# A Proof of the Erdös-Straus Conjecture Zhang Tianshu <br> Emails: chinazhangtianshu@126.com; <br> xinshijizhang@hotmail.com <br> Zhanjiang city, Guangdong province, China 

#### Abstract

In this article, we classify positive integers step by step, and use the formulation to represent a certain class therein until all classes.

First, divide all integers $\geq 2$ into 8 kinds, and formulate each of 7 kinds therein into a sum of 3 unit fractions.

For the unsolved kind, again divide it into 3 genera, and formulate each of 2 genera therein into a sum of 3 unit fractions.

For the unsolved genus, further divide it into 5 sorts, and formulate each of 3 sorts therein into a sum of 3 unit fractions.

For two unsolved sorts $\frac{4}{49+120 c}$ and $\frac{4}{121+120 c}$ where $c \geq 0$, we use two unit fractions plus a proper fraction to replace each of them, then take out these two unit fractions as $\frac{1}{X}$ and $\frac{1}{Y}$. After that, prove that the remainder can be identically converted to $\frac{1}{Z}$.

Keywords: Erdös-Straus conjecture; Diophantine equation; unit fraction

## 1. Introduction

The Erdös-Straus conjecture relates to Egyptian fractions. In 1948, Paul Erdös conjectured that for any integer $n \geq 2$, there are invariably $\frac{4}{\mathrm{n}}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$, where $\mathrm{x}, \mathrm{y}$ and z are positive integers; [1]. Later, Ernst G. Straus further conjectured that $x, y$ and $z$ satisfy $x \neq y, y \neq z$ and $\mathrm{z} \neq \mathrm{x}$, because there are the convertible formulas $\frac{1}{2 \mathrm{r}}+\frac{1}{2 r}=\frac{1}{r+1}+\frac{1}{r(r+1)}$ and $\frac{1}{2 r+1}+\frac{1}{2 r+1}=\frac{1}{r+1}+\frac{1}{(r+1)(2 r+1)}$ where $\mathrm{r} \geq 1 ;$ [2]. Thus, the Erdös conjecture and the Straus conjecture are equivalent from each other, and they are called the Erdös-Straus conjecture collectively. As a general rule, the Erdös-Straus conjecture states that for every integer $n \geq 2$, there are positive integers $x, y$ and $z$, such that $\frac{4}{n}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$. Yet it remains a conjecture that has neither is proved nor disproved; [3].

## 2. Divide integers $\geq 2$ into 8 kinds and formulate 7 kinds therein

First, divide integers $\geq 2$ into 8 kinds, i.e. $8 \mathrm{k}+1$ with $\mathrm{k} \geq 1$, and $8 \mathrm{k}+2,8 \mathrm{k}+3$, $8 \mathrm{k}+4,8 \mathrm{k}+5,8 \mathrm{k}+6,8 \mathrm{k}+7,8 \mathrm{k}+8$, where $\mathrm{k} \geq 0$, and arrange them as follows: $\mathrm{K} \backslash \mathrm{n}: 8 \mathrm{k}+1, \quad 8 \mathrm{k}+2, \quad 8 \mathrm{k}+3, \quad 8 \mathrm{k}+4, \quad 8 \mathrm{k}+5, \quad 8 \mathrm{k}+6, \quad 8 \mathrm{k}+7, \quad 8 \mathrm{k}+8$
0 ,
(1),
2 , 3 ,
4, $\quad 5$,
6, 7, 8,
1, 9 ,
10, 11,
12. 13 ,
$14, \quad 15, \quad 16$,

| 2, | 17, | 18, | 19, | 20, | 21, | 22, | 23, | 24, |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 3, | 25, | 26, | 27, | 28, | 29, | 30, | 31, | 32, |

Excepting $\mathrm{n}=8 \mathrm{k}+1$, formulate each of other 7 kinds into $\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$ :
(1) For $\mathrm{n}=8 \mathrm{k}+2$, there are $\frac{4}{8 k+2}=\frac{1}{4 k+1}+\frac{1}{4 k+2}+\frac{1}{(4 k+1)(4 k+2)}$;
(2) For $\mathrm{n}=8 \mathrm{k}+3$, there are $\frac{4}{8 k+3}=\frac{1}{2 k+2}+\frac{1}{(2 k+1)(2 k+2)}+\frac{1}{(2 k+1)(8 k+3)}$;
(3) For $\mathrm{n}=8 \mathrm{k}+4$, there are $\frac{4}{8 k+4}=\frac{1}{2 k+3}+\frac{1}{(2 k+2)(2 k+3)}+\frac{1}{(2 k+1)(2 k+2)}$;
(4) For $n=8 k+5$, there are $\frac{4}{8 k+5}=\frac{1}{2 k+2}+\frac{1}{(8 k+5)(2 k+2)}+\frac{1}{(8 k+5)(k+1)}$;
(5) For $\mathrm{n}=8 \mathrm{k}+6$, there are $\frac{4}{8 k+6}=\frac{1}{4 k+3}+\frac{1}{4 k+4}+\frac{1}{(4 k+3)(4 k+4)}$;
(6) For $\mathrm{n}=8 \mathrm{k}+7$, there are $\frac{4}{8 k+7}=\frac{1}{2 k+3}+\frac{1}{(2 k+2)(2 k+3)}+\frac{1}{(2 k+2)(8 k+7)}$;
(7) For $\mathrm{n}=8 \mathrm{k}+8$, there are $\frac{4}{8 k+8}=\frac{1}{2 k+4}+\frac{1}{(2 k+2)(2 k+3)}+\frac{1}{(2 k+3)(2 k+4)}$.

By this token, n as above 7 kinds of integers be suitable to the conjecture.

## 3. Divide the unsolved kind into 3 genera and formulate $\mathbf{2}$ genera therein

For the unsolved kind $\mathrm{n}=8 \mathrm{k}+1$ with $\mathrm{k} \geq 1$, divide it by 3 and get 3 genera:
(1) the remainder is 0 when $\mathrm{k}=1+3 \mathrm{t}$; (2) the remainder is 2 when $\mathrm{k}=2+3 \mathrm{t}$;
(3) the remainder is 1 when $\mathrm{k}=3+3 \mathrm{t}$, where $\mathrm{t} \geq 0$, and ut infra.
k :

$$
1,2, \quad 3, \quad 4, \quad 5, \quad 6, \quad 7, \quad 8, \quad 9, \quad 10,11,12, \quad 13,14, \quad 15, \ldots
$$

$8 \mathrm{k}+1: \quad 9,17,25, \quad 33,41,49, \quad 57,65,73, \quad 81,89,97, \quad 105,113,121, \ldots$

The remainder: $0,2,1, \quad 0,2,1,0,2,1,0,2,1, \quad 0,2,1, \ldots$
Excepting the genus (3), we formulate other 2 genera as follows:
(8) For $\frac{8 k+1}{3}$ where the remainder is equal to 0 , there are $\frac{4}{8 k+1}=\frac{1}{\frac{8 k+1}{3}}+\frac{1}{8 k+2}+\frac{1}{(8 k+1)(8 k+2)}$

Due to $\mathrm{k}=1+3 \mathrm{t}$ and $\mathrm{t} \geq 0$, there are $\frac{8 k+1}{3}=8 t+3$, so we confirm that $\frac{8 k+1}{3}$ in the preceding equation is an integer.
(9) For $\frac{8 k+1}{3}$ where the remainder is equal to 2 , there are $\frac{4}{8 k+1}=\frac{1}{\frac{8 k+2}{3}}+\frac{1}{8 k+1}+\frac{1}{\frac{(8 k+1)(8 k+2)}{3}}$.

Due to $\mathrm{k}=2+3 \mathrm{t}$ and $\mathrm{t} \geq 0$, there are $\frac{8 k+2}{3}=8 t+6$, so we confirm that $\frac{8 k+2}{3}$ and $\frac{(8 k+1)(8 k+2)}{3}$ in the preceding equation are two integers.

## 4. Divide the unsolved genus into 5 sorts and formulate 3 sorts therein

For the unsolved genus $\frac{8 k+1}{3}$ where the remainder is equal to 1 when $\mathrm{k}=3+3 \mathrm{t}$ and $\mathrm{t} \geq 0$, then there are $8 \mathrm{k}+1=25,49,73,97,121$ etc. So we divide
them into 5 sorts: $25+120 \mathrm{c}, 49+120 \mathrm{c}, 73+120 \mathrm{c}, 97+120 \mathrm{c}$ and $121+120 \mathrm{c}$ where $\mathrm{c} \geq 0$, and ut infra.
C\n: $25+120 \mathrm{c}, 49+120 \mathrm{c}, \quad 73+120 \mathrm{c}, \quad 97+120 \mathrm{c}, \quad 121+120 \mathrm{c}$,

| 0, | 25, | 49, | 73, | 97, | 121, |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 1, | 145, | 169, | 193, | 217, | 241, |
| 2, | 265, | 289, | 313, | 337, | 361, |
| $\ldots$, | $\ldots$, | $\ldots$, | $\ldots$, | $\ldots$, | $\ldots$, |

Excepting $n=49+120 \mathrm{c}$ and $\mathrm{n}=121+120 \mathrm{c}$, formulate other 3 sorts, they are:
(10) For $\mathrm{n}=25+120 \mathrm{c}$, there are $\frac{4}{25+120 c}=\frac{1}{25+120 c}+\frac{1}{50+240 c}+\frac{1}{10+48 c}$;
(11) For $n=73+120 \mathrm{c}$, there are $\frac{4}{73+120 c}=\frac{1}{(73+120 c)(10+15 c)}+\frac{1}{20+30 c}+\frac{1}{(73+120 c)(4+6 c)} ;$
(12) For $n=97+120 \mathrm{c}$, there are $\frac{4}{97+120 c}=\frac{1}{25+30 c}+\frac{1}{(97+120 c)(50+60 c)}+\frac{1}{(97+120 c)(10+12 c)}$.

For each of listed above 12 equations which express $\frac{4}{n}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$, please each reader self to make a check respectively.
5. Prove the sort $\frac{4}{49+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$

For a proof of the sort $\frac{4}{49+120 c}$, it means that when c is equal to each of positive integers plus 0 , there always are $\frac{4}{49+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$.

After c is given any value, $\frac{4}{49+120 c}$ can be substituted by each of infinite more a sum of two unit fractions plus a proper fraction, and that these fractions are different from one another, as listed below:
$\frac{4}{49+120 c}$
$=\frac{1}{13+30 c}+\frac{1}{(13+30 c)(49+120 c)}+\frac{2}{(13+30 c)(49+120 c)}$
$=\frac{1}{14+30 c}+\frac{1}{(14+30 c)(49+120 c)}+\frac{6}{(14+30 c)(49+120 c)}$
$=\frac{1}{15+30 c}+\frac{1}{(15+30 c)(49+120 c)}+\frac{10}{(15+30 c)(49+120 c)}$
$=\frac{1}{13+\alpha+30 c}+\frac{1}{(13+\alpha+30 c)(49+120 c)}+\frac{4 \alpha+2}{(13+\alpha+30 c)(49+120 c)}$, where $\alpha \geq 0$ and $\mathrm{c} \geq 0$

As listed above, we can first let $\frac{1}{13+\alpha+30 c}=\frac{1}{X}$ and $\frac{1}{(13+\alpha+30 c)(49+120 c)}=\frac{1}{Y}$, then go to prove $\frac{4 \alpha+2}{(13+\alpha+30 c)(49+120 c)}=\frac{1}{Z}$ where $\mathrm{c} \geq 0$ and $\alpha \geq 0$, ut infra.

Proof. First, let us compare the values of the numerator $4 \alpha+2$ and the denominator $(13+\alpha+30 c)(49+120 c)$.

Since there is $c \geq 0$, so $13+\alpha+30$ c can always be greater than $4 \alpha+2$. And then, let us just take $13+\alpha+30 \mathrm{c}$ in the denominator, while reserve
$49+120 \mathrm{c}$ for later.

In the fraction $\frac{4 \alpha+2}{13+\alpha+30 c}$, since the numerator $4 \alpha+2$ is an even number, such that the denominator $13+\alpha+30$ c must be an even numbers. Only in this case, it can reduce the fraction to become possibly an unit fraction, so $\alpha$ in the denominator $13+\alpha+30$ c can only be each of positive odd numbers. After $\alpha$ is assigned to odd numbers 1, 3, 5 and otherwise, and the numerator and the denominator of the fraction $\frac{4 \alpha+2}{13+\alpha+30 c}$ after the values assignment divided by 2 , then the fraction $\frac{4 \alpha+2}{13+\alpha+30 c}$ is turned into the fraction $\frac{3+4 t}{k+15 c}$ identically, where $\mathrm{c} \geq 0, \mathrm{t} \geq 0$ and $\mathrm{k} \geq 7$. The noteworthy point above is that $3+4 \mathrm{t}$ and $\mathrm{k}+15 \mathrm{c}$ after the values assignment make up a fraction, they are on the same order of taking values of t and k , according to the order from small to large, i.e. $\frac{3+4 t}{k+15 c}=\frac{3}{7+15 c}, \frac{7}{8+15 c}, \frac{11}{9+15 c}, \ldots$

Such being the case, letting the numerator and the denominator of the fraction $\frac{3+4 t}{k+15 c}$ divided by $3+4 t$, then we get a temporary indeterminate unit fraction, and its denominator is $\frac{k+15 c}{3+4 t}$, and its numerator is 1.

Thus, we are necessary to prove that the denominator $\frac{k+15 c}{3+4 t}$ is able to
become a positive integer in the case where $\mathrm{t} \geq 0, \mathrm{k} \geq 7$ and $\mathrm{c} \geq 0$.
In the fraction $\frac{k+15 c}{3+4 t}$, due to $k \geq 7$, the numerator $k+15 c$ after the values assignment are infinite more consecutive positive integers, while the denominator $3+4 \mathrm{t}=3,7,11$ and otherwise positive odd numbers.

The key above is that each value of $3+4 \mathrm{t}$ after the values assignment can seek its integral multiples within infinite more consecutive positive integers of $\mathrm{k}+15 \mathrm{c}$, in the case where $\mathrm{t} \geq 0, \mathrm{k} \geq 7$ and $\mathrm{c} \geq 0$.

As is known to all, there is a positive integer that contains the odd factor $2 \mathrm{n}+1$ within $2 \mathrm{n}+1$ consecutive positive integers, where $\mathrm{n}=1,2,3, \ldots$

Like that, there is a positive integer that contains the odd factor $3+4$ t within $3+4 \mathrm{t}$ consecutive positive integers of $\mathrm{k}+15 \mathrm{c}$, no matter which odd number that $3+4 \mathrm{t}$ is equal to, where $\mathrm{t} \geq 0, \mathrm{k} \geq 7$ and $\mathrm{c} \geq 0$. It is obvious that a fraction that consists of such a positive integer as the numerator and $3+4 t$ as the denominator is an improper fraction.

Undoubtedly, every such improper fraction that is found in this way, via the reduction, it is surely a positive integer.

That is to say, $\frac{k+15 c}{3+4 t}$ as the denominator of the aforesaid temporary indeterminate unit fraction can become a positive integer, and the positive integer is represented by $\mu$. So, the fraction $\frac{3+4 t}{k+15 c}$ is exactly $\frac{1}{\mu}$.

For the unit fraction $\frac{1}{\mu}$, multiply its denominator by $49+120$ c reserved, then we get the unit fraction $\frac{1}{\mu(49+120 c)}$, and let $\frac{1}{\mu(49+120 c)}=\frac{1}{Z}$.

Since $\frac{1}{(13+\alpha+30 c)(49+120 c)}+\frac{4 \alpha+2}{(13+\alpha+30 c)(49+120 c)}$ are equal to $\frac{4 \alpha+3}{(13+\alpha+30 c)(49+120 c)}$, so if $4 \alpha+3$ serve as one numerator such that $\frac{4 \alpha+3}{(13+\alpha+30 c)(49+120 c)}$ is an unit fraction, then we can multiply the denominator of the unit fraction by 2 to make a sum of two identical unit fractions, then again, convert them into the sum of two each other's distinct unit fractions by the formula $\frac{1}{2 \mathrm{r}}+\frac{1}{2 r}=\frac{1}{r+1}+\frac{1}{r(r+1)}$.

Thus it can be seen, the fraction $\frac{4 \alpha+3}{(13+\alpha+30 c)(49+120 c)}$ is able to be expressed into a sum of two each other's -distinct unit fractions in the case where $\mathrm{c} \geq 0$ and $\alpha \geq 0$.

Let us synthesize the above results inferred, then get the equation $\frac{4}{49+120 c}=\frac{1}{13+\alpha+30 c}+\frac{1}{(13+\alpha+30 c)(49+120 c)}+\frac{1}{\mu(49+120 c)} \quad$, where $\alpha \geq 0, \mu$ is an integer and $\mu=\frac{k+15 c}{3+4 t}, \mathrm{t} \geq 0, \mathrm{k} \geq 7$ and $\mathrm{c} \geq 0$.

In other words, we have proved $\frac{4}{49+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$.

## 6. Prove the sort $\frac{4}{121+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$

The proof in this section is exactly similar to that in the section 5 . Namely, for a proof of the sort $\frac{4}{121+120 c}$, it means that when c is equal to each of positive integers plus 0 , there always are $\frac{4}{121+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$. After c is given any value, $\frac{4}{121+120 c}$ can be substituted by each of infinite more a sum of two unit fractions plus a proper fraction, and that these fractions are different from one another, as listed below.

$$
\frac{4}{121+120 c}
$$

$=\frac{1}{31+30 c}+\frac{1}{(31+30 c)(121+120 c)}+\frac{2}{(31+30 c)(121+120 c)}$
$=\frac{1}{32+30 c}+\frac{1}{(32+30 c)(121+120 c)}+\frac{6}{(32+30 c)(121+120 c)}$
$=\frac{1}{33+30 c}+\frac{1}{(33+30 c)(121+120 c)}+\frac{10}{(33+30 c)(121+120 c)}$
$=\frac{1}{31+\alpha+30 c}+\frac{1}{(31+\alpha+30 c)(121+120 c)}+\frac{4 \alpha+2}{(31+\alpha+30 c)(121+120 c)}$, where $\alpha \geq 0$
and $\mathrm{c} \geq 0$.

As listed above, we can first let $\frac{1}{31+\alpha+30 c}=\frac{1}{X}$ and
$\frac{1}{(31+\alpha+30 c)(121+120 c)}=\frac{1}{Y}$, then go to prove $\frac{4 \alpha+2}{(31+\alpha+30 c)(121+120 c)}=\frac{1}{Z}$ where $\alpha \geq 0$ and $c \geq 0$, ut infra.

Proof. First, let us compare the values of the numerator $4 \alpha+2$ and the denominator $(31+\alpha+30 c)(121+120 c)$.

Since there is $c \geq 0$, so $31+\alpha+30$ c can always be greater than $4 \alpha+2$. And then, let us just take $31+\alpha+30 \mathrm{c}$ in the denominator, while reserve $121+120 \mathrm{c}$ for later.

In the fraction $\frac{4 \alpha+2}{31+\alpha+30 c}$, since the numerator $4 \alpha+2$ is an even number, such that the denominator $31+\alpha+30$ c must be an even numbers. Only in this case, it can reduce the fraction to become possibly an unit fraction, so $\alpha$ in the denominator $31+\alpha+30$ c can only be each of positive odd numbers. After $\alpha$ is assigned to odd numbers 1, 3, 5 and otherwise, and the numerator and the denominator of the fraction $\frac{4 \alpha+2}{31+\alpha+30 c}$ after the values assignment divided by 2 , then the fraction $\frac{4 \alpha+2}{31+\alpha+30 c}$ is turned into the fraction $\frac{3+4 t}{m+15 c}$ identically, where $\mathrm{c} \geq 0, \mathrm{t} \geq 0$ and $\mathrm{m} \geq 16$.

The noteworthy point above is that $3+4 \mathrm{t}$ and $\mathrm{m}+15 \mathrm{c}$ after the values assignment make up a fraction, they are on the same order of taking values of t and m , according to the order from small to large, i.e.
$\frac{3+4 t}{m+15 c}=\frac{3}{16+15 c}, \frac{7}{17+15 c}, \frac{11}{18+15 c}, \ldots$
Such being the case, letting the numerator and the denominator of the fraction $\frac{3+4 t}{m+15 c}$ divided by $3+4 t$, then we get a temporary indeterminate unit fraction, and its denominator is $\frac{m+15 c}{3+4 t}$, and its numerator is 1 .

Thus, we are necessary to prove that the denominator $\frac{m+15 c}{3+4 t}$ is able to become a positive integer in the case where $t \geq 0, \mathrm{~m} \geq 16$ and $\mathrm{c} \geq 0$.

In the fraction $\frac{m+15 c}{3+4 t}$, due to $\mathrm{m} \geq 16$, the numerator $\mathrm{m}+15 \mathrm{c}$ after the values assignment are infinite more consecutive positive integers, while the denominator $3+4 t=3,7,11$ and otherwise positive odd numbers.

The key above is that each value of $3+4 \mathrm{t}$ after the values assignment can seek its integral multiples within infinite more consecutive positive integers of $\mathrm{m}+15 \mathrm{c}$ in the case where $\mathrm{t} \geq 0, \mathrm{~m} \geq 16$ and $\mathrm{c} \geq 0$.

As is known to all, there is a positive integer that contains the odd factor $2 \mathrm{n}+1$ within $2 \mathrm{n}+1$ consecutive positive integers, where $\mathrm{n}=1,2,3, \ldots$

Like that, there is a positive integer that contains the odd factor $3+4 \mathrm{t}$ within $3+4 \mathrm{t}$ consecutive positive integers of $\mathrm{m}+15 \mathrm{c}$, no matter which odd number that $3+4 \mathrm{t}$ is equal to, where $\mathrm{t} \geq 0, \mathrm{~m} \geq 16$ and $\mathrm{c} \geq 0$. It is obvious that a fraction that consists of such a positive integer as the numerator and $3+4 \mathrm{t}$ as the denominator is an improper fraction.

Undoubtedly, every such improper fraction that is found in this way, via the reduction, it is surely a positive integer.

That is to say, $\frac{m+15 c}{3+4 t}$ as the denominator of the aforesaid temporary indeterminate unit fraction can become a positive integer, and the positive integer is represented by $\lambda$. So, the fraction $\frac{3+4 t}{m+15 c}$ is exactly $\frac{1}{\lambda}$.

For the unit fraction $\frac{1}{\lambda}$, multiply its denominator by $121+120 \mathrm{c}$ reserved, then we get the unit fraction $\frac{1}{\lambda(121+120 c)}$, and let $\frac{1}{\lambda(121+120 c)}=\frac{1}{Z}$.
Since $\frac{1}{(31+\alpha+30 c)(121+120 c)}+\frac{4 \alpha+2}{(31+\alpha+30 c)(121+120 c)}$ are equal to $\frac{4 \alpha+3}{(31+\alpha+30 c)(121+120 c)}$, so if $4 \alpha+3$ serve as one numerator such that $\frac{4 \alpha+3}{(31+\alpha+30 c)(121+120 c)}$ is an unit fraction, then we can multiply the denominator of the unit fraction by 2 to make a sum of two identical unit fractions, then again, convert them into the sum of two each other's distinct unit fractions by the formula $\frac{1}{2 \mathrm{r}}+\frac{1}{2 r}=\frac{1}{r+1}+\frac{1}{r(r+1)}$.

Thus it can be seen, the fraction $\frac{4 \alpha+3}{(31+\alpha+30 c)(121+120 c)}$ is able to be expressed into a sum of two each other's -distinct unit fractions in the case where $\alpha \geq 0$ and $c \geq 0$.

Let us synthesize the above results inferred, then get the equation
$\frac{4}{121+120 c}=\frac{1}{31+\alpha+30 c}+\frac{1}{(31+\alpha+30 c)(121+120 c)}+\frac{1}{\lambda(121+120 c)}$, where $\lambda$ is an integer and $\lambda=\frac{m+15 c}{3+4 t}, \mathrm{t} \geq 0, \mathrm{~m} \geq 16$, and $\mathrm{c} \geq 0$.

In other words, we have proved $\frac{4}{121+120 c}=\frac{1}{X}+\frac{1}{Y}+\frac{1}{Z}$.
The proof was thus brought to a close. As a consequence, the ErdösStraus conjecture is tenable.
