Abstract

A novel (to our knowledge) nonassociative and noncommutative octonionic ternary gauge field theory is explicitly constructed that it is based on a ternary-bracket structure involving the octonion algebra. The ternary bracket was defined earlier by Yamazaki. The field strengths $F_{\mu\nu}$ are given in terms of the 3-bracket $[B_\mu, B_\nu, \Phi]$ involving an auxiliary octonionic-valued scalar field $\Phi = \Phi^a e^a$ which plays the role of a "coupling" function. In the concluding remarks a list of relevant future investigations are briefly outlined.

Keywords: Octonions, ternary algebras, Lie 3-algebras, membranes, nonassociative gauge theories, nonassociative geometry.

1 Introduction

Exceptional, Jordan, Division, Clifford, noncommutative and nonassociative algebras are deeply related and are essential tools in many aspects in Physics, see [1], [2], [3], [4], [7], [24], [23], for references, among many others. For instance, the large $N$ limit of Exceptional Jordan Matrix models, advanced by [9], furnished a Chern-Simons membrane action leading to important connections to $M$ and $F$ theory [10]. It was shown in [22] how one could generalize ordinary Relativity into an Extended Relativity theory in Clifford spaces, involving polyvector valued (Clifford-algebra valued) coordinates and fields, where in addition to the speed of light there is also an invariant length scale (set equal to the Planck scale) in the definition of a generalized metric distance in Clifford spaces encoding, lengths, areas, volumes and hyper-volumes metrics. An overview of the basic features of the Extended Relativity in Clifford spaces can be found in [22].
A Chern-Simons $E_8$ Gauge theory of Gravity was proposed [21] as a unified field theory of a Lanczos-Lovelock Gravitational theory with a $E_8$ Generalized Yang-Mills field theory and which is defined in the $15D$ boundary of a $16D$ bulk space. The role of Clifford $Cl(16)$ algebras was essential. It was discussed how an $E_8$ Yang-Mills in $8D$, after a sequence of symmetry breaking processes based on the non-compact forms of the exceptional groups, as follows

$$E_8(-24) \rightarrow E_7(-14) \times SU(2) \rightarrow E_6(-14) \times SU(3) \rightarrow SO(8,2) \times U(1),$$

furnishes a Conformal gravitational theory in $8D$ based on gauging the non-compact conformal group $SO(8,2)$ in $8D$. Upon performing a Kaluza-Klein-Batakis [12] compactification on $CP^2$, from $8D$ to $4D$ involving a nontrivial torsion, leads to a Conformal Gravity-Yang-Mills unified theory based on the conformal group $SO(4,2)$ and the Standard Model group $SU(3) \times SU(2) \times U(1)$ in $4D$. Other approaches to unification based on Clifford algebras can be found in [13], [16], [14] and on $E_8$ were proposed long ago by [15].

A Nonassociative Gauge theory based on the Moufang $S^7$ loop product (not a Lie algebra) has been constructed by [26]. Taking the algebra of octonions with a unit norm as the Moufang $S^7$-loop, one reproduces a nonassociative octonionic gauge theory which is a generalization of the Maxwell and Yang-Mills gauge theories based on Lie algebras. BPST-like instantons solutions in $D = 8$ were also found. These solutions represented the physical degrees of freedom of the transverse 8-dimensions of superstring solitons in $D = 10$ preserving one and two of the 16 spacetime supersymmetries. Nonassociative deformations of Yang-Mills Gauge theories involving the left and right bimodules of the octonionic algebra were presented by [25].

Recently, tremendous activity has been launched by the seminal works of Bagger, Lambert and Gustavsson (BLG) [33], [34] who proposed a Chern-Simons type Lagrangian describing the world-volume theory of multiple M2-branes. The original BLG theory requires the algebraic structures of generalized Lie 3-algebras and also of nonassociative algebras. Later developments by [35] provided a 3D Chern-Simons matter theory with $N = 6$ supersymmetry and with gauge groups $U(N) \times U(N)$, $SU(N) \times SU(N)$. The original construction of [35] did not require generalized Lie 3-algebras, but it was later realized that it could be understood as a special class of models based on Hermitian 3-algebras [36], [37]. For more recent developments we refer to [38] and references therein.

The novel (to our knowledge) nonassociative octonionic ternary gauge theory developed in this work differs from the nonassociative gauge theories of [26], [25] in many respects, mainly that it is based on a ternary bracket involving the octonion algebra that was proposed by Yamazaki [28]. It also differs from the work by [33], [34] in that our octonionic-valued gauge fields $B^a_a e_a; a = 0,1,2,\ldots,7$ are not, and cannot be represented, in terms of matrices $A_{\mu} = A_{\mu}^{ab} f_{cd}^{ab} = (A_{\mu})^{cd}$, defined in terms of $f_{ab}^{cd}$ which are the structure constants of the 3-Lie algebra $[t_a,t_b,t_c] = f_{ab}^{cd} t_d$. This construction is not unlike writing the matrices $A_{\mu} = A_{\mu}^{ab} f_{cd} = (A_{\mu})^{bc}$ of ordinary Yang-Mills gauge theory in terms of the adjoint representation of the gauge algebra : $[t_a,t_b] = f_{ab}^{cd} t_c$. Furthermore, our field strengths $F_{\mu\nu}$ are explicitly defined in terms of a 3-bracket $[B_{\mu}, B_{\nu}, \Phi]$
involving an auxiliary octonionic-valued scalar field $\Phi = \Phi^a e_a$ which plays the role of a “coupling” function. Whereas the definition of $F_{\mu\nu}$ by $[33], [34]$ was based on the standard commutator of the matrices $(\tilde{A}_\mu)^c_d (\tilde{A}_\nu)^d_b - (\tilde{A}_\nu)^c_d (\tilde{A}_\mu)^d_b$.

A thorough discussion of the relevance of ternary and nonassociative structures in Physics has been provided in [27], [5], [6]. The earliest example of nonassociative structures in Physics can be found in Einstein’s special theory of relativity. Only colinear velocities are commutative and associative, but in general, the addition of non-colinear velocities is non-associative and non-commutative. A putative noncommutative and nonassociative gravity theory for closed strings probing curved backgrounds with non-vanishing three-form flux based on a three-bracket structure were recently discussed by [32]. Nonassociative star product deformations for $D$-brane world volume in curved backgrounds were studied by [31]. The construction relied in the Kontsevich noncommutative and nonassociative star product.

The complexification of ordinary gravity (not to be confused with Hermitian-Kahler geometry) has been known for a long time. Complex gravity requires that $g_{\mu\nu} = g(\mu\nu) + ig[\mu\nu]$ so that now one has $g_{\mu\nu} = (g_{\mu\nu})^*$, which implies that the diagonal components of the metric $g_{zz_1} = g_{zz_2} = g_{z\bar{z}_1} = g_{z\bar{z}_2}$ must be real. A treatment of a non-Riemannian geometry based on a complex tangent space and involving a symmetric $g(\mu\nu)$ plus antisymmetric $g[\mu\nu]$ metric component was first proposed by Einstein-Strauss [8] (and later on by [18]) in their unified theory of Electromagnetism with gravity by identifying the EM field strength $F_{\mu\nu}$ with the antisymmetric metric $g[\mu\nu]$ component.

Borchsenius [17] formulated the quaternionic extension of Einstein-Strauss unified theory of gravitation with EM by incorporating appropriately the $SU(2)$ Yang-Mills field strength into the degrees of freedom of a quaternion-valued metric. Oliveira and Marques [19] later on provided the Octonionic Gravitational extension of Borchsenius theory involving two interacting $SU(2)$ Yang-Mills fields and where the exceptional group $G_2$ was realized naturally as the automorphism group of the octonions.

The Octonionic Gravity developed by [19] was extended to Noncommutative and Nonassociative Spacetime coordinates associated with octonion-valued coordinates and momenta by [20]. The octonionic metric $G_{\mu\nu}$ already encompasses the ordinary spacetime metric $g_{\mu\nu}$, in addition to the Maxwell $U(1)$ and $SU(2)$ Yang-Mills fields such that implements the Kaluza-Klein Grand Unification program without introducing extra spacetime dimensions. The color group $SU(3)$ is a subgroup of the exceptional $G_2$ group which is the automorphism group of the octonion algebra. The flux of the $SU(2)$ Yang-Mills field strength $\tilde{F}_{\mu\nu}$ through the area-momentum $\tilde{\Sigma}^{\mu\nu}$ in the internal isospin space yields corrections $O(1/M_{planck}^2)$ to the energy-momentum dispersion relations without violating Lorentz invariance as it occurs with Hopf algebraic deformations of the Poincare algebra.

After this brief preamble we proceed with the main results of this work which is the construction, to our knowledge, of a novel nonassociative octonionic ternary gauge field theory. We conclude with a few remarks about the plausible
future avenues of research.

2 Octonionic Ternary Gauge Field Theories

Given an octonion $X$ it can be expanded in a basis $(e_o, e_m)$ as

$$X = x^o e_o + x^m e_m, \quad m, n, p = 1, 2, 3, ..., 7.$$  \hfill (2.1)

where $e_o$ is the identity element. The Noncommutative and Nonassociative algebra of octonions is determined from the relations

$$e_o^2 = e_o, \quad e_o e_i = e_i e_o = e_i, \quad e_i e_j = -\delta_{ij} e_o + c_{ijk} e_k, \quad i, j, k = 1, 2, 3, ..., 7.$$ \hfill (2.2)

where the fully antisymmetric structure constants $c_{ijk}$ are taken to be 1 for the combinations $(123), (516), (218), (435), (471), (673), (672)$. The octonion conjugate is defined by $\bar{e}_o = e_o, \bar{e}_m = -e_m$

$$\bar{X} = x^o e_o - x^m e_m.$$ \hfill (2.3)

and the norm is

$$N(X) = <X X^*> = Real(\bar{X} X) = (x_o x_o + x_k x_k).$$ \hfill (2.4)

The inverse

$$X^{-1} = \frac{\bar{X}}{N(X)}, \quad X^{-1}X = XX^{-1} = 1.$$ \hfill (2.5)

The non-vanishing associator is defined by

$$(X, Y, Z) = (XY)Z - X(YZ)$$ \hfill (2.6)

In particular, the associator

$$(e_i, e_j, e_k) = (e_i e_j) e_k - e_i (e_j e_k) = 2 d_{ijkl} e_l$$

$$d_{ijkl} = \frac{1}{3!} \epsilon_{ijklmnp} c^{mnp}, \quad i, j, k, ..., = 1, 2, 3, ..., 7.$$ \hfill (2.7)

The generators of the split-octonionic algebra admit a realization in terms of the $4 \times 4$ Zorn matrices (in blocks of $2 \times 2$ matrices) by writing

$$u_o = \frac{1}{2} (e_o + ie_7), \quad u_o^* = \frac{1}{2} (e_o - ie_7)$$

$$u_i = \frac{1}{2} (e_i + ie_{i+3}), \quad u_i^* = \frac{1}{2} (e_i - ie_{i+3})$$  \hfill (2.8)
\[
\begin{align*}
\mathbf{u}_o &= \begin{pmatrix} 0 & 0 \\ 0 & \omega_o \end{pmatrix} & \mathbf{u}_o^* &= \begin{pmatrix} \omega_o & 0 \\ 0 & 0 \end{pmatrix} \\
\mathbf{u}_i &= \begin{pmatrix} 0 & 0 \\ \omega_i & 0 \end{pmatrix} & \mathbf{u}_i^* &= \begin{pmatrix} 0 & -\omega_i \\ 0 & 0 \end{pmatrix}
\end{align*}
\]

(2.9)

The quaternionic generators \(\omega_o, \omega_i, i = 1, 2, 3\) obey the algebra
\(\omega_i \omega_j = \epsilon_{ijk} \omega_k - \delta_{ij} \omega_o\) and are related to the Pauli spin \(2 \times 2\) matrices by setting \(\sigma_i = i \omega_i\) and \(\omega_o = \mathbf{1}_{2 \times 2}\).

The \(\mathbf{u}_i, \mathbf{u}_i^*\) behave like fermionic creation and annihilation operators corresponding to an exceptional (non-associative) Grassmannian algebra
\[
\{\mathbf{u}_i, \mathbf{u}_j\} = \{\mathbf{u}_i^*, \mathbf{u}_j^*\} = 0, \quad \{\mathbf{u}_i, \mathbf{u}_j^*\} = -\delta_{ij}.
\]

(2.10a)

\[
\frac{1}{2} [\mathbf{u}_i, \mathbf{u}_j] = \epsilon_{ijk} \mathbf{u}_k, \quad \frac{1}{2} [\mathbf{u}_i^*, \mathbf{u}_j^*] = \epsilon_{ijk} \mathbf{u}_k, \quad \mathbf{u}_o^2 = \mathbf{u}_o, \quad (\mathbf{u}_o^* )^2 = \mathbf{u}_o^*.
\]

(2.10b)

Unlike the octonionic algebra, the split-octonionic algebra contains zero divisors and therefore is not a division algebra.

The automorphism group of the octonionic algebra is the 14-dim exceptional \(G_2\) group that admits a \(SU(3)\) subgroup leaving invariant the idempotents \(\mathbf{u}_o, \mathbf{u}_o^*\). This \(SU(3)\) was identified as the color group acting on the quarks and antiquarks triplets \([11]\) \(\Psi_\alpha = u_i \Psi^i_\alpha, \bar{\Psi}_\alpha = -u_i^* \bar{\Psi}^i_\alpha, i = 1, 2, 3\), respectively. From the split-octonionic algebra multiplication table one learns that triplet \(\times\) triplet = anti triplet and triplet \(\times\) anti triplet = singlet providing a very natural algebraic interpretation of confinement of 3 quarks.

The multiplication product of the split-octonions generators \(\mathbf{u}_o, \mathbf{u}_o^*, \mathbf{u}_i, \mathbf{u}_i^*\) is reproduced in this Zorn matrix realization. The Zorn matrix product of
\[
\mathbf{A} = \begin{pmatrix} A_o & \omega_o \\ B_i & \omega_i \end{pmatrix} \quad \mathbf{B} = \begin{pmatrix} C_o & \omega_o \\ D_i & \omega_i \end{pmatrix}
\]

is defined by
\[
\mathbf{A} \mathbf{B} = \begin{pmatrix}
(A_o C_o + A_i D_i) \omega_o \\
(C_o B_k + B_o D_k + \epsilon_{ijk} A_i C_j) \omega^k
\end{pmatrix}
\]

\[
- (A_o C_k + D_o A_k + \epsilon_{ijk} B_i D_j) \omega^k
\]

(2.11)

\[
(\mathbf{B}_o D_o + B_i C_i) \omega_o
\]

(2.12)

where we have used
\[
\omega_i \omega_j = \epsilon_{ijk} \omega_k - \delta_{ij} \omega_o \Rightarrow \omega_i \omega_i = -\omega_o, \quad \text{for each } i = 1, 2, 3 \Rightarrow
\]

\[
\hat{x} \cdot \hat{y} = (x_i \omega_i) \ (y_i \omega_i) = -x_i y_i \omega_o.
\]

(2.13)
In this section we shall focus entirely in the octonion algebra. Yamazaki [28] constructed a realization of a generalized Lie ternary-algebra using the Octonions by defining a three-bracket. It requires using the left and right operators $L_u v =uv$, $R_u v = vu$ and the derivative operator constructed by Nambu [27]

$$D_{u,v} x = ([L_u, L_v] + [R_u, R_v] + [L_u, R_v]) x. \quad (2.14)$$

The operator $D_{u,v}$ obeys the analog of Liebnitz rule

$$D_{u,v} (xy) = (D_{u,v}x)y + x(D_{u,v}y). \quad (2.15)$$

and allows to define the three-bracket as

$$[u, v, x] \equiv D_{u,v} x = \frac{1}{2} ( u(vx) - v(ux) + (xv)u - (ux)v ). \quad (2.16a)$$

For the octonionic algebra one has after a straightforward calculation

$$[e_a, e_b, e_c] = 0; \quad [e_a, e_b, e_c] = f_{abcd} e_d = [d_{abcd} - \delta_{ac} \delta_{bd} + \delta_{bc} \delta_{ad}] e_d \quad (2.16b)$$

where the totally antisymmetric associator structure constants $d_{abcd}$ are the 7-dim "duals" to the $c_{abc}$ structure constants as shown by eq-(2.7) (the identity element $e_o$ is excluded due to the triviality $[e_a, e_b, e_o] = 0$). Yamazaki [28] has shown that the 3-brackets (2.16a) obey the fundamental identity (2.20) below. This follows from the algebraic properties of derivations based on the analog of Liebnitz rules of differentiation. One should notice that

$$[u, v, x] \neq \frac{1}{2} \left( [ [u, v], x] - (u, x, v) \right) \quad (2.17)$$

where $(u, x, v) = (ux)v - u(xv)$ is the nonvanishing associator. For nonassociative algebras, the Jacobi identity is not obeyed and the Jacobiator is not zero

$$J(x, y, z) = [[x, y], z] + [[y, z], x] + [[z, x], y] \neq 0 \quad (2.18)$$

In particular, the Jacobiator associated with the octonion algebra is proportional to the associator $J(e_a, e_b, e_c) \sim (e_a, e_b, e_c) = 2d_{abcd}e_d$. The octonion algebra is also a Malcev algebra [30].

The commutator of two generalized derivative operators acting on $z$ is

$$[D_{u,v}, D_{x,y}] z = D_{u,v} D_{x,y} z - D_{x,y} D_{u,v} z = D_{u,v[x,y]} z + D_{x[u,v,y]} z = [u, v, x, y, z] + [x, u, v, y, z]. \quad (2.19)$$

The result in (2.19) is a direct consequences of the fundamental identity

$$[[x, u, v], y, z] + [x, [y, u, v], z] + [x, y, [z, u, v]] = [[x, y, z], u, v] \quad (2.20)$$
which is obeyed by the 3-bracket (2.16) [28]. A bilinear positive symmetric product \( < u, v >= < v, u > \) is required such that that the ternary bracket/derivation obeys what is called the metric compatibility condition

\[
< [u, v, x], y > = - < [u, v, y], x > = - < [u, v, y], x > \Rightarrow D_{u,v} < x, y > = 0 \quad (2.21a)
\]

The symmetric product remains invariant under derivations. There is also the additional symmetry condition required by [28]

\[
< [u, v, x], y > = < [x, y, u], y > \quad (2.21b)
\]

Okubo [4] constructed an octonionic triple product which is totally antisymmetric in all of its entries and is given by

\[
[x, y, z]_{Okubo} = \frac{1}{2} ( (x, y, z) + < x, e_o > [y, z] + < y, e_o > [z, x] )
\]

where \( e_o \) is the Octonion unit element and \((x, y, z) = (xy)z - x(yz)\) is the nonvanishing associator for nonassociative algebras.

The ternary product that we shall be using in this work is the one provided by Yamazaki (2.16) which obeys the key fundamental identity (2.20) and leads to the structure constants \( f_{abcd} \) that are pairwise antisymmetric but are not totally antisymmetric in all of their indices:
\[
f_{abcd} = -f_{bacd} = -f_{abdc} = f_{cdab}; \quad \text{however} : f_{abcd} \neq f_{c dab}; \quad \text{and} \quad f_{abcd} \neq -f_{abdc}. \]

The ternary operation for octonions \((x, y, z) = (xy)z - x(yz)\) does not obey the fundamental identity (2.20) as emphasized by [28]. For this reason we cannot use the associator to construct the 3-bracket.

Equipped with the above definition of the 3-bracket eq-(2.16) one may now proceed with the explicit construction of a nonassociative and noncommutative ternary gauge field theory based on the octonions. The building elements are the octonionic-valued gauge field \( B_{\mu} = B_{\mu}^a e_a \) and an auxiliary octonionic-valued scalar field \( \Phi = \Phi^a e_a \). The ternary infinitesimal gauge transformations for the fields \( B_{\mu}, \Phi \) are defined respectively in terms of the parameters \( \Lambda^{ab} = -\Lambda^{ba} \) and \( \Lambda^a \) as

\[
\delta \left( B_{\mu}^m e_m \right) = - \partial_\mu (\Lambda^m e_m) + \Lambda^{ab} [e_a, e_b, B_{\mu}^c e_c] =
\]

\[
- \partial_\mu (\Lambda^m e_m) + \Lambda^{ab} B_{\mu}^c f_{abcd} e_m \quad (2.23a)
\]

\[
\delta \left( \Phi^m e_m \right) = \Lambda^{ab} [e_a, e_b, \Phi^c e_c] = \Lambda^{ab} \Phi^c f_{abcd} e_m \quad (2.23b)
\]

No distinction is made between \( f_{abcd} e_m \) and \( f_{abc}^m e_m \) since the metric that raises/lowers indices is Euclidean \( \delta_{ab} \). The second rank field strength tensor
based on the ternary algebra (3-brackets) is defined differently from the Yang-Mills case (based on 2-brackets) as follows

\[ F_{\mu\nu} = \partial_{\mu} B_{\nu} - \partial_{\nu} B_{\mu} + [B_{\mu}, B_{\nu}, \Phi], \] (2.24)

where \( \Phi = \Phi^{a}e_{a} \) is the auxiliary octonionic-valued scalar field without dynamical degrees of freedom and which plays the role of an effective octonionic “coupling” function. By recurring to the infinitesimal transformations (2.23a) one has

\[ \delta(F_{\mu\nu}) = \partial_{\mu}(\delta B_{\nu}) - \partial_{\nu}(\delta B_{\mu}) + \delta([B_{\mu}, B_{\nu}, \Phi]) \] (2.25)

The inhomogeneous terms in the infinitesimal gauge transformations \( \delta F_{\mu\nu} \) of (2.25) cancel if

\[ (\partial_{\mu} \Lambda^{ab}) B^{c}_{\gamma} f_{abcm} e_{m} - (\partial_{\nu} \Lambda^{ab}) B^{c}_{\gamma} f_{abcm} e_{m} - \\
(\partial_{\nu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} - (\partial_{\mu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} = 0 \] (2.26)

Because the expression in eq-(2.31) is not explicitly anti-symmetric under the exchange of the indices \( \mu \leftrightarrow \nu \), one must perform a series of three steps. Exchanging the \( b \leftrightarrow c \) indices in the third term \( -(\partial_{\mu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} \) allows to rewrite it as

\[ - (\partial_{\mu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} \rightarrow - (\partial_{\mu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m}. \] (2.27)

Exchanging the \( a \leftrightarrow c \) indices in the fourth term of (2.26) \( -(\partial_{\nu} \Lambda^{b}) B^{a}_{\gamma} \Phi^{c} f_{abcm} e_{m} \) allows to rewrite it as

\[ - (\partial_{\nu} \Lambda^{b}) B^{a}_{\gamma} \Phi^{c} f_{abcm} e_{m} = (\partial_{\nu} \Lambda^{b}) B^{a}_{\gamma} \Phi^{c} f_{abcm} e_{m}. \] (2.28)

due to the antisymmetry under the exchange of a pair of indices \( f_{cbam} = -f_{bcam} \).

Exchanging the \( b \rightarrow a \) indices in (2.28) yields

\[ (\partial_{\nu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} \] (2.29)

Therefore the third and fourth terms of (2.26) can be re-expressed in a manifestly antisymmetric expression under the exchange of the \( \mu \leftrightarrow \nu \) indices, as it should

\[ - (\partial_{\mu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m} + (\partial_{\nu} \Lambda^{a}) B^{b}_{\gamma} \Phi^{c} f_{abcm} e_{m}. \] (2.30)

Finally, by recurring to (2.30) one can rewrite (2.26) as

\[ [ (\partial_{\mu} \Lambda^{ab}) f_{abcm} - (\partial_{\nu} \Lambda^{a}) \Phi^{b} f_{abcm} ] B^{c}_{\gamma} e_{m} - \\
[ (\partial_{\nu} \Lambda^{ab}) f_{abcm} - (\partial_{\nu} \Lambda^{a}) \Phi^{b} f_{abcm} ] B^{c}_{\gamma} e_{m} = 0 \] (2.31)

The expression in eq-(2.31) is now explicitly anti-symmetric under the exchange of the indices \( \mu \leftrightarrow \nu \). A solution expressing the gauge parameters \( \Lambda^{ab}, \Lambda^{a} \) in terms of the \( \Phi^{c} \) components can be found by setting

\[ [ (\partial_{\mu} \Lambda^{ab}) f_{abcm} - (\partial_{\nu} \Lambda^{a}) \Phi^{b} f_{abcm} ] B^{c}_{\gamma} e_{m} = 0 \] (2.32a)
\[ (\partial_\nu \Lambda^{ab}) f_{acbm} - (\partial_\nu \Lambda^a) \Phi^b f_{acbm} \mid B^b_{\mu} \epsilon_m = 0 \] (2.32b)

Eq-(2.32a) is equivalent to eq-(2.32b) since the latter is obtained from the former by a simple exchange of the \(\mu, \nu\) indices. Therefore, by setting the expression inside the parenthesis of (2.32a) to zero one arrives at the desired relation among the gauge parameters and the auxiliary field \(\Phi^c\) components.

\[ (\partial_\mu \Lambda^{ab}) f_{acbm} - (\partial_\mu \Lambda^a) \Phi^b f_{acbm} = 0 \] (2.33)

The equivalent eq-(2.32b) yields the same functional relation as (2.33) by a simple exchange of the \(\mu, \nu\) indices. Therefore, by setting the expression inside the parenthesis of (2.32a) to zero one arrives at the desired relation among the gauge parameters and the auxiliary field \(\Phi^c\) components.

\[ f_{ab}^k \left( \partial_\mu \Lambda^k \right) f_{acbm} = (\partial_\mu \Lambda^a) \Phi^b f_{acbm} \] (2.34)

Because the left hand side of (2.34) contains terms which are explicitly antisymmetric in the \(a, b\) and \(c, m\) indices one must decompose the right hand side into a symmetric and antisymmetric pieces leading then to

\[ f_{ab}^k \left( \partial_\mu \Lambda^k \right) f_{acbm} = \frac{1}{2} \left( (\partial_\mu \Lambda^a) \Phi^b - (\partial_\mu \Lambda^b) \Phi^a \right) \left( d_{acbm} + \delta_{c[b} \delta_{a]m} \right) \Rightarrow \]

\[ -12 c_{kcm} (\partial_\mu \Lambda^k) = \frac{1}{2} \left( (\partial_\mu \Lambda^a) \Phi^b - (\partial_\mu \Lambda^b) \Phi^a \right) \left( d_{acbm} + \delta_{c[b} \delta_{a]m} \right) \] (2.35a)

after using the identity \[29\] \( f_{ab}^k f_{acbm} = -6 f_{kcm} = -12 c_{kcm} \). Since the associator structure constants \(d_{acbm}\) are totally antisymmetric under the exchange of any pair of indices, the right hand side (2.35a) is antisymmetric under the exchange of the \(c, m\) indices. While the symmetric components yield the following zero contribution

\[ \frac{1}{2} \left( (\partial_\mu \Lambda^a) \Phi^b + (\partial_\mu \Lambda^b) \Phi^a \right) \left( -\delta_{ab} \delta_{cm} + \delta_{c[b} \delta_{a]m} \right) = 0 \] (2.35b)

with

\[ \delta_{c[b} \delta_{a]m} = \frac{1}{2} (\delta_{cb} \delta_{am} + \delta_{ca} \delta_{bm}); \quad \delta_{c[b} \delta_{a]m} = \frac{1}{2} (\delta_{cb} \delta_{am} - \delta_{ca} \delta_{bm}) \] (2.36)

To conclude, one can ensure that the ternary field strength \(F_{\mu\nu}\) defined in terms of the 3-brackets (2.24) transforms properly (homogeneously) under the ternary gauge transformations if eqs-(2.35a, 2.35b) are obeyed in order to ensure a cancelation of the inhomogeneous pieces under infinitesimal ternary gauge transformations. Eqs-(2.35a, 2.35b), in conjunction with the definition \(\Lambda^{ab} = 2c_{ab}^k \Lambda^k\), furnish the relationship among the gauge parameters and the auxiliary field \(\Phi^c\) components; i.e. one has then that \(\Lambda^{ab}[\Phi], \Lambda^a[\Phi]\) are auxiliary-field dependent gauge parameters. This is permissible because \(\Phi = \Phi^c e_c\) is not endowed with any dynamics, it is just another variable parameter that one can
interpret as an octonionic-valued "coupling" function and whose components can rotate into each other. The real (scalar) part $\Phi_0$ remains invariant under the transformations $\delta(\Phi^m e_m) = \Lambda^{ab}[e_a, e_b, \Phi^c e_c]$ because $[e_a, e_b, e_c] = 0$.

If eqs-(2.35a, 2.35b) do not provide a consistent set of solutions then one must abandon the ansatz $\Lambda^{ab} = f^{ab} k^{abc} \Lambda^c$ and use eq-(2.33), after a proper symmetrization and antisymmetrization procedure is made in the right hand side, as the equation which establishes the required constraint among $\Lambda^{ab}, \Lambda^a$ and $\Phi$.

To conclude finally, due to a cancelation of the inhomogeneous pieces, under infinitesimal ternary gauge transformations, one can infer that $F_{\mu\nu}$ does transform homogeneously under the infinitesimal ternary gauge transformations as

$$\delta(F^m_{\mu\nu} e_m) = \Lambda^{ab}[e_a, e_b, F^c_{\mu\nu}, e_c] = \Lambda^{ab} F^c_{\mu\nu} f^{abc} e_m \Rightarrow \delta F^m_{\mu\nu} = \Lambda^{ab} F^c_{\mu\nu} f^{abc} e_m \quad (2.37)$$

The results (2.37) is a direct consequence of the fundamental identity because the 3-bracket (2.16a) is defined as a derivation

$$\begin{align*}
&[[e_a, e_b, B_{\mu}], B_{\nu}, \Phi] + [B_{\mu}, [e_a, e_b, B_{\nu}], \Phi] + [B_{\mu}, B_{\nu}, [e_a, e_b, \Phi]] = \\
&[e_a, e_b, [B_{\mu}, B_{\nu}, \Phi]] \quad (2.38)
\end{align*}$$

Similar findings as those obtained in eqs-(2.35a, 2.35b) among the gauge parameters and the octonionic-valued auxiliary field $\Phi$ can be found such that the ternary covariant derivative of an octonionic-valued scalar field $\Theta(x^\mu) = \Theta^a(x^\mu)e_a$ defined as

$$D_{\mu}\Theta = \partial_{\mu}\Theta + [B_{\mu}, \Theta, \Phi] \quad (2.39)$$

transforms homogeneously under the transformations

$$\delta\Theta = \Lambda^{ab}[e_a, e_b, \Theta] \Rightarrow \delta(D_{\mu}\Theta) = \Lambda^{ab}[e_a, e_b, (D_{\mu}\Theta)] \quad (2.40)$$

The same relations as those in (2.35a, 2.35b) can also be found for the octonionic-valued third rank antisymmetric field strength

$$F_{\mu\nu\rho} = \partial_{\rho} B_{\mu\nu} + \partial_{\mu} B_{\nu\rho} + \partial_{\nu} B_{\rho\mu} - [B_{\mu\nu}, B_{\rho}, \Phi] - [B_{\nu\rho}, B_{\mu}, \Phi] - [B_{\rho\mu}, B_{\nu}, \Phi], \quad (2.41a)$$

such that under ternary infinitesimal gauge transformations of the form $\delta B_{\mu\nu} = \Lambda^{ab}[e_a, e_b, B_{\mu\nu}]$, it transforms as

$$\delta(F^m_{\mu\nu\rho} e_m) = \Lambda^{ab}[e_a, e_b, F^c_{\mu\nu\rho}, e_c] \quad (2.41b)$$

Similar results follow for the octonionic-valued fourth-rank antisymmetric tensor

$$F_{\mu\nu\rho\tau} = \partial_{\tau} B_{\mu\nu\rho} - \partial_{\rho} B_{\nu\mu\tau} + \partial_{\mu} B_{\tau\nu\rho} - \partial_{\nu} B_{\tau\rho\mu} - [B_{\mu\nu\rho}, B_{\tau}, \Phi] + [B_{\nu\mu\rho}, B_{\tau}, \Phi] - [B_{\tau\nu\rho}, B_{\mu}, \Phi] + [B_{\tau\rho\mu}, B_{\nu}, \Phi] \Rightarrow (2.42a)$$

$$\delta(F^m_{\mu\nu\rho\tau} e_m) = \Lambda^{ab}[e_a, e_b, F^c_{\mu\nu\rho\tau}, e_c] \quad (2.42b)$$
and so forth.

Given the octonionic valued field strength $F_{\mu\nu} = F_{\mu\nu}^a e_a$, with real valued components $F_{\mu\nu}^0, F_{\mu\nu}^i; i = 1, 2, 3, \ldots, 7$, a gauge invariant action under ternary infinitesimal gauge transformations in $D$-dim is

$$S = -\frac{1}{4\kappa^2} \int d^Dx \left< F_{\mu\nu} F^{\mu\nu} \right>$$  \hspace{1cm} (2.43)$$

$\kappa$ is a numerical parameter introduced to make the action dimensionless and it can be set to unity for convenience. The $\left< >$ operation is defined as $\left< XY \right> = \text{Real}(\bar{X}Y) = \left< YX \right> = \text{Real}(\bar{Y}X)$.

Under infinitesimal ternary gauge transformations of the action one has

$$\delta S = -\frac{1}{4} \int d^Dx \left< F_{\mu\nu} \delta F^{\mu\nu} \right> + (\delta F_{\mu\nu}) F^{\mu\nu} =$$

$$-\frac{1}{4} \int d^Dx \left< F_{\mu\nu}^c e_c \Lambda^{ab} [e_a, e_b, F^{\mu\nu} e_c] \right> =$$

$$-\frac{1}{4} \int d^Dx \left< \Lambda^{ab} [e_a, e_b, F_{\mu\nu}^c e_c] F^{\mu\nu} e_c \right> =$$

$$-\frac{1}{4} \int d^Dx \Lambda^{ab} F_{\mu\nu} F^{\mu\nu} \left( \left< e_c f_{abnk} e_k \right> + \left< f_{abck} e_k e_n \right> \right) = 0.$$  \hspace{1cm} (2.44)$$

since

$$\left< e_c f_{abnk} e_k \right> + \left< f_{abck} e_k e_n \right> = f_{abnk} \delta_{ck} + f_{abck} \delta_{kn} = f_{abnc} + f_{abcn} =$$

$$\left[ d_{abnc} - \delta_{an} \delta_{bc} + \delta_{bn} \delta_{ac} \right] + \left[ d_{abcn} - \delta_{ac} \delta_{bn} + \delta_{bc} \delta_{an} \right] = 0.$$  \hspace{1cm} (2.45a)$$

because $d_{nabc} + d_{caban} = 0$, due to the total antisymmetry of the associator structure constant $d_{nabc}$ under the exchange of any pair of indices. Invariance $\delta S = 0$, only occurs if, and only if, $\delta F = \Lambda^{ab}[e_a, e_b, F^c e_c] \neq \Lambda^{ab}[F^c e_c, e_a, e_b]$. The ordering inside the 3-bracket is crucial. One can check that if one sets $\delta F = \Lambda^{ab}[F^c e_c, e_a, e_b]$, the variation $\delta S$ leads to a term in the integral which is not zero

$$f_{nabc} + f_{cabn} = \left[ d_{nabc} - \delta_{ab} \delta_{ac} + \delta_{ab} \delta_{nc} \right] + \left[ d_{cabn} - \delta_{bc} \delta_{an} + \delta_{ab} \delta_{cn} \right] \neq 0.$$  \hspace{1cm} (2.45b)$$

However, under $\delta F = \Lambda^{ab}[e_a, e_b, F^c e_c]$, the variation $\delta S$ is indeed zero as shown. This is a consequence of the fact that $[e_a, e_b, e_c] \neq [e_c, e_a, e_b]$ when the 3-bracket is given by eqs-(2.16).

To show that the action is invariant under finite ternary gauge transformations requires to follow a few steps. Firstly, one defines

$$\left< xy \right> = \text{Real} \left[ \bar{x} y \right] = \frac{1}{2} (\bar{x} y + \bar{y} x) \Rightarrow \left< xy \right> = \left< yx \right>$$  \hspace{1cm} (2.46)$$
Despite nonassociativity, the *very special conditions*

\[ x(\bar{x}u) = (x\bar{x})u; \ x(u\bar{x}) = (\bar{x}u)x; \ x(xu) = (xx)u; \ x(ux) = (xu)x \]

are obeyed for octonions resulting from the Moufang identities. Despite that \((xy)z \neq x(yz)\) one has that their real parts obey

\[
\text{Real} \ [ \ (x \ y) \ z ] = \text{Real} \ [ \ x \ (y \ z) ]
\]

(2.48)

Due to the nonassociativity of the algebra, in general one has that \((gF)g^{-1} \neq g(Fg^{-1}).\) However, if and only if \(g^{-1} = \bar{g} \Rightarrow \bar{g}g = gg = 1\), as a result of the the *very special conditions* (2.47) one has that \(F' = (gF)g^{-1} = g(Fg^{-1}) = gFg^{-1} = gF\bar{g}\) is unambiguously defined.

Hence, by repeated use of eqs-(2.46, 2.47, 2.48), when \(g^{-1} = \bar{g}\), the action density (2.43) is also invariant under finite gauge transformations of the form

\[
< F' F' > = \text{Re} \left[ F' F' \right] = \text{Re} \left[ (gF\bar{g}) (gFg^{-1}) \right] = \text{Re} \left[ (\bar{g}F)(g^{-1} (Fg^{-1})) \right] =
\]

(2.49)

\[
= \text{Re} \left[ (\bar{g}F)(g^{-1}g) (Fg^{-1}) \right] = \text{Re} \left[ (\bar{g}F)(Fg^{-1}) \right] = \text{Re} \left[ F (g^{-1}g) \bar{F} \right] = \text{Re} \left[ F \bar{F} \right] = \text{Re} \left[ \bar{F} F \right] = < F F > .
\]

One may ask now if the expression for \(g = \exp (\alpha \Lambda^{ab}[e_a, e_b]); \ g^{-1} = \bar{g} = \exp (-\alpha \Lambda^{ab}[e_a, e_b]),\) where \(\alpha\) is a real numerical constant which is used to define the finite gauge transformations

\[
F' = e^{\alpha \Lambda^{ab}[e_a, e_b]} (F^c t_c) e^{-\alpha \Lambda^{ab}[t_a, t_b]},
\]

(2.50)

furnishes infinitesimal gauge transformations which agree with the *ternary* ones when the real parameters \(\Lambda^{ab}\) are infinitesimals

\[
\delta F = F' - F = \Lambda^{ab} F^c [e_a, e_b, e_c] = \alpha \Lambda^{ab} F^c [e_a, e_b, e_c] \Rightarrow
\]

(2.51)

\[
\Lambda^{ab} F^c f_{abcm} e_m = \alpha \Lambda^{ab} F^c (2c_{abd}) (2c_{dcm}) e_m \Rightarrow 4 \alpha c_{abd} c_{dcm} = f_{abcm}.
\]

One can verify that by choosing \(\alpha = \frac{1}{4}\), one arrives at the condition among the structure constants \(c_{ab} c_{dcm} = f_{abcm}\) which is indeed obeyed for the octonion algebra as shown in [29]; i.e. the Yamazaki 3-bracket (2.16) satisfies the identity for octonions

\[
[e_a, e_b, e_c] = f_{abcm} e_m = [d_{abcm} - \delta_{ac} \delta_{bm} + \delta_{bc} \delta_{am}] e_m =
\]

(2.52)

\[
\frac{1}{4} [e_a, e_b, e_c] = c_{abd} c_{dcm} e_m \Rightarrow
\]

\[c_{abd} c_{dcm} = f_{abcm} = d_{abcm} - \delta_{ac} \delta_{bm} + \delta_{bc} \delta_{am}\]

\(d_{abcm}\) are the associator structure constants given by the duals to the octonion structure constants as shown in eq-(2.7). A series of identities involving the
structure constants of octonions can be found in [29]. Therefore, by choosing \(\alpha = \frac{1}{4}\), the equality in eq.(2.51) is indeed satisfied for the octonion algebra and such that for infinitesimal real valued parameters \(\Lambda^{ab}\) eq.(2.50) yields to lowest order \(\delta F = F' - F = \Lambda^{ab}[e_a, e_b, F]\) recovering the homogeneous ternary infinitesimal gauge transformations for the field strengths as expected.

We should remark that when \(a = 1, 2, 3, \ldots, 7\) (excluding the unit element), having \(g = \exp(\Lambda^a e_a); \quad g^{-1} = \bar{g} = \exp(-\Lambda^a e_a)\), a finite gauge transformation of the form \(F'' = gFg^{-1} = gF\bar{g}\) leads also to an invariant action (2.43). The infinitesimal transformations are in this case \(\delta F = F'' - F = \Lambda^a[e_a, F^c e_c]\) which leave the action (2.43) invariant. However we must emphasize that we must not identify the ternary transformations with the ordinary ones based on 2-brackets: \(F' \neq F''\) and \(\Lambda^{ab}[e_a, e_b, F^c e_c] \neq \Lambda^a[e_a, F^c e_c]\).

We conclude with a few remarks. Wulkenhaar [39] succeeded in formulating another type of geometry which shares some similarities with Connes Noncommutative Geometry (NCG). The theory was coined Nonassociative geometry (NAG). The main difference with the two theories is that NAG is based on a unitary Lie algebra, instead of a unital associative star algebra. A left-right gauge model of Pati-Mohapatra within the context of Nonassociative geometry was provided by [40]. At the tree level they obtained mass relations and mixing angles identical to the ones obtained in \(SO(10)\) GUT. It is warranted to explore what kind of phenomenological particle physics models can be developed within the framework of the nonassociative octonionic ternary gauge field theory built in this work. A thorough analysis of Octonionic spinors can be found in [23].

Also, Noncommutative and Nonassociative octonionic gauge field theories of gravity deserve investigation. Comparisons with the standard Octonionic gravity [19], [20] and the \(E_8\) gauge theory of gravity in \(8D\) [21] must be made. The split-octonions ternary gauge field theory case should follow naturally. The cubic matrices \(A^a = A^a_{\mu} f^{bcd}_{\mu} = (A^a)_{\mu} f^{bcd} \) with a nonassociative ternary product

\[
(ABC)_{j_1 j_2 j_3} = A_{i_1 j_1} B_{k_1 j_2} C_{k_2 j_3},
\]

(2.53)

(where the summation is taken over repeated indices) must play an important role. The quantization program is a challenging task. The non-Desarguesian geometry of the Moufang projective plane to describe Octonionic QM was studied in detail by [11]. This would be a starting point.

Acknowledgments

We thank M. Bowers for her assistance.
