

Bayesian network and information theory

Ait-taleb Nabil *

Abstract

In this paper, we will expose the BIC score expressed as a function of the Bayesian network's entropy. We will then use this BIC score to learn a Bayesian network from an example of data frame.

1 Introduction

In this paper, we will begin by defining the notions of joint and conditional differential entropy that we find in the field of information theory. We will expose the Gaussian multivariate probability and compute its joint differential entropy and conditional differential entropy. We will then give the definition of the Bayesian network and how show to compute its entropy.

We will also expose the entropy of two particular Bayesian networks: one with a chain rule and one without edges. These two particular Bayesian networks will allow us to understand, using an inequality, the range of values in which the entropy of a Bayesian network varies.

We will present in a section the likelihood function and the BIC score expressed from a Bayesian network's entropy. We will then describe an algorithm allowing us to obtain the most likely optimal Bayesian network from a data frame using the BIC score expressed from the Bayesian network's entropy. We will briefly explain what to do to infer data from the optimal Bayesian network.

This paper will end with the application of the learning algorithm on a concrete example of a data frame.

2 Differential entropy attributed to random vectors

2.1 Differential entropy for a random vector

Definition: Given a random vector \vec{x} , defined on set \mathbb{X} of size n , with a multidimensional probability density function (pdf) $p_X(\vec{x})$, we define the differential entropy $h(X)$ as:

$$h(X) = - \int_{\mathbb{X}} p_X(\vec{x}) \ln p_X(\vec{x}) d\vec{x}$$

2.2 Joint differential entropy of two random vectors

Definition: Given two concatenated random vectors (\vec{x}_1, \vec{x}_2) , defined on the sets \mathbb{X}_1 and \mathbb{X}_2 of size n and m respectively, with a multidimensional probability density function(pdf) $p_{X_1 X_2}(\vec{x}_1, \vec{x}_2)$, we define the joint differential entropy $h(X_1, X_2)$ as:

$$h(X_1, X_2) = - \int_{\mathbb{X}_1} \int_{\mathbb{X}_2} p_{X_1 X_2}(\vec{x}_1, \vec{x}_2) \ln p_{X_1 X_2}(\vec{x}_1, \vec{x}_2) d\vec{x}_1 d\vec{x}_2$$

2.3 Conditional differential entropy of a random vector given a random vector

Definition: Given two concatenated random vectors (\vec{x}_1, \vec{x}_2) , defined on the sets \mathbb{X}_1 and \mathbb{X}_2 of size n et m respectively, with a multidimensional probability density function(pdf) $p_{X_1 | X_2}(\vec{x}_1, \vec{x}_2)$, we define the conditional differential entropy $h(X_1 | X_2)$ as:

$$h(X_1 | X_2) = - \int_{\mathbb{X}_1} \int_{\mathbb{X}_2} p_{X_1 | X_2}(\vec{x}_1, \vec{x}_2) \ln p_{X_1 | X_2}(\vec{x}_1, \vec{x}_2) d\vec{x}_1 d\vec{x}_2$$

where we have:

$$p_{X_1 | X_2}(\vec{x}_1, \vec{x}_2) = \frac{p_{X_1 X_2}(\vec{x}_1, \vec{x}_2)}{p_{X_2}(\vec{x}_2)}$$

$$P_{X_2}(\vec{x}_2) = \int_{\mathbb{X}_1} p_{X_1 X_2}(\vec{x}_1, \vec{x}_2) d\vec{x}_1$$

3 Multivariate Gaussian distribution and information theory

3.1 Joint and conditional gaussian multidimensional probability

Consider a partitioned random vector $\vec{x} = (\vec{x}_1, \vec{x}_2)$ of size $n = k_1 + k_2$, where k_1 and k_2 are the size of vectors \vec{x}_1 and \vec{x}_2 respectively, with a multivariate Gaussian distribution $P_X(\vec{x})$ with a mean vector μ_X and covariance matrix K_{X^2} :

$$P_X(\vec{x}) = \mathcal{N}(\mu_X, K_{X^2}) = (2\pi)^{-\frac{n}{2}} |K_{X^2}|^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x} - \mu_X)' K_{X^2}^{-1} (\vec{x} - \mu_X)}{2}\right\}$$

The purpose of this section is to expose the following different probabilities:

1. $P_X(\vec{x}) = P_{X_1, X_2}(\vec{x}_1, \vec{x}_2)$
2. $P_{X_2}(\vec{x}_2)$
3. $P_{X_1|X_2}(\vec{x}_1, \vec{x}_2)$

For this, we must start first from the block matrix multiplication of the covariance matrix K and the precision matrix $W = K^{-1}$ and prove the following relation:

$$W_{X_2^2} = K_{X_2^2}^{-1} + W_{X_2 X_1} \cdot W_{X_1^2}^{-1} \cdot W_{X_1 X_2}.$$

Indeed:

$$K_{X^2} W_{X^2} = \begin{pmatrix} K_{X_1^2} W_{X_1^2} + K_{X_1 X_2} W_{X_2 X_1} & K_{X_1^2} W_{X_1 X_2} + K_{X_1 X_2} W_{X_2^2} \\ K_{X_2 X_1} W_{X_1^2} + K_{X_2^2} W_{X_2 X_1} & K_{X_2 X_1} W_{X_1 X_2} + K_{X_2^2} W_{X_2^2} \end{pmatrix} = \begin{pmatrix} I_{k_1, k_1} & 0 \\ 0 & I_{k_2, k_2} \end{pmatrix}$$

$$K_{X_2 X_1} W_{X_1^2} + K_{X_2^2} W_{X_2 X_1} = 0$$

$$K_{X_2^2}^{-1} K_{X_2 X_1} W_{X_1^2} + W_{X_2 X_1} = 0$$

$$K_{X_2^2}^{-1} K_{X_2 X_1} = -W_{X_2 X_1} W_{X_1^2}^{-1}$$

$$K_{X_2^2} W_{X_2^2} + K_{X_2 X_1} W_{X_1 X_2} = I_{k_2 k_2}$$

$$W_{X_2^2} = K_{X_2^2}^{-1} - K_{X_2^2}^{-1} \cdot K_{X_2 X_1} \cdot W_{X_1 X_2}$$

Finally, we obtain:

$$W_{X_2^2} = K_{X_2^2}^{-1} + W_{X_2 X_1} \cdot W_{X_1^2}^{-1} \cdot W_{X_1 X_2}$$

Now, we will develop the Mahalanobis distance:

$$\begin{aligned}
& (\vec{x} - \mu_X)^t W_{X^2} (\vec{x} - \mu_X) \\
&= (\vec{x}_1 - \mu_{X_1}, \vec{x}_2 - \mu_{X_2}) \begin{pmatrix} W_{X_1^2} & W_{X_1 X_2} \\ W_{X_2 X_1} & W_{X_2^2} \end{pmatrix} \begin{pmatrix} \vec{x}_1 - \mu_{X_1} \\ \vec{x}_2 - \mu_{X_2} \end{pmatrix} \\
&= (\vec{x}_1 - \mu_{X_1})^t W_{X_1^2} (\vec{x}_1 - \mu_{X_1}) + (\vec{x}_1 - \mu_{X_1})^t W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2}) + (\vec{x}_2 - \mu_{X_2})^t W_{X_2 X_1} (\vec{x}_1 - \mu_{X_1}) \\
&\quad + (\vec{x}_2 - \mu_{X_2})^t W_{X_2^2} (\vec{x}_2 - \mu_{X_2})
\end{aligned}$$

Using the relation: $W_{X_2^2} = K_{X_2^2}^{-1} + W_{X_2 X_1} \cdot W_{X_1^2}^{-1} \cdot W_{X_1 X_2}$, we obtain:

$$\begin{aligned}
& (\vec{x}_1 - \mu_{X_1})^t W_{X_1^2} (\vec{x}_1 - \mu_{X_1}) + (\vec{x}_1 - \mu_{X_1})^t W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2}) + (\vec{x}_2 - \mu_{X_2})^t W_{X_2 X_1} (\vec{x}_1 - \mu_{X_1}) \\
&\quad + (\vec{x}_2 - \mu_{X_2})^t W_{X_2 X_1} W_{X_1^2}^{-1} W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2}) + (\vec{x}_2 - \mu_{X_2})^t K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2}) \\
&= [(\vec{x}_1 - \mu_{X_1}) + W_{X_1^2}^{-1} W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2})]^t [W_{X_1^2} (\vec{x}_1 - \mu_{X_1}) + W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2})] \\
&\quad + (\vec{x}_2 - \mu_{X_2})^t K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2}) \\
&= [(\vec{x}_1 - \mu_{X_1}) + W_{X_1^2}^{-1} W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2})]^t W_{X_1^2} \cdot [(\vec{x}_1 - \mu_{X_1}) + W_{X_1^2}^{-1} W_{X_1 X_2} (\vec{x}_2 - \mu_{X_2})] \\
&\quad + (\vec{x}_2 - \mu_{X_2})^t K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2})
\end{aligned}$$

We put:

$$\begin{aligned}
Q_1 &= (\vec{x}_1 - \nu_{X_1/X_2})^t (K_{X_1^2} - K_{X_1 X_2} K_{X_2^2}^{-1} K_{X_2 X_1})^{-1} (\vec{x}_1 - \nu_{X_1/X_2}) \\
\nu_{X_1|X_2} &= \mu_{X_1} + K_{X_1 X_2} K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2}) \\
Q_2 &= (\vec{x}_2 - \mu_{X_2})^t K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2})
\end{aligned}$$

We then obtain the equalities as follows:

$$\begin{aligned}
& (\vec{x} - \mu_X)^t K_{X^2}^{-1} (\vec{x} - \mu_X) = Q_1 + Q_2 \\
P_X(\vec{x}) &= (2\pi)^{-\frac{n}{2}} |K_{X^2}|^{-\frac{1}{2}} \exp\left\{-\frac{Q_1+Q_2}{2}\right\} = (2\pi)^{-\frac{n}{2}} |K_{X^2}|^{-\frac{1}{2}} \exp\{(\vec{x} - \mu_X)^t K_{X^2}^{-1} (\vec{x} - \mu_X)\} \\
P_{X_2}(\vec{x}_2) &= (2\pi)^{-\frac{k_2}{2}} |K_{X_2^2}|^{-\frac{1}{2}} \exp\left\{-\frac{Q_2}{2}\right\} = (2\pi)^{-\frac{k_2}{2}} |K_{X_2^2}| \exp\left\{-\frac{(\vec{x}_2 - \mu_{X_2})^t K_{X_2^2}^{-1} (\vec{x}_2 - \mu_{X_2})}{2}\right\}
\end{aligned}$$

Using the relation $\frac{P_{X_1 X_2}(\vec{x}_1, \vec{x}_2)}{P_{X_2}(x_2)}$:

$$P_{X_1|X_2}(x_1, x_2) = (2\pi)^{-\frac{k_1}{2}} \left(\frac{|K_{(X_1 X_2)^2}|}{|K_{X_2^2}|} \right)^{-\frac{1}{2}} \exp\left\{-\frac{Q_1}{2}\right\} = (2\pi)^{-\frac{k_1}{2}} \left(\frac{|K_{(X_1 X_2)^2}|}{|K_{X_2^2}|} \right)^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x}_1 - \nu_{X_1/X_2})^t (K_{X_1^2} - K_{X_1 X_2} K_{X_2^2}^{-1} K_{X_2 X_1})^{-1} (\vec{x}_1 - \nu_{X_1/X_2})}{2}\right\}$$

If we use the Schur's complement $K_{X_2^2|X_2} = K_{X_1^2} - K_{X_1 X_2} K_{X_2^2}^{-1} K_{X_2 X_1}$

we can express the conditional probability $P_{X_1|X_2}(\vec{x}_1, \vec{x}_2)$ as follows:

$$\begin{aligned}
P_{X_1|X_2}(\vec{x}_1, \vec{x}_2) &= (2\pi)^{-\frac{k_1}{2}} \left(\frac{|K_{(X_1 X_2)^2}|}{|K_{X_2^2}|} \right)^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x}_1 - \nu_{X_1/X_2})^t K_{X_2^2|X_2}^{-1} (\vec{x}_1 - \nu_{X_1/X_2})}{2}\right\} = (2\pi)^{-\frac{k_1}{2}} |K_{X_2^2|X_2}|^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x}_1 - \nu_{X_1/X_2})^t K_{X_2^2|X_2}^{-1} (\vec{x}_1 - \nu_{X_1/X_2})}{2}\right\}
\end{aligned}$$

3.2 Differential entropy of a Gaussian random vector

Theorem: Given random vector $\vec{x} = (x_1, x_2, \dots, x_n)$ with a multivariate Gaussian distribution:

$$P_X(\vec{x}) = \mathcal{N}(\mu_X, K_{X^2}) = (2\pi)^{-\frac{n}{2}} |K_{X^2}|^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x} - \mu_X)^t K_{X^2}^{-1} (\vec{x} - \mu_X)}{2}\right\}$$

with a mean vector μ_X and a covariance matrix K_{X^2} then the differential entropy is equal to:

$$h(X) = \frac{1}{2} \ln(2\pi e)^n |K_{X^2}|$$

Proof:

$$\begin{aligned} h(X) &= - \int_{-\infty}^{+\infty} p_X(\vec{x}) \ln\{p_X(\vec{x})\} d\vec{x} \\ &= - \int_{-\infty}^{+\infty} p_X(\vec{x}) \left[-\frac{1}{2} (\vec{x} - \mu_X)^t K_{X^2}^{-1} (\vec{x} - \mu_X) - \ln(\sqrt{2\pi})^n |K_{X^2}|^{\frac{1}{2}} \right] d\vec{x} \\ &= \frac{1}{2} E_X \left[\sum_{ij} (\vec{x}_i - \mu_{X_i})^t (K_{X^2}^{-1})_{ij} (\vec{x}_j - \mu_{X_j}) \right] + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} E_X \left[\sum_{ij} (\vec{x}_i - \mu_{X_i})^t (\vec{x}_j - \mu_{X_j}) (K_{X^2}^{-1})_{ij} \right] + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} \sum_{ij} E_X [(\vec{x}_j - \mu_{X_j})^t (\vec{x}_i - \mu_{X_i})] (K_{X^2}^{-1})_{ij} + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} \sum_{ij} [(K_{X^2})_{ji} (K_{X^2}^{-1})_{ij}] + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} \sum_j [(K_{X^2})_{jj} (K_{X^2}^{-1})_{jj}] + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} \sum_j I_{jj} + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{n}{2} + \frac{1}{2} \ln(2\pi)^n |K_{X^2}| \\ &= \frac{1}{2} \ln(2\pi e)^n |K_{X^2}| \end{aligned}$$

3.3 Conditional differential entropy of two Gaussian random vectors

Theorem: Given two concatenated Gaussian random vectors $\vec{x} = (\vec{x}_1, \vec{x}_2)$, of size k_1 and k_2 respectively, with a multivariate Gaussian distribution:

$$P_X(\vec{x}) = \mathcal{N}(\mu_X, K_{X^2}) = (2\pi)^{-\frac{n}{2}} |K_{X^2}|^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x} - \mu_X)^T K_{X^2}^{-1} (\vec{x} - \mu_X)}{2}\right\}$$

with a mean vector μ_X and a covariance matrix K_{X^2} .

In this case, the conditional differential entropy $h(X_1|X_2)$ is equal to :

$$h(X_1|X_2) = \frac{1}{2} \ln(2\pi e)^{k_1} |K_{X_1^2|X_2}|$$

Proof:

$$h(X_1|X_2) = - \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} p_{X_1 X_2}(\vec{x}_1, \vec{x}_2) \ln\{p_{X_1|X_2}(\vec{x}_1, \vec{x}_2)\} d\vec{x}_1 d\vec{x}_2$$

We know the conditional probability $P_{X_1|X_2}$ can be expressed as follows:

$$P_{X_1|X_2}(\vec{x}_1, \vec{x}_2) = (2\pi)^{-\frac{k_1}{2}} |K_{X_1^2|X_2}|^{-\frac{1}{2}} \exp\left\{-\frac{(\vec{x}_1 - \nu_{X_1|X_2})^T K_{X_1^2|X_2}^{-1} (\vec{x}_1 - \nu_{X_1|X_2})}{2}\right\}$$

So we can write:

$$\begin{aligned} h(X_1|X_2) &= - \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} p_{X_1 X_2}(\vec{x}_1, \vec{x}_2) \left[-\frac{1}{2} (\vec{x}_1 - \nu_{X_1|X_2})^T K_{X_1^2|X_2}^{-1} (\vec{x}_1 - \nu_{X_1|X_2}) - \ln(\sqrt{2\pi})^{k_1} |K_{X_1^2|X_2}|^{\frac{1}{2}} \right] d\vec{x}_1 d\vec{x}_2 \\ &= \frac{1}{2} E_{X_1 X_2} \left[\sum_{ij} \{(\vec{x}_1)_i - \nu_{(X_1|X_2)_i}\}^T (K_{X_1^2|X_2}^{-1})_{ij} \{(\vec{x}_1)_j - \nu_{(X_1|X_2)_j}\} \right] + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} E_{X_1 X_2} \left[\sum_{ij} \{(\vec{x}_1)_i - \nu_{(X_1|X_2)_i}\}^T \{(\vec{x}_1)_j - \nu_{(X_1|X_2)_j}\} (K_{X_1^2|X_2}^{-1})_{ij} \right] + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} \sum_{ij} E_{X_1 X_2} [\{(\vec{x}_1)_j - \nu_{(X_1|X_2)_j}\}^T \{(\vec{x}_1)_i - \nu_{(X_1|X_2)_i}\}] (K_{X_1^2|X_2}^{-1})_{ij} + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} \sum_{ij} (K_{X_1^2|X_2})_{ji} (K_{X_1^2|X_2}^{-1})_{ij} + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} \sum_j (K_{X_1^2|X_2})_{jj} (K_{X_1^2|X_2}^{-1})_{jj} + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} \sum_j I_{jj} + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{k_1}{2} + \frac{1}{2} \ln(2\pi)^{k_1} |K_{X_1^2|X_2}| \\ &= \frac{1}{2} \ln(2\pi e)^{k_1} |K_{X_1^2|X_2}| \end{aligned}$$

3.4 Inequalities theorem on the conditional differential entropies gaussian vectors

Theorem: Given a partitioned Gaussian random vector $\vec{x} = (\vec{x}_1, \vec{x}_2, \vec{x}_3)$, of size k_1 , k_2 and $k_3 = 1$ respectively, with the multivariate Gaussian distribution $\mathcal{N}(\mu_X, K_{X^2})$ then we can write the following inequalities:

$$h(X_3|X_1, X_2) \leq h(X_3|X_1) \leq h(X_3)$$

Proof:

For this, we must start first from the block matrix multiplication of the covariance matrix $K_{(X_1, X_2)^2}$ and the precision matrix $W_{(X_1, X_2)^2} = K_{(X_1, X_2)^2}^{-1}$ and prove the following relation:

$$W_{X_1^2} = K_{X_1^2}^{-1} + W_{X_1 X_2} \cdot W_{X_2^2}^{-1} \cdot W_{X_2 X_1}$$

$$K_{X^2} W_{X^2} = \begin{pmatrix} K_{X_1^2} W_{X_1^2} + K_{X_1 X_2} W_{X_2 X_1} & K_{X_1^2} W_{X_1 X_2} + K_{X_1 X_2} W_{X_2^2} \\ K_{X_2 X_1} W_{X_1^2} + K_{X_2^2} W_{X_2 X_1} & K_{X_2 X_1} W_{X_1 X_2} + K_{X_2^2} W_{X_2^2} \end{pmatrix} = \begin{pmatrix} I_{k_1, k_1} & 0 \\ 0 & I_{k_2, k_2} \end{pmatrix}$$

$$K_{X_1 X_2} \cdot W_{X_2^2} + K_{X_2^2} \cdot W_{X_1 X_2} = 0$$

$$K_{X_1^2}^{-1} \cdot K_{X_1 X_2} \cdot W_{X_2^2} + W_{X_1 X_2} = 0$$

$$K_{X_1^2}^{-1} \cdot K_{X_1 X_2} = -W_{X_1 X_2} \cdot W_{X_2^2}^{-1}$$

$$K_{X_1^2} \cdot W_{X_1^2} + K_{X_1 X_2} \cdot W_{X_2 X_1} = I_{k_1 k_1}$$

$$W_{X_1^2} = K_{X_1^2}^{-1} - K_{X_1^2}^{-1} \cdot K_{X_1 X_2} \cdot W_{X_2 X_1}$$

$$W_{X_1^2} = K_{X_1^2}^{-1} + W_{X_1 X_2} \cdot W_{X_2^2}^{-1} \cdot W_{X_2 X_1}$$

We must develop the following quadratic form for $n = k_1 + k_2 + k_3 = k_1 + k_2 + 1$:

$$(K_{X_3, X_1}, K_{X_3, X_2}) \cdot K_{(X_1, X_2)^2}^{-1} \cdot \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix}$$

$$= (K_{X_3, X_1}, K_{X_3, X_2}) \cdot W_{(X_1, X_2)^2} \cdot \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix}$$

$$= (K_{X_3, X_1}, K_{X_3, X_2}) \begin{pmatrix} W_{X_1^2} & W_{X_1 X_2} \\ W_{X_2 X_1} & W_{X_2^2} \end{pmatrix} \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix}$$

$$= (K_{X_3, X_1})^t W_{X_1^2} (K_{X_1 X_3}) + (K_{X_3, X_1}) W_{X_1 X_2} (K_{X_2 X_3}) + (K_{X_3, X_2}) W_{X_2 X_1} (K_{X_1 X_3})$$

$$+ (K_{X_3, X_2}) \cdot W_{X_2^2} (K_{X_2 X_3})$$

Using the relation: $W_{X_1^2} = K_{X_1^2}^{-1} + W_{X_1 X_2} \cdot W_{X_2^2}^{-1} \cdot W_{X_2 X_1}$:

$$= (K_{X_3, X_1}) \cdot K_{X_1^2}^{-1} \cdot (K_{X_1 X_3}) + (K_{X_3, X_1}) \cdot W_{X_1 X_2} \cdot W_{X_2^2}^{-1} \cdot W_{X_2 X_1} \cdot (K_{X_1 X_3})$$

$$\begin{aligned}
& + (K_{X_3 X_1}) \cdot W_{X_1 X_2} \cdot (K_{X_2 X_3}) + (K_{X_3 X_2}) \cdot W_{X_2 X_1} \cdot (K_{X_1 X_3}) \\
& + (K_{X_3 X_2}) \cdot W_{X_2^2} \cdot (K_{X_2 X_3}) \\
& = [(K_{X_2 X_3}) + W_{X_2^2}^{-1} \cdot W_{X_2 X_1} \cdot (K_{X_1 X_3})]^t \cdot [W_{X_2^2} \cdot (K_{X_2 X_3}) + W_{X_2 X_1} \cdot (K_{X_1 X_3})] \\
& + (K_{X_3 X_1}) \cdot K_{X_1^2}^{-1} \cdot (K_{X_1 X_3}) \\
& = (K_{X_3 X_1}) \cdot K_{X_1^2}^{-1} \cdot (K_{X_1 X_3}) \\
& + [(K_{X_2 X_3}) + W_{X_2^2}^{-1} \cdot W_{X_2 X_1} \cdot (K_{X_1 X_3})]^t \cdot W_{X_2^2} \cdot [(K_{X_2 X_3}) + W_{X_2^2}^{-1} \cdot W_{X_2 X_1} \cdot (K_{X_1 X_3})]
\end{aligned}$$

However both following quadratics forms are equivalents :

$$(K_{X_3 X_1}, K_{X_3 X_2}) \begin{pmatrix} W_{X_1^2} & W_{X_1 X_2} \\ W_{X_2 X_1} & W_{X_2^2} \end{pmatrix} \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix} = (K_{X_3 X_2}, K_{X_3 X_1}) \begin{pmatrix} W_{X_2^2} & W_{X_2 X_1} \\ W_{X_1 X_2} & W_{X_1^2} \end{pmatrix} \begin{pmatrix} K_{X_2 X_3} \\ K_{X_1 X_3} \end{pmatrix}$$

and are positive semidefinite if and only if:

$$W_{X_1^2} \geq 0, W_{X_2^2} - W_{X_2 X_1} \cdot W_{X_1^2}^{-1} \cdot W_{X_1 X_2} \geq 0$$

but yet

$$W_{X_2^2} \geq 0, W_{X_1^2} - W_{X_1 X_2} \cdot W_{X_2^2}^{-1} \cdot W_{X_2 X_1} \geq 0$$

As $W_{X_2^2} \geq 0$, we can write the inequalities:

$$(K_{X_3 X_1}, K_{X_3 X_2}) \cdot K_{(X_1 X_2)^2}^{-1} \cdot \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix} \geq (K_{X_3 X_1}) \cdot K_{X_1^2}^{-1} \cdot (K_{X_1 X_3}) \geq 0$$

If we use $K_{X_3^2}$, we can write:

$$K_{X_3^2} - (K_{X_3 X_1}, K_{X_3 X_2}) \cdot K_{(X_1 X_2)^2}^{-1} \cdot \begin{pmatrix} K_{X_1 X_3} \\ K_{X_2 X_3} \end{pmatrix} \leq K_{X_3^2} - (K_{X_3 X_1}) \cdot K_{X_1^2}^{-1} \cdot (K_{X_1 X_3}) \leq K_{X_3^2}$$

$$K_{X_3^2|X_1 X_2} \leq K_{X_3^2|X_1} \leq K_{X_3^2}$$

$$\frac{1}{2} \ln |K_{X_3^2|X_1 X_2}| + \frac{1}{2} \ln (2\pi e)^n \leq \frac{1}{2} \ln |K_{X_3^2|X_1}| + \frac{1}{2} \ln (2\pi e)^n \leq \frac{1}{2} \ln |K_{X_3^2}| + \frac{1}{2} \ln (2\pi e)^n$$

Finally, we have the relation:

$$h(X_3|X_1, X_2) \leq h(X_3|X_1) \leq h(X_3)$$

4 Bayesian network

4.1 Bayesian network definition

Definition A Bayesian network \mathcal{B} is a directed acyclic graph having n nodes which verify the following proprieties:

- For each node, we attribute n random variables included in a random vector $\vec{x} = (x_1, x_2, \dots, x_n)$
- For each node, we attribute a conditional probability $P_{X_j|Pa(X_j)}(x_j, Pa(x_j))$ corresponding to the probabilities of child random variables x_j given the parents random variables $Pa(x_j)$ on the graph related to Bayesian network.
- The Bayesian network verify the following factorization rule:

$$p_X(\vec{x}|\mathcal{B}) = p_X(x_1, x_2, \dots, x_n|\mathcal{B}) = \prod_{X_j \in X} p_{X_j|Pa(X_j)}(x_j, Pa(x_j))$$

where we have:

$$X = \{X_j\}_{j=1,2,\dots,n}$$

$$p_{X_j|Pa(X_j)}(x_j, Pa(x_j)) = \frac{p_{X_j, Pa(X_j)}(x_j, Pa(x_j))}{p_{Pa(X_j)}(Pa(x_j))}.$$

In what follows, we will consider **Gaussian** random vectors $\vec{x} = (x_1, x_2, \dots, x_n)$

4.2 Differential entropy of a Bayesian network

If \mathcal{B} is a Bayesian network to which we attribute a Gaussian random vector (X_1, X_2, \dots, X_n) , where the variables $X_{j=1,\dots,n}$ belong to the set of Gaussian random variables X , we can compute the differential entropy of this network as follows:

$$\begin{aligned} h(X|\mathcal{B}) &= -E_X[\ln p_X(\vec{x}|\mathcal{B})] \\ &= -E_X[\ln \prod_{X_j \in X} p_{X_j|Pa(X_j)}(x_j, Pa(x_j))] \\ &= -E_X[\sum_{X_j \in X} \ln p_{X_j|Pa(X_j)}(x_j, Pa(x_j))] \\ &= \sum_{X_j \in X} -E_X[\ln p_{X_j|Pa(X_j)}(x_j, Pa(x_j))] \\ &= \sum_{X_j \in X} h(X_j|Pa(X_j)) \\ &= \frac{1}{2} \sum_{X_j \in X} \ln(2\pi e) K_{X_j^2|Pa(X_j)} \\ &= \frac{1}{2} \sum_{X_j \in X} \ln(K_{X_j^2|Pa(X_j)}) + \frac{1}{2} \ln(2\pi e)^n \end{aligned}$$

4.3 Entropy for a Bayesian network with a chain rule

If \mathcal{B}^C is a Bayesian network with a chain rule to which we attribute a Gaussian random vector (X_1, X_2, \dots, X_n) , where the variables $X_{j=1,2,\dots,n}$ belong to the set of Gaussian random variables X , we can compute the differential entropy $h(X|\mathcal{B}^C)$ of Bayesian network \mathcal{B}^C as follows:

$$h(X|\mathcal{B}^C) = h(X_1, X_2, \dots, X_n) = h(X_1) + \sum_{i=2}^n h(X_i|X_1, \dots, X_{i-1}) = \frac{1}{2} \ln |K_{X^2}| + \frac{1}{2} \ln(2\pi e)^n$$

Note: This relation is invariant by the permutation on the nodes: we choose any order on the order of the nodes in the chain and we will obtain the same result for the entropy value.

4.4 Entropy for a Bayesian network without edges

If \mathcal{B}^R is a Bayesian network without edges to which we attribute a Gaussian random vector (X_1, X_2, \dots, X_n) , where the variables $X_{j=1,2,\dots,n}$ belong to the set of Gaussian random variables X , we can compute the differential entropy $h(X|\mathcal{B}^R)$ of Bayesian network \mathcal{B}^R as follows:

$$h(X|\mathcal{B}^R) = \sum_{i=1}^n h(X_i) = \sum_{i=1}^n \ln(K_{X_i^2}) + \frac{1}{2} \ln(2\pi e)^n$$

4.5 Lower bound and upper bound of a Bayesian network's differential entropy

Theorem Given a Gaussian random vector $\vec{x} = (x_1, x_2, \dots, x_n)$ with a multivariate Gaussian distribution $\mathcal{N}(\mu_X, K_{X^2})$ assigned to the nodes of a Bayesian network \mathcal{B} , then the entropy of this Bayesian network can be bounded as follows:

$$h(X|\mathcal{B}^C) \leq h(X|\mathcal{B}) \leq h(X|\mathcal{B}^R)$$

$$\frac{1}{2} \ln |K_{X^2}| + \frac{1}{2} \ln(2\pi e)^n \leq h(X|\mathcal{B}) \leq \frac{1}{2} \sum_{i=1}^n \ln(K_{X_i^2}) + \frac{1}{2} \ln(2\pi e)^n$$

$$h(X_1, X_2, \dots, X_n) \leq \sum_{X_j \in X} h(X_j|Pa(X_j)) \leq \sum_{X_j \in X} h(X_j)$$

where we have X_j , the following inequalities for each node :

$$h(X_j|Pa(X_j), Pa^C(X_j)) \leq h(X_j|Pa(X_j)) \leq h(X_j)$$

where $Pa^C(X_j) = X \setminus \{Pa(X_j)\}$

The lower bound is computed from the closure of a graph related to the Bayesian network.

The upper bound is computed by removing the set of edges on the graph related to the Bayesian network.

Proof:

Let's consider a Bayesian network's factorization performed in topological order $\mathcal{O}(X)$:

$$p_X(\vec{x}|\mathcal{B}) = p_X(x_1, x_2, \dots, x_n|\mathcal{B}) = \prod_{X_j \in \mathcal{O}(X)} p_{X_j|Pa(X_j)}(x_j, Pa(x^j))$$

We attribute a Bayesian network's factorization which graph is the closure of the graph related to the initial Bayesian network (this is a chain in the topological order):

$$p_X(\vec{x}|\mathcal{B}^C) = p_X(x_1, x_2, \dots, x_n|\mathcal{B}^C) = \prod_{X_j \in \mathcal{O}(X)} p_{X_j|Pa(X_j), Pa^C(X_j)}(x_j, Pa(x^j), Pa^C(X_j))$$

and a Bayesian network's factorization computed by removing the set of edges of graph related to the initial Bayesian network:

$$p_X(\vec{x}|\mathcal{B}^R) = p_X(x_1, x_2, \dots, x_n|\mathcal{B}^R) = \prod_{X_j \in \mathcal{O}(X)} p_{X_j}(x_j)$$

The entropies of the three bayesian networks can be computed as follows:

$$\begin{aligned} h(X|\mathcal{B}) &= \sum_{x_j \in \mathcal{O}(X)} h(X_j|Pa(X_j)) \\ h(X|\mathcal{B}^C) &= \sum_{x_j \in \mathcal{O}(X)} h(X_j|Pa(X_j), Pa^C(X_j)) \\ h(X|\mathcal{B}^R) &= \sum_{x_j \in \mathcal{O}(X)} h(X_j) \end{aligned}$$

However we proved: $h(X_3|X_1, X_2) \leq h(X_3|X_1) \leq h(X_3)$

We can write for each node X_j the relation:

$$h(X_j|Pa(X_j), Pa^C(X_j)) \leq h(X_j|Pa(X_j)) \leq h(X_j)$$

we obtain the lower and upper boundaries for the Bayesian network's entropy:

$$\sum_{X_j \in \mathcal{O}(X)} h(X_j, Pa(X_j, Pa^C(X_j))) \leq \sum_{X_j \in \mathcal{O}(X)} h(X_j, Pa(X_j)) \leq \sum_{X_j \in \mathcal{O}(X)} h(X_j)$$

The product of the conditional variances $K_{X_j^2|Pa(X_j)}$ and therefore of the Schur's complements give us the determinant of matrix K_{X^2} .

Therefore, the following results are computed for the lower boundary:

$$\begin{aligned} &\sum_{x_j \in \mathcal{O}(X)} h(X_j, Pa(X_j, Pa^C(X_j))) \\ &= \frac{1}{2} \ln \left(\prod_{x_j \in \mathcal{O}(X)} K_{X_j^2|Pa(X_j)} \right) + \frac{1}{2} \ln(2\pi.e)^n \\ &= \frac{1}{2} \ln(|K_{X^2}|) + \frac{1}{2} \ln(2\pi.e)^n \end{aligned}$$

and for the upper boundary :

$$\begin{aligned} &\sum_{X_j \in \mathcal{O}(X)} h(X_j) \\ &= \frac{1}{2} \sum_{X_j \in \mathcal{O}(X)} \ln(K_{X_j^2}) + \frac{1}{2} \ln(2\pi e)^n \\ &= \frac{1}{2} \sum_{i=1}^n \ln(K_{X_i^2}) + \frac{1}{2} \ln(2\pi e)^n \end{aligned}$$

Finally, we obtain:

$$\frac{1}{2} \ln(|K_{X^2}|) + \frac{1}{2} \ln(2\pi.e)^n \leq \sum_{X_j \in \mathcal{O}(X)} h(X_j, Pa(X_j)) \leq \frac{1}{2} \sum_{i=1}^n \ln(K_{X_i^2}) + \frac{1}{2} \ln(2\pi e)^n$$

Note that we can use this theorem to prove that the determinant of a symmetric positive semidefinite matrix is always less than or equal to the product of the diagonal elements of this matrix. This inequality is called *Hadamard's inequality*.(see appendix)

5 The likelihood function, the BIC score and Bayesian network's entropy

Given a Gaussian random vector $X = \{x_{j=1,2,\dots,n}\}$ and a data frame D of size $N \times n$.

As we have the relation:

$$\mu_{(X_j|Pa(X_j))} = \mu_{X_j} + K_{(X_j, Pa(X_j))} \cdot K_{Pa^2(X_j)}^{-1} (Pa(X_j) - \mu_{X_j})$$

We can put:

$$\beta_{X_j} = \mu_{X_j} - K_{(X_j, Pa(X_j))} \cdot K_{Pa^2(X_j)}^{-1} \cdot \mu_{Pa(X_j)}$$

$$\beta_{(X_j, Pa(X_j))} = K_{(X_j, Pa(X_j))} \cdot K_{Pa^2(X_j)}^{-1}$$

For each current node X_j , we can write the multivariate Gaussian distribution as follows:

$$P_{X_j|Pa(X_j)}(x_j, Pa(x_j)) = (2\pi)^{-\frac{1}{2}} K_{X_j^2|Pa(X_j)}^{-\frac{1}{2}} \exp\left\{-\frac{(x_j - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_j) - \beta_{X_j})^2}{2 \cdot K_{X_j^2|Pa(X_j)}}\right\}$$

For N points of a data frame D, we then compute the likelihood function:

$$\begin{aligned} L(D|\beta_{X_j}, \beta_{(X_j, Pa(X_j))}, K_{X_j^2|Pa(X_j)}) \\ &= \ln \prod_{i=1}^N \prod_{X_j \in X} P_{X_j|Pa(X_j)}(x_j, Pa(x_j)) \\ &= \ln \prod_{i=1}^N \prod_{X_j \in X} (2\pi)^{-\frac{1}{2}} K_{X_j^2|Pa(X_j)}^{-\frac{1}{2}} \exp\left\{-\frac{(x_{ij} - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_{ij}) - \beta_{X_j})^2}{2 \cdot K_{X_j^2|Pa(X_j)}}\right\} \\ &= \sum_{X_j \in X} \sum_{i=1}^N -\frac{1}{2} \ln(2\pi) - \frac{1}{2} \ln(K_{X_j^2|Pa(X_j)}) - \frac{1}{2K_{X_j^2|Pa(X_j)}} \cdot (x_{ij} - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_{ij}) - \beta_{X_j})^2 \\ &= \sum_{X_j \in X} -\frac{N}{2} \ln(2\pi) - \frac{N}{2} \cdot \ln(K_{X_j^2|Pa(X_j)}) - \frac{1}{2K_{X_j^2|Pa(X_j)}} \cdot \sum_{i=1}^N (x_{ij} - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_{ij}) - \beta_{X_j})^2 \\ &= \sum_{X_j \in X} \frac{-N}{2} \ln(2\pi \cdot K_{X_j^2|Pa(X_j)}) - \frac{1}{2K_{X_j^2|Pa(X_j)}} \cdot \sum_{i=1}^N (x_{ij} - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_{ij}) - \beta_{X_j})^2 \\ &= \sum_{X_j \in X} \frac{-N}{2} \ln(2\pi \cdot K_{X_j^2|Pa(X_j)}) - \frac{SSR(X_j, Pa(X_j))}{2K_{X_j^2|Pa(X_j)}} \end{aligned}$$

We know that, for a population of size N , we have the following equalities:

$$K_{X_j^2|Pa(X_j)} = K_{X_j^2} - K_{X_j Pa(X_j)} \cdot K_{Pa^2(X_j)}^{-1} \cdot K_{Pa(X_j)X_j} = \frac{SSR(X_j, Pa(X_j))}{N} = \frac{\sum_{i=1}^N (x_{ij} - \beta_{(X_j, Pa(X_j))} \cdot Pa(x_{ij}) - \beta_{X_j})^2}{N}$$

The likelihood function will therefore only depend on the slopes $\beta_{(X_j, Pa(X_j))}$ and the intercept coefficients β_{X_j} :

$$\bar{L}(D|\beta_j, \beta_{(X_j, Pa(X_j))}) = \sum_{X_j \in X} \frac{N}{2} \ln(2\pi \cdot K_{X_j^2|Pa(X_j)}) + \sum_{X_j \in X} \frac{SSR(X_j, Pa(X_j))}{2K_{X_j^2|Pa(X_j)}}$$

Using the relations:

$$\begin{aligned} & \sum_{X_j \in X} \frac{N}{2} \ln(2\pi \cdot K_{X_j^2|Pa(X_j)}) \\ &= \sum_{X_j \in X} \frac{N}{2} \ln(2\pi \cdot e \cdot K_{X_j^2|Pa(X_j)}) - \frac{n \cdot N}{2} \\ &= N \cdot \sum_{X_j \in X} h(X_j | Pa(X_j)) - \frac{n \cdot N}{2} \end{aligned}$$

and

$$\sum_{X_j \in X} \frac{SSR(X_j | Pa(X_j))}{2K_{X_j^2|Pa(X_j)}} = \frac{n \cdot N}{2}$$

we obtain:

$$\boxed{\bar{L}(D|\beta_j, \beta_{(X_j, Pa(X_j))}) = N \cdot \sum_{X_j \in X} h(X_j | Pa(X_j))}$$

From the likelihood function and the number of slopes and intercept coefficients equal to $q + n = \#\{\beta_{X_j, P(X_j)}, \beta_{X_j}\}_{j=1,2,\dots,n}$, we can build the BIC score:

$$\boxed{BIC(D|\mathcal{B}) = \bar{L}(D|\beta_j, \beta_{(X_j, Pa(X_j))}) + \frac{(q+n) \ln(N)}{2} = N \cdot \sum_{X_j \in X} h(X_j | Pa(X_j)) + \frac{(q+n) \ln(N)}{2}}$$

where:

$\sum_{X_j \in X} h(X_j | Pa(X_j))$ is the Bayesian network's entropy.

q is the number of edges (number of slopes) in the Bayesian network .

n is the number of nodes in the Bayesian network.

N is the number of points (number of rows) of the data frame D .

5.1 Algorithm for Learning data frame from Bayesian Networks

The goal of the algorithm will be to consider a large number of topological sorts linked to chain rules having an entropy equal to $h(X|\mathcal{B}^C)$ (Note that we have $n!$ possible chain rules for a data frame of size $N \times n$). For a fixed topological order, it will be necessary to iteratively remove the edges producing the smallest entropy variations of Bayesian network. After removing the edges, will remain the Bayesian network without edges having an entropy equal to $h(X|\mathcal{B}^R)$.

At each iteration, we will evaluate the Bayesian network's entropy $h(X|\mathcal{B})$ which will vary and increase between the following bounds:

$$h(X|\mathcal{B}^C) \leq h(X|\mathcal{B}) \leq h(X|\mathcal{B}^R)$$

we will compute for each iterated the BIC score:

$$BIC(D|\mathcal{B}) = \bar{L}(D|\beta_j, \beta_{(X_j, Pa(X_j))}) + \frac{(q+n) \ln(N)}{2} = N \cdot \sum_{X_j \in X} h(X_j|Pa(X_j)) + \frac{(q+n) \ln(N)}{2}$$

The most likely optimal Bayesian network \mathcal{B}^* will be the network that minimizes the following optimization problem:

$$\min_{\mathcal{B}^*} BIC(D|\mathcal{B})$$

In the example considered to apply the learning algorithm, we will set a topological order linked to a chain rule. We will show step by step the iterates leading to the optimal Bayesian network. The example will be a data frame containing car brands.

5.2 Continuous data inference from a Bayesian network

We want to infer a continuous data matrix of size $N \times n$ in topological order from the graph related to the Bayesian network. This is achieved by using OLS (Ordinary least squares):

$$x_{ij} = \sum_{y_{ij} \in Pa(x_{ij})} \beta_{ij} y_{ij} + \beta_j \quad \text{for } i=1,2,\dots,N$$

to which we add gaussian random column vectors with zero mean and a conditional variance $K_{X_j^2|Pa(X_j)}$

This data frame has 6 columns and $N = 100$ rows. In this example, we consider the topological sort $(X_5, X_2, X_4, X_3, X_1, X_6)$ and we use the notation \tilde{X}_j to remove the node X_j , the algorithm begin with the following chain rule:

$$\begin{aligned} h(X_5) + h(X_2|X_5) + h(X_4|X_5X_2) + h(X_3|X_5X_2X_4) + h(X_1|X_5X_2X_4X_3) + h(X_6|X_5X_2X_4X_3X_1) \\ = 1.399663 + 5.472459 + 0.3482677 + 5.057505 + 2.354467 + 1.587467 \\ = 16.21983 \end{aligned}$$

$$BIC(D|\mathcal{B}) = N \cdot \sum_{X_j \in X} h(X_j|Pa(X_j)) + \frac{(q+n)\ln(N)}{2} = 1621.983 + \frac{(15+6)\ln(100)}{2} = 1670.337$$

$$\begin{aligned} h(X_5) + h(X_2|X_5) + h(X_4|X_5X_2) + h(X_3|X_5X_2X_4) + h(X_1|X_5X_2X_4X_3) + h(X_6|X_5\tilde{X}_2X_4X_3X_1) \\ = 1.399663 + 5.472459 + 0.3482677 + 5.057505 + 2.354467 + 1.587633 \\ = 16.21999 \end{aligned}$$

$$BIC(D|\mathcal{B}) = N \cdot \sum_{X_j \in X} h(X_j|Pa(X_j)) + \frac{(q+n)\ln(N)}{2} = 1621.999 + \frac{(14+6)\ln(100)}{2} = 1668.051$$

$$\begin{aligned} h(X_5) + h(X_2|X_5) + h(X_4|X_5X_2) + h(X_3|X_5X_2X_4) + h(X_1|X_5X_2\tilde{X}_4X_3) + h(X_6|X_5\tilde{X}_2X_4X_3X_1) \\ = 1.399663 + 5.472459 + 0.3482677 + 5.0575505 + 2.356048 + 1.587633 \\ = 16.22162 \end{aligned}$$

$$\begin{aligned}
&h(X_5) + h(X_2|X_5) + h(X_4|\tilde{X}_5\tilde{X}_2) + h(X_3|\tilde{X}_5X_2\tilde{X}_4) + h(X_1|\tilde{X}_5\tilde{X}_2\tilde{X}_4\tilde{X}_3) + h(X_6|\tilde{X}_5\tilde{X}_2\tilde{X}_4\tilde{X}_3\tilde{X}_1) \\
&= 1.399663 + 5.472459 + 0.7943387 + 5.550476 + 3.210796 + 1.949459 \\
&= 18.37719
\end{aligned}$$

$$BIC(D|\mathcal{B}) = N \cdot \sum_{X_j \in X} h(X_j | Pa(X_j)) + \frac{(q+n) \ln(N)}{2} = 1837.719 + \frac{(1+6) \ln(100)}{2} = 1853.837$$

$$\begin{aligned}
& h(X_5) + h(X_2|\tilde{X}_5) + h(X_4|\tilde{X}_5\tilde{X}_2) + h(X_3|\tilde{X}_5\tilde{X}_2\tilde{X}_4) + h(X_1|\tilde{X}_5\tilde{X}_2\tilde{X}_4\tilde{X}_3) + h(X_6|\tilde{X}_5\tilde{X}_2\tilde{X}_4\tilde{X}_3\tilde{X}_1) \\
& = 1.399663 + 6.270549 + 0.7943387 + 5.550476 + 3.210796 + 1.949459 \\
& = 1917.528
\end{aligned}$$

$$BIC(D|\mathcal{B}) = N \cdot \sum_{X_j \in X} h(X_j|Pa(X_j)) + \frac{(q+n)\ln(N)}{2} = 1917.528 + \frac{(0+6)\ln(100)}{2} = 1931.344$$

We will represent the graph of the BIC score according to the number of edges (number of slopes)

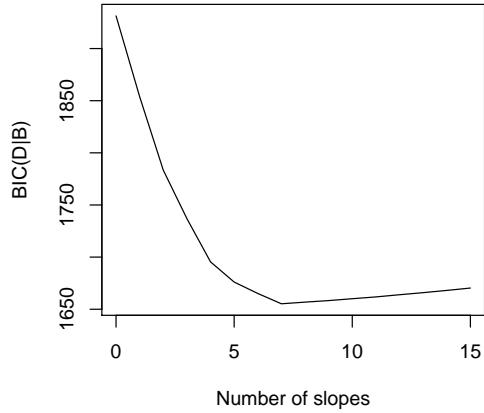

Figure 1: BIC score and number of slopes

We see that the BIC score has a minimum value:

$$\min_{\mathcal{B}^*} BIC(D|\mathcal{B}) = 1655.239$$

\mathcal{B}^* is the most likely optimal Bayesian network for the data frame D.

We will now represent the most likely optimal Bayesian network \mathcal{B}^* :

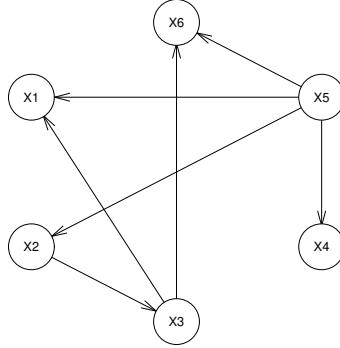

Figure 2: Bayesian network

$$\begin{aligned}
 & h(X_5) + h(X_2|X_5) + h(X_4|X_5\tilde{X}_2) + h(X_3|\tilde{X}_5X_2\tilde{X}_4) + h(X_1|X_5\tilde{X}_2\tilde{X}_4X_3) + h(X_6|X_5\tilde{X}_2\tilde{X}_4X_3\tilde{X}_1) \\
 & = 1.399663 + 5.472459 + 0.3565913 + 5.062763 + 2.361169 + 1.600407 \\
 & = 16.25305
 \end{aligned}$$

$$BIC(D|\mathcal{B}) = N \cdot \sum_{X_j \in X} h(X_j|Pa(X_j)) + \frac{(q+n) \ln(N)}{2} = 1625.305 + \frac{(7+6) \ln(100)}{2} = 1655.239$$

7 Conclusion

In this paper, we have proposed an algorithm for learning a data frame from Bayesian networks. From a data frame example, we have shown the steps leading to obtaining the most likely optimal Bayesian network.

8 Appendix

Theorem *If K is a symmetric semidefinite matrix of size $n \times n$ then the determinant of this matrix verifies the following inequalities :*

$$0 \leq \det(K) \leq \prod_{i=1}^n K_{ii}$$

where K_{ii} are the diagonal elements of the matrix K

Corollary *If K is a correlation matrix of size $n \times n$ then the determinant of this matrix verifies the following inequalities :*

$$0 \leq \det(K) \leq 1$$
