Technical Note

Abstract
In this research Technical Note the author has presented a novel method to find the Optimal Number ‘K’ in the K-Means Algorithm.

Theory

Definition of a Cluster based on Connectivity

We define a Cluster as follows:
A Cluster is a collection of Points (or objects) wherein they are scattered (their property is distributed) in such a fashion that, for a specified distance (measured in appropriate Metric of concern using appropriate Norm of concern) every point of this cluster has at least one neighbouring point also belonging to this cluster located within
(i) this specified distance * [1]
(ii) a certain small neighbourhood of this this specified distance, measured from the aforementioned point of concern.

Proximity Matrix

Given M number of points \( \bar{x}_i \in \mathbb{R}^N \), \( i = 1 \) to \( M \), each belonging to \( \mathbb{R}^N \), we find the Proximity Matrix \( P \) for each \( (M \) number of) point with each of all other \( (M \) Number of points) points, inclusive of itself. The Proximity can be found using Euclidean distance or using the concept stated in [1].

\[
P = \begin{bmatrix}
  d(1,1) & d(1,2) & d(1,3) & \ldots & d(1,(m-1)) & d(1,m) \\
  d(2,1) & d(2,2) & d(2,3) & \ldots & d(2,(m-1)) & d(2,m) \\
  d(3,1) & d(3,2) & d(3,3) & \ldots & d(3,(m-1)) & d(3,1) \\
  \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
  d((m-1),1) & d((m-1),2) & d((m-1),3) & \ldots & d((m-1),(m-1)) & d((m-1),m) \\
  d(m,1) & d(m,2) & d(m,3) & \ldots & d(m,(m-1)) & d(m,m)
\end{bmatrix}
\]
We now arrange the elements of the Proximity Matrix in Descending Order as a Set $S_1$ of at most $M_1 = \left( \frac{M^2 - M}{2} \right)$ elements, as the Proximity Matrix is Symmetric and all its diagonal elements are equal to zero.

We now plot this Set $S_1$ w.r.t to the x-axis of whole numbers. In this plot, there would be at most $M_1 = \left( \frac{M^2 - M}{2} \right)$ number of Levels. At this level, we can have at most $M_1 = \left( \frac{M^2 - M}{2} \right)$ number of Clusters, wherein we can find the points belonging to this Cluster by noting the indices of the operands responsible for the Proximity Differences in the Proximity Matrix. At this juncture, we can segregate almost similar Levels as one Level thus reducing the Number of Levels. The Final Number of levels gotten can be called as the Number ‘$K_1$’. Finally, we can find the points belonging to these $K_1$ Clusters by noting the indices of the operands responsible for the Proximity Differences in the Proximity Matrix.

**Higher Order Clusters**

For this Set $S_1$, we again find the Proximity Matrix and similarly repeat the procedure again and find another Set $S_2$ which has $M_2 = \left( \frac{M_1^2 - M_1}{2} \right)$ number of Levels. At this level, we can have at most $M_2 = \left( \frac{M_1^2 - M_1}{2} \right)$ number of Clusters, wherein we can find the points belonging to this Cluster by noting the indices of the operands responsible for the Proximity Differences in the Proximity Matrix. At this juncture, we can segregate almost similar Levels as one Level thus reducing the Number of Levels. The Final Number of levels gotten can be called as the Number ‘$K_1$’. Finally, we can find the points belonging to these $K_1$ Clusters by noting the indices of the operands responsible for the Proximity Differences in the Proximity Matrix.

We keep repeating this procedure again and again until $M_L = \left( \frac{M_{L-1}^2 - M_{L-1}}{2} \right)$ where $L$ is such that $S_L \subset S_{L-1}$ within an error of a small neighbourhood. At this level, we can have at most $M_L = \left( \frac{M_{L-1}^2 - M_{L-1}}{2} \right)$ number of Clusters. At this juncture, we can segregate almost similar Levels as one Level thus reducing the Number of Levels. The Final Number of levels gotten can be called as the Number ‘$K_L$’. Finally, we can find the points belonging to these $K_L$ Clusters by noting the indices of the operands responsible for the Proximity Differences in the Proximity Matrix.
