# A New Formula for Ellipse Perimeter Approximation yielding Absolute Relative Error less than 1.83 ppm. 

Author: K. Idicula Koshy

#### Abstract

In this article, the author presents a new formula for Ellipse Perimeter Approximation. This formula, with two parameters, is unique in form among all published formulae on Ellipse Perimeter Approximation. Of the two parameters, one is a constant and the other is a polynomial of the aspect ratio, which is dependent on the chosen constant. We were able to reduce the Absolute Relative Error to less than 1.83 parts per million (ppm) for any ellipse, by suitable choice of the parameters.

Keywords: Ellipse, Major and Minor Radii, Aspect Ratio, Eccentricity, Relative Error, ppm.

## Introduction

The ellipse, whose rectangular cartesian equation is $(x / a)^{2}+(y / b)^{2}=1$, is named here as the standard ellipse. ' $a$ ' and ' $b$ ' $(a \geq b \geq 0)$ are the major and minor radii of the ellipse. Its perimeter $\boldsymbol{P}(\boldsymbol{a}, \boldsymbol{b})$ is given by the formula:

$$
P(a, b)=\int_{0}^{2 \pi} \sqrt{\left(a^{2} \sin ^{2} \theta+b^{2} \cos ^{2} \theta\right)} d \theta
$$

where $(a \cos \theta, b \sin \theta), 0 \leq \theta<2 \pi$, is a parametric point on the ellipse. Due to the symmetry of the ellipse w. r. t. its axes, $\boldsymbol{P}(\boldsymbol{a}, \boldsymbol{b})=\mathbf{4}^{*} \boldsymbol{Q}(\boldsymbol{a}, \boldsymbol{b})$, where $\boldsymbol{Q}(\boldsymbol{a}, \boldsymbol{b})$ is the perimeter of the standard ellipse in the first quadrant. Therefore,

$$
Q(a, b)=\int_{0}^{\pi / 2} \sqrt{\left(a^{2} \sin ^{2} \theta+b^{2} \cos ^{2} \theta\right)} d \theta
$$

Obviously, $Q(a, 0)=a$, and, $Q(a, a)=\pi a / 2$ and, hence, $P(a, 0)=4 a$ and $P(a, a)=2 \pi a$. The definite integral for $Q(a, b)$ given above could not be evaluated so far by known direct integration methods. Therefore, Numerical Integration Methods are applied to approximate $Q(a, b)$ to the desired degree of accuracy. Simpson's $1 / 3$ - Rule Method is very popular in this regard. The Quarter Perimeter values $Q$ (100, b; Sim) used in Table 1 below are obtained by this method, by dividing the interval of integration $[0, \pi / 2]$ into 500 equal sub-intervals,
so that the length of each sub-interval is $h=\pi / 1000$. Then, the Absolute Relative Error is to the order of $\mathrm{h}^{4}[1]$, which is to the order of $10^{-10}$.

In an article published three years ago, the author ${ }^{[3]}$ introduced a new Formula to approximate the ellipse perimeter. It was shown there that the Integral form of $Q(a, b)$ follows Lagrange's first order linear partial differential equation in ' $a$ ' and ' $b$ '. Therefore, any solution of $Q(a, b)$, has to be a function of $\left(a^{p}+b^{p}\right)^{(1 / p)}, \mathrm{p} \neq 0$ and $\sqrt{a b}$, which are two independent particular solutions of the partial differential equation ${ }^{[1],[3]}$. Further, it was shown there that the empirical formula: $\boldsymbol{Q}(\boldsymbol{a}, \boldsymbol{b}):=\left(\boldsymbol{a}^{p}+b^{p}\right)^{(1 / \mathrm{p})}+\frac{\boldsymbol{k}(\boldsymbol{a} \boldsymbol{b})^{2}}{(\boldsymbol{a}+\boldsymbol{b})^{3}} \quad \ldots\left({ }^{*}\right)$, where $k=0.48251$ and $p=\ln (2) / \ln \left(\frac{\pi}{2}-\frac{k}{8}\right)=1.6806453 \ldots$ approximates the Quarter Perimeter with maximum Absolute Relative Error less than 60 ppm (that is: 6 cm per km ). In this article, we re-write the formula for $Q(a, b)$ given in $\left(^{*}\right)$ above in a slightly different form, from which the form of the new formula introduced in this article is adopted (see Comments/Remarks).

## Terminology and Notations

Conventional notations and terminologies related to the standard ellipse are used in this article. ' $a$ ' and ' $b$ ' denote the lengths of the semi-major axis (major radius) and the semiminor axis (minor radius) of the standard ellipse, whose rectangular cartesian equation is: $(\mathrm{x} / \mathrm{a})^{2}+(\mathrm{y} / \mathrm{b})^{2}=1$. The ratio $(b / a)$ is called the Aspect Ratio. The eccentricity of the ellipse is the constant $e=\sqrt{1-\frac{b^{2}}{a^{2}}}$. Both (b/a) and ' $e$ ' take values in [0, 1]. The terms 'Quarter Perimeter' and 'Absolute Relative Error' are abbreviated as QPM and ARE respectively. Formulae for the Quarter Perimeter named after different authors are identified in this article by adding name-indicative characters after the parameter ' $b$ '. For example, $Q$ ( $a, b$; Sim) indicates the QPM formula/values by Simpson's (1/3) Rule and $Q$ ( $a, b$; Kos) denotes the QPM formula which the author presents in this article. GM and AM are the Geometric and Arithmetic Means of ' $a$ ' and ' $b$ '.

Materials and Methods. As mentioned in the Introduction, $Q(a, b ; \operatorname{Sim})$ values used here are derived with step-width $\mathrm{h}=\pi / 1000$. Relative Error is computed taking $Q(a, b ; \operatorname{Sim})$ as basis. All computations are done in MS Excel.

## Result (New Formula for Ellipse Perimeter Approximation)

$Q(a, b ; K o s):=\left(a^{p}+b^{p}\right)^{\left(\frac{1}{p}\right)}+\left(\frac{\pi}{2}-(2)^{\left(\frac{1}{p}\right)}\right) * \sqrt{a b} *(G M / A M)^{k} \quad \ldots$
Where ' $p$ ' and ' $k$ ' are parameters, which are suitably chosen to minimize the Absolute Relative Error.

Equation (1) gives exact values for the QPM for $(b / a)=0$ (degenerate ellipse) and for $(b / a)=1$ (circle). Further, it approximates the QPM with varying ARE, depending upon the choice of ' $p$ ' and ' $k$ '.

To apply the formula, we choose ' $p$ ' at first. Although ' $p$ ' can be any number greater than or equal to 1 , we consider only those p -vales greater than 2.0 , as our objective is to reduce the ARE to the maximum extent possible,

It is found that for both ' $p$ ' $=2.1$ and ' $p$ ' $=2.11$, and for appropriate choices of ' $k$ ', the ARE is less than 2.0 ppm for ellipses of all aspect ratios.

For $p=2.11$, and $k=63957+1.6439 *(b / a)-2.1877^{*}(b / a)^{2}+1.75 *(b / a)^{3}-0.9370 *(b / a)^{4}+$ $0.2427^{*}(\mathrm{~b} / \mathbf{a})^{5}$, the ARE is less than 1.83 ppm (Table 1).

Further, in this case, the ARE is less than one ppm for all ellipses with Aspect Ratio greater than or equal to $\mathbf{0 . 3 5}$

It may be verified that for $p=2.1$, and $k=2.63595+1.6091 *(\mathrm{~b} / \mathrm{a})-2.1186^{*}(\mathrm{~b} / \mathrm{a})^{2}+$ $1.6448 *(\mathrm{~b} / \mathrm{a})^{3}-0.8366 *(\mathrm{~b} / \mathrm{a})^{4}+0.2094 *(\mathrm{~b} / \mathrm{a})^{5}$, the ARE is less than 1.93 ppm .

## Discussion/Remarks

The EPM Approximation Formula introduced in this article is independently developed by the author. It is purely empirical and is based on his discovery that EPM is a function of $\sqrt{a b}$ and $\left(a^{p}+b^{p}\right)^{(1 / p)}$, for some $p \neq 0{ }^{[3]}$. It gives the perimeter of any ellipse with very high accuracy, and, evaluation can be done on a scientific calculator. It is the lowest ARE yielding formula of its type known so far.

The form of the new formula is shaped out of the author's first formula for Ellipse Perimeter Approximation given in $\left(^{*}\right)$ above, which was published three years ago ${ }^{[3]}$. For, it is easy to verify that:

$$
\left(a^{p}+b^{p}\right)^{(1 / \mathrm{p})}+\frac{\mathrm{k}(\mathrm{ab})^{2}}{(\mathrm{a}+\mathrm{b})^{3}}=\left(a^{p}+b^{p}\right)^{(1 / \mathrm{p})}+\left(\frac{\pi}{2}-2^{\left(\frac{1}{\mathrm{p}}\right)}\right) * \sqrt{\mathrm{ab}} *\left(\frac{\mathrm{GM}}{\mathrm{AM}}\right)^{3}, \text { where } 2^{\left(\frac{1}{\mathrm{p}}\right)}+\frac{\mathrm{k}}{8}=\frac{\pi}{2} .
$$

Formula (1) is got by replacing the exponent of (GM/AM) by k.
The author has critically examined the EPM Approximation formulae named after several eminent Mathematicians: Kepler, Euler, Seki, Muir, Maertens (YNOT formula), Rivera, Lindner, Zafary, Cantrell etc. and, of course, the renowned formulae of the Great Indian Mathematical Genius Srinivasa Ramanujan. Their formulae all fail to give ARE less than 10 ppm across all ellipses ${ }^{[2], ~[5]}$. However, Ramanujan's Formula II:

$$
\mathbf{P}(\mathbf{a}, \mathrm{b} ; \text { Ram }):=\pi(a+b)\left\{1+\frac{3 h^{2}}{\left(10+\sqrt{4-3 h^{2}}\right)}\right\},
$$

where $h=(a-b) /(a+b)$, is a Colossus among such formulae. For, it generates only negligibly small ARE for ellipses of high and medium Aspect Ratios. However, ARE steadily increases to the order of $10^{-5}, 10^{-4}$ etc., for $\mathrm{b}: 0<(\mathrm{b} / \mathrm{a}) \leq 0.1$; and $\mathrm{P}(\mathrm{a}, 0 ; \mathrm{Ram})=4 \mathrm{a}$ is true only if $\pi=22 / 7$, which is incorrect.

Considering these facts, the author's new formula given in equation (1) gives much more accurate measure of the Ellipse Perimeter than all other known formulae of its category.
