The ‘One Slide’ Introduction to *Generalized* Quantum Impedances

Peter Cameron

“To understand the electron would be enough”

Einstein
Abstract

an outline of the history of generalized quantum impedances and their application to

• the unstable particle spectrum
• gravity
• non-locality and entanglement
• the black hole information paradox
• time symmetry in quantum mechanics
• the chiral anomaly,…

with a view towards proton spin
Define ‘Impedance’

Impedance - a measure of the amplitude and **phase** of opposition to the flow of a current; the ellipticity of phase space trajectories

- fundamental forces - electromagnetic \([\text{ohms}] = \frac{\text{kg-m}^2}{\text{coul}^2 \cdot \text{s}}\)
- and mechanical/inertial/gravitational \([\text{kg/s}]\)

- coupled forces - electromechanical, magnetomechanical,…

- for now stay with electromagnetic - resistance, inductance, capacitance

- distinctions between ‘classical’ and ‘quantum’
  - ‘classical’ resistance is incoherent (heat, noise,…)
  - ‘quantum’ resistance is phase-coherent (no dissipation)
  - **phase** is _not a single measurement observable_ in quantum mechanics

- scale invariant impedances (quantum Hall, centrifugal, chiral,…) communicate only quantum phase, cannot transmit energy, like gravity cannot be shielded,…

---

**scale invariant impedances appear in the EPR paradox (non-locality), time asymmetry, Aharonov-Bohm effect, chiral anomaly,…**
The Essential Point

Impedances govern the flow of energy

classical or quantum impedances,
mechanical or electromagnetic,
fermionic or bosonic,
topological or geometric, ...

Impedances govern the flow of energy

This is not a theoretical musing

This is a fundamental concept, of universal applicability

Generalization of quantum impedances extends the concept
from the photon impedance and the scale invariant Lorentz
impedance of the electron in the quantum Hall effect
to all quantum potentials
and their associated forces and impedances
'One Slide' given the Essential Point

Horizontal axis in both plots is logarithmic
Length scales are the same for both plots, and they are properly aligned
Upper plot shows particle lifetimes multiplied by the speed of light, the coherence lengths
(adapted from The Power of Alpha by Malcolm MacGregor)
Plot at left is electron impedances, details at
http://redshift.vif.com/JournalFiles/V18NO2PDF/V18N2CAM.pdf

- Alpha-spaced coherence lengths of $\eta'$, $\eta$, and $\pi_0$ are at conjunctions of mode impedances, can couple to the photon for fast EM decay
- Location of $\pi_0$ at boundary of EM and weak decays is suggestive of the chiral anomaly
- Weak decays are mismatched to the photon
- Alpha-spaced coherence length alternation of fermions/bosons in weak decays appears to be related to parity violation and electroweak enhancement of charm/tau coherence lengths
- Clustering of superheavies (top, Higgs, Z, W) at the 10GeV coherence length is tantalizing
- Impedance junctions at the classical radius are related to mass quantization and MacGregor's 70MeV 'platform state'

(Dated: April 26, 2013)

The discovery of exact impedance quantization in the quantum Hall effect was greatly facilitated by scale invariance. This letter explores the possibility that quantum impedances may be generalized, defined not just for the Lorentz force and the quantum Hall effect, but rather for all forces/potentials, resulting in a precisely structured network of scale dependent and scale invariant impedances. If the concept of generalized quantum impedances correctly describes the physical world, then such impedances govern how energy is transmitted and reflected, how the hydrogen atom is ionized by a 13.6eV photon, or why the $\pi_0$ branching ratio is what it is. An impedance model of the electron is presented, and explored as a model for the unstable particles. 

**a challenge – find the near-field photon impedance in any of the standard grad school E&M textbooks**

**INTRODUCTION**

The model presented here [1][6] comprises

- quantization of electric and magnetic flux, charge, and dipole moment
- interactions between these three topologies - flux quantum, monopole, and dipole
- confinement to a fundamental length, taken to be the Compton wavelength of the electron
- the photon

Calculated transfer impedances of the interactions are presented as a function of spatial scale/energy. Possible roles for these impedances in the creation and structure of the unstable particles are discussed.

![Diagram](image)

MECHANICAL IMPEDANCE

While the concept of electrical impedance is comfortably familiar to any electrical engineer and many physicists, mechanical impedance [1] is more obscure. It is defined as [19]

\[ Z_{\text{mech}} = \frac{F}{v} \]

where \( F \) is the applied force and \( v \) the resulting velocity. The form is similar to Newton’s second law, written as

\[ m = \frac{F}{a} \]

where \( m \) is the mass to which the force is applied and \( a \) is the resulting acceleration.

Taking the force \( F \) to be, for example, the centrifugal force

\[ F_{\text{centri}} = \frac{mv^2}{r} \]

gives the centrifugal impedance

\[ Z_{\text{centri}} = \frac{mv}{r} \]

where \( r \) is the radius of curvature of the path of the mass acted upon by this force.

The centrifugal force is in some sense a mechanical equivalent of the vector Lorentz force present in the quantum Hall effect. Like the Lorentz force, it is velocity dependent. Unlike velocity dependent forces other than the Lorentz and centrifugal forces, it is not dissipative. Like the Lorentz force, it is perpendicular to the direction of motion, and hence can do no work.

Defining \( v \) by the deBroglie relation \( v = \frac{\hbar}{mr} \) yields the simple form

\[ Z_{\text{centri}} = \frac{\hbar}{r^2} \]

The units of mechanical impedance are \([\text{kg/s}]\), those of electrical impedance \([\text{ohm}] = [(\text{kg/s})(\text{m/Coul})^2]\). Taking the second term on the right hand side, the line charge density term, to be a conversion factor between mechanical and electrical impedances and the charge to be the charge quantum \( e \) gives

\[ Z_{\text{centri}} = \frac{\hbar}{r^2} \frac{r^2}{e^2} = \frac{h}{e^2} \approx 25,812.8 \Omega \]

This impedance is numerically and symbolically identical to the scale invariant quantum Hall impedance, and is plotted in figure 2 (green dots).

The method presented in the above example can be used to calculate quantum impedances for forces other than the centrifugal and vector Lorentz forces. The impedance plot of figure 2 shows results from such calculations [2].

(Dated: June 25, 2014)

The chiral potential is inverse square. The family of inverse square potentials includes the vector Lorentz potential of the quantum Hall and Aharonov-Bohm effects, and the centrifugal, Coriolis, and three body potentials. The associated impedances are scale invariant, quantum Hall being the most familiar. Modes associated with scale invariant impedances communicate only quantum phase, not an observable in a single quantum measurement. Modes associated with scale dependent impedances, including among others those of the 1/r monopole and 1/r^3 dipole potentials, communicate both phase and energy. Making this clarifying distinction between phase (relative time) and energy explicit presents a new perspective on the anomaly. This approach is introduced via the Rosetta Stone of modern physics, the hydrogen atom. Precise impedance-based \( \bar{\pi}^0, \eta, \) and \( \eta' \) branching ratio calculations are presented as ratios of polynomials in powers of the fine structure constant, followed by discussion. Mass generation via chiral symmetry breaking is not addressed in the present paper.

INTRODUCTION

Anomalies may be defined as “...breakings of classical symmetries by quantum corrections, which arise when the regularizations needed to evaluate small fermion loop Feynman diagrams conflict with a classical symmetry of the theory.”

Stephen Adler

In a finite quantum theory chiral symmetry appears to be broken only by weak interactions. The presence of the anomaly in strong and electromagnetic quantum field theory (QFT) calculations\(^1\)\(^8\) seems to be an inevitable result of the regularization needed to remove infinities before mass and charge renormalizations can be accomplished. However, one has a choice - in the presence of the anomaly either chiral symmetry or gauge invariance must be broken.
gauge invariant (no covariant derivative) and finite (no renormalization)

The impedance approach is gauge invariant. Gauge invariance is built in. Complex impedances shift phases. Complex quantum impedances shift quantum phases. The scale invariant impedance associated with the chiral potential [9] [10] communicates quantum phase and only quantum phase [11] [13]. No need for the covariant derivative. One need only take the appropriate impedances into account.

The phase-only character of inverse square potentials, their incapacity to do work, is emphasized in the related case of the centrifugal potential of the free Schroedinger particle by Holstein [14]. The symmetry is understood to be scale invariance (unbroken sans regularization).

\[ Z_{\gamma\gamma} = \frac{1}{\frac{1}{Z_0} + \frac{1}{Z_0}} = \frac{Z_0}{2} = 188.37 \Omega \]  

(1)

and that of the e^+ e^- \gamma mode as

\[ Z_{ee\gamma} = \frac{1}{\frac{1}{R_H} + \frac{1}{R_H} + \frac{4\alpha^2}{Z_0}} = \frac{Z_0}{\frac{4\alpha^2 + 4\alpha}{4\alpha^2 + 4\alpha}} = 12.813 \Omega \]  

(2)

where \( R_H = \frac{Z_0}{2\alpha} \) is the quantum Hall resistance, so that

\[ Z_{\pi^0} = \frac{1}{\frac{1}{Z_{\gamma\gamma}} + \frac{1}{Z_{ee\gamma}}} = \frac{Z_0}{\frac{4\alpha^2 + 4\alpha + 2}{4\alpha^2 + 4\alpha + 2}} = 185.64 \Omega \]  

(3)

\[ \Gamma_{\gamma\gamma} = \frac{Z_{\pi^0}}{Z_{\gamma\gamma}} = \frac{1}{\frac{4\alpha^2 + 2\alpha + 1}{4\alpha^2 + 2\alpha + 1}} = 0.9855 (0.988) \]  

(4)

\[ \Gamma_{ee\gamma} = \frac{Z_{\pi^0}}{Z_{ee\gamma}} = \frac{2\alpha^2 + 2\alpha}{2\alpha^2 + 2\alpha + 1} = 0.0145 (0.012) \]  

(5)

\textit{unitary}

The anomaly does not arise in the impedance approach, a result of the finiteness and gauge invariance.
From the chiral anomaly note:

**eta and eta’ branching ratios**
calculated from impedance matches

\[
\Gamma_{\gamma\gamma} = \frac{Z_\eta}{Z_{\gamma\gamma}} = \frac{8}{20\alpha^2 + 68\alpha + 19} = 0.410 \ (0.393) \quad (14)
\]

\[
\Gamma_{3\pi^0} = \frac{Z_\eta}{Z_{3\pi^0}} = \frac{3(4\alpha^2 + 4\alpha + 2)}{20\alpha^2 + 68\alpha + 19} = 0.312 \ (0.326) \quad (15)
\]

\[
\Gamma_{\pi^+\pi^-\pi^0} = \frac{Z_\eta}{Z_{\pi^+\pi^-\pi^0}} = \frac{2(4\alpha^2 + 20\alpha + 2)}{20\alpha^2 + 68\alpha + 19} = 0.220 \ (0.227) \quad (16)
\]

\[
\Gamma_{\pi^+\pi^-\gamma} = \frac{Z_\eta}{Z_{\pi^+\pi^-\gamma}} = \frac{16\alpha + 1}{20\alpha^2 + 68\alpha + 19} = 0.057 \ (0.046) \quad (17)
\]

DISCUSSION

Historical Perspective on Quantum Impedances

Impedances govern the flow of energy. This is a fundamental concept of universal applicability. Historically, it has been overlooked in quantum theory.

The 1980 discovery of a new fundamental constant of nature, the Nobel Prize discovery of exact impedance quantization in the quantum Hall effect, was greatly facilitated by scale invariance. This classically peculiar impedance is topological, the measured resistance being independent of the size or shape of the Hall bar. Prior to that discovery, impedance quantization was more implied than explicit in the literature.

In the 1959 thesis of Bjorken, an approach summarized as “...an analogy between Feynman diagrams and electrical circuits, with Feynman parameters playing the role of conductance, external momenta as current sources, and coordinate differences as voltage drops. Some of that found its way into section 18.4 of...” the canonical text. As presented there, the units of the Feynman parameter are [sec/kg], the units of mechanical conductance. Form factors are proportional to conductances, inversely proportional to resistances.

With the confusion that resulted from interpreting conductance as resistance, and more importantly lacking the concept of quantized impedance, the anticipated intuitive advantage of the circuit analogy was lost and the possibility of the jump from well-considered analogy to a photon-electron impedance model was not realized.

Like the first Rochester Conference on Coherence and Quantum Optics in 1960, the 1963 paper/thesis by Vernon and Feynman on the “Interaction of Systems” was motivated by the invention of the maser. It is a particularly suggestive combination of the languages of the electrical engineer and the physicist. The authors devoted a thesis to the concepts needed for impedance matching to the maser. However, lacking again was the explicit concept of quantized impedance in the maser.

Had exact impedance quantization been discovered in 1950 rather than 1980, one wonders whether the impedance concept might have found its way into the foundation of QED at that time, before it was set in the bedrock, to underpin rather than illuminate electroweak theory, QCD, and gravity.

• origin of impedance network – two body problem & Mach’s Principle
• gravity – extend the model to the Planck particle
• state reduction and non-locality
• black hole information paradox – Rochester, Fields,…
• weak measurement and time symmetry – Berlin
• quantum interpretations – Berlin

• dark matter

• condensed matter Italics connote material in preparation

• implications of impedance approach – paradigm shift
The classical analysis of the two-body problem is frequently complicated by the introduction of a system of co-ordinates which is independent of either of the bodies. The validity of such an analysis rests upon the premise that the co-ordinate frame does not interact with the physical system via any known physical laws, and that one is therefore free to choose whatever reference frame seems most useful.

A strong epistemological argument might be advanced against this reasoning. If sufficiently rigorous constraints are placed upon the spatial properties of the interacting bodies, the introduction of an independent observer will have a radical effect upon the form of the equations which

submitted to AJP August 1975
published as an appendix to the electron impedances note
http://redshift.vif.com/JournalFiles/V18NO2PDF/V18N2CAM.pdf

It took 35 years to understand where it fits
\[ F = \frac{d(mv)}{dt} = mw\dot{r} + \frac{v}{r} \frac{dm}{dt} \]

The first term has no meaning and must be discarded. The second term would also seem to be meaningless. We have no reason to suspect that \( m_1 \) varies in time, and nothing in our initial conditions seems to require that \( m_1 \) be a point mass, a circumstance which would deprive us of the ability to observe radial velocity. Either we accept the second force term as counter-balance of the gravitational attraction or we regard the whole situation as senseless. Nothing in the initial conditions requires that the problem is senseless, so we write

\[ v_{\text{rad}} \frac{dm_1}{dt} = \frac{Gm_1 m_2}{r^2} \quad \text{or} \quad \frac{dm_1}{dt} = \left( \frac{Gm_1 m_2}{v_{\text{rad}}} \right)(1/r^2) \]

In writing this we note that it was necessary to take \( v = v_{\text{rad}} \) to maintain the co-linearity of forces. The quantity \( \frac{Gm_1 m_2}{v_{\text{rad}}} \) has units of angular momentum, which suggests

\[ \frac{dm_1}{dt} = \frac{L}{r^2} \]

integrated over one month gives the mass of the ‘moon’.
system composed of elementary particles. The Bohr model of the hydrogen atom is a familiar example. As before, we consider uniform circular motion (n=1), we consider the proton to be the center of mass, and we require that relativistic corrections be negligible and that the intrinsic angular momentum and magnetic fields of the particles be ignored. The law of force is

$$\frac{dp}{dt} = \frac{q^2}{4\pi\varepsilon_0 r^2}$$

Following the line of reasoning previously developed, we write this as

$$\frac{dm_e}{dt} = \left(\frac{q^2}{4\pi\varepsilon_0 v_{rad}}\right)\left(\frac{1}{r^2}\right)$$

which for the Bohr atom n=1

$$\frac{dm_e}{dt} = \frac{\hbar}{r^2}$$

a result which is similar in form to the previously analyzed gravitationally bound system.

equating inertial and Coulomb forces

conversion factor [kg/sec] to [ohms]

$$Z_{centri} := \frac{\hbar}{\lambda\bar{e}} \cdot \frac{\lambda\bar{e}^2}{e^2} = \frac{\hbar}{e^2} = 2.5812807554 \times 10^4 \text{ ohm}$$

this is the ‘quantum centrifugal impedance’, equal to the quantum Hall impedance
**Photon Impedance Match to a Single Free Electron**

quantum Hall impedance

Peter Cameron  
Brookhaven National Laboratory  
Upton, NY 11973  
cameron@bnl.gov

It is not surprising that consideration of impedance matching the photon to the electron, or more specifically to the quantum of resistance at the length scale defined by the mass and angular momentum of the electron, has been long ignored in quantum electrodynamics. Conceptually the development of QED preceded the discovery of ‘exact quantization’ and the associated von Klitzing constant by many decades. Additionally, the relevance of the resistance quantum to photon interactions with a single free electron has only recently begun to be appreciated. In this note we offer a simple presentation of such an impedance match, briefly discuss the unexpected emergence of the fine structure constant from these simple first principles, and suggest how the procedure can be inverted to deliver a first principles calculation of the mass of the electron.

**Possible Origin of the 70MeV Mass Quantum**

Peter Cameron  
Brookhaven National Laboratory  
Upton, NY 11973  
cameron@bnl.gov

The absence of three fundamental entities from the experimental evidence is notable. The search for two, the magnetic monopole and the electric dipole moment, is extensively documented in the literature. The third, the electric flux quantum, is remarkably absent. One is tempted to speculate that these circumstances are related, and that exploration of the electric flux quantum might shed light upon, and beyond, the absence of the magnetic monopole and the electric dipole. This note presents a tentative early effort to find a guidepost or two along the road to such an exploration, or at least a compass that permits the choice of direction. What emerges is a possible origin of the 70MeV platform state. While documentation of this mass quantum (it is simply the mass of the electron divided by the fine structure constant) in the literature is not so starkly absent as for the electric flux quantum, it is surprisingly sparse.
Magnetic and Electric Flux Quanta: the Pion Mass

Peter Cameron  
cameron@bnl.gov  
Brookhaven National Laboratory  
Upton, NY 11973

The angular momentum of the magnetic flux quantum is balanced by that of the associated supercurrent, such that in condensed matter the resultant angular momentum is zero. The notion of a flux quantum in free space is not so simple, needing both magnetic and electric flux quanta to propagate the stable dynamic structure of the photon. Considering these flux quanta at the scale where quantum field theory becomes essential, at the scale defined by the reduced Compton wavelength of the electron, exposes variants of a paradox that apparently has not been addressed in the literature. Leaving the paradox unresolved in this note, reasonable electromagnetic rationales are presented that permit to calculate the masses of the electron, muon, pion, and nucleon with remarkable accuracy. The calculated mass of the electron is correct at the nine significant digit limit of experimental accuracy, the muon at a part in one thousand, the pion at two parts in ten thousand, and the nucleon at seven parts in one hundred thousand. The accuracy of the pion and nucleon mass calculations reinforces the unconventional common notion that the strong force is electromagnetic in origin.

Electron Impedances

Peter Cameron  
cameron@bnl.gov  
Brookhaven National Laboratory  
Upton, NY 11973

It is only recently, and particularly with the quantum Hall effect and the development of nanoelectronics, that impedances on the scale of molecules, atoms and single electrons have gained attention. In what follows the possibility that characteristic impedances might be defined for the photon and the single free electron is explored is some detail, the premise being that the concepts of electrical and mechanical impedances are relevant to the elementary particle. The scale invariant quantum Hall impedance is pivotal in this exploration, as is the two body problem and Mach’s principle.

Abstract As every circuit designer knows, the flow of energy is governed by impedance matching. Classical or quantum impedances, mechanical or electromagnetic, fermionic or bosonic, topological,... To understand the flow of energy it is essential to understand the relations between the associated impedances. The connection between electromagnetism and gravitation can be made explicit by examining the impedance mismatch between the electrically charged Planck particle and the electron. This mismatch is shown to be the ratio of the gravitational and electromagnetic forces between these particles.

(Dated: May 11, 2013)

The measurement problem, the mechanism of quantum state reduction, has remained an open question for nearly a century. The ‘quantum weirdness’ of the problem was highlighted by the introduction of the Einstein-Podolsky-Rosen paradox in 1935. Motivated by Bell’s Theorem, nonlocality was first experimentally observed in 1972 by Clauser and Freedman in the entangled states of an EPR experiment, and is now an accepted fact. Special relativity requires that no energy is transferred in the nonlocal collapse of these entangled two-body wavefunctions, that no work is done, no information communicated. In the family of quantum impedances those which are scale invariant, the Lorentz and centrifugal impedances, satisfy this requirement. This letter explores their role in the collapse of the wave function.

- state reduction = decoherence (phase information is lost)
- decoherence means phase shifts - impedances shift phases
- scale invariant impedances shift phases only
- phase is not a single measurement observable in QM
- non-locality requires entanglement
- non-locality requires no communication of information (special relativity)
- phase communicates no information in a single quantum measurement
- scale invariant impedances are responsible for non-locality

Abstract: Nonlocal reduction of entangled states is clarified by considering the role of background independent scale-invariant quantum impedances in decay/decoherence of unstable elementary particles, providing simple resolution of the black hole information paradox.

© 2013 Optical Society of America
OCIS codes: 130.1640 Coherence, 270.5585 Quantum information and processing

1. Introduction

Decay of the unstable particles offers the possibility of informing nonlocal reduction of entangled states. Both follow from phase decoherence (with the resultant complication that phase is not an observable in state reduction). Unlike entangled states, where unitary evolution of the two (or more) body wave function requires nonlocal phase coherence, in the case of the unstable particles the essential coherence is self-coherence.

4. The Black Hole Information Paradox

An earlier note [8] calculated the impedance mismatch between the electron and the Planck particle. This mismatch is precisely equal to the ratio of the gravitational and electromagnetic forces between these two particles, indicating that the quantum impedance approach is valid at the event horizon, and perhaps beyond, to the singularity (which is completely decoupled by the infinitely large impedance mismatch at the dimensionless ‘point’).

As regards the paradox, if the scale invariant impedances are valid at the event horizon and responsible for nonlocal state reduction, and the holographic principle applies, then the paradox is removed.

Fig. 1. Red broken lines are the forward waves, green solid the backward waves. Green timestamps are for the TSVF interpretation. Blue timestamps and circles are for the impedance model. Unit of time is that taken for instance by a photon to travel from BS1 to M4 or BS2 to M5. Time symmetry follows from exchanging the roles of source and detector. As shown, signals from micro-oscillations of mirrors can be measured in the position-sensitive detector power spectrum.

An experiment demonstrates that even when physicists think a quantum particle has followed a single path it might not have.

Delayed Choice and Weak Measurement in the Nested Mach-Zehnder Interferometer

Peter Cameron
Strongarm Studios
Mattituck, NY USA 11952
petethepop@aol.com

Abstract: This note discusses interpretation of recent weak nested interferometer measurements in terms of state vectors traveling both forward and backward in time. A compatible quantum impedance interpretation is presented. Delayed choice variants are proposed.

OCIS codes: 000.2658, 270.5585

5. Conclusion

TSVF – the time symmetric Two State Vector Formalism of Aharonov et al

There appears to be a connection between invariant impedances, weak measurement, and time symmetry. Invariant impedances transfer no energy, only phase. Weak measurement measures phase, which is acausal. Thus the impedance model is compatible with a TSVF of state vectors coupled by invariant impedances only. A test of the TSVF interpretation would then look for f1 and f2 with insertion of BS2 after the photon has passed (!) and before t=3\sqrt{2}. This paper was motivated by Lev Vaidman’s excellent talk at Rochester.

#### the constituents of the impedance model

### from the chiral anomaly note

**'Dark' Modes and Anomalies**

The impedance plot of figure 2 is not complete. Absent are the longitudinal dipole-dipole impedances, the longitudinal and transverse charge-dipole impedances (the charge-dipole impedances are a subset of the scale invariant three body impedances), and the Coriolis impedance. There may be others, and likely are. Given the spin dependence of the weak interaction, one would expect that adding the longitudinal impedances to the figure would give additional insight into the weak decays, probably essential for instance in impedance-based calculations of those branching ratios.

**Present** in the plot are several impedances that (excepting the unstable particle spectrum) are absent in our observations of the world, do not couple to the photon, namely those associated with the electric flux quantum, magnetic monopole, and electric dipole. Figure 6 shows the alternation with topological complexity.

We see the magnetic flux quantum, electric monopole, and magnetic dipole in the stable particles which comprise our physical world, but not their electromagnetic complements. **It seems that the only place we see these 'dark' components is in the unstable particle spectrum.**

This broken symmetry is partially understood in terms of the relative strengths of the magnetic and electric charge quanta[12, 88], and might have a not-yet-obvious role in the chiral anomaly.
magnetic monopole coupling to the photon

Due to the factor-of-alpha difference in coupling strengths and the consequent reversed hierarchy of characteristic lengths, the magnetic monopole couples extremely weakly to the photon. The energetics and impedance matches are wrong.

can this rationale be extended to the electric dipole moment? the electric flux quantum?

By definition, the product of an electric charge $e$ and a distance $h/mc$ define an electric dipole moment, not magnetic. This is one example of a well hidden paradox, one that extends into our systems of units.
Paradox in our Systems of Units

- SI units of mechanical impedance are [kg/s]
  - counter-intuitive – [kg/s] suggests a flow rate, which would be proportional to conductance, not impedance
  - this is what led Bjorken (slide 17) and those who followed astray
  - non-trivial – is there a deep conceptual error in our worldview/units systems?
- EDM and MDM (previous slide) – placement of c in CGS vs SI
  - what symmetries are broken at the Compton wavelength?
  - how are they related to broken symmetries in standard model?
- another broken topology (flux quantum = monopole) - again, placement of c

Photon Sciences and Center for Functional Nanomaterials  
Call for **workshop proposals** at the  
Joint User Meeting - May 2012

Workshops will be held on the Monday and Wednesday and the meeting’s Plenary Session will be held on Tuesday. The Plenary Session includes keynote speakers and scientific talks directly related to the meeting theme, “Expanding the Toolbox for New Science”.

Please use the following link to submit your workshop proposal by **November 18, 2011**.  

In suggesting a workshop, please provide the following:  
- Name(s) of the workshop organizer(s) **Peter Cameron (possible others TBD)**  
- Name(s) of contact(s) **Peter Cameron**  
- Duration of workshop (full- or half-day) **full day**  
- A paragraph describing the workshop’s subject **Quantum Impedances**

The quantum Hall impedance follows from the vector Lorentz force. The resulting scale invariance makes this quantum impedance particularly easy to observe. More generally, quantum impedances can be defined for all forces. In the cases of the scalar Lorentz, Coulomb, and dipole forces, these impedances are not scale invariant. Therefore, these quantum impedances have no easily measurable universal values, and appear to lack the ubiquity, popularity, and utility of the quantum Hall impedance.

However, there exist physical systems in which a space scale is clearly defined. There is no ambiguity in defining characteristic length for a crystal, the superlattice, atomic hydrogen, or an electron. One can then calculate the scale dependent impedances seen by an electron, or an ion, or a spin current. One can consider how to best match them to the photon.

In the voice of extensive experience, both theoretical and practical, “Input/output is the most difficult problem in nanoscale devices” [1]. This workshop proposes to address that problem.

preliminary agenda for the world’s first workshop on generalized quantum impedances
emphasis on condensed matter – particle physics equally or more interesting

- Names of potential speakers and the tentative subjects they may address
  
  Peter Cameron – Intro and Overview
  Raphael Tsu – The Input/Output Problem in Nanoscale Devices
  TBD (B.C. Regan?) – Half Integer Lattice Spin in Graphene
  Malcolm MacGregor – Canonical Momentum in the Quantum Hall Effect
  TBD – Impedance Matching to the Lattice
  Boris Zeldovitch – Parametric Impedance Matching
  TBD (Dan Gammon?) – Quantum Dots
  Timur Datta – Quantum Wires and Waveguides
  Raphael Tsu – Quantum Wells and the Single Electron Transistor
  TBD (J. Gabelli?) – Quantum Resonators – DC and RF Impedances
  TBD – Spin Currents
  TBD – Quantum Fluctuations
  TBD – High Temperature Superconductivity
  Fritz Caspers – Near Field RF Measurements
  Ole Keller – Quantum Theory of Near-Field Electrodynamics

*condensed matter*

• implications of impedance approach—paradigm shift

*Italics connote material in preparation*
Summary

• impedances govern the flow of energy. This is a fundamental concept, of universal validity

• Mach’s principle permits calculation of background independent mechanical impedances

• the concept of quantum impedance can be generalized to all forces and potentials experienced by massive particles via these impedances

• the network that results when applying this concept to a simple electron model is intricately woven into the unstable particle spectrum

• when applied to the Planck particle, it gives an identity between gravity and impedance mismatched electromagnetism

• the impedance approach finds additional application in state reduction and non-locality, quantum information theory, time symmetry in QM, interpretation of the formalism of QM, the chiral anomaly,…

• the possibilities in condensed matter look exciting

• thus far there is no disagreement between the impedance approach and experimental data in any of the many areas investigated
not necessarily in this order:

- condensed matter – match the deBroglie wave to lattice impedances
- particle physics
  - add dynamics to the presently static impedance network
    - need phases and couplings in the network of the ‘One Slide’
    - analytical too difficult?
    - need iterative EM solver? (matlab/simulink/gate array farm?)
  - look at the only particle absent (by virtue of its ~infinite lifetime) from the ‘One Slide’ – the proton
  - understand proton spin
- impedance matching in the nucleus
  - cold fusion, quark-gluon plasma,…
  - start with the deuteron
- axion, EDM,…
- the equivalence principle as stated by Heisenberg [Physics and Philosophy p.95](#)
  “…gravitational forces can be put on the same level as centrifugal or other forces that arise as a reaction of the inertia.”
- else?
Conclusion

• hardest part is getting physicists to think in terms of impedances
• impedance approach is a paradigm shift
  • what we are learning is that paradigms don’t shift easily
  • individuals resist change, institutions more so, often fiercely
• impedance approach deconstructs the standard model
  • finite and gauge invariant - need for renormalization is removed
  • weak ‘force’ is an impedance mismatch to the photon – no need for W, Z
  • chiral ‘force’ is phase only – invariant impedances can’t communicate energy/information
  • consequently both electroweak and QCD mass generation via chiral symmetry breaking look implausible – no need for Higgs, DCSB,…
  • mass generation is via field energies in the impedance approach
  • super heavies (top, Higgs, Z, W) appear to be incredibly short-lived excitations of magnetic modes of the impedance network,…
• impedance approach includes unstable particle spectrum, gravity, dark matter, EDM, state reduction, non-locality, time asymmetry,…
• impedance approach is simple once the initial unfamiliarity passes
