

Complexity arising from Life at the Edge of Chaos-Fractal: Riemann hypothesis, Polignac's and Twin prime conjectures

John Ting

Published on August 31, 2020 in viXra

Abstract We commence this paper by outlining the manifested Chaos and Fractal phenomena derived from our concerted idiom "Complexity arising from Life at the Edge of Chaos-Fractal". COVID-19 originated from Wuhan, China in December 2019. Declared by World Health Organization on March 11, 2020; COVID-19 pandemic has resulted in unprecedented negative global impacts on health and economy. With China and US playing crucial roles, international cooperation is required to combat this "Incompletely Predictable" pandemic. We mathematically model COVID-19 and solve [unconnected] below-mentioned open problems in Number theory using our versatile Fic-Fac Ratio. Computed as Information-based complexity, our innovative Information-complexity conservation constitutes a unique all-purpose analytic tool associated with Mathematics for Incompletely Predictable problems. These problems are literally "complex systems" containing well-defined Incompletely Predictable entities such as nontrivial zeros and two types of Gram points in Riemann zeta function (or its proxy Dirichlet eta function) together with prime and composite numbers from Sieve of Eratosthenes. Correct and complete mathematical arguments for first key step of converting this function into its continuous format version, and second key step of using our unique Dimension ($2x-N$) system instead of this Sieve result in primary spin-offs from first key step consisting of providing proof for Riemann hypothesis (and explaining closely related two types of Gram points), and second key step consisting of providing proofs for Polignac's and Twin prime conjectures.

1 Introduction including Preliminary: "Complexity arising from Life at the Edge of Chaos-Fractal"

An important revelation from this paper is given by the following statement: From the concerted idiom "Complexity arising from Life at the Edge of Chaos-Fractal" with manifested Chaos and Fractal phenomena, we depict extraordinary exposure to Living Things versus Nonliving Things and Algebraic Number theory versus Analytic Number theory which will be glimpsed from providing rigorous proofs on Riemann hypothesis, Polignac's & Twin prime conjectures. This is essentially achieved when we explore the significance of Chaos and Fractals phenomena manifested by Incompletely Predictable entities.

The most famous fractal equation is the 2D Mandelbrot set, named after the mathematician Benoit Mandelbrot of Yale University, who coined the name "fractals" for the resulting shapes in 1975. The Mandelbrot set is the set of complex numbers c for which the function $f_c(z) = z^2 + c$ does not diverge when iterated from $z = 0$, i.e., for which the sequence $f_c(0), f_c(f_c(0))$, etc, remains bounded in absolute value.

Three common techniques for generating fractals are:
 Escape-time fractals – These are defined by a (deterministic) recurrence relation at each point in a space (such as the complex plane). Examples: Mandelbrot set, Julia set, Burning Ship fractal and Lyapunov fractal.
 Iterated function systems – These have a (deterministic) fixed geometric replacement rule. Examples: Cantor set, Sierpinski carpet, Sierpinski gasket, Peano curve, Koch snowflake, Harter-Heighway dragon curve, T-Square and Menger sponge.
 Random fractals – Generated by stochastic rather than deterministic processes. Examples: trajectories of the Brownian motion, Levy flight, fractal landscapes and the Brownian tree. The latter yields so-called mass- or dendritic fractals, for example, diffusion-limited aggregation or reaction-limited aggregation clusters.

Fractals can be classified according to the three types of self-similarity:
 Exact self-similarity – the fractal appears identical at different scales. Fractals defined by iterated function systems often display exact self-similarity.
 Quasi-self-similarity – the fractal appears approximately (but not exactly) identical at different scales. Quasi-self-similar fractals contain small copies of the entire fractal in distorted and degenerate forms. Fractals defined by recurrence relations are usually quasi-self-similar but not exactly self-similar.
 Statistical self-similarity – the fractal has numerical or statistical measures which are preserved across scales. Most reasonable definitions of "fractal" trivially imply some form of statistical self-similarity. (Fractal dimension itself is a numerical measure which is preserved across scales.) Random fractals are examples of fractals which are statistically self-similar, but neither exactly nor quasi-self-similar.

In mathematics, 'sensitivity to initial conditions' means that each point in a chaotic system is arbitrarily closely approximated by other points, with significantly different future paths or trajectories. Thus, an arbitrarily small change or perturbation of the current trajectory may lead to significantly different future behavior. A

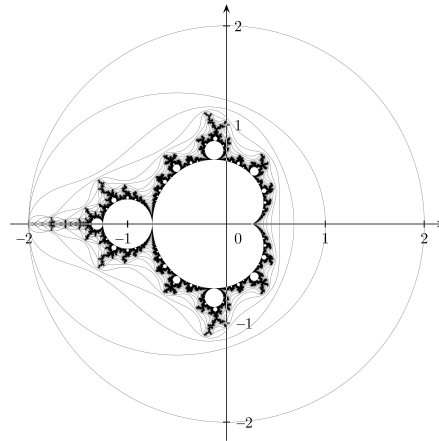

Fig. 1: The Mandelbrot set can be faithfully reproduced when iterated using identical initial conditions. It displays quasi-self-similarity.

Fig. 2: The Sierpinski gasket, also called Sierpinski triangle, is a fractal attractive fixed set with overall shape of an equilateral triangle subdivided recursively into smaller equilateral triangles. It displays exact self-similarity.

'self-similar' object is exactly or approximately similar to a part of itself (i.e., the whole has the same shape as one or more of the parts). Useful overview of deterministic [*not* stochastic] processes: 'Chaos' is [mathematically] synonymous with chaotic nonlinear dynamical systems which are "complex systems" described by discrete or continuous nonlinear (deterministic) equations or algorithms and manifesting the key feature of *sensitivity to initial conditions*. 'Fractal' is [geometrically] synonymous with fractional geometry which deals with "geometrical objects" (graphs) having fractional (fractal) dimensions and manifesting the key feature of *self-similarity*. **Each unique geometrical objects when deterministically computed from a given Chaos is precisely its Fractal.** The mentioned "complex systems" in this paper contain well-defined Incompletely Predictable entities such as nontrivial zeros and two types of Gram points specified by Riemann zeta function (or its proxy Dirichlet eta function) together with prime and composite numbers specified by Sieve of Eratosthenes. We consequently observe complete presence of Chaos and Fractals phenomena manifested in Figures 7 to 23 that involve the relevant Incompletely Predictable entities whereby these Figures all manifest **self-similarity or, more precisely, Quasi-self-similarity**. By the same token, we observe complete absence of Chaos and Fractals phenomena in Figure 24 that involves Completely Predictable entities of even & odd numbers.

The inspiring idiom "Complexity arising from Life at the Edge of Chaos-Fractal" led us to provide a Hierarchical Classification for Elementary-Emergent Fundamental Laws (EEFL). Implied by the definition for

'Fundamental Laws', then EEFL must by default be perfectly applicable to Terrestrial human beings on planet Earth (endowed with advanced civilization) and also Extraterrestrial alien beings on some hypothetical remote planet (endowed with super-advanced civilization). Thus one could also appropriately coin our Fundamental Laws as the Extraterrestrial-Terrestrial EEFL.

In order of increasing complexity, we have the following Laws:

Law I: Simple Elementary Fundamental Law for "simple" Nonliving Things with simple properties
Law II: Complex Elementary Fundamental Law for "complex" Nonliving Things with complex properties
Law III: Simple Emergent Fundamental Law for "simple" Living Things with simple properties
Law IV: Complex Emergent Fundamental Law for "complex" Living Things with complex properties

Solving Completely Predictable and Incompletely Predictable problems:

Solving Completely Predictable problems in both Simple 'Nonliving' Elementary and 'Living' Emergent cases: Many Simple properties → [Simple Elementary and Emergent Solutions]
Solving Incompletely Predictable problems in both Complex 'Nonliving' Elementary and 'Living' Emergent cases: Many Simple properties → Few Complex properties → [Complex Elementary and Emergent Solutions]

The three types of entities:

Type I Entities	Completely Unpredictable entities
Type II Entities	Completely Predictable entities
Type III Entities	Incompletely Predictable entities

The location-based definitions for Type II Entities and Type III Entities are:

Completely Predictable (Type II) Entities: Locationally defined as entities whose position is independently determined by simple calculations using simple equation or algorithm without needing to know related positions of all preceding entities in neighborhood.
Incompletely Predictable (Type III) Entities: Locationally defined as entities whose position is dependently determined by complex calculations using complex equation or algorithm with needing to know related positions of all preceding entities in neighborhood.

Postulated association between Entities and Laws:

Law I is obeyed by Type II Entities e.g. (simple Nonliving Thing) even and odd numbers with even number and odd number gaps.
Law II is obeyed by Type III Entities e.g. (complex Nonliving Thing) nontrivial zeros related to Riemann hypothesis, and prime numbers related to Polignac's & Twin prime conjectures.
Law III is obeyed by Type II + Type III Entities e.g. (simple Living Thing) human heart as an organ manifesting hemodynamic and electrical properties.
Law IV is obeyed by Type I + Type II + Type III Entities e.g. (complex Living Thing) human brain which is often dubbed "the most complex structure in the universe" manifesting a whole range of neuro-psychological and neuro-psychiatric properties.

Creationism versus Evolution debate for Nonliving Things (obeying Law I and Law II) giving rise to Living Things (obeying Law III and Law IV) is compared and contrasted below:

<p>Process of Creationism: Associated with major religions e.g. Islam and Christianity. From the Bible, Adam and Eve was estimated to be created just over 6,000 years ago by world's leading young-earth creationist organizations.</p>

<p>Process of Evolution: Atheists usually believe the Big Bang (when our Universe was created) occur about 13.8 billion years ago. The first true man appeared 13.7998 billion years after the beginning (or about 200,000 years ago).</p>

Human heart can simplistically be thought of having a "plumbing system" consisting of heart muscle pump, coronary arteries and cardiac valves; and an "electrical system" consisting of specialized heart muscle cells giving rise to pacemakers and electrical conduction pathways & networks.

Human brain is the most complex organ in human body. It produces our every thought, action, memory, feeling and experience of the world. It consists of jelly-like mass of tissue weighing around 1.4 kilograms, and contains a staggering one hundred billion nerve cells (neurons). The complexity of the connectivity between these cells is mind-blowing with each neuron making contact with thousands or even tens of thousands of others, via tiny structures called synapses. Our brains form about a million new connections per second. Our conscious mind commands and our subconscious mind obeys. Thus, our subconscious mind is an unquestioning servant that works day and night to make our behavior fits a pattern consistent with our emotionalized thoughts, hopes, and desires. The pattern and strength of the connections is constantly changing and no two brains are alike. It is in these changing connections that memories are stored, subconscious mind operate, habits learned and personalities shaped by reinforcing certain patterns of brain activity, and losing others.

Structurally, the human brain contains "grey matter" and "white matter". The grey matter is the cell bodies of the neurons, while the white matter is the branching network of thread-like tendrils called dendrites and axons that spread out from the cell bodies to connect to other neurons. However, the human brain also has another even more numerous type of cell called glial cells. These outnumber neurons about ten times over. Once thought to be support cells, they are now known to amplify neural signals and to be as important as neurons in mental calculations.

In summary, the human brain manifest Natural Intelligence, consciousness, self-awareness, memory; mental illness such as anxiety, depression, schizophrenia; "dark triad" of personality consisting of three negative traits [viz. the tendency to manipulate others (Machiavellianism), seek admiration and special treatment (narcissism), and to be callous and insensitive (psychopathy)]; and "light triad" of personality consisting of three positive traits [viz. the opposite of Machiavellianism (Kantianism), valuing dignity and worth of each individual person (humanism), and believing that people are fundamentally good (Faith in humanity)].

Artificial Intelligence (AI) in Nonliving Things can be regarded as human endeavor to simulate Natural Intelligence in Living Things using powerful computers such as super-computers or quantum computers. DNA is a double helix, while RNA is a single helix. Both have sets of nucleotides that contain genetic information. DNA is a molecule that contains instructions for Living Things to be born, mature, reproduce, and died.

One would commonly concur that there are 'Simple' Living Things such as bacteria without brain and 'Complex' Living Things such as intelligent human with highly developed brain. The dividing line between Living Things and Nonliving Things is that the former is "powered" by DNA with an important implication that Natural Intelligence, consciousness and self-awareness can only be "powered" by DNA [which are organic]. Then by reasonable assumption, properties such as consciousness and self-awareness can never be present in AI created using computers [which are inorganic].

In this research paper containing pure and applied mathematics, treatise on relevant Mathematics for Incompletely Predictable Problems required to solve Riemann hypothesis and explain the closely related two types of Gram points is outlined first; and to solve Polignac's and Twin prime conjectures is outlined subsequently. COVID-19 is an acronym that stands for Coronavirus Disease 2019 with severity ranging from asymptomatic, mild, moderate, severe to life-threatening with potential to result in chronic residual debilitating symptoms after recovery. It is a proven multi-organ disease generally affecting human lungs to the worst degree. To help ease time constraint of front-line health workers interested in reading this paper, its content is

Fig. 3: Schematically depicted *SIR* model with three compartments.

Fig. 4: Schematically depicted *SEIR* model with four compartments.

mindfully composed to succinctly include selected materials relevant to COVID-19 pandemic which was officially declared by World Health Organization (WHO) on March 11, 2020. Caused by highly contagious and moderately virulent SARS-CoV-2 [originating from Wuhan, China in December 2019]; this deadly pandemic has resulted in unprecedented negative global impacts from health and economic crisis with numerous deaths and widespread job losses. Similar to most respiratory virus, spread of infection could occur through contact (direct or indirect), $> 5 \mu\text{m}$ size droplet spray in short-range transmission, $< 5 \mu\text{m}$ size aerosol in long-range transmission (airborne transmission). International cooperation to effectively combat the pandemic is required with China and US playing crucial roles aided by other big and small countries alike such as Russia, Canada, Great Britain, Germany, Australia, New Zealand, Vietnam and Thailand.

We devote the initial few pages of this paper to highlight importance of mathematics in understanding infectious disease outbreak. *SIR* model in Figure 3 and *SEIR* model in Figure 4 are epidemiological (compartmental) models commonly used by mathematicians to compute theoretical number of people inflicted with an infectious illness such as COVID-19 in a closed population over time. Respectively, they consist of three and four compartments derived from: *S* for Susceptible Population, *E* for Exposed Population, *I* for Infectious Population, and *R* for Recovered Population [including deceased &/or immune individuals]. Both models utilize (deterministic) ordinary differential equations. Aspects of modelling this pandemic in terms of our derived Fic-Fac Ratio are loosely and intuitively perceived as "Incompletely Predictable" – a term also used when solving the [unconnected] above-mentioned open problems in Number theory.

Fig. 5: Schematic representation of Fic-Fac Ratio.

Factitious versus Fictitious and the novel & versatile Fic-Fac Ratio:

The adjective **factitious** derives from factus and therefore facere means to *correctly make or utilize something based on (true) fact* whereas **fictitious** derives from fictus and therefore fingere means to *incorrectly make or utilize something based on (false) fiction*. We predominantly refer the "something" here to include mathematical arguments (MA) and diagnostic tests (DT). These two adjectives with their given meanings are used to help create Fic-Fac Ratio, which is an acronym that stands for Fictitious-Factitious Ratio. DT 'Accuracy' refers to ability of that test to distinguish between patients with disease, and those without. Roughly considered as '**Inverse Accuracy**' [with higher Accuracy corresponding to lower Fic-Fac Ratio and *vice versa*], we advocate this Ratio to be universally applicable to all well-defined mathematical models.

With or without a "pseudo-component" (respectively) equating to '<100% accuracy' or '100% accuracy', we usefully categorize all synthesized mathematical models to be broadly associated with either "proposed states" such as Riemann hypothesis or "natural states" such as COVID-19 pandemic. During mathematical modelling of Riemann hypothesis, less accurate inequation [as opposed to more accurate equation] is the relevant pseudo-component as it contains Pseudo- Σ (all fractional exponents) – see Subsection 1.4 below. During epidemiological modelling of COVID-19 pandemic, less accurate "Pseudo-SIR" model [as opposed to more accurate SEIR model] is the relevant pseudo-component as it does not contain compartment E for Exposed Population. Modelling concepts from open problems, COVID-19 and its resulting pandemic using derived Fic-Fac Ratio [regarded as **tertiary spin-offs** from solving our mentioned open problems] are outlined next whereby we provide concrete examples of ideal gold standard MA and ideal gold standard DT with their associated MA and DT results corresponding to Fic-Fac Ratio = 0.

1.1 Fic-Fac Ratio for Open Problems, COVID-19 and its resulting Pandemic

Abbreviations: MA = mathematical arguments, DT = diagnostic tests, P = Probability (or Proportion), R = Fic-Fac Ratio. We supply definitions, equations and schematic diagram of Fic-Fac Ratio (Figure 5) depicting important inter-relationships for Fic-Fac Ratio which are applicable to MA and DT. Required MA giving [abstract] positive and [abstract] negative MA results in a specified conjecture or hypothesis must be implemented to, respectively, fully **confirm** a "proposed state" to be *correctly valid* and *correctly not invalid*. Required DT giving positive and negative DT results in a specified subject group or population must be implemented that, respectively, aim to fully **support** a "natural state" to *correctly occur* and *correctly not occur*.

Based on 2x2 contingency table in Table 1, both MA and DT have parameters forming "stable properties" and "frequency-dependent properties" as depicted below. Fic-Fac Ratio (range: 0 - ∞) is roughly '**Inverse Accuracy**' since it varies in opposite direction to that for Accuracy (range: 0 - 1).

Two stable properties:

Sensitivity (Sen) = $a/(a+c)$; Specificity (Spec) = $d/(b+d)$

Four frequency-dependent properties:

Gold standard for MA or DT:			
MA results or DT results:	Positive		Negative
	Positive	True +ve [a]	False +ve [b]
Negative	False -ve [c]	True -ve [d]	

Table 1: The 2x2 contingency table for mathematical arguments (MA) and diagnostic tests (DT).

Positive predictive value (+ve Pred value) = $a/(a+b)$; Negative predictive value (-ve Pred value) = $d/(c+d)$;
Accuracy (Accu) = $(a+d)/(a+b+c+d)$; Prevalence (Prev) = $(a+c)/(a+b+c+d)$

Using Bayes' theorem, +ve Predictive values can also be calculated as

$$\frac{[(Prev)(Sen)]}{[(Prev)(Sen) + (1 - Prev)(1 - Spec)]}$$

Factitious (Fac) = Number of (true) fact = $P(\text{Fac}) = (a+d)$.

Fictitious (Fic) = Number of (false) fiction = $P(\text{Fic}) = (b+c)$.

$P(\text{Fic}) + P(\text{Fac}) = 1 \implies P(\text{Fac}) = 1 - P(\text{Fic})$... Equation 1

$R = \frac{P(\text{Fic})}{P(\text{Fac})}$ with range of values from 0 to ["undefined"] ∞ ... Equation 2

Target: Accept $R < 1$ and Reject $R > 1$ with $R = 1$ being indeterminate.

Note: For a well-defined "proposed state" or "natural state", $P(\text{Fic})$ and $P(\text{Fac})$ may each be constituted by ≥ 1 MA or ≥ 1 DT that are mutually independent and/or dependent. Using parameter R (Equation 2), Equation 1 is equivalent to two parametric equations $P(\text{Fic}) = \frac{R}{R+1}$ & $P(\text{Fac}) = \frac{1}{R+1}$ with $R + 1 \neq 0$ & $R \neq 0$.

In *SEIR* model, extra compartment *E* for Exposed Population allows modelling to incorporate **incubation period**. This is time from exposure to causative agent until first symptoms develop and is characteristic for each disease agent. WHO estimated in early 2020 the incubation period for COVID-19 ranges from 1 to 14 days with a median incubation period of 5 to 6 days. One useful way to determine the infectiousness of COVID-19 is the reproductive rate of its causative agent SARS-CoV-2, or R_0 . R_0 measures the average number of secondary infections caused by a single case and is initially estimated by WHO to be 1.4 - 2.5 (average 1.95). Higher in countries that do not implement strong public measures such as extensive [and repeated] testing, contact tracing, case isolation and contact quarantine; R_0 is a context specific measurement which will fall to < 1 with successful control of outbreaks. Another [less useful] measure of infectiousness is household secondary attack rate, or the proportion of household members who are likely to get infected from a case. Estimates of this rate have not unexpectedly varied significantly between studies in 2020 [not quoted here], ranging from as low as 3 - 10% to as high as 100% for COVID-19. This suggests that there may be factors that vary considerably between different groups, such as types of activities, duration of event, ventilation of the household and viral shedding of the case. All the above estimates can be subsequently refined as more data becomes available.

We gave four concrete examples utilizing Fic-Fac Ratio (R) whereby their corresponding false positive and false negative MA and DT results do not exist and consequently from Table 1 with $(a+d) = 1$, $(b+c) = 0$, and $R = 0$. For optimal understanding, we discuss [hypothetical] test subject group on MA and patient group on DT with total number of each group and its two subgroups denoted (respectively) by $N_T = 100$ and $N_1 = N_2 = 50$.

Obtaining MA results for a hypothesis or conjecture using ideal gold standard MA to rigorously prove:

- (I) Riemann hypothesis to be true via (i) all nontrivial zeros are located on the critical line [true positive MA result] and (ii) all nontrivial zeros are not located away from the critical line [true negative MA result];
- (II) Twin prime conjecture to be true via (i) twin primes are infinite in magnitude [true positive MA result] and (ii) twin primes are not finite in magnitude [true negative MA result]; and
- (III) Conjecture "Ubiquitous human angiotensin-converting enzyme 2 (ACE2) receptor is sole entry receptor for SARS-CoV-2 causing COVID-19 when susceptible test subjects $N_T = 100$ are [unethically] experimentally exposed to this virus with assumed 100% infectivity rate in ideal world (but likely, say, up to around 59% infectivity rate[1] in real world)" to be true via (i) COVID-19 infection will occur in test subjects $N_1 = 50$ exposed to SARS-CoV-2 while not taking novel drug '*irreversible ACE2 blocker*' with 100% efficacy and acceptable "safety profile" [true positive MA result] and (ii) COVID-19 infection will not occur in test subjects $N_2 = 50$ exposed to SARS-CoV-2 while taking this same novel drug [true negative MA result].

Obtaining DT results for a group of individuals (patient group with $N_T = 100$) employing [hypothetical] ideal gold standard DT [with Sensitivity = 100% and Specificity = 100%] to definitively determine: (IV) proportion of patient (i) having [with true positive DT result] COVID-19 infection with $N_1 = 50$ and (ii) not having [with true negative DT result] COVID-19 infection with $N_2 = 50$.

The gene that encodes Transmembrane Serine Protease 2 (TMPRSS2) is activated when male hormones bind to androgen receptor. It can be experimentally shown that TMPRSS2 enzyme[2] is required to cleave SARS-CoV-2's spike protein – a process known as proteolytic priming – before the virus could enter cells via its spike protein binding to ACE2 receptor. Pharmacologically targeting (e.g.) ACE2 could theoretically be key to unlocking effective vaccines based on (e.g.) mRNA & DNA nucleic acid, weakened or inactivated viral forms, protein subunits and viral vectors; and effective drugs (e.g.) antiviral medication Remdesivir [by inhibiting viral replication thus shortening time to clinical recovery], 'androgen deprivation therapy', 'irreversible ACE2 blocker' and 'TMPRSS2 inhibitor'. Another hypothetical novel drug '*floating version of ACE2*' could trick the virus to preferably bind with this drug rather than ACE2 on human cells thus potentially treating COVID-19 infection, preventing viral replication and spread.

With main effect of increasing vasoconstricting angiotensin II hormone, ACE acts as a key regulatory peptide in renin-angiotensin-aldosterone system (RAAS); and with main effect of decreasing vasoconstricting angiotensin II hormone, its counterpart ACE2 acts as key counterregulatory peptide via its dual actions of firstly, acting as an ubiquitous functional receptor present in many parts of our body and secondly, simultaneously acting as an enzyme that predominantly degrade angiotensin II (and to a lesser extent cleaves angiotensin I and participates in hydrolysis of other peptides). In patients with RAAS blockade such as on ACE inhibitor (ACEI) or angiotensin II receptor blocker (ARB) therapy for hypertension or diabetes, health workers are dealing here with a double-edged sword depending on the phase of disease. Increased baseline ACE2 expression in these patients could potentially increase SARS-CoV-2 infectivity and ACEI/ARB use would be an addressable risk factor. Conversely, once infected, downregulation of ACE2 may be the hallmark of COVID-19 progression. Consequently, upregulation by preferentially employing RAAS blockade and ACE2 replacement in acute respiratory distress syndrome phase may turn out to be beneficial.

"Proposed states" such as modelling Riemann hypothesis when formulated as equation or inequation [with Pseudo- \sum (all fractional exponents)] can and must be error-free. All "proposed states" can and must have their Fic-Fac Ratio = 0 with $P(\text{Fac}) = 1$ and $P(\text{Fic}) = 0$. This is equivalent to stating mathematical-based proofs for "proposed states" must always be mathematically rigorous and error-free.

Loosely speaking, "natural states" such as Pseudo-SIR model or SEIR model for COVID-19 pandemic are "*Incompletely Predictable*" in the sense that their statistical-based proofs should be statistically significant but they can never be error-free. [Here, we will omit outlining common ordinary differential equations associated with the two models.] This is because both models as schematically displayed will (1) intrinsically be affected by obtained DT results using relevant DT e.g. never having, in practice, 100% accuracy and (2) extrinsically be affected by incorrect DT results obtained due to [unintentional] e.g. sampling errors (likely causing false negative DT results in COVID-19 patients potentially due to obtained saliva samples being insufficient, collected too early during infection or too late during recovery), observational errors, blunders, under- and over-reporting or [intentional] e.g. data fabrication and manipulation. We give an extreme "counter-example" of data fabrication and manipulation: Having ulterior motive, local investigator Mr. CB decided to intentionally send an e-mail containing (say) important test results at (say) 3:45 PM Friday February 8, 2019 to a fabricated email address XYZ. Consequently, these results will never reach the intended recipient (statistician / epidemiologist) for analysis. **Note:** Medico-legally in terms of Fic-Fac Ratio, (i) XYZ is ['positively'] a fabricated email address for recipient when used by Mr. CB since it never belong to recipient = (abstract) True Positive MA and (ii) XYZ used by Mr. CB is ['negatively'] a non-existing email address for recipient since it was never created by recipient = (abstract) True Negative MA. This unjustifiable action will lead to failure of these results to be properly incorporated into modelling an "old" epidemic occurring from (say) October 29, 2018 to February 8, 2019. Both (1) and (2) will lead to some quantifiable increase of $P(\text{Fic})$ values [with reciprocal decrease of $P(\text{Fac})$ values] affecting, for instance, I for Infectious Population. Since we generally reject [or accept] probability based Fic-Fac Ratio > 1 [or < 1], the overall goal is to always minimize $P(\text{Fic})$ &/or maximize $P(\text{Fac})$.

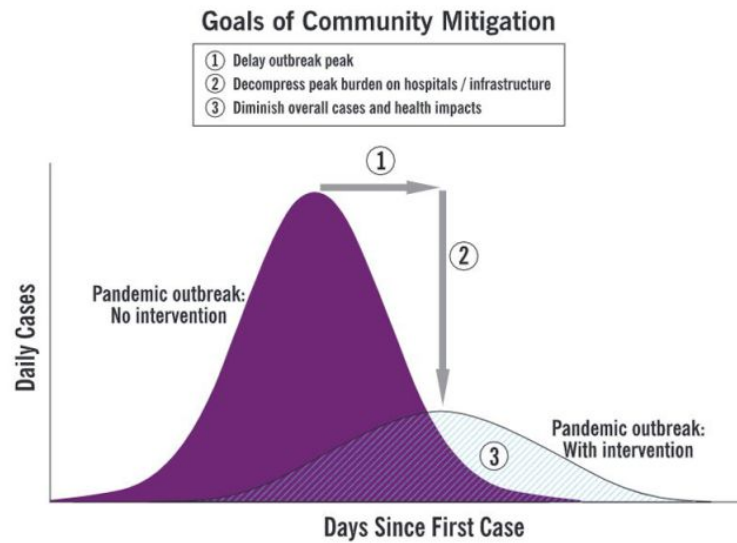

Fig. 6: Epidemiological model of pandemic (US Centers for Disease Control and Prevention).

Gold standard MA must always be an (error-free) ideal gold standard MA. Gold standard DT refers to its use in achieving a definitive diagnosis obtained by biopsy, surgery, autopsy, long-term follow-up or another acknowledged standard. In theory, an ideal gold standard DT designed to detect SARS-CoV-2 is error-free having Sensitivity = 100% (it identifies all individuals with the disease) and Specificity = 100% (it does not falsely identify individuals without the disease); and consequently will also have +ve Predictive values, -ve Predictive values, and Accuracy all = 100%. In practice, there are no ideal gold standard DT, and one tries to use a DT that is as close as possible to the ideal test. The commonly available reverse transcription-polymerase chain reaction (PCR) test on a nasal (oro/nasopharyngeal) swab detects presence of genetic material of SARS-CoV-2 causing COVID-19. Results on Sensitivity and Specificity of this newly developed test depend critically on how closely it approaches the ideal test. It likely has intrinsic Sensitivity & Specificity in the range of (say) 90 - 95%. Then assuming a high Sensitivity & Specificity of 95% meant that the test could still miss about 5% of infected people and falsely diagnose about 5% of non-infected people. If required, whole genome sequencing can additionally be performed on selected positive reverse transcription-PCR samples to detect phylogenetic clusters of SARS-CoV-2 and rapidly identify SARS-CoV-2 transmission chains. Notwithstanding potential for some false-positive test results perhaps due to people previously exposed to other less dangerous coronaviruses, IgG anti-coronavirus antibodies could be used to detect past COVID-19 infection and measure community immunity. Future development of potential tests using different methodology may be based on detecting viral components such as proteins, nucleic acids or combinations of these in patient samples.

In a study of all 217 passengers and crew on a cruise ship[1], 128 tested positive for COVID-19 on reverse transcription-PCR (59%). Of these infected patients, 19% (24) were symptomatic; 6.2% (8) required medical evacuation; 3.1% (4) were intubated and ventilated; and the mortality was 0.8% (1). The majority of infected patients were asymptomatic (81%, 104 patients). Thus prevalence of COVID-19 on affected [isolated] cruise ships [and tentatively projected by us to happen in some "hotspot" outbreak places on planet Earth] is likely to be significantly underestimated.

Remark 1.1. Difference mitigation measures *with full compliance by everyone* could make to severity of COVID-19 pandemic can be clearly illustrated by epidemiological modelling in Figure 6 courtesy of Centers for Disease Control and Prevention (CDC) [*with arising mental health problems being an addressable issue*].

Dynamic staged implementation and subsequent staged easing of [beneficial] mitigation measures such as *lockdowns, border closures, social distancing* (with practising good hand and sneeze / cough hygiene; obeying more than 1.5 - 2 metres distance between people; using Personal Protective Equipment, importantly, in the

Fig. 7: Graphical relationship: Prevalence vs Positive Predictive value with Sensitivity of 95%.

correct manner when deemed appropriate to do so by authorized health officials for public and health-care settings e.g. eye protection which included visors or face shields or goggles, among others, and three layered homemade cloth face masks or surgical masks or P2 / N95 respirators[3]; and limiting indoor / outdoor *mass gatherings* is based on experiences, expert opinions, statistical analysis of collected data or previous and recent research studies thus complying with Evidence-based Medicine and Practice.

Ability of a test to discriminate between normal (without disease) and abnormal (with disease) individuals is described by its Specificity and Sensitivity. Generally, they are inversely related to each other and may be altered by changing reference interval or normal range. In other words, one can only be improved at the expense of the other. Example, prostate specific antigen (PSA) cut-off of 4.0 ng/mL [and 3.0 ng/mL] is often given as having a sensitivity of 21% [and 32%] with specificity of 91% [and 85%] for detection of any prostate cancer. A study[4] on conventional Pap smear method to detect cervical cancer in women had Sensitivity 51%, Specificity 66.6%, +ve Predictive value 96%, -ve Predictive value 8% and Accuracy 92%. When a DT has Sensitivity of 95% (5% false -ve) and Specificity of 95% (5% false +ve), for a disease with 1% Prevalence, its +ve Predictive value is only 16% but its -ve Predictive value is 99%. Relationship between Prevalence and +ve Predictive value with Sensitivity of 95% is numerically and graphically depicted in Table 2 and Figure 7.

Lymphocytes include natural killer cells which function in cell-mediated, cytotoxic innate immunity; T cells for cell-mediated, cytotoxic adaptive immunity; and B cells for humoral, antibody-driven adaptive immunity (which is mostly mediated by differentiated B cells called plasma cells secreting Immunoglobulins G, A, M, D and E). Memory B cells are a B cell sub-type that are formed within germinal centers following primary infection. Memory B cells can survive for decades and repeatedly generate an accelerated and robust antibody-mediated immune response in the case of re-infection (also known as a secondary immune response). Memory T cells are a subset of T lymphocytes that might have some of the same functions as memory B cells e.g. Antigen-specific memory T cells against viruses or other microbial molecules can be found in both T_{CM} and T_{EM} subsets. T_{VM} subset also function in production of various cytokines. Then for a COVID-19 vaccine candi-

date targeting sufficient level of immunity against SARS-CoV-2 spike protein, it must generate the appropriate type of antibody and T cell response.

CDC indicated six stages of vaccine development against a new infection or disease: (i) exploratory, (ii) pre-clinical, (iii) clinical development, (iv) regulatory review and approval, (v) manufacturing and (vi) quality control. Clinical development is a three-phase process.

Phase I: small groups of people receive the trial vaccine. Is the vaccine safe, and what dose should be used?

Phase II: clinical study is expanded and vaccine is given to people who have characteristics (such as age & physical health) similar to those for whom vaccine is intended. Can the vaccine generate an immune response?

Phase III: vaccine is given to thousands of people and tested for efficacy and safety. Can the new vaccine protect from infection or disease?

Many vaccines will also undergo Phase IV formal, ongoing studies after the vaccine is approved and licensed. Through international collaboration, researchers are urgently speeding up the process to obtain effective and globally required COVID-19 vaccine(s) by running one trial while simultaneously recruiting for the next phase.

For optimal management of critically ill COVID-19 patients, it is vitally important for world-wide medical communities to share extra knowledge [for instance] that giving nebulized Heparin[5] should reduce severity of COVID-19 induced acute respiratory distress syndrome (ARDS) through its anti-viral effects, anti-inflammatory effects, anti-coagulant effects, and mucolytic effects; and that selectively giving corticosteroid Dexamethasone[6] through its anti-inflammatory [likely via inhibiting CD4+ Helper T cell subsets in production of various cytokines] and immunosuppressant effects [likely via inhibiting CD8+ Cytotoxic T cell subsets in destroying virus-infected cells, tumor cells and transplant rejection] to appropriate COVID-19 patients with excessive immune response called 'cytokine storm' causing harmful hyper-inflammation will reduce the risk of death.

We introduce the educational concept of 'Top-Down Approach' versus 'Bottom-Up Approach' to therapy on COVID-19 induced 'cytokine storm' causing hyper-inflammation. Assuming the simplistic but not totally accurate caveat expressed through the following statement to be true: '*Cytokine storm*' is largely caused by imbalance of two broad classes of identifiable cytokines known as pro-inflammatory cytokines and anti-inflammatory cytokines whereby there is supramaximal elevation of the former class with or without supramaximal fall of the later class. Then giving Dexamethasone acting through the non-specific (increased) anti-inflammatory effect [likely via acting non-specifically on various cytokines] constitutes 'Top-Down Approach' to therapy whereby giving novel synthetic drugs 'pro-inflammatory cytokine X blocker' and/or 'anti-inflammatory cytokine Y' acting through, respectively, their specific (reduced) pro-inflammatory effect and (increased) anti-inflammatory effect constitutes 'Bottom-Up Approach' to therapy. Finally, we opine that only globally available safe and effective COVID-19 vaccine(s) when successfully developed can ultimately control COVID-19 pandemic. This is achieved by providing mass immunization targeting sufficient herd immunity threshold [= $1 - \frac{1}{R_0}$ and estimated to be around 60 - 70%] at community level to prevent on-going transmission of this infection.

1.2 Open Problems from Riemann zeta function and Sieve of Eratosthenes

Dirichlet Sigma-Power Laws are continuous format version of discrete format Riemann zeta function (or its proxy Dirichlet eta function). Sieve of Eratosthenes is a simple ancient algorithm for finding all prime numbers up to any given limit by iteratively marking as composite (i.e., not prime) the multiples of each prime, starting with first prime number 2. Multiples of a given prime are generated as a sequence of numbers starting from that prime, with constant difference between them equal to that prime. Dimension $(2x - N)$ [see Section 8 "Information-Complexity conservation" for more details] *dependently* incorporate prime and composite numbers (and Number '1') whereas Sieve of Eratosthenes directly and indirectly give rise to prime and composite numbers (but not Number '1'). In using the unique Dimension $(2x - N)$ system with $N = 2x - \Sigma PC_x\text{-Gap}$, Dimension $(2x - N)$ when fully expanded is numerically just equal to $\Sigma PC_x\text{-Gap}$ since Dimension $(2x - N) = 2x - 2x + \Sigma PC_x\text{-Gap} = \Sigma PC_x\text{-Gap}$. In order to solve Riemann hypothesis, Polignac's and Twin prime conjectures (and explain two types of Gram points); one could in principle use Path A or Path B option in Table 3. Our chosen Path B requires Mathematics for Incompletely Predictable Problems.

<p>Riemann zeta function ↓ [Path A option] ↓ Nontrivial zeros & two types of Gram points ↑ [Path B option] ↑ Dirichlet Sigma-Power Laws</p>	<p>Sieve of Eratosthenes ↓ [Path A option] ↓ Prime & Composite numbers ↑ [Path B option] ↑ Dimension (2x - N), N = 2x - ΣPC_x-Gap</p>
---	---

Table 3: Two options to solve open problems in Number theory.

Elements of three complete sets constituted by nontrivial zeros and two types of Gram points together with elements of two complete sets constituted by prime and composite numbers are all classified as Incompletely Predictable entities. Riemann hypothesis (1859) proposed all nontrivial zeros in Riemann zeta function to be located on its critical line. Defined as Incompletely Predictable problem is essential in obtaining the continuous format version of [discrete format] Riemann zeta function dubbed Dirichlet Sigma-Power Law to prove this hypothesis. All of infinite magnitude, nontrivial zeros when geometrically depicted as corresponding Origin intercepts together with two types of Gram points when geometrically depicted as corresponding x- & y-axes intercepts explicitly confirm they intrinsically form relevant component of point-intersections in this function. Defined as Incompletely Predictable problems is essential for these explanations to be correct. Involving proposals that prime gaps and associated sets of prime numbers are infinite in magnitude, Twin prime conjecture (1846) deals with even prime gap 2 thus forming a subset of Polignac's conjecture (1849) which deals with all even prime gaps 2, 4, 6, 8, 10,.... Defined as Incompletely Predictable problems is essential to prove these conjectures using our unique Dimension (2x - N) system instead of Sieve of Eratosthenes. Thus our innovative Information-complexity conservation computed as Information-based complexity constitutes an unique all-purpose [quantitative and qualitative] analytic tool associated with Mathematics for Incompletely Predictable problems. We say these problems can literally be perceived as "complex systems" containing well-defined Incompletely Predictable entities such as nontrivial zeros and two types of Gram points in Riemann zeta function (or its proxy Dirichlet eta function) together with prime and composite numbers from Sieve of Eratosthenes.

Remark 1.2. Mathematics for Incompletely Predictable Problems equates to *sine qua non* defining problems involving Incompletely Predictable entities to be Incompletely Predictable problems achieved by incorporating certain identifiable mathematical steps with this procedure ultimately enabling us to rigorously prove or explain open problems in Number theory as **primary spin-offs**.

Obtained parallel observations: Just as there is conservation or preservation of (quantitative) "net area value" happening at appropriate times for continuous format Riemann zeta function (*aka* Dirichlet Sigma-Power Law); similar conservation or preservation of (quantitative) "net number value" will happen at appropriate times for natural numbers on one hand and prime numbers, composite numbers and Number '1' [and even and odd numbers] on the other hand when Information-Complexity conservation is enforced in both scenario. This concept will be equally applicable to prime numbers, composite numbers and Number '1' [and even and odd numbers] when depicted using Dimension (2x - N). Then qualitatively, (maximal) Information-Complexity conservation for "complex system" Riemann zeta function equates to maximal three axes-intercepts occurring only when $\sigma = \frac{1}{2}$ and with minimal two axes-intercepts occurring when $\sigma \neq \frac{1}{2}$; and maximal Information-Complexity conservation for "complex system" Dimension (2x - N) on the constituents of natural numbers equates to N = 7 being baseline maximal viz. maximal [varying] Complexity occurring only for prime-composite number pairing and with N = 4 being baseline minimal viz. minimal Complexity occurring for even-odd number pairing.

Refined information on Incompletely Predictable entities of Gram and virtual Gram points: These entities all of infinite magnitude are *dependently* calculated using *complex equation* Riemann zeta function, $\zeta(s)$, or its *proxy* Dirichlet eta function, $\eta(s)$, in critical strip (denoted by $0 < \sigma < 1$) thus forming the relevant component of point-intersections. In Figure 9, Gram[y=0], Gram[x=0] & Gram[x=0,y=0] points are respectively geometrical x-axis, y-axis & Origin intercepts at critical line (denoted by $\sigma = \frac{1}{2}$). Gram[y=0] & Gram[x=0,y=0] points are respectively synonymous with traditional 'Gram points' & *nontrivial zeros*. In Figures 10 & 11, virtual Gram[y=0] & virtual Gram[x=0] points are respectively geometrical x-axis & y-axis intercepts at non-critical lines (denoted by $\sigma \neq \frac{1}{2}$). Virtual Gram[x=0,y=0] points do not exist.

Refined information on Incompletely Predictable entities of prime and composite numbers: These entities all of infinite magnitude are *dependently* computed (respectively) directly and indirectly using *complex algorithm* Sieve of Eratosthenes. Denote \mathbb{C} to be uncountable complex numbers, \mathbf{R} to be uncountable real numbers, \mathbf{Q} to be countable rational numbers or roots [of non-zero polynomials], $\mathbf{R-Q}$ to be uncountable irrational numbers, \mathbf{A} to be countable algebraic numbers, $\mathbf{R-A}$ to be uncountable transcendental numbers, \mathbf{Z} to be countable integers, \mathbf{W} to be countable whole numbers, \mathbf{N} to be countable natural numbers, \mathbf{E} to be countable even numbers, \mathbf{O} to be countable odd numbers, \mathbf{P} to be countable prime numbers, and \mathbf{C} to be countable composite numbers. \mathbf{A} are \mathbb{C} (including \mathbf{R}) that are countable rational or irrational roots. (i) Set $\mathbf{N} = \text{Set } \mathbf{E} + \text{Set } \mathbf{O}$, (ii) Set $\mathbf{N} = \text{Set } \mathbf{P} + \text{Set } \mathbf{C} + \text{Number '1'}$, (iii) Set $\mathbf{A} = \text{Set } \mathbf{Q} + \text{Set irrational roots}$, and (iv) Set $\mathbf{N} \subset \text{Set } \mathbf{W} \subset \text{Set } \mathbf{Z} \subset \text{Set } \mathbf{Q} \subset \text{Set } \mathbf{R} \subset \text{Set } \mathbb{C}$. Then Set $\mathbf{R-Q} = \text{Set irrational roots} + \text{Set } \mathbf{R-A}$.

Cardinality of a given set: With increasing size, arbitrary Set \mathbf{X} can be countable finite set (CFS), countable infinite set (CIS) or uncountable infinite set (UIS). Cardinality of Set \mathbf{X} , $|\mathbf{X}|$, measures "number of elements" in Set \mathbf{X} . E.g. Set **negative Gram[y=0] point** has CFS of negative Gram[y=0] point with **negative Gram[y=0] point** = 1, Set **even P** has CFS of even **P** with **even P** = 1, Set \mathbf{N} has CIS of \mathbf{N} with $|\mathbf{N}| = \aleph_0$, and Set \mathbf{R} has UIS of \mathbf{R} with $|\mathbf{R}| = c$ (cardinality of the continuum).

Differentiation of terms "Incompletely Predictable" versus "Completely Predictable": Set $\mathbf{N} = \text{Set } \mathbf{E} + \text{Set } \mathbf{O}$. The two subsets of even and odd numbers are "Independent" and "Completely Predictable". Examples: Even number after 2,984 viz. $2,984 / 2 = 1,492$ nd even number is [easily] calculated independently using *simple algorithm* to be $2,984+2 = 2,986$ viz. $2,986 / 2 = 1,493$ rd even number. Odd number after 2,985 viz. $(2,985+1) / 2 = 1,493$ rd odd number is [easily] calculated independently using *simple algorithm* to be $2,985+2 = 2,987$ viz. $(2,987+1) / 2 = 1,494$ th odd number. Set $\mathbf{N} = \text{Set } \mathbf{P} + \text{Set } \mathbf{C} + \text{Number '1'}$. The two subsets of prime and composite numbers are "Dependent" and "Incompletely Predictable". Example: Sixth prime number '13' [after fifth prime number '11'] is [not easily] computed dependently using *complex algorithm* from scratch via: 2 is 1st prime number, 3 is 2nd prime number, 4 is 1st composite number, 5 is 3rd prime number, 6 is 2nd composite number, 7 is 4th prime number, 8 is 3rd composite number, 9 is 4th composite number, 10 is 5th composite number, 11 is 5th prime number, 12 is 6th composite number, and desired 13 is 6th prime number.

Formal definitions for Completely Predictable (CP) entities and Incompletely Predictable (IP) entities: In this paper, the word "number" [singular noun] or "numbers" [plural noun] in reference to prime & composite numbers, nontrivial zeros & two types of Gram points can interchangeably be replaced with the word "entity" [singular noun] or "entities" [plural noun]. Respectively, an IP (CP) number is locationally defined as a number whose position is *dependently (independently)* determined by complex (simple) calculations using complex (simple) equation or algorithm with (without) needing to know related positions of all preceding numbers in neighborhood. Simple properties are inferred from a sentence such as "This simple equation or algorithm by itself will intrinsically incorporate actual location [and actual positions] of all CP numbers". Solving CP problems with simple properties amendable to *simple* treatments using *usual* mathematical tools such as Calculus result in 'Simple Elementary Fundamental Laws'-based solutions. Complex properties, or "meta-properties", are inferred from a sentence such as "This complex equation or algorithm by itself will intrinsically incorporate actual location [but not actual positions] of all IP numbers". Solving IP problems with complex properties amendable to *complex* treatments using *unusual* mathematical tools such as Dimension ($2x - N$) system, exact and inexact Dimensional analysis homogeneity as well as using *usual* mathematical tools such as Calculus result in 'Complex Elementary Fundamental Laws'-based solutions.

Based on Mathematics for Incompletely Predictable Problems, we compare and contrast CP entities (obeying Simple Elementary Fundamental Laws) against IP entities (obeying Complex Elementary Fundamental Laws) using examples:

(I) \mathbf{E} are CP entities constituted by CIS of \mathbf{Q} 2, 4, 6, 8, 10, 12....

(II) \mathbf{O} are CP entities constituted by CIS of \mathbf{Q} 1, 3, 5, 7, 9, 11....

(III) \mathbf{P} are IP entities constituted by CIS of \mathbf{Q} 2, 3, 5, 7, 11, 13....

(IV) \mathbf{C} are IP entities constituted by CIS of \mathbf{Q} 4, 6, 8, 9, 10, 12....

(V) With values traditionally given by parameter t , nontrivial zeros in Riemann zeta function are IP entities constituted by CIS of $\mathbf{R-A}$ [rounded off to six decimal places]: 14.134725, 21.022040, 25.010858, 30.424876, 32.935062, 37.586178,....

(VI) Traditional 'Gram points' (or Gram[$y=0$] points) are x-axis intercepts with choice of index 'n' for 'Gram points' historically chosen such that first 'Gram point' [by convention at $n = 0$] corresponds to the t value which is larger than (first) nontrivial zero located at $t = 14.134725$. 'Gram points' – see Appendix A for more details – are IP entities constituted by CIS of $\mathbf{R-A}$ [rounded off to six decimal places] with the first six given at $n = -3, t = 0$; at $n = -2, t = 3.436218$; at $n = -1, t = 9.666908$; at $n = 0, t = 17.845599$; at $n = 1, t = 23.170282$; at $n = 2, t = 27.670182$. We will not calculate any values for Gram[$x=0$] points here.

Denoted by parameter t; nontrivial zeros, 'Gram points' and Gram[$x=0$] points all belong to well-defined CIS of $\mathbf{R-A}$ which will twice obey the relevant location definition [in CIS of $\mathbf{R-A}$ themselves and in CIS of numerical digits after decimal point of each $\mathbf{R-A}$]. First and only negative 'Gram point' (at $n = -3$) is obtained by substituting CP $t = 0$ resulting in $\zeta(\frac{1}{2} + it) = \zeta(\frac{1}{2}) = -1.4603545$, a $\mathbf{R-A}$ number [rounded off to seven decimal places] calculated as a limit similar to limit for Euler-Mascheroni constant or Euler gamma with its precise (1st) position only determined by computing positions of all preceding (nil) 'Gram point' in this case. '0' and '1' are special numbers being neither \mathbf{P} nor \mathbf{C} as they represent nothingness (zero) and wholeness (one). In this setting, the ideas of (i) having factors for '0' and '1', or (ii) treating '0' and '1' as CP or IP numbers, is meaningless. All entities derived from well-defined simple/complex algorithms or equations are "dual numbers" as they can be simultaneously depicted as CP and IP numbers. For instance, $\mathbf{Q} '2'$ as \mathbf{P} (& \mathbf{E}), '97' as \mathbf{P} (& \mathbf{O}), '98' as \mathbf{C} (& \mathbf{E}), '99' as \mathbf{C} (& \mathbf{O}); CP '0' values in $x=0, y=0$ & simultaneous $x=0, y=0$ associated with various IP t values in $\zeta(s)$.

1.3 Algebraic number theory versus Analytic number theory

Set $\mathbf{P} \subset \text{Set } \mathbf{Z} \subset \text{Set } \mathbf{Q}$. Gaussian rationals, and Gaussian integers are complex numbers whose real and imaginary parts are (respectively) both rational numbers, and integer numbers. Gaussian primes are Gaussian integers $z = a + bi$ satisfying one of the following properties.

1. If both a and b are nonzero, then $a+bi$ is a Gaussian prime iff $a^2 + b^2$ is an ordinary prime [whereby iff is the written abbreviation for 'if and only if'].
2. If $a = 0$, then bi is a Gaussian prime iff $|b|$ is an ordinary prime and $|b| = 3 \pmod{4}$.
3. If $b = 0$, then a is a Gaussian prime iff $|a|$ is an ordinary prime and $|a| = 3 \pmod{4}$.

Prime numbers which are also Gaussian primes are 3, 7, 11, 19, 23, 31, 43,.... In Eq. (2.1) below, we noted that the equivalent Euler product formula with product over prime numbers [instead of summation over natural numbers] faithfully represent Riemann zeta function, $\zeta(s)$. Eq. (2.2) below is Riemann's functional equation involving transcendental number π ($= 3.14159\dots$). With denominators on the left involving odd numbers and named after Gottfried Leibniz, Leibniz formula for π states that $\frac{1}{1} - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \frac{1}{9} - \dots = \frac{\pi}{4}$. Expression $\zeta(2) = \frac{1}{1^2} + \frac{1}{2^2} + \frac{1}{3^2} + \dots = \frac{\pi^2}{6} \approx 1.64493406684822643647$ involves $\pi \implies$ division concerning two unrelated transcendental (irrational) numbers $\frac{\zeta(2)}{\pi^2}$ interestingly results in rational number $\frac{1}{6}$.

Algebraic number theory is loosely defined to deal with new number systems involving Completely Predictable or Incompletely Predictable entities such as even & odd numbers, prime & composite numbers, p -adic numbers, Gaussian primes, Gaussian rationals & integers, and complex numbers. A p -adic number is an extension of the field of rationals such that congruences modulo powers of a fixed prime number p are related to proximity in so-called " p -adic metric". The extension is achieved by an alternative interpretation of concept of "closeness" or absolute value viz. p -adic numbers are considered to be close when their difference is divisible by a high power of p : the higher the power, the closer they are. This property enables p -adic numbers to encode congruence information in a way that turns out to have powerful applications in number theory including, for example, attacking certain Diophantine equations and in the famous proof of Fermat's Last Theorem by English mathematician Sir Andrew John Wiles in 1995.

Analytic number theory is loosely defined to deal with functions of a complex variable such as Riemann zeta function [containing nontrivial zeros and two types of Gram points] and other L-functions. Study of prime numbers, complex numbers and π being braided together in a pleasing trio is usefully visualized to be located

at intersection of this two main branches of number theory. We separate our relatively elementary proof for Riemann hypothesis and relatively elementary explanations for two types of Gram points to belong to Analytic number theory, and our relatively elementary proofs for Polignac's and Twin prime conjectures [expectedly associated with paucity of functions involving a complex variable] to belong to Algebraic number theory.

Secondary spin-offs from solving Riemann hypothesis are often stated as "With this one solution, we have proven five hundred theorems or more at once". This apply to many important theorems in Number theory (mostly on prime numbers) that rely on properties of Riemann zeta function such as where trivial and nontrivial zeros are / are not located. A classical example is resulting absolute and full delineation of prime number theorem which relates to prime counting function. This function, usually denoted by $\pi(x)$, is defined as the number of prime numbers $\leq x$. Public-key cryptography that is widely required for financial security in E-Commerce traditionally depend on solving difficult problem of factoring prime numbers for astronomically large numbers. The intrinsic "Incompletely Predictable" property present in prime numbers, composite numbers, nontrivial zeros and two types of Gram points can never be altered to "Completely Predictable" property. For this stated reason, it is a mathematical impossibility that providing rigorous proofs such as for Riemann hypothesis will, in principle, ever result in crypto-apocalypse. However, utilizing parallel computing (more than serial computing), fast supercomputers and far-more-powerful quantum computers would theoretically allow solving difficult factorization problem in quick time, resulting in less secure encryption and decryption. Then using, for instance, quantum cryptography that relies on principles of quantum mechanics to encrypt and transmit data in a way that cannot be hacked will combat this issue.

Proposed by German mathematician Bernhard Riemann (September 17, 1826 – July 20, 1866) in 1859, Riemann hypothesis is mathematical statement on $\zeta(s)$ that critical line denoted by $\sigma = \frac{1}{2}$ contains complete Set **nontrivial zeros** with $|\text{nontrivial zeros}| = \aleph_0$. Alternatively, this hypothesis is geometrical statement on $\zeta(s)$ that generated curves at $\sigma = \frac{1}{2}$ contain complete Set **Origin intercepts** with $|\text{Origin intercepts}| = \aleph_0$.

$$\zeta(s) = \frac{e^{(\ln(2\pi) - 1 - \frac{\gamma}{2})s}}{2(s-1)\Gamma(1 + \frac{s}{2})} \prod_p \left(1 - \frac{s}{p}\right) e^{\frac{s}{p}} = \pi^{\frac{s}{2}} \frac{\prod_p \left(1 - \frac{s}{p}\right)}{2(s-1)\Gamma(1 + \frac{s}{2})}$$

Depicted in full and abbreviated version, Hadamard product above is infinite product expansion of $\zeta(s)$ based on Weierstrass's factorization theorem displaying a simple pole at $s = 1$. It contains both trivial & nontrivial zeros indicating their common origin from $\zeta(s)$. Set **trivial zeros** occurs at $\sigma = -2, -4, -6, -8, -10, \dots, \infty$ with $|\text{trivial zeros}| = \aleph_0$ due to Γ function term in denominator. Nontrivial zeros occur at $s = \rho$ with γ denoting Euler-Mascheroni constant.

Remark 1.3. Confirming first 10,000,000,000,000 nontrivial zeros location on critical line implies but does not prove Riemann hypothesis to be true.

Locations of first 10,000,000,000,000 nontrivial zeros on critical line have previously been computed to be correct. Hardy in 1914[7], and with Littlewood in 1921[8], showed infinite nontrivial zeros on critical line by considering moments of certain functions related to $\zeta(s)$. This discovery cannot constitute rigorous proof for Riemann hypothesis because they have not exclude theoretical existence of nontrivial zeros located away from this line.

1.4 Exact and inexact Dimensional analysis homogeneity for equations and inequations

Respectively for 'base quantities' such as *length*, *mass* and *time*; their fundamental SI 'units of measurement' meter (m) is defined as distance travelled by light in vacuum for time interval $1/299\,792\,458$ s with speed of light $c = 299,792,458 \text{ ms}^{-1}$, kilogram (kg) is defined by taking fixed numerical value Planck constant h to be $6.626\,070\,15 \times 10^{-34}$ Joules-second (Js) [whereby Js is equal to $\text{kgm}^2\text{s}^{-1}$] and second (s) is defined in terms of $\Delta\nu\text{Cs} = \Delta(^{133}\text{Cs})_{hfs} = 9,192,631,770 \text{ s}^{-1}$. Derived SI units such as J and ms^{-1} respectively represent 'base quantities' *energy* and *velocity*. The word 'dimension' is commonly used to indicate all those mentioned 'units of measurement' in well-defined equations.

Dimensional analysis (DA) is an analytic tool with DA homogeneity and non-homogeneity (respectively) denoting valid and invalid equation occurring when 'units of measurements' for 'base quantities' are "balanced" and "unbalanced" across both sides of the equation. E.g. equation $2\text{ m} + 3\text{ m} = 5\text{ m}$ is valid and equation $2\text{ m} + 3\text{ kg} = 5\text{ 'm}\cdot\text{kg}'$ is invalid (respectively) manifesting DA homogeneity and non-homogeneity.

Remark 1.4. We can validly apply exact and inexact Dimensional analysis homogeneity to well-defined equations and inequations.

Let $(2n)$ and $(2n-1)$ be 'base quantities' in our derived Dirichlet Sigma-Power Laws formatted in simplest forms as equations and inequations. E.g. DA on exponent $\frac{1}{2}$ in $(2n)^{\frac{1}{2}}$ when depicted in simplest form is desirable for our purpose but DA on exponent $\frac{1}{4}$ in equivalent $(2^2n^2)^{\frac{1}{4}}$ not depicted in simplest form is undesirable for our purpose. Fractional exponents as 'units of measurement' given by $(1 - \sigma)$ for equations and $(\sigma + 1)$ for inequations when $\sigma = \frac{1}{2}$ coincide with exact DA homogeneity¹; and $(1 - \sigma)$ for equations and $(\sigma + 1)$ for inequations when $\sigma \neq \frac{1}{2}$ coincide with inexact DA homogeneity². Respectively for equations and inequations, exact DA homogeneity at $\sigma = \frac{1}{2}$ denotes $\Sigma(\text{all fractional exponents})$ as $2(1 - \sigma)$ and Pseudo- $\Sigma(\text{all fractional exponents})$ as $2(\sigma + 1)$ equates to ["exact"] whole number '1' and '3'; and inexact DA homogeneity at $\sigma \neq \frac{1}{2}$ denotes $\Sigma(\text{all fractional exponents})$ as $2(1 - \sigma)$ and Pseudo- $\Sigma(\text{all fractional exponents})$ as $2(\sigma + 1)$ equates to ["inexact"] fractional number ' $\neq 1$ ' and ' $\neq 3$ '. R1 terms in all inequations contain $(2n)$ and $(2n-1)$ 'base quantities' but these are endowed with exponent 1 [and not with fractional exponent $(\sigma+1)$] as relevant 'unit of measurement' thus giving rise to our Pseudo- $\Sigma(\text{all fractional exponents})$.

Footnote 1, 2: Exact & inexact DA homogeneity occur in Dirichlet Sigma-Power Laws as equations or inequations for Gram $[y=0]$ points, Gram $[x=0]$ points & nontrivial zeros. *Law of Continuity* is a heuristic principle *whatever succeed for the finite, also succeed for the infinite*. These Laws which inherently manifest themselves on finite & infinite time scale should "succeed for the finite, also succeed for the infinite".

Outline of proof for Riemann hypothesis. {Validity in using the inequations with their Pseudo- $\Sigma(\text{all fractional exponents})$ given by $2(\sigma + 1)$ instead of their [actual] $\Sigma(\text{all fractional exponents})$ given by $(\sigma + 2)$ is allowed since the absolute difference between the two terms is simply the constant σ . For equations, their [actual] $\Sigma(\text{all fractional exponents})$ given by $2(1 - \sigma)$ meant that the absolute difference between this term and the Pseudo- $\Sigma(\text{all fractional exponents})$ given by $2(\sigma + 1)$ or [actual] $\Sigma(\text{all fractional exponents})$ given by $(\sigma + 2)$ for inequations is, respectively, simply the constant 4σ or 3σ , thus lending further support to this validity.} To simultaneously satisfy two mutually inclusive conditions: I. *With rigid manifestation of exact DA homogeneity*, Set **nontrivial zeros** with $|\text{nontrivial zeros}| = \aleph_0$ is located on critical line (viz. $\sigma = \frac{1}{2}$) when $2(1 - \sigma)$ [or $2(\sigma + 1)$] as $\Sigma(\text{all fractional exponents}) = \text{whole number '1'}$ [or Pseudo- $\Sigma(\text{all fractional exponents}) = \text{whole number '3'}$] in Dirichlet Sigma-Power Law³ as equation [or inequation]. II. *With rigid manifestation of inexact DA homogeneity*, Set **nontrivial zeros** with $|\text{nontrivial zeros}| = \aleph_0$ is not located on non-critical lines (viz. $\sigma \neq \frac{1}{2}$) when $2(1 - \sigma)$ [or $2(\sigma + 1)$] as $\Sigma(\text{all fractional exponents}) = \text{fractional number ' $\neq 1$ '}$ [or Pseudo- $\Sigma(\text{all fractional exponents}) = \text{fractional number ' $\neq 3$ '}$] in Dirichlet Sigma-Power Law³ as equation [or inequation].

Footnote 3: Derived from original $\eta(s)$ (proxy for $\zeta(s)$) as equation or inequation, this Law symbolizes end-result proof on Riemann hypothesis.

Riemann hypothesis mathematical foot-prints. Six identifiable steps to prove Riemann hypothesis: *Step 1* Use $\eta(s)$, proxy for $\zeta(s)$, in critical strip. *Step 2* Apply Euler formula to $\eta(s)$. *Step 3* Obtain "simplified" Dirichlet eta function which intrinsically incorporates *actual location [but not actual positions]* of all non-trivial zeros⁴. *Step 4* Apply Riemann integral to "simplified" Dirichlet eta function in discrete (summation) format. *Step 5* Obtain Dirichlet Sigma-Power Law in continuous (integral) format as equation or inequation. *Step 6* Confirm exact or inexact DA homogeneity for $\Sigma(\text{all fractional exponents})$ and Pseudo- $\Sigma(\text{all fractional exponents})$.

Footnote 4: Respectively Gram $[y=0]$ points, Gram $[x=0]$ points and nontrivial zeros are Incompletely Predictable entities with actual positions determined by setting $\Sigma \text{Im}\{\eta(s)\} = 0$, $\Sigma \text{Re}\{\eta(s)\} = 0$ and $\Sigma \text{ReIm}\{\eta(s)\} = 0$ to *dependently* calculate relevant positions of all preceding entities in neighborhood. Respectively actual location of Gram $[y=0]$ points, Gram $[x=0]$ points and nontrivial zeros; and virtual Gram $[y=0]$ points, virtual Gram $[x=0]$ points and "absent" nontrivial zeros occur precisely at $\sigma = \frac{1}{2}$; and $\sigma \neq \frac{1}{2}$.

2 Riemann zeta and Dirichlet eta functions

An L-function consists of a Dirichlet series with a functional equation and an Euler product. Examples of L-functions come from modular forms, elliptic curves, number fields, and Dirichlet characters, as well as more generally from automorphic forms, algebraic varieties, and Artin representations. They form an integrated component of 'L-functions and Modular Forms Database' (LMFDB) with far-reaching implications. In perspective, $\zeta(s)$ is the simplest example of an L-function. It is a function of complex variable $s (= \sigma \pm it)$ that analytically continues sum of infinite series $\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s} = \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \dots$. The common convention is to write s as $\sigma + it$ with $t = \sqrt{-1}$, and with σ and t real. Valid for $\sigma > 0$, we write $\zeta(s)$ as $\text{Re}\{\zeta(s)\} + i\text{Im}\{\zeta(s)\}$ and note that $\zeta(\sigma + it)$ when $0 < t < +\infty$ is the complex conjugate of $\zeta(\sigma - it)$ when $-\infty < t < 0$.

Also known as alternating zeta function, $\eta(s)$ must act as *proxy* for $\zeta(s)$ in critical strip (viz. $0 < \sigma < 1$) containing critical line (viz. $\sigma = \frac{1}{2}$) because $\zeta(s)$ only converges when $\sigma > 1$. This implies $\zeta(s)$ is undefined to left of this region in critical strip which then requires $\eta(s)$ representation instead. They are related to each other as $\zeta(s) = \gamma \cdot \eta(s)$ with proportionality factor $\gamma = \frac{1}{(1-2^{1-s})}$ and $\eta(s) = \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s} = \frac{1}{1^s} - \frac{1}{2^s} + \frac{1}{3^s} - \dots$.

$$\begin{aligned} \zeta(s) &= \sum_{n=1}^{\infty} \frac{1}{n^s} \\ &= \frac{1}{1^s} + \frac{1}{2^s} + \frac{1}{3^s} + \dots \\ &= \prod_{p \text{ prime}} \frac{1}{(1-p^{-s})} \\ &= \frac{1}{(1-2^{-s})} \cdot \frac{1}{(1-3^{-s})} \cdot \frac{1}{(1-5^{-s})} \cdot \frac{1}{(1-7^{-s})} \cdot \frac{1}{(1-11^{-s})} \dots \frac{1}{(1-p^{-s})} \dots \end{aligned} \quad (2.1)$$

Eq. (2.1) is defined for only $1 < \sigma < \infty$ region where $\zeta(s)$ is absolutely convergent with no zeros located here. In Eq. (2.1), equivalent Euler product formula with product over prime numbers [instead of summation over natural numbers] also represents $\zeta(s) \implies$ all prime numbers are (intrinsically) "encoded" in $\zeta(s)$. This observation alone represents a strong reason to conveniently combine proofs for Riemann hypothesis, Polignac's and Twin prime conjectures in our [one] paper.

$$\zeta(s) = 2^s \pi^{s-1} \sin\left(\frac{\pi s}{2}\right) \cdot \Gamma(1-s) \cdot \zeta(1-s) \quad (2.2)$$

With $\sigma = \frac{1}{2}$ as symmetry line of reflection, Eq. (2.2) is Riemann's functional equation valid for $-\infty < \sigma < \infty$. It can be used to find all trivial zeros on horizontal line at $t = 0$ occurring when $\sigma = -2, -4, -6, -8, -10, \dots, \infty$ whereby $\zeta(s) = 0$ because factor $\sin\left(\frac{\pi s}{2}\right)$ vanishes. Γ is gamma function, an extension of factorial function [a product function denoted by ! notation whereby $n! = n(n-1)(n-2)\dots(n-(n-1))$] with its argument shifted down by 1, to real and complex numbers. That is, if n is a positive integer, $\Gamma(n) = (n-1)!$

$$\begin{aligned} \zeta(s) &= \frac{1}{(1-2^{1-s})} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s} \\ &= \frac{1}{(1-2^{1-s})} \left(\frac{1}{1^s} - \frac{1}{2^s} + \frac{1}{3^s} - \dots \right) \end{aligned} \quad (2.3)$$

Eq. (2.3) is defined for all $\sigma > 0$ values except for simple pole at $\sigma = 1$. As alluded to above, $\zeta(s)$ without $\frac{1}{(1-2^{1-s})}$ viz. $\sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n^s}$ is $\eta(s)$. It is a holomorphic function of s defined by analytic continuation and is

Fig. 8: INPUT for $\sigma = \frac{1}{2}, \frac{2}{5},$ and $\frac{3}{5}$. $\zeta(s)$ has countable infinite set (CIS) of Completely Predictable trivial zeros at $\sigma =$ all negative even numbers and [proposed] CIS of Incompletely Predictable nontrivial zeros at $\sigma = \frac{1}{2}$ for various t values.

Fig. 9: OUTPUT for $\sigma = \frac{1}{2}$. Figures 9 represents schematically depicted polar graph of $\zeta(\frac{1}{2} + it)$ plotted along critical line for real values of t running from 0 to 34, horizontal axis: $Re\{\zeta(\frac{1}{2} + it)\}$, and vertical axis: $Im\{\zeta(\frac{1}{2} + it)\}$. There are presence of Origin intercepts which are totally absent in Figures 10 and 11 [with identical axes definitions].

mathematically defined at $\sigma = 1$ whereby analogous trivial zeros with presence only for $\eta(s)$ [but not for $\zeta(s)$] on vertical straight line $\sigma = 1$ are found at $s = 1 \pm i \frac{2\pi k}{\ln(2)}$ where $k = 1, 2, 3, 4, 5, \dots, \infty$.

Figure 8 depict complex variable $s (= \sigma \pm it)$ as INPUT with x-axis denoting real part $Re\{s\}$ associated with σ , and y-axis denoting imaginary part $Im\{s\}$ associated with t . Figures 9, 10 and 11 respectively depict $\zeta(s)$ as OUTPUT for real values of t running from 0 to 34 at $\sigma = \frac{1}{2}$ (critical line), $\sigma = \frac{2}{5}$ (non-critical line), and $\sigma = \frac{3}{5}$ (non-critical line) with x-axis denoting real part $Re\{\zeta(s)\}$ and y-axis denoting imaginary part $Im\{\zeta(s)\}$. There are infinite types-of-spirals possibilities associated with each σ value arising from all infinite σ values in critical strip. Mathematically proving all nontrivial zeros location on critical line as denoted by solitary $\sigma = \frac{1}{2}$ value equates to geometrically proving all Origin intercepts occurrence at solitary $\sigma = \frac{1}{2}$ value. Both result in rigorous proof for Riemann hypothesis.

Fig. 10: OUTPUT for $\sigma = \frac{2}{5}$.Fig. 11: OUTPUT for $\sigma = \frac{3}{5}$.

3 Prerequisite lemma, corollary & propositions for Riemann hypothesis

Original equation $\eta(s)$, proxy for $\zeta(s)$, is treated as unique mathematical object with key properties and behaviors. Containing all x-axis, y-axis and Origin intercepts, it will intrinsically incorporate *actual location [but not actual positions]* of all Gram[y=0] points, Gram[x=0] points and nontrivial zeros. Proofs on lemma, corollary and propositions on nontrivial zeros depict exact and inexact DA homogeneity in both derived equation and inequation. Parallel procedure on Gram[y=0] and Gram[x=0] points in Section 5 below depict exact and inexact DA homogeneity in similarly derived equations and inequations.

Lemma 3.1. "Simplified" Dirichlet eta function is derived directly from Dirichlet eta function with Euler formula application and it will intrinsically incorporate actual location [but not actual positions] of all nontrivial zeros.

Proof. Denote complex number (\mathbb{C}) as $z = x + iy$. Then $z = \text{Re}(z) + i \cdot \text{Im}(z)$ with $\text{Re}(z) = x$ and $\text{Im}(z) = y$; modulus of z , $|z| = \sqrt{\text{Re}(z)^2 + \text{Im}(z)^2} = \sqrt{x^2 + y^2}$; and $|z|^2 = x^2 + y^2$.

Euler formula is commonly stated as $e^{ix} = \cos x + i \cdot \sin x$. Euler identity (where $x = \pi$) is $e^{i\pi} = \cos \pi + i \cdot \sin \pi = -1 + 0$ [or stated as $e^{i\pi} + 1 = 0$]. The n^s of $\zeta(s)$ is expanded to $n^s = n^{(\sigma+it)} = n^\sigma e^{t \ln(n) \cdot i}$ since $n^t = e^{t \ln(n)}$. Apply Euler formula to n^s result in $n^s = n^\sigma (\cos(t \ln(n)) + i \cdot \sin(t \ln(n)))$. This is written in trigonometric form [designated by short-hand notation $n^s(\text{Euler})$] whereby n^σ is modulus and $t \ln(n)$ is polar angle (argument).

Apply n^s (Euler) to Eq. (2.1). Then $\zeta(s) = \text{Re}\{\zeta(s)\} + \iota \cdot \text{Im}\{\zeta(s)\}$ with $\text{Re}\{\zeta(s)\} = \sum_{n=1}^{\infty} n^{-\sigma} \cos(t \ln(n))$ and $\text{Im}\{\zeta(s)\} = \sum_{n=1}^{\infty} n^{-\sigma} \sin(t \ln(n))$. As Eq. (2.1) is defined only for $\sigma > 1$ where zeros never occur, we will not carry out further treatment here on this equation.

Apply n^s (Euler) to Eq. (2.3). Then $\zeta(s) = \gamma \cdot \eta(s) = \gamma \cdot [\text{Re}\{\eta(s)\} + \iota \cdot \text{Im}\{\eta(s)\}]$ with $\text{Re}\{\eta(s)\} = \sum_{n=1}^{\infty} ((2n-1)^{-\sigma} \cos(t \ln(2n-1)) - (2n)^{-\sigma} \cos(t \ln(2n)))$;

$\text{Im}\{\eta(s)\} = \sum_{n=1}^{\infty} ((2n)^{-\sigma} \sin(t \ln(2n)) - (2n-1)^{-\sigma} \sin(t \ln(2n-1)))$; and proportionality factor $\gamma = \frac{1}{(1-2^{1-s})}$.

Complex number s in critical strip is designated by $s = \sigma + it$ for $0 < t < +\infty$ and $s = \sigma - it$ for $-\infty < t < 0$. Nontrivial zeros equating to $\zeta(s) = 0$ give rise to our desired $\eta(s) = 0$. Modulus of $\eta(s)$, $|\eta(s)|$, is defined as $\sqrt{(\text{Re}\{\eta(s)\})^2 + (\text{Im}\{\eta(s)\})^2}$ with $|\eta(s)|^2 = (\text{Re}\{\eta(s)\})^2 + (\text{Im}\{\eta(s)\})^2$. Mathematically $|\eta(s)| = |\eta(s)|^2 = 0$ is an unique condition giving rise to $\eta(s) = 0$ occurring only when $\text{Re}\{\eta(s)\} = \text{Im}\{\eta(s)\} = 0$ as any non-zero values for $\text{Re}\{\eta(s)\}$ and/or $\text{Im}\{\eta(s)\}$ will always result in $|\eta(s)|$ and $|\eta(s)|^2$ having non-zero values. Important implication is that sum of $\text{Re}\{\eta(s)\}$ and $\text{Im}\{\eta(s)\}$ equating to zero [given by Eq. (3.1)] must always hold when $|\eta(s)| = |\eta(s)|^2 = 0$ and consequently $\eta(s) = 0$.

$$\sum \text{ReIm}\{\eta(s)\} = \text{Re}\{\eta(s)\} + \text{Im}\{\eta(s)\} = 0 \quad (3.1)$$

In principle, advocating for existence of theoretical s values leading to non-zero values in $\text{Re}\{\eta(s)\}$ and $\text{Im}\{\eta(s)\}$ depicted as possibility $+\text{Re}\{\eta(s)\} = -\text{Im}\{\eta(s)\}$ or $-\text{Re}\{\eta(s)\} = +\text{Im}\{\eta(s)\}$ could satisfy Eq. (3.1). This reverse implication is not necessarily true as these s values will not result in $|\eta(s)| = |\eta(s)|^2 = 0$. In any event, we need not consider these two possibilities since solving Riemann hypothesis involves nontrivial zeros defined by $\eta(s) = 0$ with non-zero values in $\text{Re}\{\eta(s)\}$ and/or $\text{Im}\{\eta(s)\}$ not compatible with $\eta(s) = 0$.

Riemann hypothesis proposed all nontrivial zeros to be located on critical line. This location is conjectured to be uniquely associated with presence of exact DA homogeneity in derived equation & inequation of Dirichlet Sigma-Power Law with Eq. (3.1) intrinsically incorporated into this Law as $\eta(s) = 0$ definition for nontrivial zeros equates to Eq. (3.1).

Apply trigonometry identity $\cos(x) - \sin(x) = \sqrt{2} \sin\left(x + \frac{3}{4}\pi\right)$ to $\text{Re}\{\eta(s)\} + \text{Im}\{\eta(s)\}$ to get Eq. (3.2) with terms in last line built by mixture of terms from $\text{Re}\{\eta(s)\}$ & $\text{Im}\{\eta(s)\}$.

$$\begin{aligned} \sum \text{ReIm}\{\eta(s)\} &= \sum_{n=1}^{\infty} [(2n-1)^{-\sigma} \cos(t \ln(2n-1)) - (2n)^{-\sigma} \sin(t \ln(2n-1)) \\ &- (2n)^{-\sigma} \cos(t \ln(2n)) + (2n)^{-\sigma} \sin(t \ln(2n))] \\ &= \sum_{n=1}^{\infty} [(2n-1)^{-\sigma} \sqrt{2} \sin(t \ln(2n-1) + \frac{3}{4}\pi) - (2n)^{-\sigma} \sqrt{2} \sin(t \ln(2n) + \frac{3}{4}\pi)] \end{aligned} \quad (3.2)$$

When depicted in terms of Eq. (3.1), Eq. (3.2) becomes

$$\begin{aligned} \sum_{n=1}^{\infty} (2n)^{-\sigma} \sqrt{2} \sin(t \ln(2n) + \frac{3}{4}\pi) &= \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \sqrt{2} \sin(t \ln(2n-1) + \frac{3}{4}\pi) \\ \sum_{n=1}^{\infty} (2n)^{-\sigma} \sqrt{2} \sin(t \ln(2n) + \frac{3}{4}\pi) &- \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \sqrt{2} \sin(t \ln(2n-1) + \frac{3}{4}\pi) = 0 \end{aligned} \quad (3.3)$$

Eq. (3.3) in discrete (summation) format is a non-Hybrid integer sequence equation – see Appendix C. $\eta(s)$ calculations for all σ values result in infinitely many non-Hybrid integer sequence equations for $0 < \sigma < 1$ critical strip region of interest with $n = 1, 2, 3, 4, 5, \dots, \infty$ as discrete integer number values, or $n = 1$ to ∞ as continuous real numbers values with Riemann integral application. These equations will geometrically represent entire plane of critical strip, thus (at least) allowing our proposed proof to be of a complete nature.

Finally, Eq. (3.3) being the "simplified" Dirichlet eta function derived directly from $\eta(s)$ will intrinsically incorporate *actual location [but not actual positions]* of all nontrivial zeros. *The proof is now complete for Lemma 3.1*□.

Proposition 3.2. Dirichlet Sigma-Power Law in continuous (integral) format given as equation and in-equation can both be derived directly from "simplified" Dirichlet eta function in discrete (summation) format with Riemann integral application. [Note: Dirichlet Sigma-Power Law in continuous (integral) format refers to end-product obtained from "first key step of converting Riemann zeta function into its continuous format version".]

Proof. In Calculus, integration is reverse process of differentiation viewed geometrically as numerical "total area value" solution enclosed by curve of function and x-axis. Apply definite integral I between limits (or points) a and b is to compute its value when $\Delta x \rightarrow 0$, i.e. $I = \lim_{\Delta x \rightarrow 0} \sum_{i=1}^n f(x_i) \Delta x_i = \int_a^b f(x) dx$. This is Riemann integral of function $f(x)$ in interval $[a, b]$ where $a < b$. Apply Riemann integral to "simplified" Dirichlet eta function in $[\Delta x \rightarrow 1]$ discrete (summation) format which intrinsically incorporates *actual location [but not actual positions]* of all nontrivial zeros criterion to obtain Dirichlet Sigma-Power Law in $[\Delta x \rightarrow 0]$ continuous (integral) format with the later validly representing the former. Then Dirichlet Sigma-Power Law will also fulfill this criterion. Due to resemblance to power law functions in σ from $s = \sigma + it$ being exponent of a power function n^σ , logarithm scale use, and harmonic $\zeta(s)$ series connection in Zipf's law; we elect to call this Law by its given name. A characteristic and crucial part of this Law is its exact formula expression in usual mathematical language $[y = f(x_1, x_2)]$ format description for a 2-variable function with $(2n)$ and $(2n - 1)$ as 'base quantities' consist of $y = f(t, \sigma)$ with discrete $n = 1, 2, 3, 4, 5, \dots, \infty$ or continuous $n = 1$ to ∞ ; $-\infty < t < +\infty$; and $0 < \sigma < 1$.

A proper integral is a definite integral which has neither limit a or b infinite and from which the integrand does not approach infinity at any point in the range of integration. Only a proper integral will have its [solitary] combined +ve (above x-axis) and -ve (below x-axis) non-zero numerical "total area value" solution successfully computed from applying Riemann integral. An improper integral is a definite integral that has either or both limits a and b infinite or an integrand that approaches infinity at one or more points in the range of integration.

The resulting Dirichlet Sigma-Power Law, being improper integral (with lower limit $a = 1$ and upper limit $b = \infty$) obtained from [validly] applying Riemann integral to "simplified" Dirichlet eta function, will [expectedly] have its [multiple] +ve (above x-axis) minus -ve (below x-axis) numerical "net area value" solutions successfully computed – see Propositions 3.3 and 3.4 below. All relevant antiderivatives in this paper are derived from improper integrals with format $\int_1^\infty f(n) dn$ based on Eqs. (3.3), (5.2) & (5.4). Example for Eq. (3.3), involved improper integrals are from $\int_1^\infty (2n)^{-\sigma} \sqrt{2} \sin(t \ln(2n) + \frac{3}{4}\pi) dn - \int_1^\infty (2n-1)^{-\sigma} \sqrt{2} \sin(t \ln(2n-1) + \frac{3}{4}\pi) dn = 0$. These improper integrals are seen to involve [periodic] sine function between limits 1 and ∞ . Each improper integral can be validly expanded as $\int_{n=1}^{n=2} f(n) dn + \int_{n=2}^{n=3} f(n) dn + \int_{n=3}^{n=4} f(n) dn + \dots + \int_{n=\infty-1}^{n=\infty} f(n) dn$ which, for all sufficiently large t as $t \rightarrow \infty$, will manifest *divergence by oscillation* (viz. for all sufficiently large t as $t \rightarrow \infty$, this cumulative total will not diverge in a particular direction to a solitary well-defined limit value such as $\sin \pi/2 = 1$ or less well-defined limit value such as $+\infty$).

With steps of manual integration shown using indefinite integrals [for simplicity], we solve definite integral based on numerator portion of R1 with $(2n)$ parameter in Eq. (3.3):

$$\int_1^\infty \frac{2^{\frac{1}{2}-\sigma} \sin(t \ln(2n) + \frac{3\pi}{4})}{n^\sigma} dn = \int_1^\infty -\frac{\sin(t \ln(2n)) - \cos(t \ln(2n))}{2^\sigma n^\sigma} dn.$$

We deduce most other important integrals to be "variations" of this particular integral containing (i) deletion of $(2n)^{-\sigma}$, $\sqrt{2}$ or $\frac{3}{4}\pi$ terms, and/or (ii) interchange of sine and cosine function. We check all derived antiderivatives to be correct using computer algebra system Maxima.

$$\text{Simplifying and applying linearity, we obtain } 2^{\frac{1}{2}-\sigma} \int \frac{\sin(t \ln(2n) + \frac{3\pi}{4})}{n^\sigma} dn.$$

Now solving $\int \frac{\sin(t \ln(2n) + \frac{3\pi}{4})}{n^\sigma} dn$. Substitute $u = t \ln(2n) + \frac{3\pi}{4} \rightarrow$
 $dn = \frac{n}{t} du$, use $n^{1-\sigma} = e^{\frac{(1-\sigma)(u - t \ln(2) - \frac{3\pi}{4})}{t}} = \frac{e^{\frac{(\sigma-1)(4t \ln(2) + 3\pi)}{4t}}}{t} \int e^{\frac{(1-\sigma)u}{t}} \sin(u) du$.

Now solving $\int e^{\frac{(1-\sigma)u}{t}} \sin(u) du$. We integrate by parts twice in a row: $\int f g' = f g - \int f' g$. First time:
 $f = \sin(u)$, $g' = e^{\frac{(1-\sigma)u}{t}}$

Then $f' = \cos(u)$, $g = \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}}}{\sigma^2 - 2\sigma + 1}$:

$$= \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \sin(u)}{\sigma^2 - 2\sigma + 1} - \int \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \cos(u)}{\sigma^2 - 2\sigma + 1} du$$

Second time: $f = \cos(u)$, $g' = \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}}}{\sigma^2 - 2\sigma + 1}$

Then $f' = -\sin(u)$, $g = \frac{t^2 e^{\frac{(1-\sigma)u}{t}}}{\sigma^2 - 2\sigma + 1}$:

$$= \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \sin(u)}{\sigma^2 - 2\sigma + 1} - \left(\frac{t^2 e^{\frac{(1-\sigma)u}{t}} \cos(u)}{\sigma^2 - 2\sigma + 1} - \int -\frac{t^2 e^{\frac{(1-\sigma)u}{t}} \sin(u)}{\sigma^2 - 2\sigma + 1} du \right)$$

Apply linearity:

$$= \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \sin(u)}{\sigma^2 - 2\sigma + 1} - \left(\frac{t^2 e^{\frac{(1-\sigma)u}{t}} \cos(u)}{\sigma^2 - 2\sigma + 1} + \frac{t^2}{\sigma^2 - 2\sigma + 1} \int e^{\frac{(1-\sigma)u}{t}} \sin(u) du \right)$$

As integral $\int e^{\frac{(1-\sigma)u}{t}} \sin(u) du$ appears again on Right Hand Side, we solve for it:

$$= \frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \sin(u) - e^{\frac{(1-\sigma)u}{t}} \cos(u)}{\frac{\sigma^2 - 2\sigma + 1}{t^2} + 1}$$

Plug in solved integrals: $\frac{e^{\frac{(\sigma-1)(4t \ln(2) + 3\pi)}{4t}}}{t} \int e^{\frac{(1-\sigma)u}{t}} \sin(u) du$

$$= \frac{e^{\frac{(\sigma-1)(4t \ln(2) + 3\pi)}{4t}} \left(\frac{(1-\sigma)t e^{\frac{(1-\sigma)u}{t}} \sin(u)}{t} - e^{\frac{(1-\sigma)u}{t}} \cos(u) \right)}{\left(\frac{\sigma^2 - 2\sigma + 1}{t^2} + 1 \right) t}$$

Undo substitution $u = t \ln(2n) + \frac{3\pi}{4}$ and simplifying:

$$= \frac{e^{\frac{(\sigma-1)(4t \ln(2) + 3\pi)}{4t}} \left(\frac{(1-\sigma)t e^{\frac{(1-\sigma)(t \ln(2n) + \frac{3\pi}{4})}{t}} \sin(t \ln(2n) + \frac{3\pi}{4})}{t} - e^{\frac{(1-\sigma)(t \ln(2n) + \frac{3\pi}{4})}{t}} \cos(t \ln(2n) + \frac{3\pi}{4}) \right)}{\left(\frac{\sigma^2 - 2\sigma + 1}{t^2} + 1 \right) t}$$

Plug in solved integrals: $2^{\frac{1}{2}-\sigma} \int \frac{\sin(t \ln(2n) + \frac{3\pi}{4})}{n^\sigma} dn$

$$= \frac{2^{\frac{1}{2}-\sigma} e^{\frac{(\sigma-1)(4t \ln(2) + 3\pi)}{4t}} \left(\frac{(1-\sigma)t e^{\frac{(1-\sigma)(t \ln(2n) + \frac{3\pi}{4})}{t}} \sin(t \ln(2n) + \frac{3\pi}{4})}{t} - e^{\frac{(1-\sigma)(t \ln(2n) + \frac{3\pi}{4})}{t}} \cos(t \ln(2n) + \frac{3\pi}{4}) \right)}{\left(\frac{\sigma^2 - 2\sigma + 1}{t^2} + 1 \right) t}$$

By rewriting and simplifying, $\int_1^\infty \frac{2^{\frac{1}{2}-\sigma} \sin(t \ln(2n) + \frac{3\pi}{4})}{n^\sigma} dn$ is finally solved as

$$\left[\frac{(2n)^{1-\sigma} ((t + \sigma - 1) \sin(t \ln(2n)) + (t - \sigma + 1) \cos(t \ln(2n)))}{2(t^2 + (\sigma - 1)^2)} + C \right]_1^\infty \quad (3.4)$$

Denominator portion of R1 with $(2n - 1)$ parameter in Eq. (3.3), Eq. (3.4) equates to

$$\left[\frac{(2n - 1)^{1-\sigma} ((t + \sigma - 1) \sin(t \ln(2n - 1)) + (t - \sigma + 1) \cos(t \ln(2n - 1)))}{2(t^2 + (\sigma - 1)^2)} + C \right]_1^\infty \quad (3.5)$$

Dirichlet Sigma-Power Law as equation derived from Eq. (3.3) is given by:

$$\frac{1}{2(t^2 + (\sigma - 1)^2)} \cdot [(2n)^{1-\sigma} ((t + \sigma - 1) \sin(t \ln(2n)) + (t - \sigma + 1) \cos(t \ln(2n))) - (2n - 1)^{1-\sigma} ((t + \sigma - 1) \sin(t \ln(2n - 1)) + (t - \sigma + 1) \cos(t \ln(2n - 1)))]_1^\infty = 0 \quad (3.6)$$

Apply Ratio Study to Eq. (3.3) – see Appendix B. This involves [intentional] incorrect but "balanced" rearrangement of terms in Eq. (3.3) giving rise to Eq. (3.7) which is a non-Hybrid integer sequence inequation. Left-hand side contains 'cyclical' sine function in first term (Ratio R1) and 'non-cyclical' power function in second term (Ratio R2).

$$\frac{\sum_{n=1}^{\infty} \sqrt{2} \sin(t \ln(2n) + \frac{3}{4}\pi)}{\sum_{n=1}^{\infty} \sqrt{2} \sin(t \ln(2n - 1) + \frac{3}{4}\pi)} - \frac{\sum_{n=1}^{\infty} (2n)^\sigma}{\sum_{n=1}^{\infty} (2n - 1)^\sigma} \neq 0 \quad (3.7)$$

Apply Riemann integral to selected parts of Eq. (3.7) without depicting steps of calculation:

$$\int_1^\infty \sqrt{2} \sin\left(t \ln(2n) + \frac{3\pi}{4}\right) dn = \left[\frac{(2n) ((t - 1) \sin(t \ln(2n)) + (t + 1) \cos(t \ln(2n)))}{2(t^2 + 1)} + C \right]_1^\infty$$

and $\int_1^\infty \sqrt{2} \sin\left(t \ln(2n - 1) + \frac{3\pi}{4}\right) dn = \left[\frac{(2n - 1) ((t - 1) \sin(t \ln(2n - 1)) + (t + 1) \cos(t \ln(2n - 1)))}{2(t^2 + 1)} + C \right]_1^\infty$

$$\int_1^\infty (2n)^\sigma dn = \left[\frac{(2n)^{\sigma+1}}{2(\sigma + 1)} + C \right]_1^\infty \quad \text{and} \quad \int_1^\infty (2n - 1)^\sigma dn = \left[\frac{(2n - 1)^{\sigma+1}}{2(\sigma + 1)} + C \right]_1^\infty$$

Dirichlet Sigma-Power Law as inequation derived from Eq. (3.7) is given by:

$$\left[\frac{(2n) ((t - 1) \sin(t \ln(2n)) + (t + 1) \cos(t \ln(2n)))}{2(t^2 + 1)} - \frac{(2n)^{\sigma+1}}{2(\sigma + 1)} \right]_1^\infty \neq 0 \quad (3.8)$$

Intended derivation of Dirichlet Sigma-Power Law as equation and inequation have been successful. *The proof is now complete for Proposition 3.2*□.

Proposition 3.3. Exact Dimensional analysis homogeneity at $\sigma = \frac{1}{2}$ in Dirichlet Sigma-Power Law as equation and inequation is (respectively) indicated by $\sum(\text{all fractional exponents}) = \text{whole number '1'}$ and Pseudo- $\sum(\text{all fractional exponents}) = \text{whole number '3'}$.

Proof. Preliminary discussion on using three types of symmetry for a given function: (1) symmetry about the vertical y-axis ["function is even"] e.g. cosine, arccos (2) symmetry about the origin ["function is odd"] e.g. sine, arcsin, tangent, arctan and (3) in all other cases ["function is neither even nor odd"]. Even function has its Cumulative Total areas symmetrical about the vertical axis and odd function has its Cumulative Total areas symmetrical about the origin (with conservation or preservation of areas derived from [opposite side] numerical "net area value" always equal to zero in both cases).

We classify our antiderivatives below using these functions with their basic properties such as sum [or difference] of two even (odd) functions is even (odd); sum [or difference] of an even and odd function is neither

even nor odd (unless one of the functions is equal to zero over the given domain); product [or quotient] of two even or odd functions is an even function; and product [or quotient] of an even function and an odd function is an odd function. We will shortly see that only Dirichlet Sigma-Power Laws as equation and inequation pertaining to calculations intended for Gram[x=0,y=0] points will uniquely manifest "functions that are neither even nor odd".

Dirichlet Sigma-Power Law as equation for $\sigma = \frac{1}{2}$ value is given by:

$$\frac{1}{2t^2 + \frac{1}{2}} \cdot [(2n)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2n)) + (t + \frac{1}{2}) \cos(t \ln(2n)) \right) - (2n - 1)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2n - 1)) + (t + \frac{1}{2}) \cos(t \ln(2n - 1)) \right)]_1^{\infty} = 0 \tag{3.9}$$

Respectively evaluation of definite integrals Eq. (3.9), Eq. (5.9) and Eq. (5.11) using limit as $n \rightarrow +\infty$ for $0 < t < +\infty$ enable countless computations resulting in t values for CIS of nontrivial zeros, Gram[y=0] and Gram[x=0] points. Larger n values used for computations will correspond to increasing accuracy of these entities (which are all transcendental numbers). We evaluate Eq. (3.9) to obtain its expanded antiderivative:

$$\begin{aligned} & \frac{1}{2t^2 + \frac{1}{2}} \cdot [(2\infty)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2\infty)) + (t + \frac{1}{2}) \cos(t \ln(2\infty)) \right) - (2\infty - 1)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2\infty - 1)) + (t + \frac{1}{2}) \cos(t \ln(2\infty - 1)) \right) \\ & - (2)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2)) + (t + \frac{1}{2}) \cos(t \ln(2)) \right) + (1)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(1)) + (t + \frac{1}{2}) \cos(t \ln(1)) \right)] = 0 \end{aligned}$$

$$\begin{aligned} & \frac{1}{2t^2 + \frac{1}{2}} \cdot [(2\infty)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2\infty)) + (t + \frac{1}{2}) \cos(t \ln(2\infty)) \right) - (2\infty - 1)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2\infty - 1)) + (t + \frac{1}{2}) \cos(t \ln(2\infty - 1)) \right) \\ & - (2)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2)) + (t + \frac{1}{2}) \cos(t \ln(2)) \right) + (t + \frac{1}{2})] = 0 \end{aligned}$$

We are interested in the last two terms [equivalent to substituting in $n = 1$]

$$\frac{1}{2t^2 + \frac{1}{2}} \cdot [-(2)^{\frac{1}{2}} \left((t - \frac{1}{2}) \sin(t \ln(2)) + (t + \frac{1}{2}) \cos(t \ln(2)) \right) + (t + \frac{1}{2})]$$

Equivalent evaluation on Eq. (3.9) to obtain its expanded antiderivative depicted as linear combination of sine and cosine waves: $a \sin x + b \cos x = c \sin(x + \varphi)$ with $c = \sqrt{a^2 + b^2}$ and $\varphi = \text{atan2}(b, a) = \tan^{-1}(\frac{b}{a})$ for a

$$\begin{aligned} > 0: \frac{1}{2t^2 + \frac{1}{2}} \cdot [((2\infty)(2t^2 + \frac{1}{2}))^{\frac{1}{2}} \sin \left((t \ln 2\infty) + \tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right) - ((2\infty - 1)(2t^2 + \frac{1}{2}))^{\frac{1}{2}} \sin \left((t \ln 2\infty - 1) + \tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right) - ((2)(2t^2 + \frac{1}{2}))^{\frac{1}{2}} \sin \left((t \ln 2) + \tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right) + (2t^2 + \frac{1}{2})^{\frac{1}{2}} \sin \left(\tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right)] = 0 \end{aligned}$$

We look at the last two terms

$$\frac{1}{2t^2 + \frac{1}{2}} \cdot [-(2)(2t^2 + \frac{1}{2})^{\frac{1}{2}} \sin \left((t \ln 2) + \tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right) + (2t^2 + \frac{1}{2})^{\frac{1}{2}} \sin \left(\tan^{-1} \left(\frac{t + \frac{1}{2}}{t - \frac{1}{2}} \right) \right)]$$

Relevant t values for all nontrivial zeros at $\sigma = \frac{1}{2}$ and $n = 1$ [and combined $n = 1, 2$ and 3] plotted against the expanded antiderivative depicted as linear combination of sine and cosine waves is shown in Figure 12 [and in Figure 13]. We see the phenomenon of "monotonously decreasing height waves of varying amplitude with different n values" comply with functions that are neither even nor odd. As mentioned previously, all improper integrals are seen to involve [periodic] sine function between limits 1 and ∞ . Then from Figure 13 for nontrivial zeros, we can geometrically visualize that fully computing (for instance) $\int_{n=1}^{n=2} f(n)dn$ and $\int_{n=2}^{n=3} f(n)dn$ will result in respective antiderivatives that still involve sine functions [of varying frequency and amplitude]. Identical arguments can be extended to Gram[y=0] and Gram[x=0] points.

Fig. 12: Nontrivial zeros [first 10 plotted] at $\sigma = \frac{1}{2}$ for $n = 1$ using Dirichlet Sigma-Power Law.

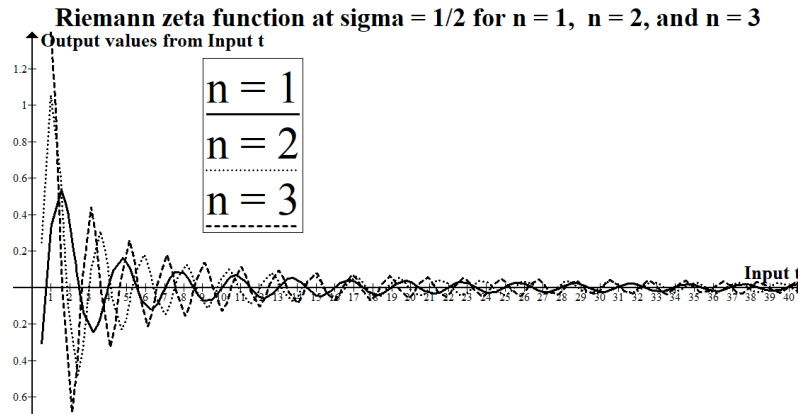

Fig. 13: Nontrivial zeros at $\sigma = \frac{1}{2}$ for $n = 1, 2$ and 3 using Dirichlet Sigma-Power Law.

Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{1}{2}$ value is given by:

$$\left[\frac{(2n)((t-1)\sin(t\ln(2n)) + (t+1)\cos(t\ln(2n)))}{(2n-1)((t-1)\sin(t\ln(2n-1)) + (t+1)\cos(t\ln(2n-1)))} - \frac{(2n)^{\frac{3}{2}}}{(2n-1)^{\frac{3}{2}}} \right]_1^{\infty} \neq 0 \quad (3.10)$$

From the two allocated σ values in Figure 14 at $n = 1$ when depicted using calculations with Dirichlet Sigma-Power Law as inequation, we justifiably deduce the following: Manifesting phenomenon of "constant height waves of varying amplitude with different n values" that comply with functions that are neither even nor odd will always occur at $\sigma = \frac{1}{2}$ & all $\sigma \neq \frac{1}{2}$ values. Without depicting parallel steps of calculation, the equivalent **inequations** Dirichlet Sigma-Power Law for last two terms [expanded antiderivative depicted as linear combination of sine and cosine waves] for nontrivial zeros [first 10 plotted] at $\sigma = \frac{1}{2}$ & $\sigma = \frac{2}{3}$ when $n = 1$ is, respectively & sequentially, given as:

$$- \frac{(2) \left((2t^2 + 2)^{\frac{1}{2}} \sin\left(t \ln 2 + \tan^{-1}\left(\frac{t+1}{t-1}\right)\right) \right)}{(1) \left((2t^2 + 2)^{\frac{1}{2}} \sin\left(t \ln 1 + \tan^{-1}\left(\frac{t+1}{t-1}\right)\right) \right)} + \frac{(2)^{\frac{3}{2}}}{(1)^{\frac{3}{2}}}$$

Fig. 14: Nontrivial zeros [first 10 plotted] present at $\sigma = \frac{1}{2}$ and nil nontrivial zeros present at $\sigma = \frac{2}{5}$ for $n = 1$ using Dirichlet Sigma-Power Law as inequation.

$$- \frac{(2) \left((2t^2 + 2)^{\frac{1}{2}} \sin((t \ln 2) + \tan^{-1}(\frac{t+1}{t-1})) \right)}{(1) \left((2t^2 + 2)^{\frac{1}{2}} \sin((t \ln 1) + \tan^{-1}(\frac{t+1}{t-1})) \right)} + \frac{(2)^{\frac{7}{5}}}{(1)^{\frac{7}{5}}}$$

Σ (all fractional exponents) as $2(1 - \sigma) = \text{whole number '1'}$ for Eq. (3.9) and Pseudo- Σ (all fractional exponents) as $2(\sigma + 1) = \text{whole number '3'}$ for Eq. (3.10). These findings signify presence of complete set nontrivial zeros for Eq. (3.9) and Eq. (3.10). *The proof is now complete for Proposition 3.3*□.

Corollary 3.4. Inexact Dimensional analysis homogeneity at $\sigma \neq \frac{1}{2}$ [illustrated using $\sigma = \frac{2}{5}$] in Dirichlet Sigma-Power Law as equation and inequation is (respectively) indicated by Σ (all fractional exponents) = fractional number ' $\neq 1$ ' and Pseudo- Σ (all fractional exponents) = fractional number ' $\neq 3$ '.

Proof. Dirichlet Sigma-Power Law as equation for $\sigma = \frac{2}{5}$ value is given by:

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[(2n)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2n)) + (t + \frac{3}{5}) \cos(t \ln(2n)) \right) - (2n-1)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2n-1)) + (t + \frac{3}{5}) \cos(t \ln(2n-1)) \right) \right]_1^{\infty} = 0 \quad (3.11)$$

We evaluate Eq. (3.11) to obtain its expanded antiderivative:

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[(2\infty)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2\infty)) + (t + \frac{3}{5}) \cos(t \ln(2\infty)) \right) - (2\infty-1)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2\infty-1)) + (t + \frac{3}{5}) \cos(t \ln(2\infty-1)) \right) - (2)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2)) + (t + \frac{3}{5}) \cos(t \ln(2)) \right) + (1)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(1)) + (t + \frac{3}{5}) \cos(t \ln(1)) \right) \right] = 0$$

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[(2\infty)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2\infty)) + (t + \frac{3}{5}) \cos(t \ln(2\infty)) \right) - (2\infty-1)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2\infty-1)) + (t + \frac{3}{5}) \cos(t \ln(2\infty-1)) \right) - (2)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2)) + (t + \frac{3}{5}) \cos(t \ln(2)) \right) \right]$$

We are interested in the last two terms [equivalent to substituting in $n = 1$]

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[-(2)^{\frac{3}{5}} \left((t - \frac{3}{5}) \sin(t \ln(2)) + (t + \frac{3}{5}) \cos(t \ln(2)) \right) + (1)^{\frac{3}{5}} \right]$$

Equivalent valuation on Eq. (3.11) to obtain its expanded antiderivative depicted as linear combination of sine and cosine waves: $a \sin x + b \cos x = c \sin(x + \varphi)$ with $c = \sqrt{a^2 + b^2}$ and $\varphi = \text{atan2}(b, a) = \tan^{-1}(\frac{b}{a})$ for $a > 0$:

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[\left((2\infty)^{\frac{3}{5}} (2t^2 + \frac{18}{25})^{\frac{1}{2}} \sin \left((t \ln 2\infty) + \tan^{-1} \left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}} \right) \right) \right) \right]$$

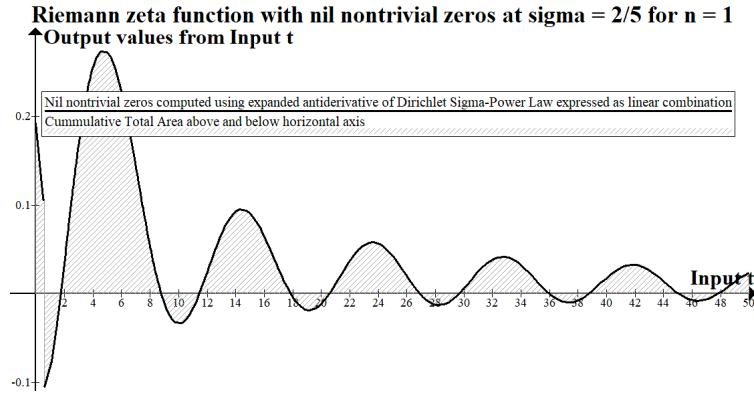

Fig. 15: Nil nontrivial zeros present at $\sigma = \frac{2}{5}$ for $n = 1$ using Dirichlet Sigma-Power Law.

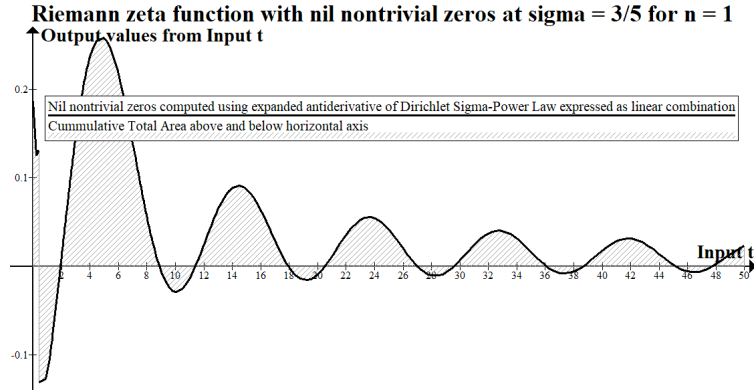

Fig. 16: Nil nontrivial zeros present at $\sigma = \frac{3}{5}$ for $n = 1$ using Dirichlet Sigma-Power Law.

$$\begin{aligned}
 & -((2\infty - 1)^{\frac{3}{5}}(2t^2 + \frac{18}{25}))^{\frac{1}{2}} \sin\left((t \ln 2\infty - 1) + \tan^{-1}\left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}}\right)\right) \\
 & - \left((2)^{\frac{3}{5}}(2t^2 + \frac{18}{25})^{\frac{1}{2}} \sin\left((t \ln 2) + \tan^{-1}\left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}}\right)\right) + (2t^2 + \frac{18}{25})^{\frac{1}{2}} \sin\left(\tan^{-1}\left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}}\right)\right) \right) = 0
 \end{aligned}$$

We look at the last two terms

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[-(2^{\frac{3}{5}}(2t^2 + \frac{18}{25}))^{\frac{1}{2}} \sin\left((t \ln 2) + \tan^{-1}\left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}}\right)\right) + (2t^2 + \frac{18}{25})^{\frac{1}{2}} \sin\left(\tan^{-1}\left(\frac{t + \frac{3}{5}}{t - \frac{3}{5}}\right)\right) \right]$$

The last two terms of expanded antiderivative depicted as linear combination of sine and cosine waves at $\sigma = \frac{3}{5}$ for $n = 1$ using Dirichlet Sigma-Power Law (Figure 16) is given by

$$\frac{1}{2t^2 + \frac{8}{25}} \cdot \left[-(2^{\frac{2}{5}}(2t^2 + \frac{8}{25}))^{\frac{1}{2}} \sin\left((t \ln 2) + \tan^{-1}\left(\frac{t + \frac{2}{5}}{t - \frac{2}{5}}\right)\right) + (2t^2 + \frac{8}{25})^{\frac{1}{2}} \sin\left(\tan^{-1}\left(\frac{t + \frac{2}{5}}{t - \frac{2}{5}}\right)\right) \right].$$

Relevant t values (for non-existent nontrivial zeros) at $\sigma = \frac{2}{5}$ [and $\sigma = \frac{3}{5}$] for $n = 1$ plotted against expanded antiderivative depicted as linear combination of sine and cosine waves is shown in Figure 15 [and in Figure 16]. We see the phenomenon of "monotonously decreasing height waves of varying amplitude with different n values" comply with functions that are neither even nor odd occurring at $\sigma \neq \frac{1}{2}$.

Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{2}{5}$ value [as was previously described and depicted in Figure 15 at Proposition 3.3 above] is given by:

$$\left[\frac{(2n)((t-1)\sin(t\ln(2n)) + (t+1)\cos(t\ln(2n)))}{(2n-1)((t-1)\sin(t\ln(2n-1)) + (t+1)\cos(t\ln(2n-1)))} - \frac{(2n)^{\frac{7}{5}}}{(2n-1)^{\frac{7}{5}}} \right]_1^{\infty} \neq 0 \quad (3.12)$$

Σ (all fractional exponents) as $2(1 - \sigma) =$ fractional number ' $\neq 1$ ' for Eq. (3.11) and Pseudo- Σ (all fractional exponents) as $2(\sigma + 1) =$ fractional number ' $\neq 3$ ' for Eq. (3.12). These findings signify absence of complete set nontrivial zeros for Eq. (3.11) and Eq. (3.12). *The proof is now complete for Corollary 3.4*□.

4 Rigorous Proof for Riemann hypothesis summarized as Theorem Riemann I – IV

$$\zeta(s) = \frac{1}{s-1} + \frac{1}{2} + 2 \int_0^{\infty} \frac{\sin(s \arctan t)}{(1+t^2)^{\frac{s}{2}} (e^{2\pi t} - 1)} dt$$

is integral relation (cf. Abel-Plana summation formula [9][10]) for all $s \in \mathbb{C}$ and $s \neq 1$. This integral is insufficient for our purpose as it involves integration with respect to t [instead of n] for $\zeta(s)$ [instead of $\eta(s)$]. Relatively elementary proof for Riemann hypothesis is summarized by Theorem Riemann I – IV. One could obtain this proof with only using Dirichlet Sigma-Power Law [solely] as equation. For completeness and clarification of this proof, we supply following important mathematical arguments.

For $0 < \sigma < 1$, then $0 < 2(1 - \sigma) < 2$. The only whole number between 0 & 2 is '1' which coincide with $\sigma = \frac{1}{2}$. When $0 < \sigma < \frac{1}{2}$ & $\frac{1}{2} < \sigma < 1$, then [correspondingly] $0 < 2(1 - \sigma) < 1$ & $1 < 2(1 - \sigma) < 2$.

For $0 < \sigma < 1$, $2 < 2(\sigma + 1) < 4$. The only whole number between 2 & 4 is '3' which coincide with $\sigma = \frac{1}{2}$. When $0 < \sigma < \frac{1}{2}$ & $\frac{1}{2} < \sigma < 1$, then [correspondingly] $2 < 2(\sigma + 1) < 3$ & $3 < 2(\sigma + 1) < 4$.

Legend: \mathbf{R} = all real numbers. For $0 < \sigma < 1$, σ consist of $0 < \mathbf{R} < 1$. For $0 < 2(1 - \sigma) < 2$ and $2 < 2(\sigma + 1) < 4$, $2(1 - \sigma)$ and $2(\sigma + 1)$ must (respectively) consist of $0 < \mathbf{R} < 2$ and $2 < \mathbf{R} < 4$. An important caveat is that previously used phrases such as " Σ (all fractional exponents) = whole number '1' / fractional number ' $\neq 1$ ' [or Pseudo- Σ (all fractional exponents) = whole number '3' / fractional number ' $\neq 3$ ']", although not incorrect *per se*, should respectively be replaced by " Σ (all real exponents) = whole number '1' / real number ' $\neq 1$ ' [or Pseudo- Σ (all real exponents) = whole number '3' / real number ' $\neq 3$ ']" for complete accuracy. We apply this caveat to Theorem Riemann I – IV.

Footnote 5: As whole numbers \subset real numbers, one could also depict this phrase as " Σ (all real exponents) or Pseudo- Σ (all real exponents) = real number '1' / real number ' $\neq 1$ ' or real number ' $\neq 1$ ' / ' $\neq 3$ '".

Theorem Riemann I. Derived from *proxy* Dirichlet eta function, "simplified" Dirichlet eta function will exclusively contain *de novo* property for actual location [but not actual positions] of all nontrivial zeros.

Proof. The phrase "actual location [but not actual positions] of all nontrivial zeros" can be validly shortened to "actual location of all nontrivial zeros" as used in Theorem Riemann II, III and IV. *The proof for Theorem Riemann I is now complete as it successfully incorporates proof for Lemma 3.1*□.

Theorem Riemann II. Dirichlet Sigma-Power Law [in continuous (integral) format] as equation and inequation which are both derived from "simplified" Dirichlet eta function [in discrete (summation) format] will exclusively manifest exact DA homogeneity in equation and inequation only when real number exponent $\sigma = \frac{1}{2}$.

Proof. *The proof for Theorem Riemann II is now complete as it successfully incorporates proofs from Proposition 3.2 on derivation for equation and inequation of Dirichlet Sigma-Power Law [with both containing de novo property for "actual location of all nontrivial zeros"] and Proposition 3.3 on manifestation of exact DA homogeneity in Dirichlet Sigma-Power Law as equation and inequation when real number exponent $\sigma = \frac{1}{2}$* □.

Theorem Riemann III. Real number exponent $\sigma = \frac{1}{2}$ in Dirichlet Sigma-Power Law as equation and inequation satisfying exact DA homogeneity is identical to σ variable in Riemann hypothesis which propose σ to also have exclusive value of $\frac{1}{2}$ (representing critical line) for "actual location of all nontrivial zeros", thus fully supporting Riemann hypothesis to be true with further clarification by Theorem Riemann IV.

Proof. Since $s = \sigma \pm it$, complete set of nontrivial zeros which is defined by $\eta(s) = 0$ is exclusively associated

with one (and only one) particular $\eta(\sigma \pm it) = 0$ value solution, and by default one (and only one) particular σ [conjecturally] = $\frac{1}{2}$ value solution. When performing exact DA homogeneity on Dirichlet Sigma-Power Law as equation and inequation [with both containing *de novo* property for "actual location of all nontrivial zeros"], the phrase "If real number exponent σ has exclusively $\frac{1}{2}$ value, only then will exact DA homogeneity be satisfied" implies one (and only one) possible mathematical solution. Theorem Riemann III reflect Theorem Riemann II on presence of exact DA homogeneity for $\sigma = \frac{1}{2}$ in Dirichlet Sigma-Power Law as equation and inequation. This Law has identical σ variable as that referred to by Riemann hypothesis [whereby σ here uniquely refer to critical line]. *The proof for Theorem Riemann III is now complete as it independently refers to simultaneous association of confirmed (i) solitary $\sigma = \frac{1}{2}$ value in Dirichlet Sigma-Power Law as equation and inequation satisfying exact DA homogeneity and (ii) critical line defined by solitary $\sigma = \frac{1}{2}$ value being the "actual location [but with no request to determine actual positions]" of all nontrivial zeros as proposed in original Riemann hypothesis*□.

Theorem Riemann IV. Condition 1. All $\sigma \neq \frac{1}{2}$ values (non-critical lines), viz. $0 < \sigma < \frac{1}{2}$ and $\frac{1}{2} < \sigma < 1$ values, exclusively does not contain "actual location of all nontrivial zeros" [manifesting *de novo* inexact DA homogeneity in equation and inequation], together with Condition 2. One (& only one) $\sigma = \frac{1}{2}$ value (critical line) exclusively contains "actual location of all nontrivial zeros" [manifesting *de novo* exact DA homogeneity in equation and inequation], confirm Riemann hypothesis to be true when these two mutually inclusive conditions are met.

Proof. Condition 2 Theorem Riemann IV simply reflect proof from Theorem Riemann III [incorporating Proposition 3.3] for "actual location of all nontrivial zeros" exclusively on critical line manifesting *de novo* exact DA homogeneity \sum (all real number exponents) = real number '1' for equation [or Pseudo- \sum (all real number exponents) = real number '3' for inequation]. *The proof for Condition 2 Theorem Riemann IV is now complete*□. Corollary 3.4 confirms *de novo* inexact DA homogeneity manifested as \sum (all real number exponents) = real number ' $\neq 1$ ' for equation [or Pseudo- \sum (all real number exponents) = real number ' $\neq 3$ ' for inequation] by all $\sigma \neq \frac{1}{2}$ values (non-critical lines) that are exclusively not associated with "actual location of all nontrivial zeros". Applying inclusion-exclusion principle: Exclusive presence of nontrivial zeros on critical line for Condition 2 Theorem Riemann IV implies exclusive absence of nontrivial zeros on non-critical lines for Condition 1 Theorem Riemann IV. *The proof for Condition 1 Theorem Riemann IV is now complete*□.

We logically deduce that explicit mathematical explanation why presence and absence of nontrivial zeros⁶ should (respectively) coincide precisely with $\sigma = \frac{1}{2}$ and $\sigma \neq \frac{1}{2}$ [literally the Completely Predictable meta-properties ('overall' *complex properties*)] will require "complex" mathematical arguments. Attempting to provide explicit mathematical explanation with "simple" mathematical arguments would intuitively mean nontrivial zeros have to be (incorrectly and impossibly) treated as Completely Predictable entities.

Footnote 6: Completely Predictable meta-properties for Gram and virtual Gram points equating to "Presence of Gram[y=0] and Gram[x=0] points, and virtual Gram[y=0] and virtual Gram[x=0] points (respectively) coincide precisely with $\sigma = \frac{1}{2}$, and $\sigma \neq \frac{1}{2}$ ".

5 Prerequisite lemma, corollary & propositions for Gram[x=0] & Gram[y=0] points conjectures

For Gram[y=0] & Gram[x=0] points (and corresponding virtual Gram[y=0] & virtual Gram[x=0] points with totally different values), we apply a parallel procedure carried out on nontrivial zeros but only depict abbreviated treatments and discussions. We supply geometrical manifestations and related commentaries for equivalent "last two terms" at $n = 1$ for each entity using expanded antiderivative (at $\sigma = \frac{1}{2}$ & $\frac{2}{3}$) depicted as linear combination of sine and cosine waves: $a \sin x + b \cos x = c \sin(x + \varphi)$ with $c = \sqrt{a^2 + b^2}$.

Lemma 5.1. "Simplified" Gram[y=0] and Gram[x=0] points-Dirichlet eta functions are derived directly from Dirichlet eta function with Euler formula application and (respectively) they will intrinsically incorporate actual location [but not actual positions] of all Gram[y=0] and Gram[x=0] points.

Proof. For Gram[y=0] points, the equivalent of Eq. (3.1) and Eq. (3.3) are respectively given by Eq. (5.1) and Eq. (5.2) below.

$$\sum ReIm\{\eta(s)\} = Re\{\eta(s)\} + 0, \text{ or simply } Im\{\eta(s)\} = 0 \tag{5.1}$$

$$\begin{aligned} \sum_{n=1}^{\infty} (2n)^{-\sigma} \sin(t \ln(2n)) &= \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \sin(t \ln(2n-1)) \\ \sum_{n=1}^{\infty} (2n)^{-\sigma} \sin(t \ln(2n)) - \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \sin(t \ln(2n-1)) &= 0 \end{aligned} \tag{5.2}$$

For Gram[x=0] points, the equivalent of Eq. (3.1) and Eq. (3.3) are respectively given by Eq. (5.3) and Eq. (5.4) below.

$$\sum ReIm\{\eta(s)\} = 0 + Im\{\eta(s)\}, \text{ or simply } Re\{\eta(s)\} = 0 \tag{5.3}$$

$$\begin{aligned} \sum_{n=1}^{\infty} (2n)^{-\sigma} \cos(t \ln(2n)) &= \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \cos(t \ln(2n-1)) \\ \sum_{n=1}^{\infty} (2n)^{-\sigma} \cos(t \ln(2n)) - \sum_{n=1}^{\infty} (2n-1)^{-\sigma} \cos(t \ln(2n-1)) &= 0 \end{aligned} \tag{5.4}$$

Eq. (5.2) and Eq. (5.4) being the "simplified" Gram[y=0] and Gram[x=0] points-Dirichlet eta functions derived directly from $\eta(s)$ will intrinsically incorporate *actual location [but not actual positions]* of (respectively) all Gram[y=0] and Gram[x=0] points. *The proof is now complete for Lemma 5.1*□.

Proposition 5.2. Gram[y=0] and Gram[x=0] points-Dirichlet Sigma-Power Laws in continuous (integral) format given as equations and inequations can both be (respectively) derived directly from "simplified" Gram[y=0] and Gram[x=0] points-Dirichlet eta functions in discrete (summation) format with Riemann integral application. [Note: Gram[y=0] and Gram[x=0] points-Dirichlet Sigma-Power Laws in continuous (integral) format here refers to relevant end-products obtained from "first key step of converting Riemann zeta function into its continuous format version".]

Proof. Antiderivatives below using (2n) parameter help obtain all subsequent equations: first two for Gram[y=0] points and second two for Gram[x=0] points.

$$\begin{aligned} \int_1^{\infty} (2n)^{-\sigma} \sin(t \ln(2n)) dn &= \left[-\frac{(2n)^{1-\sigma} ((\sigma-1) \sin(t \ln(2n)) + t \cos(t \ln(2n)))}{2(t^2 + (\sigma-1)^2)} + C \right]_1^{\infty} \\ \int_1^{\infty} \sin(t \ln(2n)) dn &= \left[\frac{(2n)(\sin(t \ln(2n)) - t \cos(t \ln(2n)))}{2(t^2 + 1)} + C \right]_1^{\infty} \\ \int_1^{\infty} (2n)^{-\sigma} \cos(t \ln(2n)) dn &= \left[\frac{(2n)^{1-\sigma} (t \sin(t \ln(2n)) - (\sigma-1) \cos(t \ln(2n)))}{2(t^2 + (\sigma-1)^2)} + C \right]_1^{\infty} \\ \int_1^{\infty} \cos(t \ln(2n)) dn &= \left[\frac{(2n)(t \sin(t \ln(2n)) + \cos(t \ln(2n)))}{2(t^2 + 1)} + C \right]_1^{\infty} \end{aligned}$$

For Gram[y=0] points-Dirichlet Sigma-Power Law, the equivalent of Eq. (3.6) and Eq. (3.8) are respectively given by Eq. (5.5) as equation and Eq. (5.6) as inequation.

$$\begin{aligned} -\frac{1}{2(t^2 + (\sigma-1)^2)} \cdot [(2n)^{1-\sigma} ((\sigma-1) \sin(t \ln(2n)) + t \cos(t \ln(2n))) - \\ (2n-1)^{1-\sigma} ((\sigma-1) \sin(t \ln(2n-1)) + t \cos(t \ln(2n-1)))]_1^{\infty} = 0 \end{aligned} \tag{5.5}$$

$$\left[\frac{(2n)(\sin(t \ln(2n)) - t \cos(t \ln(2n)))}{(2n-1)(\sin(t \ln(2n-1)) - t \cos(t \ln(2n-1)))} - \frac{(2n)^{\sigma+1}}{(2n-1)^{\sigma+1}} \right]_1^{\infty} \neq 0 \tag{5.6}$$

For Gram[x=0] points-Dirichlet Sigma-Power Law, the equivalent of Eq. (3.6) and Eq. (3.8) are respectively given by Eq. (5.7) as equation and Eq. (5.8) as inequation.

Fig. 17: Gram[y=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{1}{2}$ at $n = 1$.

$$\frac{1}{2(t^2 + (\sigma - 1)^2)} \cdot [(2n)^{1-\sigma} (t \sin(t \ln(2n)) - (\sigma - 1) \cos(t \ln(2n))) - (2n-1)^{1-\sigma} (t \sin(t \ln(2n-1)) - (\sigma - 1) \cos(t \ln(2n-1)))]_1^\infty = 0 \quad (5.7)$$

$$\left[\frac{(2n)(t \sin(t \ln(2n)) + \cos(t \ln(2n)))}{(2n-1)(t \sin(t \ln(2n-1)) + \cos(t \ln(2n-1)))} - \frac{(2n)^{\sigma+1}}{(2n-1)^{\sigma+1}} \right]_1^\infty \neq 0 \quad (5.8)$$

Intended derivation of Gram[y=0] and Gram[x=0] points-Dirichlet Sigma-Power Laws as equations and inequations is successful. *The proof is now complete for Lemma 5.2*□.

Proposition 5.3. Exact Dimensional analysis homogeneity at $\sigma = \frac{1}{2}$ in Gram[y=0] and Gram[x=0] points-Dirichlet Sigma-Power Laws as equations and inequations are (respectively) indicated by \sum (all fractional exponents) = whole number '1' and Pseudo- \sum (all fractional exponents) = whole number '3'.

Proof. Gram[y=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{1}{2}$ value is given by:

$$-\frac{1}{2t^2 + \frac{1}{2}} \cdot [(2n)^{\frac{1}{2}} \left(t \cos(t \ln(2n)) - \frac{1}{2} \sin(t \ln(2n)) \right) - (2n-1)^{\frac{1}{2}} \left(t \cos(t \ln(2n-1)) - \frac{1}{2} \sin(t \ln(2n-1)) \right)]_1^\infty = 0 \quad (5.9)$$

"Last two terms" at $n = 1$:

$$\frac{1}{2t^2 + \frac{1}{2}} \left[\left(2t^2 + \frac{1}{4} \right)^{\frac{1}{2}} \sin((t \ln 2) - \tan^{-1}(2t)) - \left(t^2 + \frac{1}{4} \right)^{\frac{1}{2}} \sin(\tan^{-1}(2t)) \right]$$

In Figure 17, the phenomenon of "monotonously decreasing height waves of varying amplitude with different n values" comply with functions that are odd occurring at $\sigma = \frac{1}{2}$.

Gram[y=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{1}{2}$ value is given by:

$$\left[\frac{(2n)(\sin(t \ln(2n)) - t \cos(t \ln(2n)))}{(2n-1)(\sin(t \ln(2n-1)) - t \cos(t \ln(2n-1)))} - \frac{(2n)^{\frac{3}{2}}}{(2n-1)^{\frac{3}{2}}} \right]_1^\infty \neq 0 \quad (5.10)$$

$$\text{"Last two terms" at } n = 1 \text{ (as inequation): } -\frac{(2) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 2) - \tan^{-1}(t)) \right)}{(1) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 1) - \tan^{-1}(t)) \right)} + \frac{(2)^{\frac{3}{2}}}{(1)^{\frac{3}{2}}}$$

In Figure 18, the phenomenon of "constant height waves of varying amplitude with different n values" comply with functions that are even occurring at $\sigma = \frac{2}{5}$.

Gram[x=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{1}{2}$ value is given by:

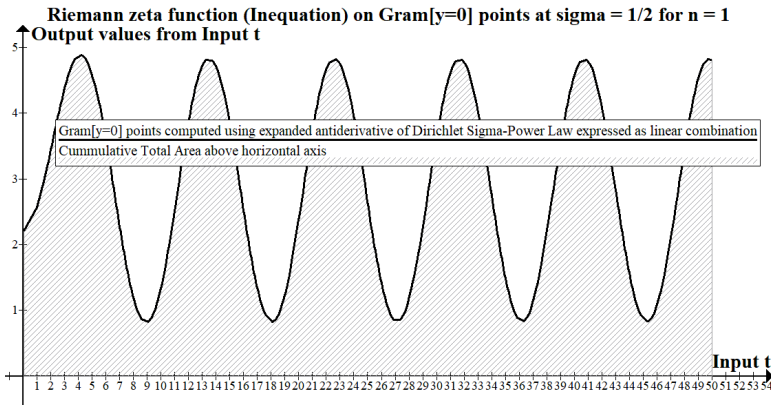

Fig. 18: Gram[y=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{1}{2}$ at $n = 1$.

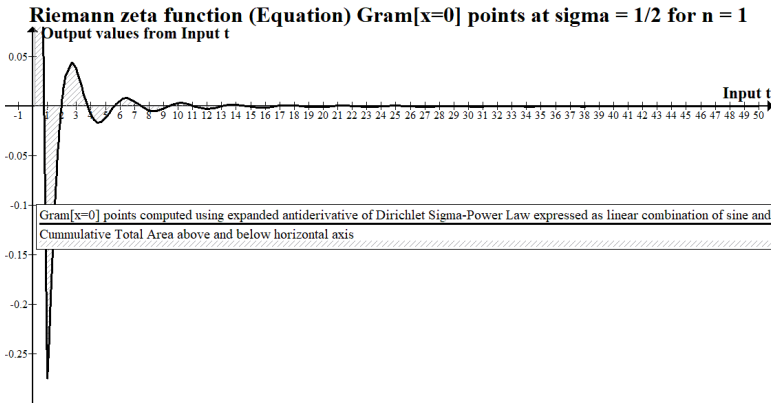

Fig. 19: Gram[x=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{1}{2}$ at $n = 1$.

$$\frac{1}{2t^2 + \frac{1}{2}} \cdot [(2n)^{\frac{1}{2}} (t \sin(t \ln(2n)) + \frac{1}{2} \cos(t \ln(2n))) -$$

$$(2n - 1)^{\frac{1}{2}} \left(t \sin(t \ln(2n - 1)) + \frac{1}{2} \cos(t \ln(2n - 1)) \right)]_1^{\infty} = 0 \tag{5.11}$$

”Last two terms” at $n = 1$:

$$\frac{1}{2t^2 + \frac{1}{2}} \left[-\left(2\left(t^2 + \frac{1}{4}\right)\right)^{\frac{1}{2}} \sin\left(t \ln 2 - \tan^{-1}\left(\frac{1}{2t}\right)\right) + \left(t^2 + \frac{1}{4}\right)^{\frac{1}{2}} \sin\left(\tan^{-1}\left(\frac{1}{2t}\right)\right) \right]$$

In Figure 19, the phenomenon of ”monotonously decreasing height waves of varying amplitude with different n values” comply with functions that are odd occurring at $\sigma = \frac{1}{2}$.

Gram[x=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{1}{2}$ value is given by:

$$\left[\frac{(2n)(t \sin(t \ln(2n)) + \cos(t \ln(2n)))}{(2n - 1)(t \sin(t \ln(2n - 1)) + \cos(t \ln(2n - 1)))} - \frac{(2n)^{\frac{3}{2}}}{(2n - 1)^{\frac{3}{2}}} \right]_1^{\infty} \neq 0 \tag{5.12}$$

Fig. 20: Gram[x=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{1}{2}$ at $n = 1$.

”Last two terms” at $n = 1$ (as inequation):
$$- \frac{(2) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 2) + \tan^{-1}(\frac{1}{t})) \right)}{(1) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 1) + \tan^{-1}(\frac{1}{t})) \right)} + \frac{(2)^{\frac{3}{2}}}{(1)^{\frac{3}{2}}}$$

In Figure 20, phenomenon of ”monotonously increasing height waves of varying amplitude with different n values” comply with functions that are even occurring at $\sigma = \frac{2}{5}$. Σ (all fractional exponents) as $2(1 - \sigma) =$ whole number ’1’ for Eqs. (5.9) & (5.11), and Pseudo- Σ (all fractional exponents) as $2(\sigma + 1) =$ whole number ’3’ for Eqs. (5.10) & (5.12). These findings signify presence of complete sets Gram[y=0] points for Eqs. (5.9) & (5.10) and Gram[x=0] points for Eqs. (5.11) & (5.12). *The proof is now complete for Proposition 5.3*□.

Corollary 5.4. Inexact Dimensional analysis homogeneity at $\sigma \neq \frac{1}{2}$ [illustrated using $\sigma = \frac{2}{5}$] in Gram[y=0] and Gram[x=0] points-Dirichlet Sigma-Power Laws as equations and inequations are (respectively) indicated by Σ (all fractional exponents) = fractional number ’ $\neq 1$ ’ and Pseudo- Σ (all fractional exponents) = fractional number ’ $\neq 3$ ’.

Proof. Gram[y=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{2}{5}$ value is given by:

$$- \frac{1}{2t^2 + \frac{18}{25}} \cdot [(2n)^{\frac{3}{5}} \left(t \cos(t \ln(2n)) - \frac{3}{5} \sin(t \ln(2n)) \right) - (2n - 1)^{\frac{3}{5}} \left(t \cos(t \ln(2n - 1)) - \frac{3}{5} \sin(t \ln(2n - 1)) \right)]_1^{\infty} = 0 \quad (5.13)$$

”Last two terms” at $n = 1$:

$$\frac{1}{2t^2 + \frac{18}{25}} \left[(2^{\frac{3}{5}} (t^2 + \frac{9}{25})^{\frac{1}{2}} \sin \left((t \ln 2) - \tan^{-1}(\frac{5t}{3}) \right) - (t^2 + \frac{9}{25})^{\frac{1}{2}} \sin \left(\tan^{-1}(\frac{5t}{3}) \right) \right]$$

In Figure 21, the phenomenon of ”monotonously decreasing height waves of varying amplitude with different n values” comply with functions that are odd occurring at $\sigma \neq \frac{1}{2}$.

Gram[y=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{2}{5}$ value is given by:

$$\left[\frac{(2n)(\sin(t \ln(2n)) - t \cos(t \ln(2n)))}{(2n - 1)(\sin(t \ln(2n - 1)) - t \cos(t \ln(2n - 1)))} - \frac{(2n)^{\frac{7}{5}}}{(2n - 1)^{\frac{7}{5}}} \right]_1^{\infty} \neq 0 \quad (5.14)$$

”Last two terms” at $n = 1$ (as inequation):
$$- \frac{(2) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 2) - \tan^{-1}(t)) \right)}{(1) \left((t^2 + 1)^{\frac{1}{2}} \sin((t \ln 1) - \tan^{-1}(t)) \right)} + \frac{(2)^{\frac{7}{5}}}{(1)^{\frac{7}{5}}}$$

Fig. 21: Gram[y=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{2}{5}$ at $n = 1$.

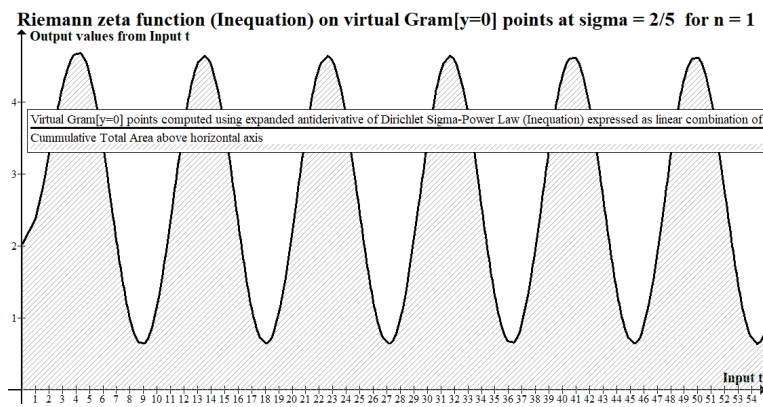

Fig. 22: Gram[y=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{2}{5}$ at $n = 1$.

In Figure 22, the phenomenon of "constant height waves of varying amplitude with different n values" comply with functions that are even occurring at $\sigma \neq \frac{1}{2}$.

Gram[x=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{2}{5}$ value is given by:

$$\frac{1}{2t^2 + \frac{18}{25}} \cdot \left[(2n)^{\frac{3}{5}} \left(t \sin(t \ln(2n)) + \frac{3}{5} \cos(t \ln(2n)) \right) - (2n-1)^{\frac{3}{5}} \left(t \sin(t \ln(2n-1)) + \frac{3}{5} \cos(t \ln(2n-1)) \right) \right]_1^\infty = 0 \tag{5.15}$$

"Last two terms" at $n = 1$: $\frac{1}{2t^2 + \frac{18}{25}} \left[-\left(2^{\frac{3}{5}} \left(t^2 + \frac{9}{25}\right)^{\frac{1}{2}} \sin\left(\left(t \ln 2 - \tan^{-1}\left(\frac{3}{5t}\right)\right)\right) + \left(t^2 + \frac{9}{25}\right)^{\frac{1}{2}} \sin\left(\tan^{-1}\left(\frac{3}{5t}\right)\right) \right]$

In Figure 23, the phenomenon of "monotonously decreasing height waves of varying amplitude with different n values" comply with functions that are odd occurring at $\sigma \neq \frac{1}{2}$.

Gram[x=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{2}{5}$ value is given by:

$$\left[\frac{(2n)(t \sin(t \ln(2n)) + \cos(t \ln(2n)))}{(2n-1)(t \sin(t \ln(2n-1)) + \cos(t \ln(2n-1)))} - \frac{(2n)^{\frac{7}{5}}}{(2n-1)^{\frac{7}{5}}} \right]_1^\infty \neq 0 \tag{5.16}$$

Fig. 23: Gram[x=0] points-Dirichlet Sigma-Power Law as equation for $\sigma = \frac{2}{5}$ at $n = 1$.

Fig. 24: Gram[x=0] points-Dirichlet Sigma-Power Law as inequation for $\sigma = \frac{2}{5}$ at $n = 1$.

”Last two terms” at $n = 1$ (as inequation):

$$-\frac{(2) \left((t^2 + 1)^{\frac{1}{2}} \sin\left(t \ln 2 + \tan^{-1}\left(\frac{1}{t}\right)\right) \right)}{(1) \left((t^2 + 1)^{\frac{1}{2}} \sin\left(t \ln 1 + \tan^{-1}\left(\frac{1}{t}\right)\right) \right)} + \frac{(2)^{\frac{7}{5}}}{(1)^{\frac{7}{5}}}$$

In Figure 24, the phenomenon of ”monotonously increasing height waves of varying amplitude with different n values” comply with functions that are even occurring at $\sigma \neq \frac{1}{2}$.

Σ (all fractional exponents) as $2(1 - \sigma) =$ fractional number ‘ $\neq 1$ ’ for Eqs. (5.13) and (5.15), and Pseudo- Σ (all fractional exponents) as $2(\sigma + 1) =$ fractional number ‘ $\neq 3$ ’ for Eqs. (5.14) and (5.16). These findings signify presence of complete sets virtual Gram[y=0] points for Eqs. (5.13) and (5.14) and virtual Gram[x=0] points for Eqs. (5.15) and (5.16). *The proof is now complete for Corollary 5.4*□.

6 Prime and Composite numbers

Prime & Composite numbers are Incompletely Predictable entities dependently linked together in a sequential, cumulative & eternal manner since relationship Number '1' + Prime numbers + Composite numbers = Natural numbers holds for all Natural numbers.

6.1 Dimensional analysis on Cardinality and "Dimensions" for Prime numbers

We use the word "Dimensions" to denote well-defined Incompletely Predictable entities obtained from using our unique Dimension (2x - N) system. Relevant "Dimensions" *dependently* represent Number '1', **P** and **C**. Then *by default* any (sub)sets of **P** and **C** in well-defined equations can also be represented by their corresponding "Dimensions".

Remark 6.1. We can apply Dimensional analysis to "Dimensions" from Information-Complexity conservation and cardinality of relevant sets in certain well-defined equations.

Let **X** denote **E**, **O**, **N** [which are classified as Completely Predictable numbers], **P** and **C** [which are classified as Incompletely Predictable numbers]. For $x = 1, 2, 3, 4, 5, \dots, \infty$; consider all $\mathfrak{X} \leq x$. Then this "all $\mathfrak{X} \leq x$ " is definition for $\mathfrak{X}-\pi(x)$ [denoting " \mathfrak{X} counting function"] resulting in following two types of equations coined as (I) 'Exact' equation $\mathfrak{N}-\pi(x) = \mathfrak{E}-\pi(x) + \mathfrak{O}-\pi(x)$ with "non-varying" relationships $\mathfrak{E}-\pi(x) = \mathfrak{O}-\pi(x)$ for all $x = \mathfrak{E}$ and $\mathfrak{E}-\pi(x) = \mathfrak{O}-\pi(x) - 1$ for all $x = \mathfrak{O}$, and (II) 'Inexact' equation $\mathfrak{N}-\pi(x) = 1 + \mathfrak{P}-\pi(x) + \mathfrak{C}-\pi(x)$ with "varying" relationships $\mathfrak{P}-\pi(x) > \mathfrak{C}-\pi(x)$ for all $x \leq 8$; $\mathfrak{P}-\pi(x) = \mathfrak{C}-\pi(x)$ for $x = 9, 11, \text{ and } 13$; and $\mathfrak{P}-\pi(x) < \mathfrak{C}-\pi(x)$ for $x = 10, 12, \text{ and all } x \geq 14$.

Let "Dimensions" and different (sub)sets of **E**, **O**, **N**, **P** and **C** be 'base quantities'. Then exponent '1' of "Dimensions" and cardinality of these (sub)sets in well-defined equations are corresponding 'units of measurement'. Performing DA on "Dimensions" for **PC** pairing is depicted later on. Performing DA on cardinality is depicted next.

For Set $\mathfrak{N} = \text{Set } \mathfrak{E} + \text{Set } \mathfrak{O}$, then $|\mathfrak{N}| = |\mathfrak{E}| + |\mathfrak{O}| \implies \mathfrak{N}_0 = \mathfrak{E}_0 + \mathfrak{O}_0$ thus conforming with DA homogeneity.

For Set $\mathfrak{N} = \text{Set } \mathfrak{P} + \text{Set } \mathfrak{C} + \text{Number '1'}$, then Set $\mathfrak{N} - \text{Number '1'}$ = Set $\mathfrak{P} + \text{Set } \mathfrak{C}$ and $|\mathfrak{N} - \text{Number '1'}| = |\mathfrak{P}| + |\mathfrak{C}| \implies \mathfrak{N}_0 = \mathfrak{P}_0 + \mathfrak{C}_0$ thus conforming with DA homogeneity.

For Set $\mathfrak{N} - \text{Set even } \mathfrak{P} - \text{Number '1'}$ = Set $\text{odd } \mathfrak{P} + \text{Set even } \mathfrak{C} + \text{Set odd } \mathfrak{C}$, then $|\mathfrak{N} - \text{even } \mathfrak{P} - \text{Number '1'}| = |\text{odd } \mathfrak{P}| + |\text{even } \mathfrak{C}| + |\text{odd } \mathfrak{C}| \implies \mathfrak{N}_0 = \mathfrak{P}_0 + \mathfrak{C}_0 + \mathfrak{C}_0$ thus conforming with DA homogeneity. Symbolically represented by all available **O** prime gap = 1 and **E** prime gaps = 2, 4, 6, 8, 10, ...; **O** composite gap = 1 and **E** composite gap = 2; and **O** natural gap = 1; then $|\text{Gap } 1 \mathfrak{N} - \text{Gap } 1 \mathfrak{P} - \text{Number '1'}| = |\text{Gap } 2 \mathfrak{P}| + |\text{Gap } 4 \mathfrak{P}| + |\text{Gap } 6 \mathfrak{P}| + |\text{Gap } 8 \mathfrak{P}| + |\text{Gap } 10 \mathfrak{P}| + \dots + |\text{Gap } 1 \mathfrak{C}| + |\text{Gap } 2 \mathfrak{C}| \implies \mathfrak{N}_0 = \mathfrak{P}_0 + \mathfrak{P}_0 + \mathfrak{P}_0 + \mathfrak{P}_0 + \mathfrak{P}_0 + \dots + \mathfrak{P}_0 + \mathfrak{C}_0$ thus conforming with DA homogeneity. It is known that $|\text{Gap } 1 \mathfrak{P}| = |\text{Number '2'}| = 1$ and $|\text{Gap } 1 \mathfrak{N}| = |\text{Gap } 1 \mathfrak{C}| = |\text{Gap } 2 \mathfrak{C}| = \mathfrak{N}_0$. Then solving Polignac's and Twin prime conjectures translate to successfully proving $|\text{Gap } 2 \mathfrak{P}| = |\text{Gap } 4 \mathfrak{P}| = |\text{Gap } 6 \mathfrak{P}| = |\text{Gap } 8 \mathfrak{P}| = |\text{Gap } 10 \mathfrak{P}| = \dots = \mathfrak{N}_0$ with $|\mathfrak{E} \text{ prime gaps}| = \mathfrak{N}_0$.

Outline of proof for Polignac's and Twin prime conjectures. Requires simultaneously satisfying two mutually inclusive conditions: I. *With rigid manifestation of DA homogeneity*, quantitative⁷ fulfillment by considering $i \in \mathfrak{E}$ for each Subset $\text{odd } \mathfrak{P}_i$ generated by **E** prime gap = i from Set **E prime gaps** occurs only if

solitary cardinality value is present in equation Set $\text{odd } \mathfrak{P} = \sum_{i=2}^{\infty} \text{Subset } \text{odd } \mathfrak{P}_i$ with $|\text{odd } \mathfrak{P}| = |\text{odd } \mathfrak{P}_i| = |\mathfrak{E}$

prime gaps}| = \mathfrak{N}_0, and II. *With rigid manifestation of DA non-homogeneity*, quantitative⁷ fulfillment by considering $i \in \mathfrak{E}$ for each Subset $\text{odd } \mathfrak{P}_i$ generated by **E prime gap = i from Set **E prime gaps** does not occur if more**

than one cardinality values are present in equation Set $\text{odd } \mathfrak{P} > \sum_{i=2}^{\infty} \text{Subset } \text{odd } \mathfrak{P}_i$ with $|\mathfrak{E} \text{ prime gaps}| = \mathfrak{N}_0$

having incorrect $|\text{Subset(s) } \text{odd } \mathfrak{P}| = \mathfrak{N}$ (finite value) &/or Set $\text{odd } \mathfrak{P} > \sum_{i=2}^{\mathfrak{N}} \text{Subset } \text{odd } \mathfrak{P}_i$ with $|\text{odd } \mathfrak{P}_i| = \mathfrak{N}_0$

having incorrect $|\mathfrak{E} \text{ prime gaps}| = \mathfrak{N}$ (finite value).

Footnote 7: Qualitative fulfillment of $|\text{odd } \mathfrak{P}| = |\text{odd } \mathfrak{P}_i| = |\text{all } \mathfrak{E} \text{ prime gaps}| = \mathfrak{N}_0$ equates to Plus-Minus Gap 2 Composite Number Alternating Law being precisely obeyed by all **E** prime gaps apart from first **E** prime

gap precisely obeying Plus Gap 2 Composite Number Continuous Law. Derived using Dimension $(2x - N)$ system, these Laws symbolize "end-result" proof on Polignac's and Twin prime conjectures. *Law of Continuity* is a heuristic principle *whatever succeed for the finite, also succeed for the infinite*. Then these Laws which inherently manifest 'Gap 2 Composite Number' on finite and infinite time scale should in principle "succeed for the finite, also succeed for the infinite".

Polignac's and Twin prime conjectures mathematical foot-prints. Six identifiable steps to prove these conjectures: *Step 1* Let $N = 2x - \Sigma PC_x$ -Gap. Define Dimension $(2x - N)$ to validly represent **P** & **C**. Considering $x \in \mathbf{N}$, obtain Dimensions $(2x - 2), (2x - 4), (2x - 5), (2x - 7), (2x - 8), (2x - 9), \dots, (2x - \infty)$ with specific groupings to constitute all elements of Set **P** [culminating in obtaining all prime gaps (= **E** prime gaps + Solitary **O** prime gap) with **|all prime gaps|** = \aleph_0]. Note Dimension $(2x - 2)$ represents $x = 1$ (Number '1') which is neither **P** nor **C**. Confirm all the obtained Dimension $(2x - N)$ will comply with Information-complexity conservation. *Step 2* Considering $i \in \mathbf{E}$, confirm perpetual recurrences of individual **E** prime gap = i (associated with its unique odd P_i) occur only when depicted as specific groupings of Dimension $(2x - N)^1$ now endowed with exponent '1' for all ranges of x . *Step 3* Perform DA on exponent '1' in these Dimensions. *Step 4* Perform DA on equation Set **odd P** = $\sum_{i=2}^{\infty}$ Subset **odd P_i** to obtain **|odd P|** = **|odd P_i|** = \aleph_0 whereby Subset **odd P_i** is derived from its associated unique **E** prime gap = i with **|E prime gaps|** = \aleph_0 . *Step 5* Confirm 'Prime number' variable and 'Prime gap' variable complex algorithm "containing" all **P** with knowing their overall actual location [but not actual positions]⁸. *Step 6* Derive Plus-Minus Gap 2 Composite Number Alternating Law & Plus Gap 2 Composite Number Continuous Law with Dimension $(2x - N)^1$.

Footnote 8: This phrase implies all **P** (and **C**) are Incompletely Predictable numbers. Actual positions require using complex algorithm Sieve of Eratosthenes to *dependently* calculate positions of all preceding **P** (and **C**) in neighborhood – see Lemma 8.4 [whereby $P_{n+1} = 2 + \sum_{i=1}^n G_{P_i}$ with '2' denoting P_1] & Lemma 8.5

[whereby $C_{n+1} = 4 + \sum_{i=1}^n G_{C_i}$ with '4' denoting C_1].

'Complex Elementary Fundamental Laws'-based solutions of Plus-Minus Gap 2 Composite Number Alternating Law and Plus Gap 2 Composite Number Continuous Law are obtained by undertaking the non-negotiable mathematical steps outlined above. These Laws are literally Completely Predictable meta-properties ('overall' *complex properties*) arising from "interactions" between **P** and **C** producing relevant patterns of Gap 2 Composite Number perpetual appearances [albeit with Incompletely Predictable timing]. We logically deduce explicit mathematical explanation for these meta-properties requires "complex" mathematical arguments. Attempts to give explicit mathematical explanation with "simple" mathematical arguments intuitively meant Incompletely Predictable numbers **P** and **C** are (incorrectly & impossibly) treated as Completely Predictable numbers.

6.2 Brief overview of Polignac's and Twin prime conjectures

Occurring over 2000 years ago (c. 300 BC), ancient Euclid's proof on infinitude of **P** in totality [viz. **|P|** = \aleph_0 for Set **P**] predominantly by *reductio ad absurdum* (proof by contradiction) is earliest known but not the only proof for this simple problem in Number theory. Since then dozens of proofs have been devised such as three chronologically listed: Goldbach's Proof using Fermat numbers (written in a letter to Swiss mathematician Leonhard Euler, July 1730), Furstenberg's Topological Proof in 1955[11], and Filip Saidak's Proof in 2006[12]. The strangest candidate is likely to be Furstenberg's Topological Proof.

In 2013, Yitang Zhang proved a landmark result showing some unknown even number 'N' < 70 million such that there are infinitely many pairs of **P** that differ by 'N'[13]. By optimizing Zhang's bound, subsequent Polymath Project collaborative efforts using a new refinement of GPY sieve in 2013 lowered 'N' to 246; and assuming Elliott-Halberstam conjecture and its generalized form have further lower 'N' to 12 and 6, respectively. Then 'N' has intuitively more than one valid values such that there are infinitely many pairs of **P** that differ by each of those 'N' values [thus proving existence of more than one Subset **odd P_i** with **|odd P_i|** = \aleph_0].

Prime gap	Following prime number	Prime gap	Following prime number
1*	2	18*	523
2*	3	20*	887
4*	7	22*	1129
6*	23	24	1669
8*	89	26	2477
10	139	28	2971
12	199	30	4297
14*	113	32	5591
16	1831

Legend: maximal prime gaps is depicted with asterisk symbol (*) and non-maximal prime gaps is depicted without asterisk symbol.

Table 4: First 17 prime gaps depicted in format using maximal prime gaps & non-maximal prime gaps.

We can only theoretically lower 'N' to 2 (in regards to **P** with 'small gaps') but there are still an infinite number of **E** prime gaps (in regards to **P** with 'large gaps') that require "the proof that each will generate its unique set of infinite **P**".

Remark 6.2. Existence of maximal and non-maximal prime gaps supply crucial indirect evidence to intuitively support but does not prove "Each even prime gap will generate an infinite magnitude of odd prime numbers on its own accord".

Comments relevant to Remark 6.2 are given in the next section below.

7 Supportive role of maximal and non-maximal prime gaps

We analyze data of all **P** obtained when extrapolated out over a wide range of $x \geq 2$ integer values. As sequence of **P** carries on, **P** with ever larger prime gaps appears. For given range of x integer values, prime gap = n_2 is a 'maximal prime gap' if prime gap = $n_1 <$ prime gap = n_2 for all $n_1 < n_2$. In other words, largest such prime gaps in this range are called maximal prime gaps. The term 'first occurrence prime gaps' refers to first occurrences of maximal prime gaps whereby maximal prime gaps are prime gaps of "at least of this length". We use maximal prime gaps to denote 'first occurrence prime gaps'. CIS non-maximal prime gaps (endorsed with nickname 'slow jumpers') always lag behind CIS maximal prime gaps for onset appearances in **P** sequence. These are shown for first 17 prime gaps in Table 4. Apart from **O** prime gap = 1 representing solitary even **P** '2', remaining **P** in Table 4 consist of representative single odd **P** for each **E** prime gap. These odd **P** individually make one-off appearance in **P** sequence in a *perpetual albeit Incompletely Predictable manner*. Initial seven of [majority] "missing" odd **P** are 5, 11, 13, 17, 19, 29, 31,... belonging to Subset **P** with 'residual' prime gaps are potential source of odd **P** in relation to proposal that each **E** prime gap from Set **E prime gaps** will generate its specific Subset **odd P**. Set **all P** from all prime gaps = Subset **P** from maximal prime gaps + Subset **P** from non-maximal prime gaps + Subset **P** from 'residual' prime gaps. Subset **P** from 'residual' prime gaps with representation from all **E** prime gaps includes all correctly selected "missing" odd **P**. These observations support but does not prove the proposition that each **E** prime gap will generate its own Subset **odd P** with $|\text{odd P}| = \aleph_0$.

For $i \in \mathbb{N}$; primordial $P_i\#$ is analog of usual factorial for **P** = 2, 3, 5, 7, 11, 13,.... Then $P_1\# = 2$, $P_2\# = 2 \times 3 = 6$, $P_3\# = 2 \times 3 \times 5 = 30$, $P_4\# = 2 \times 3 \times 5 \times 7 = 210$, $P_5\# = 2 \times 3 \times 5 \times 7 \times 11 = 2310$, $P_6\# = 2 \times 3 \times 5 \times 7 \times 11 \times 13 = 30030$, etc. English mathematician John Horton Conway coined the term 'jumping champion' in 1993. An integer n is a 'jumping champion' if n is the most frequently occurring difference (prime gap) between consecutive $\mathbf{P} < x$ for some x integer values. Example: for any x with $7 < x < 131$, $n = 2$ (indicating twin **P**) is the 'jumping champion'. It has been conjectured that (i) the only 'jumping champions' are 1, 4 and primorials 2, 6, 30, 210, 2310, 30030,... and (ii) 'jumping champions' tend to infinity. Their required proofs will likely need proof of k-tuple conjecture. **P** from 'jumping champion' prime gaps have their onset appearances in **P** sequence in a *perpetual albeit Incompletely Predictable manner* [as another example to that outlined in previous paragraph].

8 Information-Complexity conservation

A formula, as equation or algorithm, is simply a Black Box generating necessary Output (with qualitative-like structural 'Complexity') when supplied with given Input (with quantitative-like data 'Information'). This Information-based complexity are literally what is referred to in 'Information-Complexity conservation'. **P** and **C** numbers are traditionally "analyzed separately". The key definition behind Dimension ($2x - N$) is used to abstractly represent *dependent P* and *C* numbers (and Number '1') in a combined manner whereby $N = 2x - \Sigma PC_x\text{-Gap}$. This will lead to required mathematical arguments based on Information-Complexity conservation and patterns in Gap 2 Composite Number to obtain Plus-Minus Gap 2 Composite Number Alternating Law & Plus Gap 2 Composite Number Continuous Law which will [respectively] solve Polignac's & Twin prime conjectures.

N (CIS): 1, 2, 3, ..., $+\infty$. Let x be from Set **X** such that $x \in \mathbf{N}$. Consider x for upper boundary of interest in Set **X** whereby **X** is chosen from **N, E, O, P** or **C**.

Lemma 8.1. Natural counting function $\mathbf{N}\text{-}\pi(x)$, defined as $|\mathbf{N} \leq x|$, is Completely Predictable by independently using simple algorithm to be equal to x .

Proof Formula to generate **N** with 100% certainty is $\mathbf{N}_i = i$ whereby \mathbf{N}_i is the i^{th} **N** and $i = 1, 2, 3, \dots, \infty$. For a given \mathbf{N}_i , its i^{th} position is simply i . Natural gap ($G_{\mathbf{N}_i}$) = $\mathbf{N}_{i+1} - \mathbf{N}_i$, with $G_{\mathbf{N}_i}$ always = 1. There are $x \mathbf{N} \leq x$. Thus $\mathbf{N}\text{-}\pi(x) = |\mathbf{N} \leq x| = x$. *The proof is now complete for Lemma 8.1* \square .

Lemma 8.2. Even counting function $\mathbf{E}\text{-}\pi(x)$, defined as $|\mathbf{E} \leq x|$, is Completely Predictable by independently using simple algorithm to be equal to $\text{floor}(x/2)$.

Proof. Formula to generate **E** with 100% certainty is $\mathbf{E}_i = iX2$ whereby \mathbf{E}_i is the i^{th} **E** and $i = 1, 2, 3, \dots, \infty$ abiding to mathematical label "All **N** always ending with a digit 0, 2, 4, 6 or 8". For a given \mathbf{E}_i , its i^{th} position is calculated as $i = \mathbf{E}_i/2$. Even gap ($G_{\mathbf{E}_i}$) = $\mathbf{E}_{i+1} - \mathbf{E}_i$, with $G_{\mathbf{E}_i}$ always = 2. There are $\lfloor \frac{x}{2} \rfloor \mathbf{E} \leq x$. Thus $\mathbf{E}\text{-}\pi(x) = |\mathbf{E} \leq x| = \text{floor}(x/2)$. *The proof is now complete for Lemma 8.2* \square .

Lemma 8.3. Odd counting function $\mathbf{O}\text{-}\pi(x)$, defined as $|\mathbf{O} \leq x|$, is Completely Predictable by independently using simple algorithm to be equal to $\text{ceiling}(x/2)$.

Proof. Formula to generate **O** with 100% certainty is $\mathbf{O}_i = (iX2) - 1$ whereby \mathbf{O}_i is the i^{th} odd number and $i = 1, 2, 3, \dots, \infty$ abiding to mathematical label "All **N** always ending with a digit 1, 3, 5, 7, or 9". For a given \mathbf{O}_i number, its i^{th} position is calculated as $i = (\mathbf{O}_i + 1)/2$. Odd gap ($G_{\mathbf{O}_i}$) = $\mathbf{O}_{i+1} - \mathbf{O}_i$, with $G_{\mathbf{O}_i}$ always = 2. There are $\lceil \frac{x}{2} \rceil \mathbf{O} \leq x$. Thus $\mathbf{O}\text{-}\pi(x) = |\mathbf{O} \leq x| = \text{ceiling}(x/2)$. *The proof is now complete for Lemma 8.3* \square .

Lemma 8.4. Prime counting function $\mathbf{P}\text{-}\pi(x)$, defined as $|\mathbf{P} \leq x|$, is Incompletely Predictable with Set **P** independently obtained using complex algorithm Sieve of Eratosthenes.

Proof. Algorithm to generate \mathbf{P}_i whereby $\mathbf{P}_1 (= 2)$, $\mathbf{P}_2 (= 3)$, $\mathbf{P}_3 (= 5)$, $\mathbf{P}_4 (= 7)$, ..., ∞ with 100% certainty is based on Sieve of Eratosthenes abiding to mathematical label "All **N** apart from 1 that are evenly divisible by itself and by 1". Although we can check primality of a given **O** by trial division, we can never determine its position without knowing positions of preceding **P**. Prime gap ($G_{\mathbf{P}_i}$) = $\mathbf{P}_{i+1} - \mathbf{P}_i$, with $G_{\mathbf{P}_i}$ constituted by all **E** except $1^{\text{st}} G_{\mathbf{P}_1} = 3 - 2 = 1$. $\mathbf{P}\text{-}\pi(x) = |\mathbf{P} \leq x|$. This is Incompletely Predictable and is calculated via mentioned algorithm. Using definition of prime gap, every **P** [represented here with aid of 'n' notation instead of usual 'i' notation] is written as $\mathbf{P}_{n+1} = 2 + \sum_{i=1}^n G_{\mathbf{P}_i}$ with '2' denoting \mathbf{P}_1 . Here i & $n = 1, 2, 3, 4, 5, \dots, \infty$. *The proof is now complete for Lemma 8.4* \square .

Lemma 8.5. Composite counting function $\mathbf{C}\text{-}\pi(x)$, defined as $|\mathbf{C} \leq x|$, is Incompletely Predictable with Set **C** derived as Set **N**-Set **P** [dependently obtained using complex algorithm Sieve of Eratosthenes]-Number '1'.

Proof. Composite numbers abide to mathematical label "All **N** apart from 1 that are evenly divisible by numbers other than itself and 1". Algorithm to generate \mathbf{C}_i whereby $\mathbf{C}_1 (= 4)$, $\mathbf{C}_2 (= 6)$, $\mathbf{C}_3 (= 8)$, $\mathbf{C}_4 (= 9)$, ..., ∞ with 100% certainty is based [indirectly] on Sieve of Eratosthenes via selecting non-prime **N** to be **C**. We define Composite gap $G_{\mathbf{C}_i}$ as $\mathbf{C}_{i+1} - \mathbf{C}_i$ with $G_{\mathbf{C}_i}$ constituted by 1 & 2. $\mathbf{C}\text{-}\pi(x) = |\mathbf{C} \leq x|$. This is Incompletely Predictable and need to be calculated indirectly via the mentioned algorithm. Using definition of composite gap, every **C** [represented here with aid of 'n' notation instead usual 'i' notation] is written as $\mathbf{C}_{n+1} = 4 + \sum_{i=1}^n G_{\mathbf{C}_i}$ with '4' denoting \mathbf{C}_1 . Here i & $n = 1, 2, 3, 4, 5, \dots, \infty$. *The proof is now complete for Lemma 8.5* \square .

Fig. 25: Prime-Composite finite scale mathematical (graphed) landscape. Data for $x = 2$ to 64.

Denote \mathbf{X} to be \mathbf{N} , \mathbf{E} , \mathbf{O} , \mathbf{P} or \mathbf{C} . $X-\pi(x) = |\mathbf{X} \leq x|$ with $x \in \mathbf{N}$. We define and compute entity 'Grand-Total Gaps for \mathbf{X} at x ' (Grand-Total ΣX_x -Gaps).

Proposition 8.6. For any given $x \geq 1$ values in Set \mathbf{N} , designated Complexity is represented by ΣN_x -Gaps = $x - N$ with $N = 1$.

Proof. Set \mathbf{N} (for $x = 1$ to 12): 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12. $N-\pi(x) = 12$. There are $x - 1 = 11$ \mathbf{N} -Gaps each of '1' magnitude: 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1. ΣN_x -Gaps = $11 \times 1 = 11$. This equates to ' $x - 1$ ' – regarded as Complexity for solitary \mathbf{N} . *The proof is now complete for Proposition 8.6*□.

Proposition 8.7. For any given $x \geq 1$ values in constituent Set \mathbf{E} and Set \mathbf{O} , designated Complexity is represented by ΣEO_x -Gaps = $2x - N$ with $N = 4$ being baseline minimal.

Proof. Set \mathbf{E} and Set \mathbf{O} (for $x = 1$ to 12): 2, 4, 6, 8, 10, 12 and 1, 3, 5, 7, 9, 11. $\mathbf{E}-\pi(x) = 6$ and $\mathbf{O}-\pi(x) = 6$. There are $\lfloor \frac{x}{2} \rfloor - 1 = 5$ \mathbf{E} -Gaps each of '2' magnitude: 2, 2, 2, 2, 2. ΣE_x -Gaps = $5 \times 2 = 10$, and $\lfloor \frac{x}{2} \rfloor - 1 = 5$ \mathbf{O} -Gaps each of '2' magnitude: 2, 2, 2, 2, 2. ΣO_x -Gaps = $5 \times 2 = 10$. Grand-Total ΣEO_x -Gaps = $10 + 10 = 20$. Depicted by Table 6 & Figure 26 in Appendix D, $2x - N = "2x - 4"$ [perpetual constant appearances of " $N=4$ being baseline minimal"] is Complexity for \mathbf{E} & \mathbf{O} pairing. *The proof is now complete for Proposition 8.7*□.

Proposition 8.8. For selected $x \geq 2$ values in constituent Set \mathbf{P} and Set \mathbf{C} , designated Complexity is cyclically represented by ΣPC_x -Gaps = $2x - N$ with $N = 7$ being baseline maximal.

Proof. Set \mathbf{P} and Set \mathbf{C} (for $x = 2$ to 12): 2, 3, 5, 7, 11 and 4, 6, 8, 9, 10, 12. $\mathbf{P}-\pi(x) = 5$ and $\mathbf{C}-\pi(x) = 6$. There are four \mathbf{P} -Gaps of 1, 2, 2, 4 magnitude and five \mathbf{C} -Gaps of 2, 2, 1, 1, 2 magnitude. ΣP_x -Gaps = $1 + 2 + 2 + 4 = 9$. ΣC_x -Gaps = $2 + 2 + 1 + 1 + 2 = 8$. Grand-Total ΣPC_x -Gaps = $9 + 8 = 17$. Depicted by Table 5 and Figure 25, $2x - N = "2x - 7"$ [perpetual intermittent and cyclical appearances of " $N = 7$ being baseline maximal"] is Complexity for \mathbf{P} and \mathbf{C} pairing. *The proof is now complete for Proposition 8.8*□.

Designated Complexity is (i) $x - N$ with $N = 1$ for Completely Predictable \mathbf{N} , (ii) $2x - N$ with $N = 7$ (baseline maximal) for Incompletely Predictable \mathbf{P} & \mathbf{C} , and (iii) $2x - N$ with $N = 4$ (baseline minimal) for Completely Predictable \mathbf{E} & \mathbf{O} . Interpretations: \mathbf{N} has "nil" Complexity, \mathbf{E} & \mathbf{O} have minimal Complexity, and \mathbf{P} & \mathbf{C} have maximal [varying] Complexity since " $2x - 4$ " Grand-Total Gaps [with $N = 4$ as defacto baseline] occurring in $\mathbf{E}-\mathbf{O}$ pairing is less than " $2x - \geq 7$ " Grand-Total Gaps [with $N = 7$ as defacto baseline] occurring in $\mathbf{P}-\mathbf{C}$ pairing.

Let both x & $N \in \mathbf{N}$. We tabulate in Table 5 and graph in Figure 25 [Incompletely Predictable] $\mathbf{P}-\mathbf{C}$ mathematical landscape for a relatively larger $x = 2$ to 64 here (and ditto for [Completely Predictable] $\mathbf{E}-\mathbf{O}$ mathematical landscape for relatively larger $x = 1$ to 64 in Appendix D). The term "mathematical landscape" denotes specific mathematical patterns in tabulated and graphed data. "Dimension" contextually denotes Dimension $2x - N$ whereby (i) allocated [infinite] N values result in Dimensions $2x - 7, 2x - 8, 2x - 9, \dots, 2x - \infty$ for $\mathbf{P}-\mathbf{C}$ finite scale mathematical landscape and (ii) allocated [finite] N values for $\mathbf{E}-\mathbf{O}$ finite scale mathematical

Legend: C = composite, P = prime, Dim = Dimension, Y = 2x - 7 (for visual clarity), N/A = Not Applicable.

Table 5 Prime-Composite finite scale mathematical (tabulated) landscape. Data for x = 2 to 64.

landscape result in Dimension 2x - 4. For **P-C** pairing, initial one-off Dimensions 2x - 2, 2x - 4 and 2x - 5 (in consecutive order) are exceptions [with Dimension 2x - 2 validly representing Number '1' which is neither **P** nor **C**]. For **E-O** pairing, initial one-off Dimension 2x - 2 is an exception. **P-C** mathematical landscape consisting of Dimensions will intrinsically incorporate **P** and **C** in an integrated manner and there are infinite times whereby relevant Dimensions deviate away from 'baseline' Dimension 2x - 7 simply because **P** [and, by default, **C**] in totality are rigorously proven to be infinite in magnitude. In contrast, there is a complete lack of deviation away from 'baseline' Dimension 2x - 4 apart from one-off deviation caused by the initial Dimension 2x - 2 in Appendix D.

Bottom graph in Figure 25 symbolically represent "Dimensions" using ever larger negative integers. Dimensions 2x - 7, 2x - 8, 2x - 9, ..., 2x - ∞ are symbolically represented by -7, -8, -9, ..., ∞ with 2x - 7 displayed as 'baseline' Dimension whereby Dimension trend (Cumulative Sum Gaps) must repeatedly reset itself onto this 'baseline' Dimension on a perpetual basis. Dimensions represented by ever larger negative integers will correspond to **P** associated with ever larger prime gaps and this phenomenon will generally happen at ever larger x values (with complete presence of Chaos and Fractals being manifested in our graph). At ever larger x values, **P-π(x)** will overall become larger but with a *decelerating* trend whereas **C-π(x)** will overall become larger but with an *accelerating* trend. This support ever larger prime gaps appearing at ever larger x values.

Definitive derivation of data in Table 5 is illustrated by two examples for position x = 31 & 32. For i & x ∈ ℕ; EPC_x-Gap = ΣPC_{x-1}-Gap + Gap value at P_{i-1} or Gap value at C_{i-1} whereby (i) P_i or C_i at position x is determined by whether relevant x value belongs to a **P** or **C**, and (ii) both ΣPC₁-Gap and ΣPC₂-Gap = 0. Example, for position x = 31: 31 is **P** (**P11**). Desired Gap value at **P10** = 2. Thus ΣPC₃₁-Gap (55) = ΣPC₃₀-

Gap (53) + Gap value at **P10** (2). Example, for position $x = 32$: 32 is **C** (**C20**). Desired Gap value at **C19** = 2. Thus ΣPC_{32} -Gap (57) = ΣPC_{31} -Gap (55) + Gap value at **C20** (2). Note: in our Dimension $(2x - N)$ system, $N = 2x - \Sigma PC_x$ -Gap. 'Overall magnitude of **C** will always be greater than that of **P**' will hold true from $x = 14$ onwards. For instance, position $x = 61$ corresponds to **P** 61 which is 18th **P**, whereas [one lower] position $x = 60$ corresponding to **C** 60 is [much higher] 42nd **C**.

9 Polignac's and Twin prime conjectures

Previous section alludes to **P-C** finite scale mathematical landscape. This section alludes to **P-C** infinite scale mathematical landscape. Let 'Y' symbolizes (baseline) Dimension $2x - 7$. Let prime gap at $P_i = P_{i+1} - P_i$ with P_i & P_{i+1} respectively symbolizes consecutive "first" & "second" **P** in any P_i - P_{i+1} pairings. We denote (i) Dimensions YY grouping [depicted by $2x - 7$ initially appearing twice in (iii)] to represent signal for appearances of **P** pairings other than twin **P** such as cousin **P**, sexy **P**, etc; (ii) Dimension YYYYY grouping to represent signal for appearances of **P** pairings as twin **P**; and (iii) Dimension $(2x - \geq 7)$ -Progressive-Grouping allocated to $2x - 7, 2x - 7, 2x - 8, 2x - 9, 2x - 10, 2x - 11, \dots, 2x - \infty$ as elements of *precise* and *proportionate* CFS Dimensions representation of an individual P_i with its associated prime gap namely, Dimensions $2x - 7$ & $2x - 7$ pairing = twin **P** (with both its prime gap & CFS cardinality = 2); $2x - 7, 2x - 7, 2x - 8$ & $2x - 9$ pairing = cousin **P** (with both its prime gap & CFS cardinality = 4); $2x - 7, 2x - 7, 2x - 8, 2x - 9, 2x - 10$ & $2x - 11$ pairing = sexy **P** (with both its prime gap & CFS cardinality = 6); and so on. The higher order [traditionally defined as closest possible] prime groupings of three **P** as **P** triplets, of four **P** numbers as prime quadruplets, of five **P** numbers as prime quintuplets, etc consist of serendipitous groupings abiding to mathematical rule: With exception of three 'outlier' **P** 3, 5, & 7; groupings of any three **P** as **P, P+2, P+4** combination (viz. manifesting two consecutive twin **P**) is a mathematical impossibility. The 'anomaly' one of every three consecutive **O** is a multiple of three, and hence this number cannot be **P**, explains this impossibility. Then closest possible **P** grouping [viz. for prime triplet] must be either **P, P+2, P+6** or **P, P+4, P+6** format.

P groupings not respecting traditional closest-possible-prime groupings are also the norm occurring infinitely often, indicating continual presence of prime gaps ≥ 6 . As **P** become sparser at larger range, perpetual presence of (i) prime gaps ≥ 6 [proposed to arbitrarily represent 'large gaps'] and (ii) prime gaps 2 & 4 [proposed to arbitrarily represent 'small gaps'] with progressive greater magnitude will cumulatively occur for each prime gap but always in a decelerating manner. With permanent requirement at larger range of intermittently resetting to baseline Dimension $2x - 7$ occurring [either two or] four times in a row, nature seems to dictate, at the very least, perpetual twin **P** or one other non-twin **P** occurrences is inevitable.

We dissect Dimension YYYYY unique signal for twin **P** appearances: Initial two CFS Dimensions YY components of YYYYY represent "first" **P** component of twin **P** pairing. Last two Dimensions YY components of YYYYY signifying appearance of "second" **P** component of twin **P** pairing is also the initial first-two-element component of full CFS Dimensions representation for "first" **P** component of following non-twin **P** pairing. Twin **P** are uniquely represented by repeating *single* type Dimension $2x - 7$. In all other 'higher order' **P** pairings (with prime gaps ≥ 4), they require *multiple* types Dimension representation. There is qualitative aspect association of *single* type Dimension representation for twin **P** resulting in "less colorful" Plus Gap 2 Composite Number *Continuous Law* as opposed to *multiple* types Dimension representation for all other 'higher order' **P** pairings resulting in "more colorful" Plus-Minus Gap 2 Composite Number *Alternating Law*. 'Gap 2 Composite Number' occurrences in both Laws on finite scale are (directly) observed in Figure 25 & Table 5 for $x = 2$ to 64, and on infinite scale are (indirectly) deduced using logical arguments for all x values.

We endow all "Dimensions" with exponent of '1' for perusal in on-going mathematical arguments. $P_1 = 2$ is represented by CFS as Dimension $(2x - 4)^1$ (with both prime gap & CFS cardinality = 1); $P_2 = 3$ is represented by CFS as Dimensions $(2x - 5)^1$ & $(2x - 7)^1$ (with both prime gap & CFS cardinality = 2); $P_3 = 5$ is represented by CFS Dimension $(2x - 7)^1$ & $(2x - 7)^1$ (with both prime gap & CFS cardinality = 2), etc.

Proposition 9.1. Let Case 1 be Completely Predictable **E** & **O** pairing and Case 2 be Incompletely Predictable **P** & **C** pairing. Furthermore, let Case 1 and Case 2 be independent of each other. Then for any given x value, there exist grand total number of Dimensions such that it exactly equal to either two combined subto-

tal number of Dimensions to precisely represent **E & O** in Case 1, or three combined subtotal number of Dimensions to precisely represent **P & C & Number '1'** in Case 2.

Proof. **N** is directly constituted from either combined **E & O** in Case 1 or combined **P & C & Number '1'** in Case 2 – Number '1' is neither **P** nor **C**. Correctly designated infinitely many CFS of Dimensions used to represent combined **E & O** in Case 1 and combined **P & C & Number '1'** in Case 2 must also directly and proportionately be representative of relevant **N** arising from combined subtotal of **E & O** in Case 1 and from combined subtotal of **P & C & Number '1'** in Case 2. *The proof is now complete for Proposition 9.1*□.

Proposition 9.2. Let Case 1 be Completely Predictable **E & O** pairing and Case 2 be Incompletely Predictable **P & C** pairing. Furthermore, let Case 1 and Case 2 be independent of each other. Part I: For any given x value apart from $x = 1$ value in Case 1 and $x = 1, 2,$ and 3 values in Case 2; Dimension $(2x - N)^1$ representations of all Completely Predictable **E & O** in Case 1 and all Incompletely Predictable **P & C & Number '1'** in Case 2 are given by $N = 4$ in Case 1 and by $N \geq 7$ in Case 2. Part II: Complying with Information-complexity conservation, odd **P** obeys Plus-Minus Composite Gap 2 Number Alternating Law for prime gaps ≥ 4 and Plus Composite Gap 2 Number Continuous Law for prime gap = 2.

Proof. Apart from first Dimension $(2x - 2)^1$ representation in **E & O** pairing in Case 1 and first three Dimension $(2x - 2)^1$, Dimension $(2x - 4)^1$ and Dimension $(2x - 5)^1$ representations in **P & C** pairing in Case 2; possible N value in Dimension $(2x - N)^1$ representation are shown to be (constantly) baseline minimum 4 for Case 1 and (variably) baseline maximal 7 for Case 2. For Case 2, we again note Dimension $(2x - 2)^1$ to (validly) represent Number '1' which is neither **P** nor **C**. These nominated Dimensions represent possible (constant) baseline "2x - 4" Grand-Total Gaps as per Proposition 8.7 for Case 1 & (variable) baseline "2x - 7" Grand-Total Gaps as per Proposition 8.8 for Case 2. All CFS of Dimensions that can be used to precisely represent combined **E & O** in Case 1 will persistently consist of same Dimension $(2x - 4)^1$ after first Dimension $(2x - 2)^1$. Perpetual repeated deviation of N values away from $N = 7$ (baseline maximum) in Case 2 is simply representing infinite magnitude of **P & C**. *The proof is now complete for Part I of Proposition 9.2*□.

With exception of Number '1', all natural numbers must comply with Information-complexity conservation in the sense that they can always be represented by unique CFS Dimensions $(2x - N)$ in a dual manner as **E** or **P** (for solitary Number '2'), **E** or **C**, **O** or **P**, and **O** or **C**. Dimension $(2x - 2)$ validly represents Number '1' which is **O** but is neither **P** nor **C**. Derived Dimensions will comply with Incompletely Predictable property as explained using **P '61'**. At Position $x = 61$ equating to $P_{18} = 61$, it is represented by CFS Dimensions $(2x - 7)^1$, $(2x - 7)^1$, $(2x - 8)^1$, $(2x - 9)^1$, $(2x - 10)^1$ & $(2x - 11)^1$ (with both prime gap & CFS cardinality = 6). This representation indicates an "unknown but correct" **P** with prime gap = 6 when we intentionally conceal full information '61' = 31st **O** = 18th **P** with prime gap = 6. But to arrive at this unique representation requires complex calculations of all preceding CFS Dimensions thus manifesting hallmark Incompletely Predictable property of CFS Dimensions. This is not so when '61' is treated as Completely Predictable **O** with its position simply calculated as $(61 + 1) / 2 = 31^{\text{st}}$ **O** and uniquely represented by CFS Dimension $(2x - 4)$.

Overall sum total of individual CFS Dimensions required to represent every **P** is infinite in magnitude as $|\text{all } \mathbf{P}| = \aleph_0$. Standalone Dimensions YY groupings [representing signals for "higher order" non-twin **P** appearances] &/or as front Dimensions YY (sub)groupings [which by itself is fully representative of twin **P** as Dimensions YYYY appearances] need to recur on an indefinite basis. Then twin **P** and "higher order" cousin **P**, sexy **P**, etc should aesthetically all be infinite in magnitude because (respectively) they regularly and universally arise as part of Dimension YYYY and Dimension YY appearances. An isolated **P** is defined as a **P** such that neither $\mathbf{P} - 2$ nor $\mathbf{P} + 2$ is **P**. In other words, isolated **P** is not part of a twin **P** pair. E.g., 23 is an isolated **P** since 21 & 25 are both **C**. Repeated inevitable presence of Dimension YY grouping is nothing more than indicating repeated occurrences of isolated **P**. This constitutes another view on Dimension YY.

CIS of Gap 1 Composite Numbers are fully associated with non-twin **P** as they eternally occur in between any two consecutive non-twin **P**. CIS of Gap 2 Composite Numbers are (i) fully associated with twin **P** as they are eternally present in between any twin **P** pair, and (ii) partially associated with non-twin **P** as they are eternally present alternatingly or intermittently in between any two consecutive non-twin **P**. Then (i) Gap 1 Composite Numbers do not have valid representation by **E** prime gap = 2, and (ii) Gap 2 Composite Numbers have valid representations by all **E** prime gaps = ["consistently" only for] 2, ["inconsistently" for each of] 4, 6, 8, 10,.... This is an alternative view on **P** from perspective of CFS composite gaps [instead of CIS prime gaps]

with intrinsic patterns having *alternating presence* and *absence* of Gap 2 Composite Numbers associated with every CFS Dimensions representations of \mathbf{P} with prime gaps ≥ 4 , viz. 'Plus-Minus Gap 2 Composite Number Alternating Law'. CFS Dimensions representations of Twin \mathbf{P} are associated with Gap 2 Composite Numbers, viz. 'Plus Gap 2 Composite Number Continuous Law'.

Examples for both Laws: A twin \mathbf{P} (prime gap = 2) in its unique CFS Dimensions format always has Gap 2 Composite Numbers in a [constant] pattern. A cousin \mathbf{P} (prime gap = 4) in its unique CFS Dimensions format always has two Gap 1 Composite Numbers & then one Gap 2 Composite Number [combined] pattern *alternating* with three consecutive Gap 1 Composite Numbers [non-combined] pattern. From this simple observation alone, we deduce we can generate an infinite magnitude of \mathbf{C} from each composite gaps 1 & 2. Gap 2 Composite Numbers *alternating* pattern behavior in cousin \mathbf{P} will not hold true unless twin \mathbf{P} & all other non-cousin \mathbf{P} are infinite in magnitude and integratedly supplying essential "driving mechanism" to eternally sustain this Gap 2 Composite Numbers *alternating* pattern behavior in cousin \mathbf{P} . Thus we establish twin \mathbf{P} and cousin \mathbf{P} in their CFS Dimensions formats are CIS intertwined together when depicted using \mathbf{C} with composite gaps = 1 & 2 with each supplying their own peculiar (infinite) share of associated Gap 2 Composite Numbers [thus contributing to overall pool of Gap 2 Composite Numbers].

An inevitable statement in relation to "Gap 2 Composite Numbers pool contribution" based on above reasoning: At the bare minimum, *either* twin \mathbf{P} *or* at least one of non-twin \mathbf{P} must be infinite in magnitude. An inevitable impression: All generated subsets of \mathbf{P} from 'small gaps' [of 2 & 4] and 'large gaps' [of ≥ 6] alike should each be CIS thus allowing true uniformity in \mathbf{P} distribution. Again we see in Table 2 depicting $\mathbf{P-C}$ data for $x = 2$ to 64 that, for instance, \mathbf{P} with prime gap = 6 must also persistently have this 'last-place' Gap 2 Composite Numbers intermittently appearing in certain rhythmic *alternating* patterns, thus complying with Plus-Minus Gap 2 Composite Number Alternating Law. This CFS Dimensions representation for \mathbf{P} with prime gaps = 6 will again generate their infinite share of associated Gap 2 Composite Numbers to contribute to this pool. The presence of this last-place Gap 2 Composite Numbers in various *alternating* pattern in appearances & non-appearances must *self-generatingly* be similarly extended in a mathematically consistent fashion *ad infinitum* to all other remaining infinite number of prime gaps [which were not discussed in details above]. *The proof is now complete for Part II of Proposition 9.2*□.

10 Rigorous Proofs for the now-named as Polignac's and Twin prime hypotheses

The proofs on lemmas and propositions from previous section supply all necessary evidences to fully support Theorem Polignac-Twin prime I to IV below thus depicting proofs for Polignac's and Twin prime conjectures in a rigorous manner. Gap 1 Composite Numbers do not have valid representation by \mathbf{E} prime gap = 2, and Gap 2 Composite Numbers have valid representations by all \mathbf{E} prime gaps = ["consistently" only for] 2, ["inconsistently" for each of] 4, 6, 8, 10,.... Plus-Minus Gap 2 Composite Number Alternating Law confirms that Gap 2 Composite Numbers present in each \mathbf{P} with prime gaps ≥ 4 situation must appear as some sort of "rhythmic patterns of alternating presence and absence" for Gap 2 Composite Numbers. Twin \mathbf{P} with prime gap = 2 obeying Plus Gap 2 Composite Number Continuous Law can be understood as special situation of "(non-)rhythmic patterns with continual presence" for relevant Gap 2 Composite Numbers.

In 1849 when French mathematician Alphonse de Polignac (1826 - 1863) was admitted to Polytechnique, he created Polignac's conjecture which relates complete set of odd \mathbf{P} to all \mathbf{E} prime gaps. Made earlier by de Polignac in 1846, Twin prime conjecture relating twin prime numbers to prime gap = 2, is then simply a subset of Polignac's conjecture.

Theorem Polignac-Twin prime I. Incompletely Predictable prime numbers $\mathbf{P}_n = 2, 3, 5, 7, 11, \dots, \infty$ or composite numbers $\mathbf{C}_n = 4, 6, 8, 9, 10, \dots, \infty$ are CIS with overall actual location [but not actual positions] of all prime or composite numbers accurately represented by complex algorithm involving prime gaps G_{P_i} viz. $\mathbf{P}_{n+1} = 2 + \sum_{i=1}^n G_{P_i}$ or involving composite gaps G_{C_i} viz. $\mathbf{C}_{n+1} = 4 + \sum_{i=1}^n G_{C_i}$ whereby prime & composite numbers are symbolically represented here with aid of 'n' notation instead of usual 'i' notation; and i & $n = 1, 2, 3, 4,$

5, ..., ∞ . Number '2' in first algorithm represents P_1 , the very first (and only even) P . Number '4' in second algorithm represent C_1 , the very first (and even) C .

Proof. We treat above algorithms as unique mathematical objects looking for key intrinsic properties and behaviors. Each P or C is assigned a unique prime or composite gap. Absolute number of P or C and (thus) prime or composite gaps are infinite in magnitude. As original formulae containing all P or C by themselves (viz. without supplying prime or composite gaps as "input information" to generate P or C as "output complexity"), these algorithms intrinsically incorporate overall actual location [but not actual positions] of all P or C . *The proof is now complete for Theorem Polignac-Twin prime I* \square .

Theorem Polignac-Twin prime II. Set of prime gaps $G_{P_i} = 2, 4, 6, 8, 10, \dots, \infty$ is infinite in magnitude whereby these prime gaps accurately and completely represented by Dimensions $(2x - 7)^1, (2x - 8)^1, (2x - 9)^1, \dots, (2x - \infty)^1$ must satisfy Information-complexity conservation in a consistent manner.

Proof. Part I of Proposition 9.2 proved all P are represented by Dimension $(2x - N)^1$ with $N \geq 7$ for any given x value (except for $x = 2$ & 3 values). Although $x = 1$ is neither P nor C , it is validly represented by Dimension $(2x - 2)^1$. If each P is endowed with a specific prime gap value, then each such prime gap must [via logical mathematical deduction] be represented by Dimension $(2x - N)^1$. Complete argument to support this nominated method of prime gap representation using Dimensions will fully comply with Information-complexity conservation was given in Part II of Proposition 9.2. The preceding mathematical statements are correct as there is a unique prime gap value associated with each P . Proposition 10.1 below based on principles from Set theory provides further supporting materials that prime gaps are infinite in magnitude. *The proof is now complete for Theorem Polignac-Twin prime II* \square .

Theorem Polignac-Twin prime III. To maintain Dimensional analysis (DA) homogeneity, those Dimensions $(2x - N)^1$ from Theorem Polignac-Twin prime II must contain eternal repetitions of well-ordered sets constituted by Dimensions $(2x - 7)^1, (2x - 8)^1, (2x - 9)^1, (2x - 10)^1, (2x - 11)^1, \dots, (2x - \infty)^1$.

Proof. This Theorem is stated in greater details as "To maintain DA homogeneity, those aforementioned [endowed with exponent 1] Dimensions $(2x - N)^1$ from Theorem Polignac-Twin prime II must repeat themselves indefinitely in following specific combinations – (i) Dimension $(2x - 7)^1$ only appearing as twin [two-times-in-a-row] and quadruplet [four-times-in-a-row] sequences, and (ii) Dimensions $(2x - 8)^1, (2x - 9)^1, (2x - 10)^1, (2x - 11)^1, \dots, (2x - \infty)^1$ appearing as progressive groupings of E 2, 4, 6, 8, 10, ..., ∞ ." To accommodate the only even P '2', exceptions to this DA homogeneity compliance will expectedly occur right at beginning of P sequence – (i) one-off appearance of Dimensions $(2x - 2)^1, (2x - 4)^1$ and $(2x - 5)^1$ and (ii) one-off appearance of Dimension $(2x - 7)^1$ as a quintuplet [five-times-in-a-row] sequence which is equivalent to (eternal) non-appearance of Dimension $(2x - 6)^1$ at $x = 4$. [We again note Dimension $(2x - 2)^1$ validly represent Number '1' which is neither P nor C .] These sequentially arranged sets are CFS whereby from $x = 11$ onwards, each set always commence initially as 'baseline' Dimension $(2x - 7)^1$ at $x = O$ values and always end with its last Dimension at $x = E$ values. Each set also have varying cardinality with values derived from all E ; and correctly combined sets always intrinsically generate two infinite sets of P and, by default, C in an integrated manner. Our Theorem Polignac-Twin prime III simply represent a mathematical summary derived from Sections 8 & 9 of all expressed characteristics of Dimension $(2x - N)^1$ when used to represent P with intrinsic display of DA homogeneity. See Proposition 10.2 for more details on DA aspect. *The proof is now complete for Theorem Polignac-Twin prime III* \square .

Theorem Polignac-Twin prime IV. Aspect 1. The "quantitative" aspect to existence of both prime gaps and their associated prime numbers as sets of infinite magnitude will be shown to be correct by utilizing principles from Set theory. Aspect 2. The "qualitative" aspect to existence of both prime gaps and their associated prime numbers as sets of infinite magnitude will be shown to be correct by 'Plus-Minus Gap 2 Composite Number Alternating Law' and 'Plus Gap 2 Composite Number Continuous Law'.

Proof. Required concepts from Set theory involve cardinality of a set with its 'well-ordering principle' application. Supporting materials for these concepts based on 'pigeonhole principle' in relation to Aspect 1 are outlined in Proposition 10.1 below. 'Plus-Minus Gap 2 Composite Number Alternating Law' is applicable to all E prime gaps [apart from first E prime gap = 2 for twin primes]. The prime gap = 2 situation will obey 'Plus Gap 2 Composite Number Continuous Law'. These Laws are in essence Laws of Continuity inferring underlying intrinsic driving mechanisms that enables infinity magnitude association for both prime gaps & prime numbers

to co-exist. By the same token, these Laws have important implication that they must be applicable to the relevant prime gaps on an perpetual time scale. Supporting materials in relation to Aspect 2 are found in Proposition 9.2. *The proof is now complete for Theorem Polignac-Twin prime IV*□.

Two mutually inclusive conditions: Condition 1. Presence of all Dimensions that repeat themselves on an indefinite basis and with exponent of '1' give rise to complete sets of **P** & **C** ["DA-wise one & only one mathematical possibility argument" associated with inevitable *de novo* DA homogeneity], and Condition 2. Presence of any Dimension(s) that do not repeat itself (themselves) on an indefinite basis or with exponent other than '1' give rise to incomplete set of **P** & **C** or incorrect set of non-**P** & non-**C** ["DA-wise mathematical impossibility argument" associated with inevitable *de novo* DA non-homogeneity]. When met, these two conditions fully support the point CFS Dimensions representations of **P** & **C** [with respective prime & composite gaps] are totally accurate. Condition 1 reflect proof from Theorem Polignac-Twin prime III as all **P** & **C** are associated with DA homogeneity when their Dimensions are endowed with exponent of '1'. Condition 2 invoke corollary on inevitable appearance of incomplete **P** or **C** or non-**P** or non-**C** [associated with DA non-homogeneity] being tightly incorporated into this mathematical framework. See Propositions 10.1 & 10.2, and Corollary 10.3 for supporting materials on DA homogeneity & non-homogeneity.

We analyze **P** (& **C**) in terms of (i) measurements based on cardinality of CIS and (ii) pigeonhole principle which states that if n items are put into m containers, with $n > m$, then at least one container must contain more than one item. We note that ordinality of all infinite **P** (& **C**) is "fixed" implying that each one of the infinite well-ordered Dimension sets conforming to CFS type as constituted by Dimensions $(2x - 7)^1$, $(2x - 8)^1$, $(2x - 9)^1$, $(2x - 10)^1$, $(2x - 11)^1$, ..., $(2x - \infty)^1$ on respective gaps for **P** (& **C**) must also be "fixed".

Proposition 10.1. "Even number prime gaps are infinite in magnitude with each even number prime gap generating odd prime numbers which are again infinite in magnitude" is supported by principles from Set theory and two Laws based on Gap 2 Composite Number.

Proof. We validly exclude even **P** '2' here. Let (i) cardinality $T = \aleph_0$ for Set **all odd P** derived from **E** prime gaps 2, 4, 6, ..., ∞ , (ii) cardinality $T_2 = \aleph_0$ for Subset **odd P** derived from **E** prime gap 2, cardinality $T_4 = \aleph_0$ for Subset **odd P** derived from **E** prime gap 4, cardinality $T_6 = \aleph_0$ for Subset **odd P** derived from **E** prime gap 6, etc. Paradoxically, (as sets) $T = T_2 + T_4 + T_6 + \dots + T_\infty$ equation is valid despite (their cardinality) $T = T_2 = T_4 = T_6 = \dots = T_\infty$ [with well-ordering principle "stating that every non-empty set of positive integers contains a least element" fulfilled by each (sub)set]; and **E** prime gaps are 'infinite in magnitude' can justifiably be perceived instead as 'arbitrarily large in magnitude' since cumulative sum total of **E** prime gaps is relatively much slower to attain the 'infinite in magnitude' status when compared to cumulative sum total of **P** which rapidly attain this status. But if Subset **odd P** derived from one or more **E** prime gap(s) are finite in magnitude, this will breach the \aleph_0 cardinality 'uniformity' resulting in (i) DA non-homogeneity and (ii) inequality (as sets) $T > T_2 + T_4 + T_6 + \dots + T_\infty$. In language of pigeonhole principle "stating that if n items are put into m containers with $n > m$, then at least one container must contain more than one item", residual **odd P** (still CIS in magnitude) not accounted for by CFS-type **E** prime gap(s) will have to be [incorrectly] contained in one (or more) of composite gap(s). These arguments using cardinality constitute proof that **E** prime gaps & odd **P** generated from each **E** prime gap, are all CIS. *The proof [on "quantitative" aspect] is now complete for Proposition 10.1*□.

Complete set of **P** is represented by Dimensions $(2x - N)^1$. Table 5 & Figure 25 on **PC** finite scale mathematical landscape depict perpetual repeating features used in "qualitative" statements supporting (i) Plus-Minus Gap 2 Composite Number Alternating Law (stated as **C** with composite gaps = 2 present in each of **P** with prime gaps ≥ 4 situation must be observed to appear as some sort of rhythmic patterns of alternating presence and absence of this type of **C**), and (ii) Plus Gap 2 Composite Number Continuous Law (stated as **C** with composite gaps = 2 continual appearances in each of (twin) **P** with prime gap = 2 situation). Plus-Minus Gap 2 Composite Number Alternating Law has built-in intrinsic mechanism to automatically generate all prime gaps ≥ 4 in a mathematically consistent *ad infinitum* manner. Plus Gap 2 Composite Number Continuous Law has built-in intrinsic mechanism to automatically generate prime gap = 2 appearances in a mathematically consistent *ad infinitum* manner. These two Laws refer to end-products obtained from "the second key step of using our unique Dimension $(2x - N)$ system instead of Sieve of Eratosthenes". *The proof [on "qualitative" aspect] is now complete for Proposition 10.1*□.

Proposition 10.2. The presence of Dimensional analysis homogeneity always result in correct and complete set of prime (and composite) numbers.

Proof. DA homogeneity is completely dependent on all Dimensions being consistently endowed with exponent '1'. As all **P** (& **C**) are "fixed", we deduce from Figure 25 & Table 5 that there is one (& only one) way to represent Information-Complexity conservation using our defined Dimensions. Thus, there is one (& only one) way to depict all **P** (& **C**) using these Dimensions in a self-consistent manner and this is achieved with the one (& only one) DA homogeneity possibility. *The proof is now complete for Proposition 10.2*□.

Corollary 10.3. The presence of Dimensional analysis non-homogeneity always result in incorrect and/or incomplete set of prime (and composite) numbers.

Proof. For optimal clarity, we endow all Dimensions with exponent '1' depicted as $(2x - 7)^1, (2x - 8)^1, (2x - 9)^1, (2x - 10)^1, (2x - 11)^1, \dots, (2x - \infty)^1$. Proposition 10.2 equates DA homogeneity with correct & complete set of **P** (& **C**). There are "more than one" DA possibilities when, for instance, a particular [first] term from $(2x - 7)^0, (2x - 8)^1, (2x - 9)^1, \dots, (2x - \infty)^1$ "terminates" prematurely and does not perpetually repeat [with loss of continuity]. There are intuitively two 'broad' DA possibilities here; namely, (one) DA homogeneity possibility and (one) DA non-homogeneity possibility – Dimension $(2x - 7)^0 [= 1]$ with its exponent arbitrarily set as '0' against-all-trend in this case. Thus Dimension $(2x - 7)^1$ that stop recurring at some point in **P** (or **C**) sequence may cause well-ordered CFS sets from progressive groupings of **[E]** 2, 4, 6, 8, 10, ..., ∞ for Dimensions $(2x - 8)^1, (2x - 9)^1, (2x - 10)^1, (2x - 11)^1, \dots, (2x - \infty)^1$ to stop existing (and ultimately for sequential **P** (or **C**) to stop appearing) at that point with ensuing outcome that **P** (or **C**) may overall be incorrectly finite or incomplete in magnitude. Finally also manifesting DA non-homogeneity, a Dimension endowed with fractional exponent values other than '1' such as ' $\frac{2}{5}$ ' or ' $\frac{3}{5}$ ' will result in non-**P** (or non-**C**) [fractional] numbers. *The proof is now complete for Corollary 10.3*□.

Each [fixed] finite scale mathematical landscape "page" as part of [fixed] infinite scale mathematical landscape "pages" for **P** & **C** display Chaos [sensitivity to initial conditions viz. positions of subsequent **P** & **C** are "sensitive" to positions of initial **P** & **C**] and Fractals [manifesting fractal dimensions with self-similarity viz. those aforementioned Dimensions for **P** & **C** are always present, albeit in non-identical manner, for all ranges of $x \geq 2$]. Advocated in another manner, Chaos and Fractals phenomena of those Dimensions for **P** & **C** are always present signifying accurate composition of **P** & **C** in different [predetermined] finite scale mathematical landscape "(snapshot) pages" for **P** & **C** that are self-similar but never identical – and there are an infinite number of these finite scale mathematical landscape "(snapshot) pages". The crucial mathematical step in representing all **P** (& **C**) and prime (& composite) gaps with "Dimensions" based on Information-Complexity conservation allows us to obtain the two Laws based on Gap 2 Composite Numbers and perform DA on these entities. The 'strong' principle argument is DA homogeneity equates to complete set of **P** (& **C**) whereas DA non-homogeneity does not equate to complete set of **P** (& **C**). We also advocate for a 'weak' principle argument supporting DA homogeneity for **P** (& **C**) in that nature should not "favor" any particular Dimension(s) to terminate and therefore DA non-homogeneity cannot exist for **P** (& **C**). Abiding to an advocated convention that 'conjecture' be termed 'hypothesis' once proven; we now label these conjectures as Polignac's and Twin prime hypotheses.

11 Conclusions

This original expository paper is advocated to be a novel achievement as we manage to simultaneously model COVID-19 from Medicine as well as solve [unconnected] intractable open problems from Number theory using our versatile Fic-Fac Ratio. In other words, we successfully relate open problems from Number theory when considered as a frontier branch of Mathematics to COVID-19 from Medicine when considered as other science, technology and biology. Transmitted between animals and people, zoonotic virus SARS-CoV-2 which originated from Wuhan, China causing COVID-19 has been clearly shown not to be a laboratory construct or a purposefully manipulated virus[14]. Some overall goals of publishing this paper are to promote Mathematics as the 'Universal Language of Science', and foster global cooperation between all nations on planet Earth to effectively combat and better understand the deadly 2020 Coronavirus pandemic. **Note:** The contextual use

of supramaximal elevation or fall of cytokines is based on phenomenon and proposed homeostatic mechanism of *supramaximal elevation* in B-type natriuretic peptide and its N-terminal fragment levels in anephric patients with heart failure (previously introduced by us in 2012[15]). This mechanism consists of analyzing the permutations with repetition formula: $n^r = n^2$ from combinatorics involving 'n' individual factors that tend to have **non-linear** elevating or lowering properties viz. 'r' = 2. Antibody-directed therapy such as convalescent plasma, hyperimmune-globulin and monoclonal antibodies may also play an important role in more rapid control and clearance of SARS-CoV-2.

From our August 12, 2020 13-page paper entitled "Showing role of Angiotensin-converting enzyme 2 in COVID-19 using novel Fic-Fac Ratio" (J. Y. C. Ting) located at URL <https://vixra.org/abs/2008.0082> Science Category: Physics of Biology, we also provide a Case Report for medically-oriented readers of a 43 year-old man with acute respiratory distress syndrome (ARDS) from viral pneumonia together with applications from Fic-Fac Ratio to creatively explain COVID-19's drug and vaccine developments, and mitigation measures to combat the resulting pandemic. This patient had initial severe Type 1 Respiratory Failure viz. decreased PaO₂ < 60 mmHg (8.0 kPa) with normal or subnormal PaCO₂ < 50 mmHg (6.7 kPa) which rapidly deteriorated to severe Type 2 Respiratory Failure viz. decreased PaO₂ < 60 mmHg (8.0 kPa) and increased PaCO₂ > 50 mmHg (6.7 kPa) requiring intubation and ventilation.

We mathematically envisage two *mutually exclusive* groups of entities: [totally] Unpredictable entities and [totally] Predictable entities. The first group dubbed Type I entities or Completely Unpredictable entities can arise as [totally] random physical processes in nature e.g. radioactive decay is a stochastic (random) process occurring at level of single atoms. According to Quantum theory, it is impossible to predict when a particular atom will decay regardless of how long the atom has existed. For a collection of atoms, expected decay rate is characterized in terms of their measured decay constants or half-lives. The second group is constituted by two subgroups: dubbed Type II entities or Completely Predictable entities e.g. Even-Odd number pairing in Table 6 (with abbreviation 'Y' = Dimension $2x-4$) and dubbed Type III entities or Incompletely Predictable entities e.g. Prime-Composite number pairing in Table 5 (with abbreviation 'Y' = Dimension $2x-7$). **Note:** The [only] two common situations to identically use Dimension $2x-2$ to represent Number '1' & Dimension $2x-4$ to represent Number '2' occurs in both pairings from Tables 5 & 6. Intuitively, every single mathematical argument from complete set of mathematical arguments required to fully solve a given Incompletely Predictable Problem (containing *dependent* types of Incompletely Predictable entities) must be correct obeying Mathematics for Completely Predictable Problems. Then Mathematics for Incompletely Predictable Problems is literally the mathematical framework for describing complex properties present in these entities. For Even-Odd number pairing in Appendix D, one can [redundantly] introduce Mathematics for Completely Predictable Problems as the mathematical framework describing this Completely Predictable Problem containing *independent* types of Completely Predictable entities endowed with simple properties.

CIS of [Completely Predictable] natural numbers 1, 2, 3, 4, 5, 6, 7,... having CIS of [Completely Predictable] natural gaps 1, 1, 1, 1, 1,... are constituted by three dependent sets of numbers: (i) CIS of [Incompletely Predictable] odd prime numbers 3, 5, 7, 11, 13, 17,... having CIS of [Incompletely Predictable] prime gaps 2, 2, 4, 2, 4,... plus CFS of solitary [Incompletely Predictable] even prime number 2 having CFS of [Incompletely Predictable] prime gap 1 (ii) CIS of [Incompletely Predictable] even and odd composite numbers 4, 6, 8, 9, 10, 12,... having CIS of [Incompletely Predictable] composite gaps 2, 2, 1, 1, 2, 2,... and (iii) CFS of solitary odd number '1' [neither prime nor composite]. Treated as Incompletely Predictable problems endowed with "meta-properties", we gave relatively elementary proofs on Polignac's & Twin prime conjectures by (1) employing our unique Dimension $(2x - N)$ system instead of Sieve of Eratosthenes to obtain prime & composite numbers [and Number '1'] and then self-consistently derive 'Plus Gap 2 Composite Number Continuous Law' for prime gap equal to 2 & 'Plus-Minus Gap 2 Composite Number Alternating Law' for prime gaps greater than 2; and (2) demonstrating DA homogeneity with presence of [solitary] cardinality value \aleph_0 occurring in all [even number prime gap] subsets of prime numbers and in set of even number prime gaps. **Note:** By virtue of wordings used in these two mentioned Laws; then apart from first prime number '2', all other prime numbers [represented by prime gap = 2 and prime gaps > 2] are *dependently* linked to composite numbers [represented by Gap 2 Composite Number].

Harnessed properties: (1) Nontrivial zeros & two types of Gram points are [*dependently*] derived from "Axes intercept relationship interface" using Riemann zeta function, or its *proxy* Dirichlet eta function; and (2) Prime & composite numbers are [*dependently*] derived from "Numerical relationship interface" using Sieve of Eratosthenes. Using prime gaps as analogy, there are (for instance) "nontrivial zeros gaps" between any two nontrivial zeros with all these gaps of infinite magnitude being Incompletely Predictable entities. Prime number theorem describes asymptotic distribution of prime numbers among positive integers by formalizing intuitive idea that prime numbers become less common as they become larger through precisely quantifying rate at which this occurs using probability. Secondary spin-off arising out of solving Riemann hypothesis result in absolute and full delineation of prime number theorem. This theorem relates to prime counting function which is usually denoted by $\pi(x)$ with $\pi(x)$ = number of prime numbers $\leq x$. In other words, solving Riemann hypothesis is instrumental in proving efficacy of techniques that estimate $\pi(x)$ efficiently. This confirm "best possible" bound for error ("smallest possible" error) of prime number theorem.

In mathematics, logarithmic integral function or integral logarithm $\text{li}(x)$ is a special function. Relevant to problems of physics with number theoretic significance, it occurs in prime number theorem as an estimate of $\pi(x)$ whereby its form is defined so that $\text{li}(2) = 0$; viz. $\text{li}(x) \equiv \int_2^x \frac{du}{\ln u} = \text{li}(x) - \text{li}(2)$. There are less accurate ways of estimating $\pi(x)$ such as conjectured by Gauss and Legendre at end of 18th century. This is approximately $x/\ln x$ in the sense $\lim_{x \rightarrow \infty} \frac{\pi(x)}{x/\ln x} = 1$. Skewes' number is any of several extremely large numbers used by South African mathematician Stanley Skewes as upper bounds for smallest natural number x for which $\text{li}(x) < \pi(x)$. These bounds have since been improved by others: there is a crossing near $e^{727.95133}$ but it is not known whether this is the smallest. John Edensor Littlewood who was Skewes' research supervisor proved in 1914[16] that there is such a [first] number; and found that sign of difference $\pi(x) - \text{li}(x)$ changes infinitely often. This refute all prior numerical evidence that seem to suggest $\text{li}(x)$ was always $> \pi(x)$. The key point is [100% accurate] perfect $\pi(x)$ mathematical tool being "wrapped around" by [less-than-100% accurate] approximate $\text{li}(x)$ mathematical tool infinitely often via this 'sign of difference' changes meant that $\text{li}(x)$ is the most efficient approximate mathematical tool. Contrast this with "crude" $x/\ln x$ approximate mathematical tool where we studied values diverge away from $\pi(x)$ at increasingly greater rate for larger range of prime numbers.

Using classification system in Appendix C, a formula is either non-Hybrid or Hybrid integer sequence. Inequation with two 'necessary' Ratio (R) or equation with one 'unnecessary' R contains non-Hybrid integer sequence. Equation with one 'necessary' R contains Hybrid integer sequence. "In the limit" Hybrid integer sequence approach unique Position X, it becomes non-Hybrid integer sequence for all Positions \geq Position X. Kinetic energy (KE) has its endowed units in MJ when m_0 = rest mass in kg and v = velocity in ms^{-1} . In classical mechanics concerning low velocity with $v \ll c$, Newtonian KE = $\frac{1}{2}m_0v^2$. In relativistic mechanics concerning high velocity with $v \geq 0.01c$, Relativistic KE = $\frac{m_0c^2}{\sqrt{1 - (v^2/c^2)}} - m_0c^2$. Obtained from the later by binomial approximation or by taking first two terms of Taylor expansion for reciprocal square root, the former approximates the later well at low speed. We arbitrarily denote inexact DA homogeneity for '<100% accuracy' Newtonian KE and exact DA homogeneity for '100% accuracy' Relativistic KE. "In the limit" Newtonian KE at low speed approach Relativistic KE at high speed, we achieve *perfection*.

Useful analogy: "In the limit" all three versions of Dirichlet Sigma-Power Laws for Gram[$y=0$] points, Gram[$x=0$] points and nontrivial zeros as '<100% accuracy' inequations approach *perfection* as '100% accuracy' equations, compliance with inexact DA homogeneity becomes compliance with exact DA homogeneity. **Note:** Absence of fractional exponent ($\sigma+1$) as relevant 'unit of measurement' in R1 terms of all inequations giving rise to the so-called Pseudo- Σ (all fractional exponents). Fully understanding the validity of this entity has greatly contributed to designing the extremely useful Fic-Fac Ratio which we regard as tertiary spin-offs from solving our open problems in Number theory. Treated as Incompletely Predictable problems, we gave relatively elementary proof of Riemann hypothesis and explain two types of Gram points by analyzing the "meta-properties" of relevant Dirichlet Sigma-Power Laws viz. (1) **exact DA homogeneity [occurring when $\sigma = \frac{1}{2}$] in both their equations & inequations** and (2) **inexact DA homogeneity [occurring when $\sigma \neq \frac{1}{2}$] in both their equations & inequations**.

We define two terms: *perfect symmetry* to denote "even functions" [which are symmetric about vertical y-axis] and "odd functions" [which are symmetric about origin]; and *broken symmetry* to denote "neither even nor odd functions" [which are neither symmetric about vertical y-axis nor origin]. Relevant types of Gram points (at $\sigma = \frac{1}{2}$) and virtual Gram points (at $\sigma \neq \frac{1}{2}$) represent their corresponding x-axis, y-axis and origin intercepts with two true statements:

(1) **Dirichlet Sigma-Power Laws pertaining to Gram[x=0,y=0] points (nontrivial zeros) in Riemann hypothesis and virtual Gram[x=0,y=0] points will manifest broken symmetry** viz. not satisfying particular symmetry relations present in "even functions" or "odd functions" to **combinedly be classified as "neither even nor odd functions" for all their equations and inequations.**

(2) **Dirichlet Sigma-Power Laws pertaining to Gram[y=0] points, virtual Gram[y=0] points, Gram[x=0] points and virtual Gram[x=0] points will manifest perfect symmetry** viz. satisfying particular symmetry relations present in "even functions" or "odd functions" to **separately be classified as "even functions" for all their inequations and "odd functions" for all their equations.**

Conflict of Interest Statement This work was supported by private research grant of AUS \$5,000 generously offered by Mrs. Connie Hayes and Mr. Colin Webb on January 20, 2020. The author further discloses receiving an additional AUS \$3,250 reimbursement from Q-Pharm for participating in EyeGene Shingles trial commencing on March 10, 2020. This paper aims to promote human knowledge of Mathematics and its indispensable role in increasing advancements on Medicine for benefit of all mankind during the 2020 Coronavirus pandemic. It does not contain any compromising or intrusive materials such as sensitive criticisms on national or international policies from selected countries.

Acknowledgements Huge thanks to Australian mathematicians Rodney Williams and Tony O'Hagan for constructive criticisms; and experts for peer reviews. This research paper is dedicated to the author's daughter Jelena (birth weight 1010 grams) born 13 weeks early on May 14, 2012 and all front-line health workers globally fighting against the deadly 2020 Coronavirus pandemic.

A Appendix A: Gram's Law and traditional 'Gram points'

Named after Danish mathematician Jørgen Pedersen Gram (June 27, 1850 – April 29, 1916), traditional 'Gram points' (Gram $[y=0]$ points) are other conjugate pairs values on critical line defined by $Im\{\zeta(\frac{1}{2} \pm it)\} = 0$. Belonging to Incompletely Predictable entities, they obey Gram's Rule and Rosser's Rule with some characteristic properties outlined by our brief exposition below: Z function is used to study Riemann zeta function on critical line. Defined in terms of Riemann-Siegel theta function & Riemann zeta function by $Z(t) = e^{i\theta(t)} \zeta(\frac{1}{2} + it)$ whereby $\theta(t) = \arg(\Gamma(\frac{2t+1}{4})) - \frac{\ln \pi}{2} t$; it is also called Riemann-Siegel Z function, Riemann-Siegel zeta function, Hardy function, Hardy Z function, & Hardy zeta function.

The algorithm to compute Z(t) is called Riemann-Siegel formula. Riemann zeta function on critical line, $\zeta(\frac{1}{2} + it)$, will be real when $\sin(\theta(t)) = 0$. Positive real values of t where this occurs are called 'Gram points' and can also be described as points where $\frac{\theta(t)}{\pi}$ is an integer. Real part of this function on critical line tends to be positive, while imaginary part alternates more regularly between positive & negative values. That means sign of Z(t) must be opposite to that of sine function most of the time, so one would expect nontrivial zeros of Z(t) to alternate with zeros of sine term, i.e. when θ takes on integer multiples of π . This turns out to hold most of the time and is known as Gram's Rule (Law) – a law which is violated infinitely often though. Thus Gram's Law is statement [on the manifested property] that nontrivial zeros of Z(t) alternate with 'Gram points'. 'Gram points' which satisfy Gram's Law are called 'good', while those that do not are called 'bad'. A Gram block is an interval such that its first & last points are good 'Gram points' and all 'Gram points' inside this interval are bad. Counting nontrivial zeros then reduces to counting all 'Gram points' where Gram's Law is satisfied and adding the count of nontrivial zeros inside each Gram block. With this process we need not locate nontrivial zeros but just have to accurately compute Z(t) to show that it changes sign.

B Appendix B: Ratio Study and Inequations

A mathematical equation, containing \geq one variables, is a statement that values of two ['left-hand side' (LHS) and 'right-hand side' (RHS)] mathematical expressions is related as equality: LHS = RHS; or as inequalities: LHS < RHS, LHS > RHS, LHS \leq RHS, or LHS \geq RHS. A ratio is one mathematical expression divided by another. The term 'unnecessary' Ratio (R) for any given equation is explained by two examples: (1) LHS = RHS and with rearrangement, 'unnecessary' R is given by $\frac{LHS}{RHS} = 1$ or $\frac{RHS}{LHS} = 1$; and (2) LHS > RHS and with rearrangement, 'unnecessary' R is given by $\frac{LHS}{RHS} > 1$ or $\frac{RHS}{LHS} < 1$. Consider exponent $y \in$ all \mathbf{R} values and base $x \in \mathbf{R} \geq 0$ values for mathematical expression x^y . Equations such as $x^1 = x$, $x^0 = 1$ and $0^y = 0$ are all valid. Simultaneously letting both x and y = 0 is an incorrect mathematical action because x^y as function of two-variables is not continuous and is undefined at Origin. If we elect to carry out this "balanced" action [equally] on x and y, we obtain (simple) inequation $0^0 \neq 1$ with associated perpetual obeyance of '=' equality symbol in x^y for all applicable \mathbf{R} values except when both x and y = 0. The Number '1' value in this inequation is justified by two arguments: I. Limit of x^y value as both x and y tend to zero (from right) is 1 [thus fully satisfying criterion " x^y is right continuous at the Origin"]; and II. Expression x^y is product of x with itself y times [and thus x^0 , the "empty product", should be 1 (no matter what value is given to x)].

Mathematical operator 'summation' obey the law: We can break up a summation across a sum or difference but not across a product or quotient viz, factoring a sum of quotients into a corresponding quotient of sums is an incorrect mathematical action. But if we elect to carry out this action equally on LHS and RHS products or quotients in a suitable equation, we obtain two (unique) 'necessary' R denoted by R1 for LHS and R2 for RHS whereby $R1 \neq R2$ relationship always hold. We define 'Ratio Study' as intentionally performing this incorrect [but "balanced"] mathematical action on suitable equation [equivalent to one (non-unique) 'unnecessary' R] to obtain its inequation [equivalent to two (unique) 'necessary' R]. We note that performing Ratio Study to obtain inequations involving \mathbb{C} does not involve defining a relation between two \mathbb{C} . Given Set \mathbb{C} is a field (but not an ordered field), it is also not possible to define a relation between two given (z_1 and z_2) \mathbb{C} as $z_1 < z_2$ since inequality operation is not compatible with addition and multiplication.

C Appendix C: Hybrid method of Integer Sequence classification

Hybrid method of Integer Sequence classification enables meaningful division of all integer sequences into either Hybrid or non-Hybrid integer sequences. Our exotic A228186 integer sequence[17] was published on The On-line Encyclopedia of Integer Sequences website in 2013. With challenge to discover more, it is the first ever [infinite length] Hybrid integer sequence synthesized from Combinatorics Ratio. In 'Position i' notation, let $i = 0, 1, 2, 3, 4, 5, \dots, \infty$ be complete set of natural numbers.

A228186 "Greatest $k > n$ such that ratio $R < 2$ is a maximum rational number with $R = \frac{\text{CombinationsWithRepetition}}{\text{CombinationsWithoutRepetition}}$ " is equal to [infinite length] non-Hybrid (usual garden-variety) integer sequence A100967[18] except for finite 21 'exceptional' terms at Positions 0, 11, 13, 19, 21, 28, 30, 37, 39, 45, 50, 51, 52, 55, 57, 62, 66, 70, 73, 77, and 81 with their values given by relevant A100967 terms plus 1. The first 49 terms [from Position 0 to Position 48] of A100967 "Least k such that $\text{binomial}(2k+1, k-n) \geq \text{binomial}(2k, k)$ " are listed below: 3, 9, 18, 29, 44, 61, 81, 104, 130, 159, 191, 225, 263, 303, 347, 393, 442, 494, 549, 606, 667, 730, 797, 866, 938, 1013, 1091, 1172, 1255, 1342, 1431, 1524, 1619, 1717, 1818, 1922, 2029, 2138, 2251, 2366, 2485, 2606, 2730, 2857, 2987, 3119, 3255, 3394, and 3535. For those 21 'exceptional' terms: at Position 0, A228186 (= 4) is given by A100967 (= 3) + 1; at Position 11, A228186 (= 226) is given by A100967 (= 225) + 1; at Position 13, A228186 (= 304) is given by A100967 (= 303) + 1; at Position 19, A228186 (= 607) is given by A100967 (= 606) + 1; etc. A useful concept: Commencing from Position 0 onwards "in the limit" this Position approaches 82, A228186 Hybrid integer sequence is identical to / becomes A100967 non-Hybrid integer sequence for all Positions ≥ 82 .

D Appendix D: Tabulated and graphical data on Even-Odd mathematical landscape

We tabulate in Table 6 and graph in Figure 26 [Completely Predictable] E-O mathematical landscape for x = 1 to 64. Involved Dimensions are $2x - 2$ & $2x - 4$ with Y denoting Dimension $2x - 4$ for visual clarity. Mathematical landscape of Dimension $2x - 4$ (except for first and only Dimension $2x - 2$) intrinsically incorporates E & O in an integrated manner. Except for first O, all Completely Predictable E & O and their associated gaps are represented by countable finite set of [single] Dimension $2x - 4$. Dimensions $2x - 2$ & $2x - 4$ are symbolically represented by -2 & -4 with $2x - 4$ displayed as 'baseline' Dimension whereby Dimension trend (Cumulative Sum Gaps) must reset itself onto this (Grand-Total Gaps) 'baseline' Dimension after initial Dimension $2x - 2$ on a permanent basis. Graphical appearances of Dimensions symbolically represented by two negative integers are Completely Predictable with both Even- $\pi(x)$ and Odd- $\pi(x)$ becoming larger at a constant rate. There is a complete absence of Chaos and Fractals phenomena.

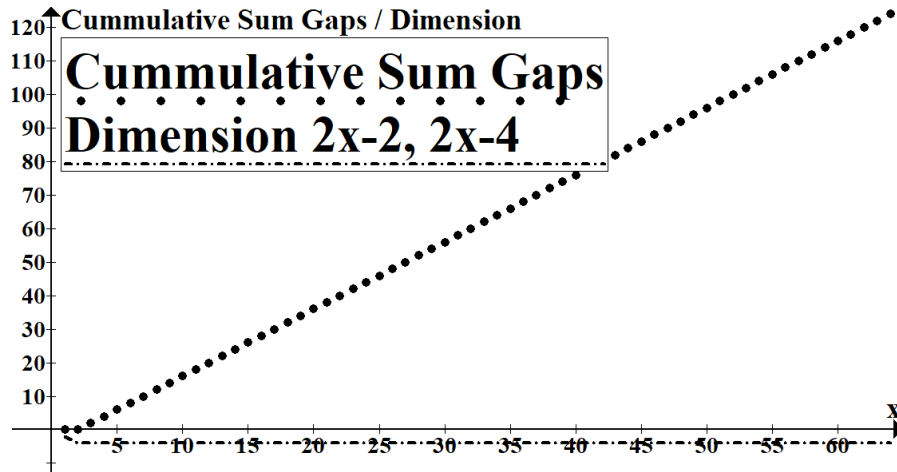

Fig. 26: Even-Odd mathematical (graphed) landscape. Data for $x = 1$ to 64.

Definitive derivation of data in Table 6 is illustrated by two examples for position $x = 31$ & 32 . For i & $x \in 1, 2, 3, \dots, \infty$; $\Sigma EO_x\text{-Gap} = \Sigma EO_{x-1}\text{-Gap} + \text{Gap value at } E_{i-1} \text{ or Gap value at } O_{i-1}$ whereby (i) E_i or O_i at position x is determined by whether relevant x value belongs to **E** or **O**, and (ii) both $\Sigma EO_1\text{-Gap}$ and $\Sigma EO_2\text{-Gap} = 0$. Example, for position $x = 31$: 31 is **O** (O16). Our desired Gap value at O15 = 2. Thus $\Sigma EO_{31}\text{-Gap} (58) = \Sigma EO_{30}\text{-Gap} (56) + \text{Gap value at O15} (2)$. Example, for position $x = 32$: 32 is **E** (E16). Our desired Gap value at E15 = 2. Thus $\Sigma EO_{32}\text{-Gap} (60) = \Sigma EO_{31}\text{-Gap} (58) + \text{Gap value at E15} (2)$. Note: in our Dimension $(2x - N)$ system, $N = 2x - \Sigma EO_x\text{-Gap}$. Then in this unique Dimension $(2x - N)$ system with $N = 2x - \Sigma EO_x\text{-Gap}$, Dimension $(2x - N)$ when fully expanded is numerically just equal to $\Sigma EO_x\text{-Gap}$ since Dimension $(2x - N) = 2x - 2x + \Sigma EO_x\text{-Gap} = \Sigma EO_x\text{-Gap}$.
