Main viewpoint and conclusion:

The particle decay is the spontaneous process of one unstable subatomic particle transforming into multiple other particles. The particles created in this process (the final state) must each be less massive than the original, although the total invariant mass of the system must be conserved. [1]

And, the "electronic mode" was discovered at the CERN in 1958: $\pi \rightarrow e + \nu$; a free π -meson fission into an electron and a neutrino. [2]

Same time, there are $n \rightarrow p + e + \nu$; a free neutron fission into a proton, an electron and a neutrino. [3]

Then, there be

$$m_\pi = m_e + m_\nu, \quad m_n = m_p + m_e + m_\nu = m_p + m_\pi, \quad \text{and } m_\pi = m_n - m_p;$$
$$m_n = 1.00866491682 \text{ u}, \quad m_p = 1.00727647012 \text{ u}, \quad m_e = 0.0005485799 \text{ u}. [4]$$

And

$$m_\pi = 0.0013884467 \text{ u} = 1.29794 \text{ MeV}/c^2. [4]$$

Besides

$$m_\mu = 105.658369 \text{ MeV}/c^2. [5]$$

Thus, we get $m_\pi \ll m_\mu$.

So, the π -meson couldn't able to decays into a μ -meson; or decays into a μ -meson and a μ -neutrino pairs.

Therefore, the related experimental results and the phenomenon observed needs a new interpretation and explanation. [6][7]
