Abstract

The one-dimensional Navier-Stokes equations are used to derive analytical expressions for the relation between pressure and volumetric flow rate in capillaries of five different converging-diverging axisymmetric geometries for Newtonian fluids. The results are compared to previously-derived expressions for the same geometries using the lubrication approximation. The results of the one-dimensional Navier-Stokes are identical to those obtained from the lubrication approximation within a non-dimensional numerical factor. The derived flow expressions have also been validated by comparison to numerical solutions obtained from discretization with numerical integration. Moreover, they have been certified by testing the convergence of solutions as the converging-diverging geometries approach the limiting straight geometry.

Keywords: Fluid dynamics; One-dimensional Navier-Stokes; Converging-diverging capillaries; Newtonian fluids.
1 Introduction

Modeling the flow through capillaries of converging-diverging geometries is an important subject and has many scientific and industrial applications. Moreover, it is required for modeling viscoelasticity, yield-stress and the flow of Newtonian and non-Newtonian fluids through porous media [1–8].

There are many previous attempts to model the flow through capillaries of various geometries. However, they either apply to tubes of regular cross sections [9, 10] or deal with very special cases. Most these studies use numerical meshing techniques such as finite difference and spectral methods to obtain numerical results. Some examples of these attempts are Kozicki et al. [11], Miller [12], Oka [13], Williams and Javadpour [14], Phan-Thien et al. [15, 16], Lahbabi and Chang [17], Burdette et al. [18], Pilitsis et al. [19, 20], James et al. [21], Talwar and Khomami [22], Koshiba et al. [23], Masuleh and Phillips [24], and Davidson et al. [25].

In this article we use the one-dimensional Navier-Stokes equations, which are widely used to describe axisymmetric flows in large vessels, to derive analytical expressions for the flow of Newtonian fluids in tubes of five axisymmetric converging-diverging geometries, some of which are schematically depicted in Figure 1, and compare our results to previously-derived expressions using the lubrication approximation [26]. Other validation tests have also been presented.

Figure 1: Profiles of converging-diverging axisymmetric capillaries.
The widely-used one-dimensional form of the Navier-Stokes equations to describe the flow in a tube of length $L$ where its axis is aligned with the $x$ axis and its midpoint is at $x = 0$ is given by the following continuity and momentum balance relations respectively assuming negligible gravitational body forces \[27–39\]

\[
\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = 0 \quad t \geq 0, \quad x \in \left[\frac{-L}{2}, \frac{L}{2}\right] \tag{1}
\]

\[
\frac{\partial Q}{\partial t} + \frac{1}{\alpha} \frac{\partial}{\partial x} \left( \alpha Q^2 \right) + \frac{A \rho}{\rho} \frac{\partial p}{\partial x} + \kappa \frac{Q}{A} = 0 \quad t \geq 0, \quad x \in \left[\frac{-L}{2}, \frac{L}{2}\right] \tag{2}
\]

In these equations, $A$ is the tube cross sectional area, $t$ is time, $Q$ (= $A\bar{u}$ with $\bar{u}$ being the mean axial fluid speed) is the volumetric flow rate, $x$ is the axial coordinate along the tube, $\alpha$ (= $\int \frac{u^2 dA}{A\bar{u}}$ with $u$ being the local axial fluid speed) \[29, 33, 40\] is the correction factor for axial momentum flux, $\rho$ is the fluid mass density, $p$ is the pressure, and $\kappa$ is a viscosity friction coefficient which is given by $\kappa = \frac{2\pi \rho \mu}{\rho(\alpha - 1)}$ \[35, 37\] with $\mu$ being the fluid dynamic viscosity. This model is considered one-dimensional due to the fact that the $\theta$ dependency of a cylindrically-coordinated capillary is ignored due to the axisymmetric flow assumption while the $r$ dependency is neglected because of the simplified consideration of the flow profile within a lumped parameter which is the momentum correction factor. Therefore, the only explicitly-considered dependency is the dependency in the flow direction, $x$.

For steady flow, the time terms are zero, and hence $Q$ as a function of $x$ is constant according to the continuity equation. The momentum equation then becomes

\[
\frac{\partial}{\partial x} \left( \frac{\alpha Q^2}{A} \right) + \frac{A \rho}{\rho} \frac{\partial p}{\partial x} + \kappa \frac{Q}{A} = 0 \tag{3}
\]

that is
\[
\frac{\partial p}{\partial x} = -\frac{\rho}{A} \frac{\partial}{\partial x} \left( \frac{\alpha Q^2}{A} \right) - \kappa \rho Q A^2 - \frac{\rho \alpha Q^2}{A^3} \frac{\partial A}{\partial x} - \kappa \frac{Q}{A^2} \quad (4)
\]

For a flow in the positive \( x \) direction, the pressure gradient is negative and hence

\[
p = \int_X \kappa \rho \frac{Q}{A^2} \, dx - \int_X \frac{\rho \alpha Q^2}{A^3} \frac{\partial A}{\partial x} \, dx
\]

\[
= \int_X \kappa \rho \frac{Q}{A^2} \, dx - \int_A \frac{\rho \alpha Q^2}{A^3} \, dA
\]

\[
= \kappa \rho Q \int_X \frac{dx}{A^2} - \rho \alpha Q^2 \int_A \frac{dA}{A^3}
\]

that is

\[
p = \kappa \rho Q \int_{x=-L/2}^{L/2} \frac{dx}{A^2} + \frac{\rho \alpha Q^2}{2} \left[ \frac{1}{A^2} \right]_{x=-L/2}^{L/2}
\]

Due to the tube symmetry with respect to \( x = 0 \)

\[
\int_{x=-L/2}^{L/2} \frac{dx}{A^2} = 2 \int_{x=0}^{L/2} \frac{dx}{A^2}
\]

and

\[
\left[ \frac{1}{A^2} \right]_{x=-L/2}^{L/2} = 0
\]

Hence

\[
p = 2\kappa \rho Q \int_{x=0}^{L/2} \frac{dx}{A^2}
\]

This expression is dimensionally consistent.
1.1 Conical Tube

For a tube of conical profile, depicted in Figure 2, the radius $r$ as a function of the axial distance $x$ is given by

$$r(x) = a + bx, \quad -L/2 \leq x \leq L/2$$  \hspace{1cm} (12)

where

$$a = R_{\text{min}} \quad \text{and} \quad b = \frac{2(R_{\text{max}} - R_{\text{min}})}{L}$$  \hspace{1cm} (13)

Hence, Equation 11 becomes

$$p = 2\kappa\rho Q \int_{x=0}^{L/2} \frac{dx}{A^2} = 2\kappa\rho Q \int_{x=0}^{L/2} \frac{dx}{\pi^2 (a + bx)^4}$$  \hspace{1cm} (14)

$$= -2\kappa\rho Q \left[ \frac{1}{3\pi^2 b (a + bx)^3} \right]_{0}^{L/2}$$  \hspace{1cm} (15)

$$= -2\kappa\rho Q \left[ \frac{1}{3\pi^2 \frac{2(R_{\text{max}} - R_{\text{min}})}{L} \left( \frac{R_{\text{min}} + \frac{2(R_{\text{max}} - R_{\text{min}})}{L} x}{L} \right)^3} \right]_{0}^{L/2}$$  \hspace{1cm} (16)
1.2 Parabolic Tube

\[ p = \frac{\kappa \rho Q L}{3\pi^2 (R_{\text{max}} - R_{\text{min}})} \left[ \frac{1}{R_{\text{min}}} - \frac{1}{R_{\text{max}}} \right] \]  

that is

\[ p = \frac{2\kappa \rho Q}{6\pi^2 (R_{\text{max}} - R_{\text{min}})} \left[ \frac{L}{R_{\text{max}}^3} - \frac{L}{R_{\text{min}}^3} \right] \]  

1.2 Parabolic Tube

![Figure 3: Schematic representation of the radius of a converging-diverging capillary with a parabolic profile as a function of the distance along the tube axis.](image)

For a tube of parabolic profile, depicted in Figure 3, the radius is given by

\[ r(x) = a + bx^2 \quad -L/2 \leq x \leq L/2 \]  

where

\[ a = R_{\text{min}} \quad \text{and} \quad b = \left( \frac{2}{L} \right)^2 (R_{\text{max}} - R_{\text{min}}) \]  

Therefore, Equation 11 becomes

\[ p = 2\kappa \rho Q \int_{x=0}^{L/2} \frac{dx}{A^2} = 2\kappa \rho Q \int_{x=0}^{L/2} \frac{dx}{\pi^2 (a + bx^2)^3} \]  

1.3 Hyperbolic Tube

For a tube of hyperbolic profile, similar to the profile in Figure 3, the radius is given by

\[ r(x) = \sqrt{a + bx^2} \quad -\frac{L}{2} \leq x \leq \frac{L}{2} \quad a, b > 0 \]  

(24)

where

\[ a = R_{\text{min}}^2 \quad \text{and} \quad b = \left(\frac{2}{L}\right)^2 (R_{\text{max}}^2 - R_{\text{min}}^2) \]  

(25)

Therefore, Equation 11 becomes

\[ p = \frac{2\kappa \rho Q L}{2\pi^2} \left[ \frac{1}{3R_{\text{min}} R_{\text{max}}^3} + \frac{5}{12R_{\text{min}}^2 R_{\text{max}}^2} + \frac{5}{8R_{\text{min}}^3 R_{\text{max}}} + \frac{5 \arctan \left( \sqrt{\frac{b}{a}} \right)}{8R_{\text{min}}^2 \sqrt{R_{\text{max}} - R_{\text{min}}}} \right] \]  

(23)

that is

\[ p = \frac{\kappa \rho Q}{2\pi^2} \left[ \frac{x}{6a(a + bx^2)} + \frac{5x}{24a^2(a + bx^2)^2} + \frac{5x}{16a^3(a + bx^2)} + \frac{5 \arctan \left( x \sqrt{\frac{b}{a}} \right)}{16a^{7/2}b} \right]^{L/2} \]  

(22)

and

\[ p = \frac{\kappa \rho Q L}{2\pi^2} \left[ \frac{1}{3R_{\text{min}} R_{\text{max}}^3} + \frac{5}{12R_{\text{min}}^2 R_{\text{max}}^2} + \frac{5}{8R_{\text{min}}^3 R_{\text{max}}} + \frac{5 \arctan \left( \sqrt{\frac{b}{a}} \right)}{8R_{\text{min}}^2 \sqrt{R_{\text{max}} - R_{\text{min}}}} \right] \]  

(23)

that is

\[ p = \frac{2\kappa \rho Q}{\pi^2} \left[ \frac{x}{2a(a + bx^2)} + \frac{\arctan(x \sqrt{b/a})}{2a \sqrt{ab}} \right]^{L/2} \]  

(27)

that is
1.4 Hyperbolic Cosine Tube

For a tube of hyperbolic cosine profile, similar to the profile in Figure 3, the radius is given by

\[ r(x) = a \cosh(bx) \quad -L/2 \leq x \leq L/2 \]  

(29)

where

\[ a = R_{\text{min}} \quad \text{and} \quad b = \frac{2}{L} \arccosh \left( \frac{R_{\text{max}}}{R_{\text{min}}} \right) \]  

(30)

Hence, Equation 11 becomes

\[ p = \frac{\kappa \rho Q L}{2\pi^2} \left[ \frac{1}{R_{\text{min}}^2 R_{\text{max}}^2} + \frac{\arctan \left( \sqrt{\frac{R_{\text{max}}^2 - R_{\text{min}}^2}{R_{\text{min}}^2}} \right)}{R_{\text{min}}^3 \sqrt{R_{\text{max}}^2 - R_{\text{min}}^2}} \right] \]  

(28)

1.5 Sinusoidal Tube

For a tube of sinusoidal profile, depicted in Figure 4, where the tube length \( L \) spans one complete wavelength, the radius is given by

\[ r(x) = a \sinh(bx) \quad -L/2 \leq x \leq L/2 \]  

(31)

where

\[ a = R_{\text{min}} \quad \text{and} \quad b = \frac{2}{L} \arcsin \left( \frac{R_{\text{max}}}{R_{\text{min}}} \right) \]  

(32)

Hence, Equation 11 becomes

\[ p = \frac{\kappa \rho Q L}{2\pi^2} \left[ \frac{1}{R_{\text{min}}^2} + \frac{\tanh(bx) \left[ \text{sech}^2(bx) + 2 \right]}{3a^2} \right]_{-L/2}^{L/2} \]  

(33)

that is

\[ p = \frac{\kappa \rho Q L}{3\pi^2} \left[ \frac{\tanh \left( \arccosh \left( \frac{R_{\text{max}}}{R_{\text{min}}} \right) \right) \left[ \text{sech}^2 \left( \arccosh \left( \frac{R_{\text{max}}}{R_{\text{min}}} \right) \right) + 2 \right]}{\arccosh \left( \frac{R_{\text{max}}}{R_{\text{min}}} \right)} \right] \]  

(34)
Figure 4: Schematic representation of the radius of a converging-diverging capillary with a sinusoidal profile as a function of the distance along the tube axis.

\[ r(x) = a - b \cos(kx) \quad -L/2 \leq x \leq L/2 \quad a > b > 0 \quad (34) \]

where

\[ a = \frac{R_{\text{max}} + R_{\text{min}}}{2} \quad b = \frac{R_{\text{max}} - R_{\text{min}}}{2} \quad \& \quad k = \frac{2\pi}{L} \quad (35) \]

Hence, Equation 11 becomes

\[ p = 2\kappa \rho Q \int_{x=0}^{L/2} \frac{dx}{A^2} = 2\kappa \rho Q \int_{x=0}^{L/2} \frac{dx}{\pi^2 [a - b \cos(kx)]^4} \quad (36) \]

On performing this integration, the following relation is obtained

\[ p = \frac{2\kappa \rho Q}{\pi^2 b^4 k} [I]_{L/2} \quad (37) \]

where

\[ I = \frac{(6B^3 + 9B)}{3(B^2 - 1)^{7/2}} \arctan \left( \frac{(B - 1) \tan(kx)}{\sqrt{B^2 - 1}} \right) - \frac{(11B^2 + 4) \sin(kx)}{6(B^2 - 1)^3[B + \cos(kx)]} \]

\[ - \frac{5B \sin(kx)}{6(B^2 - 1)^2[B + \cos(kx)]^2} - \frac{\sin(kx)}{3(B^2 - 1)[B + \cos(kx)]^3} \quad (38) \]
\& B = \frac{R_{\text{max}} + R_{\text{min}}}{R_{\text{min}} - R_{\text{max}}} \tag{39}

On taking \( \lim_{x \to \frac{L}{4}} I \) the following expression is obtained

\[ p = \frac{2\kappa \rho Q}{\pi^2 b^4 k} \left[ -\frac{(6B^3 + 9B) \pi}{3(B^2 - 1)^{7/2}} \right] = -\frac{\kappa \rho Q(6B^3 + 9B)}{3\pi b^4 k(B^2 - 1)^{7/2}} \tag{40} \]

Since \( B < -1 \), \( p > 0 \) as it should be. On substituting for \( B \), \( b \) and \( k \) in the last expression we obtain

\[ p = \frac{\kappa \rho Q L (R_{\text{max}} - R_{\text{min}})^3}{16\pi^2 (R_{\text{max}} R_{\text{min}})^{7/2}} \left[ 2 \left( \frac{R_{\text{max}} + R_{\text{min}}}{R_{\text{max}} - R_{\text{min}}} \right)^3 + 3 \left( \frac{R_{\text{max}} + R_{\text{min}}}{R_{\text{max}} - R_{\text{min}}} \right) \right] \tag{41} \]

It is noteworthy that all these relations (i.e. Equations 18, 23, 28, 33 and 41), are dimensionally consistent.

## 2 Validation

The derived converging-diverging formulae (Equations 18, 23, 28, 33 and 41) have been validated by three different ways: comparison to previously-derived formulae based on lubrication approximation, numerical integration, and testing the convergence behavior of the analytical solutions in the limiting cases where the converging-diverging geometries approach a straight tube geometry. These validation methods are outlined in the following subsections.

### 2.1 Comparison to Lubrication Formulae

For \( \alpha = 4/3 \), the derived five relations are identical to the previously-derived expressions using the lubrication approximation (refer to Table 1). Since \( \alpha = 4/3 \) corresponds to a fully-developed parabolic velocity profile (Poiseuille flow), the
2.2 Numerical Integration

Lubrication approximation formulae are special cases of the more general 1D Navier-Stokes relations which can accommodate other velocity profiles, such as flat profile (plug flow) when $\alpha$ approaches unity [27, 29, 33, 34, 37, 41].

Table 1: Lubrication approximation table. These formulae are derived in [26].

</tr>
</tbody>
</table>

2.2 Numerical Integration

The derived converging-diverging formulae have also been validated by comparison to numerical solutions based on numerical integration by discretizing the converging-diverging tubes of these geometries and solving for a Newtonian flow in each element by averaging the radius of that element. This method has been applied to these geometries using diverse sets of fluid, flow and tube parameters which include $\mu$, $\rho$, $Q$, $\alpha$, $L$, $R_{\text{min}}$, and $R_{\text{max}}$. A sample of these numerical validations is presented in Figure 5 for the five geometries using typical parameters. As seen, the numerical solutions converge to the analytical solutions fairly quickly in all cases. The two solutions become virtually identical for a typical meshing of 40–50 elements. The qualitative difference in convergence behavior between the conical and sinusoidal on one hand and the other geometries on the other hand seems to arise from the converging-diverging nature of these geometries and how gradually it takes place over the tube length. These two types of observed conver-
gence behavior (i.e. oscillatory like conical and asymptotic like parabolic) occur in various numerical contexts and have been observed in different numerical implementations by the author and by other researchers. Another remark is that the convergence rate indicates the quality of the average radius as an indicator of the effective radius of the element. The rapid convergence of the sinusoidal tube may support this guess as the smoothness of the sinusoidal profile makes the average radius very good representative of the effective radius of the discretized sinusoidal segments.

2.3 Convergence to Straight Tube Solution

For \( \alpha = 4/3 \) (parabolic velocity profile) the sinusoidal equation reduces to the Poiseuille expression when \( R_{\text{max}} = R_{\text{min}} \). With regard to the other geometries, despite the fact that the other four equations are not defined when \( R_{\text{max}} = R_{\text{min}} \), they converge to the Poiseuille value as \( R_{\text{max}} \) approaches \( R_{\text{min}} \), and hence for all practical purposes they are numerically identical to the Poiseuille value when the difference between the two radii is negligible.
Figure 5: The ratio of numeric to analytic solutions (y-axis) as a function of the number of discretization elements (x-axis) for the five converging-diverging geometries using typical values for the flow, fluid and capillary parameters. Similar convergence behavior has been observed for other sets of parameters.
3 Conclusions

In this paper we derived analytical expressions relating the pressure drop to the volumetric flow rate for Newtonian fluids in five different converging-diverging geometries using the one-dimensional Navier-Stokes flow equations in axisymmetric rigid tubes. The results obtained in this paper are identical, within a non-dimensional numerical factor, to those derived in [26] using the lubrication approximation. The results have also been validated numerically by comparing the analytical solutions to numerical results obtained from numerical integration for a wide range of flow, fluid and tube characteristics. Moreover, they have been endorsed by testing the convergence behavior of the analytical solutions as the converging-diverging geometries approach the limiting case of a straight tube geometry when $R_{\text{max}} \rightarrow R_{\text{min}}$.

These expressions can be used in various practical scientific and engineering situations to describe isothermal, uniform, laminar, time-independent flow of incompressible Newtonian fluids through converging-diverging flow paths. These situations include the flow in corrugated vessels and the flow in the pores and throats of porous media where the converging-diverging nature can be idealized by these relatively-simple geometries. The analytical method can also be used to derive expressions for geometries other than those presented in this paper.
