacci sequence is also (sds).

For a sequence \( \sigma \) of positive integers, concepts as (usual) monotonicity, multiplicatively convergence to zero, divisibility, have been independently studied by many authors. A unifying treatment of these concepts can be achieved if we remark that they are monotonicity or convergence conditions of a given sequence \( \sigma : \mathbb{N}^* \to \mathbb{N}^* \), for adequate lattices on \( \mathbb{N}^* \).

We shall consider now all the possibilities to define a sequence of positive integers, with respect to the lattices \( N_0 \) and \( N_d \). To make briefly evident the kind of the lattice considered on the domain and on the range of \( \alpha \), we shall use the following notation:

(a) a sequence \( \sigma_{oo} : N_0 \to N_0 \) is an \( (oo) \)-sequence

(b) a sequence \( \sigma_{od} : N_0 \to N_d \) is an \( (od) \)-sequence

(c) a sequence \( \sigma_{do} : N_d \to N_0 \) is an \( (do) \)-sequence

(d) a sequence \( \sigma_{dd} : N_d \to N_d \) is a \( (dd) \)-sequence

We have already seen (Remark 2.1) that, considering \( (mcz) \) sequences, the Smarandache function may be generalized.

In order to generalize the Smarandache function for each type of the above sequences, it is necessary to consider the monotonicity and the existence of a limit corresponding to each of the cases (a) - (d).

Of course, the limit is *infinity* for \( N_0 \)-valued sequence and it is *zero* for the others.

We have four kinds of monotonicity.

For a \( (do) \)-sequence \( \sigma_{do} \), the monotonicity reads:

\[ (m_{do}) \quad (\forall) n, n_1, n_2 \in \mathbb{N}^*, \quad n_1 \leq n_2 \Rightarrow \sigma_{do}(n_1) \leq \sigma_{do}(n_2) \]

and the condition of convergence to infinity is:

\[ (c_{do}) \quad (\forall) n \in \mathbb{N}^* \quad (\exists) m_n \in \mathbb{N}^* \quad (\forall) m \geq m_n \Rightarrow \sigma_{do}(m) \geq n. \]

Similarly, for a \( (dd) \)-sequence \( \sigma_{dd} \), the monotonicity reads:
\[(m_{dd}) \quad (\forall) n_1, n_2 \in N^*, \quad n_1 \leq n_2 \Rightarrow \sigma_{dd}(n_1) \leq \sigma_{dd}(n_2)\]

and the convergence to zero is:
\[(c_{dd}) \quad (\forall) n \in N^* \quad (\exists) m_n \in N^* \quad (\forall) m \geq m_n \Rightarrow \sigma_{dd}(m) \geq n.\]

**Definition 2.3.** The generalized Smarandache function associated to a sequence \(\sigma_{ij}\) satisfying the condition \((c_{ij})\), with \(i, j \in \{0, d\}\), is
\[
S_{ij}(n) = \min \{m_n | \text{given by the condition } (c_{ij})\}
\]

Remark that \((oo)-sequences\) are the classical sequences of positive integers. As examples of \((od)-sequences\) we quote the \((mcz)\) sequences. Examples of \((dd)-sequences\) are \((ds)\) and \((sds)-sequences\) . Finally, the generalized Smarandache functions \(S_{od}\) associated with \((od)-sequences\) satisfying the condition \((c_{od})\) are \((do)-sequences\).

The functions \(S_{ij}\) have the following properties:

**Theorem 2.1.** Every function \(S_{oo}\) satisfies:

(i) \((\forall) n_1, n_2 \in N^*, \quad n_1 \leq n_2 \Rightarrow S_{oo}(n_1) \leq S_{oo}(n_2),\)

that is \(S_{oo}\) satisfies \((m_{oo})\).

(ii) \(S_{oo}(n_1 \lor n_2) = S_{oo}(n_1) \lor S_{oo}(n_2)\)

(iii) \(S_{oo}(n_1 \land n_2) = S_{oo}(n_1) \land S_{oo}(n_2)\).

**Proof:** (i) The definition of \(S_{oo}(n)\) implies that:
\[
S_{oo}(n_i) = \min \{m_n | (\forall) m \geq m_n \Rightarrow \sigma_{oo}(m) \geq n_i\}, \text{ for } i = 1, 2
\]

Therefore
\[
(\forall) m \geq S_{oo}(n_2) \Rightarrow \sigma_{oo}(m) \geq n_2 \geq n_i
\]

and so \(S_{oo}(n_i) \leq S_{oo}(n_2)\). The equalities (ii) and (iii) are consequences of (i).

**Theorem 2.2.** Every function \(S_{od}\) has the following properties:

(iv) \((\forall) n_1, n_2 \in N^*, \quad n_1 \leq n_2 \Rightarrow S_{od}(n_1) \leq S_{od}(n_2)\)

that is \(S_{od}\) satisfies \((m_{od})\).

(v) \(S_{od}(n_1 \lor n_2) = S_{od}(n_1) \lor S_{od}(n_2)\).

(vi) \(S_{od}(n_1 \land n_2) \leq S_{od}(n_1) \land S_{od}(n_2)\).

**Proof:** The equality (v) may be proved in the same manner as the equality (3) for the function \(S\). Then from (v) it follows (iv).

For (vi) let us note \(u = S_{od}(n_1) \land S_{od}(n_2)\). From
\[
n_1 \land n_2 \leq n_1, \quad n_1 \land n_2 \leq n_2 \leq n_2 
\]

54
and from (iv), it follows that
\[ S_{ad}(n_1 \land n_2) \leq S_{ad}(n_1), \quad S_{ad}(n_1 \land n_2) \leq S_{ad}(n_2), \]
so \[ S_{ad}(n_1 \land n_2) \leq S_{ad}(n_1) \land S_{ad}(n_2). \]

Theorem 2.3. The functions \( S_{do} \) satisfy:

(vii) \( (\forall) n_1, n_2 \in \mathbb{N}^*, \ n_1 \leq n_2 \Rightarrow S_{do}(n_1) \leq S_{do}(n_2). \)

(viii) \( S_{do}(n_1 \lor n_2) \leq S_{do}(n_1) \lor S_{do}(n_2). \)

(ix) \( S_{do}(n_1 \lor n_2) = S_{do}(n_1) \lor S_{do}(n_2). \)

(x) \( S_{do}(n_1 \land n_2) = S_{do}(n_1) \land S_{do}(n_2). \)

Proof: Let us note that (ix) and (x) are consequences of (vii). In our terms (vii) is just the fact that the Smarandache generalized function \( S_{do} \) associated with a \((do)\)-sequence is \((oo)\)-monotonous. To prove this assertion, let \( n_1 \leq n_2 \). Then for every \( m \geq m_{n_1} \), we have
\[ \sigma_{do}(m) \geq n_2 \geq n_1 \]
and so \( S_{do}(n_1) \leq S_{do}(n_2). \)

(viii) For \( i = 1, 2 \) we have:
\[ S_{do}(n_i) = \min \left\{ m_{n_i} | (\forall) m \geq m_{n_i} \Rightarrow \sigma_{do}(m) \geq n_i \right\} \]
Let us suppose that \( n_1 \leq n_2 \), so \( n_1 \lor n_2 = n_2 \) and \( S_{do}(n_1 \lor n_2) = S_{do}(n_2) \). If we take \( m_{n_1} = S_{do}(n_1) \lor S_{do}(n_2), \) then for every \( m \geq m_{n_1} \) it follows that \( \sigma_{do}(m) \geq n_i \), for \( i = 1, 2 \), so \( \sigma_{do}(m) \geq n_1 \lor n_2 \), whence the desired inequality.

Consequence 2.1. \( S_{do}(n_1) \land S_{do}(n_2) \leq S_{do}(n_1) \land S_{do}(n_2) = S_{do}(n_1 \land n_2) \leq S_{do}(n_1) \lor S_{do}(n_2). \)

Theorem 2.4. The functions \( S_{dd} \) satisfy:

(xi) \( S_{dd}(n_1, n_2) \leq S_{dd}(n_1) \lor S_{dd}(n_2). \)

(xii) If \( n_1 \leq n_2 \) or \( n_2 \leq n_1 \), then
\[ S_{dd}(n_1, n_2) = S_{dd}(n_1) \lor S_{dd}(n_2). \]

(xiii) \( S_{dd}(n_1 \land n_2) \leq S_{dd}(n_1) \land S_{dd}(n_2). \)

Proof: The proof of (xi) is similar to the proof of (viii) and the other assertions may be easily obtained by using the definition of \( S_{dd} \) from (17) (for \( i = j = d \)).

Consequence 2.2. For all \( n_1, n_2 \in \mathbb{N}^* \) we have
\[
S_{dd}(n_1) \cup S_{dd}(n_2) \leq S_{dd}(n_1 \oplus n_2) \leq S_{dd}(n_1) \cup S_{dd}(n_2).
\]

This follows from the fact that
\[
n_i \leq n_1 \oplus n_2 \quad \text{for } i = 1, 2 \Rightarrow S_{dd}(n_i) \leq S_{dd}(n_1 \oplus n_2).
\]

If \( \sigma_{dd} \) is a divisibility sequence, the above theorem implies that the associated Smarandache function satisfies the inequality \((xi)\). In the following we shall see that, if the sequence \( \sigma_{dd} \) is a divisibility sequence with additional properties, namely if it is a strong divisibility sequence, then the inequality \((xi)\) becomes equality.

**Theorem 2.5:** If \( \sigma_{dd} \) is a (sds) satisfying the condition \((c_{dd})\), then:
\[
S_{dd}(n_1 \oplus n_2) = S_{dd}(n_1) \cup S_{dd}(n_2)
\]
and
\[
(\forall)n_1, n_2 \in \mathbb{N}^*, \quad n_1 \leq n_2 \Rightarrow S_{dd}(n_1) \leq S_{dd}(n_2)
\]
(i.e. \( S_{dd} \) satisfies the monotonicity condition \((m_{dd})\)).

**Proof:** In order to prove the equality (17), it is sufficient to show that
\[
S_{dd}(n_1) \cup S_{dd}(n_1 \oplus n_2), \quad \text{for } i = 1, 2.
\]
But if, for instance, the above inequality does not hold for \( n_1 \) and we denote
\[
d_o = S_{dd}(n_1) \cap S_{dd}(n_1 \oplus n_2),
\]
it follows that \( d_o < S_{dd}(n_1) \) and taking into account that
\[
\sigma_{dd}(S_{dd}(n_1)) \geq n_1 \quad \text{and} \quad n_1 \leq S_{dd}(n_1 \oplus n_2) \leq \sigma_{dd}(S_{dd}(n_1)),
\]
we have
\[
\sigma_{dd}(d_o) = \sigma_{dd}(S_{dd}(n_1) \cap S_{dd}(n_1 \oplus n_2)) = \\
= \sigma_{dd}(S_{dd}(n_1)) \cap \sigma_{dd}(S_{dd}(n_1 \oplus n_2)) \geq n_1 \wedge n_1 = n_1.
\]
Thus, we obtain the contradiction
\[
S_{dd}(n_1) \leq d_o < S_{dd}(n_1).
\]
So, if the sequence \( \sigma_{dd} \) is a (sds), that is if the equality (15) holds, then the corresponding Smarandache function \( S_{dd} \) satisfies the dual equality (17).

**Example.** The Fibonacci sequence \( (F_n)_{n \in \mathbb{N}^*} \) is a (sds). Therefore, the generalized Smarandache function \( S_F \) associated with this sequence satisfy:
\[ S_F\left( n_1 \lor n_2 \right) = S_F\left( n_1 \right) \lor S_F\left( n_2 \right) \]  

(19)

By means of this equality, the computation of \( S_F\left( n \right) \) reduces to the determination of \( S_F\left( p^a \right) \), where \( p \) is a prime number. For instance

\[ S_F\left( 52 \right) = \min \left\{ m \mid \forall m \geq m_a \Rightarrow 52 \mid F(m) \right\} = S_F\left( 2^2 \right) \lor S_F\left( 13 \right) = \min \left\{ 6 \lor 7 \right\} = 7. \]

So, 7 is the smallest positive integer \( m \) such that \( F(m) \) is divisible by 52.

Also, we have

\[ S_F\left( 12 \right) = S_F\left( 2^2 \cdot 3 \right) = S_F\left( 2^2 \right) \lor S_F\left( 3 \right) = 6 \lor 4 = 6, \]

therefore \( n = 12 \) is a fixed point of \( S_F \).

The values of \( S_F\left( p^a \right) \) may be obtained by writing all \( F_n \) in the scale \( (p) \) given by (6), which is a difficult operation. At the time being, we are not able to provide a closed formula for the computation of \( S_F\left( p^a \right) \). However, we shall present some partial results in this direction. In [8] it is stated that

\[ 3^k \leq F_n \iff 4 \cdot 3^{k-1} \leq n \]

\[ 2^k \leq F_n \iff 3 \cdot 2^{k-2} \leq n, \quad \text{for } k \geq 3. \]

It is known (see for instance [6], [7]) that if \( \sigma \) is a non-degenerate second-order linear recurrence sequence defined by

\[ \sigma(n) = A \sigma(n - 1) - B \sigma(n - 2) \]  

(21)

where \( A \) and \( B \) are fixed non-zero coprime integers and \( \sigma(1) = 1, \quad \sigma(2) = A \), then

\[ n \in \mathbb{Z}^+, \quad n \land B = 1 \Rightarrow (3) m \in \mathbb{N}^* \quad n \leq \sigma(m). \]  

(22)

The least index of these terms is called the rank of appearance of \( n \) in the sequence and is denoted by \( r(n) \).

If \( D = A^2 - 4B \) and \( (D/n) \) stands for the Jacobi symbol, then for \( mn \land BD = 1 \) and \( p \) a prime we have ([6])

\[ n \leq \sigma(m) \iff r(n) \leq m; \quad r(p) \leq p - (D/p), \]

\[ r(p) \leq \frac{p - (D/p)}{2} \iff (B/p) = 1; \quad r\left( \frac{m \lor n}{d} \right) = r\left( \frac{m}{d} \right) \lor r\left( \frac{n}{d} \right) \]  

(23)

Let us denote \( N_B^* = \left\{ n \in N^* \mid n \land B = 1 \right\} \). Obviously, if \( r \) is considered as a function

\[ r : N_B^* \to N^*, \]  

then we can write

\[ r(n) = \min \left\{ m \mid n \leq \sigma(m) \right\}. \]

Whence an evident parallel between the above methods described for the construction of the generalized Smarandache functions and the definition of the function \( r \).

For the Fibonacci sequence \( \left( F_n \right) \) we have \( A = 1, \quad B = -1 \) and so \( D = 5 \).

This implies

\[ p = 5k \pm 1 \Rightarrow \left( 5/p \right) = 1 \]  

(24)
\[ p = 5k \pm 2 \Rightarrow (5/p) = -1 \]  

(25)

and it follows that if (24) holds, then \( p \) divides \( F_{p-1} \). Thus \( S_F(p) \) is a divisor of \( p - 1 \). In the second case \( p \) divides \( F_{p+1} \) and \( S_F(p) \) is a divisor of \( p + 1 \).

From (23) we deduce

\[ S_F(p) \leq p - (5/p) \]

for any prime number \( p \).

Lemma 2 from [6] implies that the fraction \( (p - (5/p))/S_F(p) \) is unbounded. We also have

\[ p^k \leq F_n \Leftrightarrow S_F(p^k) \leq n. \]

Example. For \( p = 11 \) it follows \( (5/p) = 1 \), so \( S_F(11) \leq 10 \). In fact, we have precisely \( S_F(11) = 11 - (5/11) = 10 \), but there exist prime numbers such that \( S_F(p) < p - (5/p) \). For instance, \( p = 17 \), for which \( p - (5/p) = 18 \) and \( S_F(17) = 9 \).

Definition 2.4. The sequence \( \sigma \) is a dual strong divisibility sequence (dsds) if

\[ \sigma(dn \lor m) = \sigma(d)n \lor \sigma(m) \quad \text{for all } n, m \in N^*. \]

(26)

It may be easily seen that every strong divisibility sequence is a divisibility sequence. We also have:

**Proposition 2.1** Every dual strong divisibility sequence is a divisibility sequence.

**Proof.** We have to prove that (26) implies (14). But if \( n \leq m \), it follows

\[ n \lor m = m \quad \text{and then} \quad \sigma(m) = \sigma(n \lor m) = \sigma(n) \lor \sigma(m) \]

(27)

so, \( \sigma(n) \leq \sigma(m) \).

Then Theorem 2.5 asserts that the Smarandache generalized function \( S_\sigma \) associated with any strong divisibility sequence \( \sigma \) is a dual strong divisibility sequence. Of course, in this case, both sequences \( \sigma \) and \( S_\sigma \) are divisibility sequences.

It would be very interesting to prove whether the converse assertion holds. That is if \( S_{dd} \) is the generalized Smarandache function associated with a (divisibility) sequence \( \sigma_{dd} \) satisfying the condition \( (c_{dd}) \), then the equality (17) implies the strong divisibility.

**Remarks.** (1) It is known that the Smarandache function \( S \) is onto. But given a (dd) - sequence \( \sigma_{dd} \), even if it is a (sds), it does not follow that the associated function \( S_{dd} \) is onto. Indeed, the function \( S_F \) associated with the Fibonacci sequence is not onto, because \( n = 2 \) is not a value of \( S_F \).
One of the most interesting diophantine equations associated with a Smarandache type function is that which provides its fixed points. We remember that the fixed points for the Smarandache function are all the primes and the composite number $n = 4$. For the functions $S_d$, the equation providing the fixed points reads $S_d(x) = x$ and for $S_f$ we have as solutions, for instance, $n = 5, n = 12$.

At the end of this paper we quote the following question on the Smarandache function, also related to the Fibonacci sequence:

T. Yau [10] wondered if there exist triplets of positive integers $(n, n-1, n-2)$ such that the corresponding values of the Smarandache function satisfy the Fibonacci recurrence relation $S(n) = S(n - 1) + S(n - 2)$.

He found two such triplets, namely for $n = 11$ and for $n = 121$. Indeed, we have $S(9) + S(10) = S(11)$ and $S(119) + S(120) = S(121)$.

Using a computer, Charles Ashbacher [2] found additional values. These are for $n = 4902, n = 26245, n = 32112, n = 64010, n = 368139, n = 415664$.

Recently H. Ibsent [4] proposed an algorithm permitting to find, by means of a computer, much more values. But the question posed by T. Yau "How many other triplets with the same property exist?" is still unsolved.
