# Skolem Revisited 

## Thoralf's Achilles heel

Hannes Hutzelmeyer

## Summary

The author has developed an approach to logics that comprises, but also goes beyond predicate logic. The FUME method contains two tiers of precise languages: object-language Funcish and metalanguage Mencish. It allows for a very wide application in mathematics from geometry, number theory, recursion theory and axiomatic set theory with first-order logic, to higher-order logic theory of real numbers and a precise analysis of foundation of mathematics in general, including theory of types.

A famous paper by Thoralf Skolem of 1934 is usually put at the beginning of publications on nonstandard arithmetic. A critical investigation shows that it has serious, if not even insurmountable problems. Firstly one notices that it is based on second-order logic, it has unary and binary functionvariables, and binary operator-constants (that map two functions to a function). It seems strange that one makes a fundamental statement about first-order logic systems using second order.

In proving Satz 1 on the asymptotic behavior of arithmetic functions Skolem has some inaccuracies and formal errors. These minor problems can be solved by diligent work. But even if one has replaced his metalingual use of his relation symbols $\boldsymbol{B}_{\boldsymbol{i}}$ by an ontologically correct method there remains secondly the problem of transitivity of the minority relation of functions that is neglected by Skolem.

Thirdly, in constructing the strictly ascending function $g$ of Satz 1 use is made of recursion by a dot-dot-dot notation. This is not an admissible procedure in object-language, although there may be a correct way to solve the problem in metalanguage.
Therefore one does not only need second-order logic in combination with a precise object-language (in order to avoid ontology problems) but also a precise use of metalanguage (in order to avoid dot-dot-dot) for justifying Skolem's Satz 1 after one has eventually solved the transitivity problem; Skolem's Satz 2 would then be valid. However, as long as Satz 1 is not confirmed it does not pay to treat Satz 3 and Satz 4 , leaving open the existence of non-standard models of arithmetic on the basis of Skolem's work.

## Warning

The author has taken the liberty of changing the usual meaning of some expressions and to coin some new expressions. He has tried to mark these appearances properly; if he has failed to do so in some places he asks for your understanding. Your comments are welcome.

## 1. FUME-method object-language and metalanguage

It all started in the year of 1879 when Gottlieb Frege put forward his revolutionary 'Begriffsschrift'. Until then the syllogism logic of Aristotle had been considered to be sufficient as the basis of logical reasoning and therefore also of mathematics. Besides the usual logical characters $=\neq \neg \vee \wedge \rightarrow \leftrightarrow$ quantors $\exists$ $\forall$ and variables like e.g. A1 or A13 were introduced together with the rules for omnition $\forall \mathrm{A}_{1}[\ldots]$ and entition $\exists \mathrm{A}_{2}[\ldots$ ] as well as relation-constant and function-constant strings that allowed for expressing logic-sentences in a proper fashion. Freges notation differs from this modern form, but that is irrelevant.

The author has put forward a precise system of object-language and metalanguage that overcomes certain difficulties of predicate logic and that can be extended to a full theory of types. In order to describe an object-language one also needs a metalanguage. According to the author's principle metalanguage has to be absolutely precise as well, normal English will not do. The FUME-method contains at least three tiers of language:

| Funcish | object-language | formalized precise |
| :--- | :--- | :--- |
| Mencish | metalanguage | formalized precise |
| English | supralanguage | common, mostly not precise |

'Calcule' is the name given to a mathematical system with the precise language-metalanguage method Funcish-Mencish . 'Calcule' is an expression coined by the author in order to avoid confusion. The word 'calculus' is conventionally used for real number mathematics and various logical systems. As a German translation 'Kalkul' is proposed for 'calcule' versus conventional 'Kalkül' that usually is translated as 'calculus'.

A concrete calcule talks about a codex of concrete individuals (given as strings of characters) and concrete functions and relations that can be realized by 'machines' (called calculators). An abstract calcule talks about nothing. It only says: if some entities exist with such and such properties they also have certain other properties. Essentially there are only 'if-then' statements. E.g. 'if there are entities that obey the Euclid axioms the following sentence is true for these entities' .

Calcules with first-order logic FOL are called haplo-calcules, calcules with higher-order logic HOL for a theory of types are called hypso-calcules. An abstract calcule is based on a finite count or on enumerably many axioms as opposed to a concrete calcule whose foundation can be put into practice by a machine. Axiom strings are certain sentence strings, they can also be provided with a metalingual Axiom mater (rather than the usual 'scheme' or 'schema', as the expression scheme has a different meaning in Mencish), that produce enumerably many Axiom strings.

In supralanguage English calcules are given names based on the Greek sort names. They are constructed from the sort strings that appear in it, using the Latin names of the Greek letters of object language Funcish. Concrete calcule sort strings have all-capital-letter or all-capital-letter-onset words, abstract calcules have small-letter words. The first letter of the first sort name classifies a calcule according to some convention rules.The sort string names are separated by blank and completely underlined. Higherorder logic calcules are characterized by a final letter python ${ }^{1)} \varpi$ separated by a blank. Python is also the final character in relevant sort strings. Examples:
abstract calcules
alpha with sort $\alpha$
concrete calcule

- ALPHA with sort A
- ALPHApython with sort A $\quad$.
${ }^{1)}$ Distinguish the Greek characters: capital pi $\Pi$, small pi $\pi$ and python $\varpi$ (pronounce as in 'Monty Python').

The fonts-method allows to distinguish between object-language (Arial and Symbol, normal, e.g. $\forall \alpha 1[$ ), metalanguage (Arial and Symbol, boldface italics e.g. $\alpha 1$ or Axiom) and supralanguage English (Times New Roman).

For quoting Skolem and sometimes for better understanding mathematical expressions are written conventionally in supralanguage English using italics (heuristically, not fully precise) e.g. :

- numbers $012 \ldots$ constants $a b \ldots$ variables $i j m n t x y \ldots$ symbols $+-/()=,\langle \rangle$ multiplication $x y$
- a series of unary functions $f_{0} f_{1} f_{2} \ldots$ with values at $x$ denoted as $f_{0}(x) f_{1}(x) f_{2}(x) \ldots$
- the value of binary function $f$ with values at $x, y$ denoted as $f(x, y)$
- a binary operator $B$ with value at unary functions $f$ and $g$ denoted as $B(f, g)$ and its value at $x$ denoted as $B(f, g)(x)$, composition of $f$ and $g$ denoted as $\left(f^{o} g\right)(x)=f(g(x))$
- the appearance of a variable e.g. $t$ in an expression means 'for all $t^{\prime}$.

In supralanguage English metacalcules are given names that correspond uniquely to their objectcalcules: the Times New Roman fonts are chosen as boldface italic, otherwise they are the same.

Figure 1 Hierarchy of languages and codices for two example calcules
Metalanguage Mencish is chosen with perfect exactness, just as object-language Funcish. They both have to meet the calculation criterion of truth: every step of reasoning must be such that it can be checked by a calculating machine. Funcish and Mencish sentences and metasentences resp.are understandable without context: 'wherefore by their words ye shall know them' (vs. Mathew 7.20).

On first sight Funcish and Mencish look familiar to what one knows from predicate-logic. However, they are especially adapted to a degree of precision so that they can be used universally for all kind of mathematics. And they lend themselves immediately to a treatment by computers, as they have perfect syntax and semantics. It is not the place to go into details. Both Funcish and Mencish have essentially the same syntax. Notice that Funcish has a context-independent notation, which implies that one can determine the category of every object uniquely from its syntax. The reader may be puzzled by some expressions that are either newly coined by the author or used slightly different from convention. This is done in good faith; the reason for the so-called Bavarian notation is to avoid ambiguities.

The essential parts of a language are its sentences. A sentence is a string of characters of a given alphabet that fulfills certain syntactical and semantical rules. This means that metalanguage talks about the strings of the object-language. The essential parts of the metalanguage are the metasentences (that are strings of characters as well, just in boldface italics). In supralanguage one talks about the metasentences, just as metalanguage talks about object-language. Here it is not discussed in general what an object-language talks about .

## 2. Concrete hypso-calcule ALPHApython of Monty-arithmetic with second-order logic

In 1934 Thoralf Skolem put forward his famous paper ${ }^{1)}$ that shows how to construct non-standard models of arithmetic. Skolem's shortcoming is his use of second-order logic. In the world of denumerability second-order logic has no rightful place! Can one remove this bond ? The language system of the FUMEmethod is a theory of types and therefore capable of expressing higher-order logic precisely. So the first thing to do is to to express Skolem's theorems Satz 1, Satz 2, Satz 3 and Satz 4 in proper language.

For further discussion one has to take refuge to examples. Although Skolem uses second-order logic, he only regards entities that are at most denumerable. It will be investigated to what extent this justifies Skolem's reasoning. Here we do not use the full machinery of Mencish by whose application everything can be done with absolute preciseness. We just write down the Basiom strings in the Appendix , that are basic true sentence strings (that are obtained by observing the defining aponom strings - not treated here) and correspond to Axiom strings of abstract calcules.
The concrete calcule ALPHA of arithmetic of naturals can be set up properly, here just its ontological basis is sketched. It is a haplo-calcule as it has first-order logic.

```
sort :: A
individual :: natural :: 0 | 1 | 2 ...
individual-constant :: An | Au | Ab ...
basis-function-constant :: (A+A) | (A }\times\textrm{A})|\quad\mathrm{ | addition, multiplication
(A\divA) trunctraction (truncated subtraction)
basis-relation-constant :: A<A minority
extra-function-constant:: A' | (A\div) succession, predecssion
extra-relation-constant :: A}\leq\textrm{A
```

Starting from haplo-calcule ALPHA of arithmetic of naturals the concrete hypso-calcule ALPHApython ${ }^{2)}$ of Monty-arithmetic of naturals is introduced. It will be the system for a reconstruction of Skolem's ideas in a precise fashion.
ontological basis is

| sort : | Aø |  |
| :---: | :---: | :---: |
| sort-array : |  | unary, binary, ternary, ... |
| type : | $(A \varpi)$ ' $(\mathrm{A} \varpi ; \mathrm{A} \varpi) \ldots$ | property, binary relation, ... |
|  | A $\ddagger$ ( $\mathrm{A} \varpi)$ ' $\mathrm{A} \varpi(\mathrm{A} \varpi ; \mathrm{A} \varpi)$ i | unary function, binary function, ... |
|  | ( $\mathrm{A} \varpi(\mathrm{A} \varpi) ; А \varpi(\mathrm{~A} \varpi))$ | binary unary-function-predicate |
| basis-function-constant : : | $(\mathrm{A} \varpi+\mathrm{A} \varpi) \mathrm{i}(\mathrm{A} \varpi \times \mathrm{A} \varpi) \mathrm{i}$ | addition, multiplication |
|  | ( $\mathrm{A} \varpi \div \mathrm{A} \varpi$ ) | trunctraction |
| basis-relation-constant :: | A $\varpi<$ A $\varpi$ | minority |
| extra-function-constant : | $A \varpi^{\prime}{ }^{\prime}(\mathrm{A} \div)$ | succession, predecession |
| extra-relation-constant :: | $A \sigma \leq A \varpi$ | equal-minority |

There are two ways to look at unary arithmetic functions. With second-order logic a unary function is anything formally introduced such that it produces a unique output value for an input value (one can say 'for all functions' and 'there exist a function' . With first-order logic the best one can do is to have a binary function-constant and treat the first argument as a parameter so that one can say 'for all functions of a series' .
${ }^{1)}$ Skolem, Thoralf "Über die Nicht-charakterisierbarkeit der Zahlenreihe mittels endlich oder abzählbar unendlich vieler Aussagen mit ausschliesslich Zahlenvariablen" Fundamenta Mathematicae T. XXIII (1934) p. 150-161
${ }^{2)}$ pronounce as in Monty Python

## 3. Skolem's Satz 1 in precise language

Skolem's Satz 1 is translated as follows: For a binary arithmetic function ${ }^{1)} f(x, y)$ (Skolem calls it a series ${ }^{2)}$ $\left.f_{0}(t), f_{l}(t), f_{2}(t) \ldots\right)$ there is a strictly ascending function ${ }^{1)} g(y)$ and a binary arithmetic function ${ }^{1)} t(x, y)$ such that for any pair of first arguments $x=a$ for $x=b$ it holds that the two unary functions of $y$ i.e. $f(a, g(y))$ and $f(b, g(y))$ are either equal or minor or major to each other for all $y$ greater than $t(a, b)$.

Observation 1: Skolem does not specify what he considers to be an arithmetic function. It is trivial that the three possibilities are mutually exclusive. It is not stated that there is only one functions $g$, different functions $g$ may lead to different ordering of functions of the series. For a chosen unary function $g$ there is one binary $t$ that gives the lowest limit, all binary $s$ with greater values $t(x, y)<s(x, y)$ would do as well.

It reads as sentence in ALPHApython, with series written as $\mathrm{A} \varpi 1(0 ; A \varpi), \mathrm{A} \varpi 1(1 ; \mathrm{A} \varpi), \mathrm{A} \varpi 1(2 ; \mathrm{A} \varpi) \ldots$
A $\varpi$ S-Skolem1 $=\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi ; \mathrm{A} \varpi)[\exists \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[$

$[\forall \mathrm{A} \varpi 3[[\mathrm{~A} \varpi 2(\mathrm{~A} \varpi 1 ; \mathrm{A} \varpi 2)<\mathrm{A} \varpi 3] \rightarrow[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 1 ; \mathrm{A} \varpi 1(\mathrm{~A} \varpi 3))=\mathrm{A} \varpi 1(\mathrm{~A} \varpi 2 ; \mathrm{A} \varpi 1(\mathrm{~A} \varpi 3))]]] \vee$
$[\forall \mathrm{A} \varpi 3[[\mathrm{~A} \varpi 2(\mathrm{~A} \varpi 1 ; \mathrm{A} \varpi 2)<\mathrm{A} \varpi 3] \rightarrow[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 1 ; \mathrm{A} \varpi 1(\mathrm{~A} \varpi 3))<\mathrm{A} \varpi 1(\mathrm{~A} \varpi 2 ; \mathrm{A} \varpi 1(\mathrm{~A} \varpi 3))]]]] \vee$

What kind of animals are $A \varpi 1(A \varpi)$ so that one can call one of them $A \varpi G(A \varpi)$ ? Can it be contained in $A \varpi 1(A \varpi ; A \varpi)$ by a special $A \varpi g$ ? What kind of animals are $A \varpi 2(A \varpi ; A \varpi)$ so that one can call the smallest $A \varpi T(A \varpi ; A \varpi)$ ? Can it be constructed from $A \varpi 1$. Skolem starts with auxiliary sentence :

## 4. Auxiliary sentence for function pair comparison

For two unary arithmetic functions $a$ and $b$ there is a strictly ascending function $g$ such that along $g(t)$ the composed functions ( $a^{o} g$ ) and $\left(b^{o} g\right)$ with values $a(g(t))$ and $b(g(t))$ are equal $\boldsymbol{B}:=$, minor $\boldsymbol{B}:<$ or major $\boldsymbol{B}$ : > to each other: $a(g(t)) \boldsymbol{B} b(g(t))^{3)}$; the binary operator composition is written as $a(g(t))=\left(a^{o} g\right)(t)$. Actually it is meant that there is a binary operator $G$ that maps two functions $a$ and $b$ to function $g$, i.e. $g=G(a, b)$ and thus $g(t)=G(a, b)(t)$. Notice that $\boldsymbol{B}$ is a strange metalingual animal that has yet to be translated into a proper form so that one can use it in proper language.

```
AmS-Skolem1a= }\forall\textrm{A}\varpi1(\textrm{A}\varpi)[\forall\textrm{A}\varpi2(\textrm{A}\varpi)
[\existsA\varpi3(A\varpi)[[\forallA\varpi1[\forallA\varpi2[[A\varpi1<A\varpi2]->[A\varpiз(A\varpi1)<A\varpiз(A\varpi2)]]]]^
[[[\forallA\varpi1[A\varpi1(A\varpi3(A\varpi1))=A\varpi2(A\varpi3(A\varpi1))]]\vee[\forallA\varpi1[A\varpi1(A\varpiз(A\varpi1))<A\varpi2(A\varpi3(A\varpi1))]]]\vee
[\forallA\varpi1[A\varpi2(A\varpi3(A\varpi1))<A\varpi1(A\varpiз(A\varpi1))]]]]]]]
```

Observation 2: What kind of animal is Ашз(Аш) and how do you construct it? Three cases can be defined by three binary unary-function-predicates (that include unlimited enticles $\exists \mathrm{A} \omega 2$ [ ). The infinity condition in connection with $\exists \mathrm{A} \omega 2$ [ cannot be answered in general without having further information on $\mathrm{A} \omega 1(\mathrm{~A} \varpi)$ and $\forall \mathrm{A} \boldsymbol{\omega}_{2}(\mathrm{~A} \varpi)$, a problem not considered by Skolem.

```
\(\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[[\mathrm{EQG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi))] \leftrightarrow\)
    \(\left.\left.\left[\forall \mathrm{A} \varpi 1\left[\exists \mathrm{~A} \omega_{2}[[\mathrm{~A} \varpi 1<\mathrm{A} \varpi 2] \wedge[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 2)=\mathrm{A} \varpi 2(\mathrm{~A} \varpi 2)]]\right]\right]\right]\right]\)
\(\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[[\mathrm{MIG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi))] \leftrightarrow\)
    \([\forall \mathrm{A} \varpi 1[\exists \mathrm{~A} \varpi 2[[\mathrm{~A} \varpi 1<\mathrm{A} \varpi 2] \wedge[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 2)<\mathrm{A} \varpi 2(\mathrm{~A} \varpi 2)]]]]]]\)
\(\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[[\mathrm{MAG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi))] \leftrightarrow[\)
    \([\forall \mathrm{A} \varpi 1[\exists \mathrm{~A} \varpi 2[[\mathrm{~A} \varpi 1<\mathrm{A} \varpi 2] \wedge[\mathrm{A} \varpi 2(\mathrm{~A} \varpi 2)<\mathrm{A} \varpi 1(\mathrm{~A} \varpi 2)]]]]]]\)
```

${ }^{1)}$ usual sloppy conventional notation, the name of the function is $f$ and its values at $x$ and $y$ are $f(x, y)$
2) Skolem starts with index 1
${ }^{3)}$ in conventional notation the appearance of a variable $t$ in an expression means 'for all $t$ ' (in proper notation with $\forall$ )

Skolem then has added the auxiliary sentence $A \varpi S$-Skolem1a, but is it really a THEOREM ?
Observation 3: The three cases can be mutually exclusive but they are are not always mutually exclusive as the example in classical notation shows where $e(x)$ denotes the entirition function for rounding-down

| take for | $\mathrm{A} \varpi 1(\mathrm{~A} \varpi)$ | function | $x-3 e(x / 3)$ | 0 | 1 | 2 | 0 | 1 | 2 | $\ldots$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| and for | $\mathrm{A} \varpi 2(\mathrm{~A} \varpi)$ | function | $2-(x-3 e(x / 3))$ | 2 | 1 | 0 | 2 | 1 | 0 | $\ldots$ |

Three choices of strictly ascending $\mathrm{A} \varpi 3(\mathrm{~A} \varpi)$ allow for all of the three possibilities:
$A \varpi M I G(A \omega) \quad 3 x \quad 0361215 \ldots$ minority-infinition
$A \varpi E Q G(A \varpi) 3 x+1 \quad 147101316 \ldots$ equality-infinition
A $\varpi M A G(A \varpi) \quad 3 x+258111417 \ldots$ majority-infinition
Determine $\mathrm{A} \varpi 3(\mathrm{~A} \varpi)$ recursively as $\mathrm{A} \varpi 0(\mathrm{~A} \varpi)$ for any of the three choices, say equality-infinity. It is always defined as it is put to 0 if the predicate is not met.
$\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[\exists \mathrm{A} \varpi 0(\mathrm{~A} \varpi)[[[\neg[\mathrm{EQG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi))]] \rightarrow[\forall \mathrm{A} \varpi 1[\mathrm{~A} \varpi 0(\mathrm{~A} \varpi 1)=0]]] \wedge$
$\left[[\mathrm{EQG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi))] \rightarrow\left[\left[\forall \mathrm{A} \boldsymbol{\omega}_{1}[[[\mathrm{~A} \varpi 1(\mathrm{~A} \varpi 1)=\mathrm{A} \varpi 2(\mathrm{~A} \varpi 1)] \wedge\right.\right.\right.$
$\left.\left.\left.\left[\forall \mathrm{A} \boldsymbol{\omega}_{2}\left[\left[\mathrm{~A} \boldsymbol{\omega}_{1}(\mathrm{~A} \varpi 2)=\mathrm{A} \varpi 2(\mathrm{~A} \varpi 2)\right] \rightarrow[\mathrm{A} \varpi 1 \leq \mathrm{A} \varpi 2]\right]\right]\right] \rightarrow[\mathrm{A} \varpi 0(0)=\mathrm{A} \varpi 1]\right]\right] \wedge$

$\left.\left.\left.\left.\left.\left.\left.\left.\left.[\forall \mathrm{A} \varpi 3[[[\mathrm{~A} \varpi 0(\mathrm{~A} \varpi 1)<\mathrm{A} \varpi 3] \wedge[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 3)=\mathrm{A} \varpi 2(\mathrm{~A} \varpi 3)]] \rightarrow[\mathrm{A} \varpi 2 \leq \mathrm{A} \varpi 3]]]] \rightarrow\left[\mathrm{A} \varpi 0\left(\mathrm{~A} \varpi 1^{\prime}\right)=\mathrm{A} \varpi 2\right]\right]\right]\right]\right]\right]\right]\right]\right]\right]$
Minority-infinity $\mathrm{A} \varpi \mathrm{MIG}(\mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi)$ and
majority-infinity $\mathrm{A} \varpi \mathrm{MAG}(\mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi)$ are defined accordingly.
Observation 4: This is a formulo with input $\mathrm{A} \varpi 1(\mathrm{~A} \varpi)$ and $\mathrm{A} \varpi 2(\mathrm{~A} \varpi)$ for output $\mathrm{A} \varpi 0(\mathrm{~A} \varpi)$. But how do you prove that it is a UNEX-binary-formulo that gives rise to an operator adjection $A \varpi E Q G(A \varpi(A \varpi) ; A \varpi(A \varpi) ; A \varpi)$ ? Similarily for adjections $A \varpi M I G(A \varpi(A \varpi) ; A \varpi(A \varpi) ; A \varpi)$ and $A \varpi M A G(A \varpi(A \varpi) ; A \varpi(A \varpi) ; A \varpi)$. Notice that the adjections produce the zero-function if the conditions are not fulfilled and therefor not ascending. The simple test is e.g. $\mathrm{A} \varpi E \mathrm{EG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; 1)=0$
Observation 5: One needs an algorithm for the unique definition of $А \varpi з(A \varpi)$. Firstly define a simple ternary relation comparity $\mathrm{CB}(\mathrm{A} \varpi ; \mathrm{A} \mp ; \mathrm{A} \varpi)$ as a mere junctive abbreviation
[CB(Aø1;Aø2;Aø3)] $\leftrightarrow$
$\left[\left[\left[\left[A \omega_{3}=0\right] \wedge\left[A \omega_{1}=A \omega_{2}\right]\right] \vee\left[\left[A \omega_{3}=1\right] \wedge\left[A \omega_{1}<A \omega_{2}\right]\right]\right] \vee\left[\left[1<A \omega_{3}\right] \wedge\left[A \omega_{2}<A \omega_{1}\right]\right]\right]$
Comparing adjection $\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1)=0$ or 1 or 2
Secondly define operator adjections comparison-selection $A \varpi G(A \varpi(A \varpi) ; A \varpi(A \varpi) ; A \varpi)$ (Skolem's $g(t)$ ) and comparison-codification $\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi)$ (for Skolem's $B$ ) that also take care of the case that there can be more than one possibility of equality, minority and majority. A first choice would be: prefer firstly equality and secondly minority:
$\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)\left[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)\left[\forall \mathrm{A} \mathrm{m}_{1}[\mathrm{[ }\right.\right.$
$[[A \varpi E Q G(A \varpi 1(A \varpi) ; A \varpi 2(A \varpi) ; 1) \neq 0] \rightarrow$
[[A $\varpi G(A \varpi 1(A \varpi) ; A \varpi 2(A \varpi) ; A \varpi 1)=A \varpi E Q G(A \varpi 1(A \varpi) ; A \varpi 2(A \varpi) ; A \varpi 1)] \wedge$
$[\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1)=0]]] \vee$
$[[[\mathrm{A} \varpi E Q G(\mathrm{~A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; 1)=0] \wedge[\mathrm{A} \varpi \mathrm{MIG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; 1) \neq 0]] \rightarrow$
[[A $\ddagger \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1)=\mathrm{A} \varpi \mathrm{MIG}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1) \wedge$
$[\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1)=1]]]] \vee$

## 5. Problems for the auxilary function

Now there is a uniquely defined function, but there might result problems furtherdown, if one uses this algorithm.

Observation 6: On the way to an ordering of functions that are supposed to constitue non-standard arithmetics it is aimed for some kind of equality and minority of two functions. It is based on a comparison-selection and usual equality and minority of the two functions along this line. With the above method it is not guaranteed that the choice of comparison-code is such that the relation is antisymmetric. One can circumnavigate the problem if one defines minority or majority only with respect to $i$ and $j$ where $i<j$ and adds the reflected case by negation.

| $i \mathrm{j}$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 |  |

comparison-codification $b(i, j)$
0 for $\sim 1$ for $\{2$ for $\}$

Observation 7: Furthermore: with the above method it is not yet proven that the choice of comparisoncode is such that the relation is transitive. One has yet to show that there is an algorithm for choosing the code for ambiguous cases so that transitivity is guaranteed!

$A \varpi S$-Skolem1aa $=\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 1[\forall \mathrm{~A} \varpi 2[[\mathrm{~A} \omega 1<\mathrm{A} \varpi 2] \rightarrow$
$[\mathrm{A} \varpi \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 1)<\mathrm{A} \varpi \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2)]]]]] \wedge$
[ $\forall \mathrm{A} \varpi 3$ [[CB( $\mathrm{A} \varpi 1(\mathrm{~A} \varpi \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 3)) ; \quad \mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 3)) ;$
$\mathrm{A} \varpi 2(\mathrm{~A} \varpi \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 3))]]]]]$
where $\mathrm{A} \varpi \mathrm{G}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 3)$ is Skolem's $G(a, b)(t)$ depending on two functions $a$ and $b$ with values $a(t)$ and $b(t)$ resp. and a chosen $B$ according to preference algorithm, that is now properly expressed by $\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi 1(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 2(\mathrm{~A} \varpi) ; \mathrm{A} \varpi 3)$

## 6. Auxiliary theorem of pair ordering

Skolem then adds another sentence that is actually a THEOREM, but still one has to improve his choice.
The pairs ( $i, j$ ) of numbers can be arranged as a series by antidiagonal pair-coding adpair $(i, j)=i+((i+j)(i+j+1)) / 2$. The reverse functions adrow and adcol are expressed with auxiliaryroot function $\operatorname{aux}(n)=e\left(\left(\left(e\left(^{2} r t(8 n+1)-1\right) / 2\right)\right.\right.$ by means of $\operatorname{adrow}(n)=e(n-(\operatorname{aux}(n)(\operatorname{aux}(n)+1)) / 2)$ and $\operatorname{adcol}(n)=e(((\operatorname{aux}(n)+1)(\operatorname{aux}(n)+2)) / 2-(n+1))$ using entirition $e(x)$.

A $\varpi$ S-Skolem1b $=\forall \mathrm{A} \varpi 1\left[\forall \mathrm{~A} \varpi 2\left[\exists \mathrm{~A} \varpi 0\left[(\mathrm{~A} \varpi 0+\mathrm{A} \varpi 0)=\left((\mathrm{A} \varpi 1+\mathrm{A} \varpi 1)+\left((\mathrm{A} \varpi 1+\mathrm{A} \varpi 2) \times\left(\mathrm{A} \varpi 1+\mathrm{A} \varpi 2^{\prime}\right)\right)\right)\right]\right]\right]$ determines antidiagonal-pair function $\operatorname{A} \omega \mathrm{PAI}(\mathrm{A} \varpi ; \mathrm{A} \omega)$ or Cantor pairing function and the inverses for row and column $\mathrm{A} \varpi \mathrm{ADROW}(\mathrm{A} \varpi)$ and $\mathrm{A} \varpi \mathrm{ADCOL}(\mathrm{A} \varpi)$ resp. using $\mathrm{A} \varpi \mathrm{AUX}(\mathrm{A} \varpi)$
$\forall A \varpi 1\left[\exists \mathrm{~A} \varpi 0\left[\left[(8 \times \mathrm{A} \varpi 1)^{\prime} \leq\left((4 \times(\mathrm{A} \varpi 0 \times \mathrm{A} \varpi 0))^{\prime} \times(4 \times(\mathrm{A} \varpi 0 \times \mathrm{A} \varpi 0))^{\prime}\right)\right] \wedge \wedge\right.\right.$ A $\omega \mathrm{AUX}(\mathrm{A} \varpi)$
$\left.\left.\left[\left((4 \times(\mathrm{A} \varpi 0 \times \mathrm{A} \varpi 0))^{\prime} \times(4 \times(\mathrm{A} \omega 0 \times \mathrm{A} \varpi 0))^{\prime}\right)<(8 \times \mathrm{A} \varpi 1)^{\prime \prime}\right]\right]\right]$
$\forall \mathrm{A} \varpi 1\left[\exists \mathrm{~A} \varpi 0\left[\exists \mathrm{~A} \varpi 2\left[\left[\left[(8 \times \mathrm{A} \varpi 1)^{\prime} \leq\left((4 \times(\mathrm{A} \varpi 2 \times \mathrm{A} \varpi 2))^{\prime} \times(4 \times(\mathrm{A} \varpi 2 \times \mathrm{A} \varpi 2))^{\prime}\right)\right] \wedge\right.\right.\right.\right.$ for A $\varpi \mathrm{ADROW}(\mathrm{A} \varpi)$
$\left.\left.\left.\left.\left[\left((4 \times(\mathrm{A} \varpi 2 \times \mathrm{A} \omega 2))^{\prime} \times(4 \times(\mathrm{A} \omega 2 \times \mathrm{A} \varpi 2))^{\prime}\right)<(8 \times \mathrm{A} \varpi 1)^{\prime \prime}\right]\right] \wedge\left[\left((\mathrm{A} \varpi 0+\mathrm{A} \varpi 0)+\left(\mathrm{A} \omega 2 \times \mathrm{A} \varpi 2^{\prime}\right)\right)=(\mathrm{A} \omega 1+\mathrm{A} \varpi 1)\right]\right]\right]\right]$

$\left.\left.\left.\left.\left[\left((4 \times(\mathrm{A} \varpi 2 \times \mathrm{A} \varpi 2))^{\prime} \times(4 \times(\mathrm{A} \varpi 2 \times \mathrm{A} \varpi 2))^{\prime}\right)<(8 \times \mathrm{A} \varpi 1)^{\prime \prime}\right]\right] \wedge\left[\left(\mathrm{A} \varpi 2^{\prime} \times \mathrm{A} \varpi 2^{\prime \prime}\right)=\left(2 \times\left(\mathrm{A} \varpi 0+\mathrm{A} \varpi 1^{\prime}\right)\right)\right]\right]\right]\right]$
Actually it would be better to denumerate only the pairs $(i, j)$ of numbers with $i<=j$, as the denumeration of pairs will only be applied to pairs where the diagonal-symmetric pairs are either equal or antisymmetric with pair coding $d$ spair $(i, j)=i+(j /(j+1)) / 2$ and the reverses with
$j=\operatorname{dscol}(n)=\operatorname{aux}(n)$ and $i=\operatorname{dsrow}(n)=n-((\operatorname{aux}(n)(\operatorname{aux}(n)+1)) / 2)$
A $\varpi$ S-Skolem1c $=\forall \mathrm{A} \varpi 1\left[\exists \mathrm{~A} \varpi 0\left[\left[(2 \times \mathrm{A} \varpi 1) \leq\left(\mathrm{A} \varpi 0 \times \mathrm{A} \varpi 0^{\prime}\right)\right] \wedge\left[\left(\mathrm{A} \varpi 0 \times \mathrm{A} \varpi 0^{\prime}\right)<\left(2 \times \mathrm{A} \varpi 1^{\prime}\right)\right]\right]\right]$
A $\omega$ DSCOL $(A \varpi)=A \varpi D S A U X(A \varpi)$
$(\mathrm{A} \varpi 1) \forall \mathrm{A} \varpi 1\left[\exists \mathrm{~A} \varpi 0\left[(2 \times \mathrm{A} \varpi 1)=\left((2 \times \mathrm{A} \varpi 0)+\left(\mathrm{A} \varpi \mathrm{DSAUX}(\mathrm{A} \varpi 1) \times\left(\mathrm{A} \varpi \mathrm{DSAUX}(\mathrm{A} \varpi 1)^{\prime}\right)\right)\right.\right.\right.$ for $\mathrm{A} \varpi \mathrm{DSROW}(\mathrm{A} \varpi)$

Skolem does not treat the problem if the above formulo strings are UNEX- which is necessary for introducing the corresponding functions by implicit definition.
$\forall A \varpi_{1}\left[\right.$ [ [ UNEX-unary-norm-formulo(A $\left.\left.A \varpi_{1}\right)\right] \leftrightarrow$
 $\left[\right.$ TRUTH $\left.\left.\left.\left(\forall \mathrm{A} \omega_{1}\left[\exists \mathrm{~A} \omega_{0}\left[\left[A \omega_{1}\right] \wedge\left[\forall A \omega_{2}\left[\left[\left(A \omega_{1} ; \mathrm{A} \omega_{0} \int A \omega_{2}\right)\right] \rightarrow\left[A \varpi_{2}=\mathrm{A} \omega_{0}\right]\right]\right]\right]\right]\right)\right]\right]\right]$
Implicit definition is justified in second-order logic by second-order Axiom

## $\forall A \varpi 1$ [ [ UNEX-unary-norm-formulo $(A \varpi 1)] \rightarrow$

[TRUTH( $\exists \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[[[\forall \mathrm{A} \varpi 1[\forall \mathrm{~A} \varpi 0[[A \varpi 1] \leftrightarrow[\mathrm{A} \varpi 1(\mathrm{~A} \varpi 1)=\mathrm{A} \varpi 0]]]] \wedge$
$[\forall \mathrm{A} \varpi 2(\mathrm{~A} \varpi)[\forall \mathrm{A} \varpi 1[\forall \mathrm{~A} \varpi 0[[\mathrm{~A} \varpi 1] \leftrightarrow[\mathrm{A} \varpi 2(\mathrm{~A} \varpi 1)=\mathrm{A} \varpi 0]]]]]] \rightarrow[\forall \mathrm{A} \varpi 1[\mathrm{~A} \varpi 1(\mathrm{~A} \varpi 1)=\mathrm{A} \varpi 2(\mathrm{~A} \varpi 1)]]])]]$
Observation 8: This means that one has to make sure that ALPHApython is strong enough to prove that the three formulo strings are UNEX. This should be the least problem, Skolem just has not realized that there might be a problem.

## 7. Ontological problem and metalingual detours

Returning to Skolem's proof for $\boldsymbol{A} \boldsymbol{\sigma}$-Skolem1 one has to apply $\boldsymbol{A} \boldsymbol{\sigma}$ S-Skolem1aa to $\mathrm{A} \varpi 1(0 ; \mathrm{A} \varpi)$, $\mathrm{A} \varpi 1(1 ; \mathrm{A} \omega), \mathrm{A} \varpi 1(2 ; \mathrm{A} \boldsymbol{\sigma}), \ldots$ as Skolem's $f_{0}(t), f_{1}(t), f_{2}(t) \ldots$
$a(g(t)) \boldsymbol{B} b(g(t)) \quad$ hence $a(G(a, b)(t)) \boldsymbol{B}(a, b) b(G(a, b)(t))$
$f_{0}\left(G\left(f_{0}, f_{l}\right)(t)\right) \boldsymbol{B}\left(f_{0}, f_{l}\right) f_{l}\left(G\left(f_{0}, f_{l}\right)(t)\right) \quad$ hence $\left(f_{0}{ }^{o} G\left(f_{0}, f_{l}\right)\right)(t) \boldsymbol{B}_{0, l}\left(f_{l}{ }^{o} G\left(f_{0}, f_{l}\right)\right)(t)$
If one translates from conventional language into Funcish using the FUME -method one has a the first step for $g=G\left(f_{0}, f_{1}\right)$

One gets a series of series of sentence strings. For better understanding it is done in conventional language.

Observation 9: However, notice that the animals $\boldsymbol{B}_{i, j}$ (one of the characters $=<>$ ) are not properly expressible in object-language! Notice furthermore that dot-dot-dot is not proper object-language either! Be it first-order or higher-order logic.

The first problem cannot be avoided in conventional language. Only with proper FUME and using ternary comparity $\mathrm{CB}(\mathrm{A} \varpi ; \mathrm{A} \varpi ; \mathrm{A} \varpi)$ and comparison-codification $\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi)$ one can express it properly. The second problem necessitates a detour to metalanguage, as one has no recursion in calcule ALPHApython but only in metacalcule ALPHApython .

## 8. Conventional reconstruction of Skolem's construction

On page 152 and 153 of Skolem's paper there are inaccuracies and even misleading uses of the same expressions for different entities. This is corrected for in the following four tables. The problem dot-dotdot like in $\left(c_{0}{ }^{o}\left(c_{1}{ }^{o}\left(c_{2}{ }^{o} \ldots\left(c_{n-1}{ }^{o} c_{n}\right)\right)\right)\right)$ is ignored - recursion of composition is not admissible in objectlanguage. The $\boldsymbol{B}_{i, j}$ problem as described in the preceding section is not resolved either.

\(g_{i, j+1}=G\left(\left(f_{0}{ }^{o} g_{i, j}\right),\left(f_{j+1}{ }^{o} g_{i, j}\right)\right)\)
```

$\left(f_{i}^{o} g_{i, i}\right)(t) \boldsymbol{B}_{i, i}\left(f_{i}^{o} g_{i, i}\right)(t)$
$\left(f_{i}^{o}\left(g_{i, i}{ }^{o} g_{i, i+1}\right)\right)(t) \boldsymbol{B}_{i, i+1}\left(f_{i+1}{ }^{o}\left(g_{i, i}{ }^{o} g_{i, i+1}\right)\right)(t)$
$\left(f_{i}^{o}\left(g_{i, i}{ }^{o}\left(g_{i, i+1}{ }^{o}\left(g_{i, i+2}\right)\right)\right)(t) \boldsymbol{B}_{i, i+2}\left(f_{i+2}{ }^{o}\left(g_{i, i}{ }^{o}\left(g_{i, i+1}{ }^{o} g_{i, i+2}\right)\right)\right)(t)\right.$
$\left(f_{i}^{o}\left(g_{i, i}{ }^{o}\left(g_{i, i+1}{ }^{o}\left(g_{i, i+2} \ldots{ }^{o} g_{i, j}\right) \ldots\right)\right)\right)(t) \boldsymbol{B}_{i, j}\left(\left(f_{j+1}{ }^{o}\left(g_{i, i}{ }^{o}\left(g_{i, i+1} l^{o}\left(g_{i, i+2} \ldots{ }^{o} g_{i, j}\right) \ldots\right)\right)(t)\right.\right.$

Put all together from $g_{0,1}$ to $g_{i, j}$ in diagonal-symmetric ordering succession:

```
g(i,j)=(\mp@subsup{g}{0,1}{o}
```

Observation 10: One can include recursion in calcules but this necessitates special prerequisites, it cannot just be added to a given calcule. Notice that simple synaptic recursion, however, is an essential part of metalanguage.

$n=((j(j+1)) / 2+i)=t(i, j)$
$j=d s \operatorname{col}(n)=\operatorname{aux}(n)$
$i=\operatorname{dsrow}(n)=n-((\operatorname{aux}(n)(\operatorname{aux}(n)+1)) / 2)$
$g(n)=g(d s r o w(n), d s c o l(n))$
$g(n, t)=g(n)(t)$
$g(t)=g(t)(t)$
$\left(f_{i}^{o} g(i, j)(t) \boldsymbol{B}_{i, j}\left(\left(f_{j+1}{ }^{o} g(i, j)(t)\right.\right.\right.$

## 9. Skolem's Satz 1 ?

There is still the problem that $\boldsymbol{B}_{i, j}$ cannot be expressed in object-language so that one can apply $f_{i}(g(t)) \sim f_{j}(g(t))$ or $f_{i}(g(t))\left\langle f_{j}(g(t))\right.$ or $f_{j}(g(t))\left\langle f_{i}(g(t))\right.$ for $t(i, j)<t$
$t(i, j)<t$ implying $\quad f_{i}(g(t))=f_{j}(g(t))$ or $f_{i}(g(t))<f_{j}(g(t))$ or $f_{i}(g(t))<f_{i}(g(t))$
Using FUME-method one can write it down properly as sentence in ALPHApython as variant of sentence $A \varpi S$-Skolem1 :

| $f_{i}(t)$ | $g(t)$ | B | $i$ | $j$ | $t(i, j)$ | $t$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\forall \mathrm{A} \varpi 1(\mathrm{~A} \varpi ; \mathrm{A} \varpi)[\exists \mathrm{A} \varpi 1(\mathrm{~A} \varpi)[\exists \mathrm{A} \varpi 2(\mathrm{~A} \varpi ; \mathrm{A} \varpi))[\forall \mathrm{A} \varpi 1[\forall \mathrm{~A} \varpi 2[\forall \mathrm{~A} \varpi 3[$ |  |  |  |  |  |  |
| $\left[(\mathrm{A} \varpi 3+\mathrm{A} \varpi 3)=\left((\mathrm{A} \varpi 1+\mathrm{A} \varpi 1)+\left((\mathrm{A} \varpi 1+\mathrm{A} \varpi 2) \times\left(\mathrm{A} \varpi 1+\mathrm{A} \varpi 2^{\prime}\right)\right) \mathrm{)}\right] \rightarrow\right.$ |  |  |  |  |  | [ $\forall \mathrm{A}$ |
|  |  |  |  |  |  |  |
| $f_{i}(g(t)) \quad f_{j}(g(t)) \quad$ coding $\boldsymbol{B}_{i, j}$ |  |  |  |  |  |  |

where the relation-constant $\mathrm{CB}(\mathrm{A} \varpi ; \mathrm{A} \varpi ; \mathrm{A} \varpi)$ is just a handy abbreviation.
Observation 11: The adjection $\mathrm{A} \varpi \mathrm{B}(\mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi(\mathrm{A} \varpi) ; \mathrm{A} \varpi)$ with values 0 for equality, 1 for minority and 2 majority carries the blemish of unsure antisymmetry. Furthermore the construction of $\mathrm{A} \varpi 1(\mathrm{~A} \varpi)$ (Skolem's unary function $g$ ) involves metalingual recursion within second-order logic and thus is not free of doubts either. Therefor Satz 1 properly expressed by $\boldsymbol{A} \boldsymbol{\sigma}$ S-Skolem1 cannot be considered to be proven.

## 10. Existence of non-standard models of arithmetic?

Observation 12: Suppose that Skolem's Satz 1 can be proven, then Satz 2 actually becomes a THEOREM . It can be translated as follows: The arithmetic functions that appear in the set $M$ of true statements (which include multinomials) form set $\boldsymbol{M}$. The functions that are constructed by application of Satz 1 form set $N^{*}$, they are ordered by an equivalence and a minority relation. They contain the set $N$ of constant functions as a so-called initial part that corresponds one-to-one to the natural numbers. If one assumes that set $M$ only contains omnications 'for all ... ') of junctive formulae (i.e. only disjunction, conjunction and negation of equalities, no quantors) the true statements of set $M$ become true statements for the functions of $N^{*}$.

It will be a different story with Satz 3 and Satz 4 that extend Satz 2 to the complete set of $M$ allowing for all kind of sentence strings. Besides Kleene's normal form it makes ample use of dot-dot-dot . The author has not looked into this any further and has not investigated if there is a way to justify Skolem's arguing in these sentence strings. It only pays if one knows that Skolem's Satz 1 is valid. Therefor Satz 4 cannot yet be considered to be proven.

Non-standard models of arithmetic are in limbo as far as Skolem's work is concerned.
However, there is a positive aspect of Skolem's paper. For certain examples of series $f_{0}(t), f_{1}(t), f_{2}(t) \ldots$ one can actually construct the strictly ascending unary function $g$ and the binary function $t$ in such a way that Satz 1 is a THEOREM . The shortcoming is that one can add further true statements to the set of $M$ with more functions such that they are not true for the examples. The author will put forward that in both cases the functions $g$ and $t$ can be constructed effectively.

- $\quad$ Concrete calcule ALPHATHETA of Tho-arithmetics that fulfills Basiom strings B1 to B17 of the Appendix but not Basiom B18. In this case $g$ is the identity function and $t$ gives the start for function-equality $\sim$ and function-minority $\{$
- Concrete calcule ALPHASIGMA of Sko-arithmetics that fulfills Basiom strings B1 to B18 of the Appendix but not Basiom B19. In this case $g$ and $t$ are based on a prime-number technique.
