Abstract

This paper presents the mechanism of gravitation based on an approach where the energies of electrons and positrons are stored in fundamental particles (FPs) that move radially and continuously through a focal point in space, point where classically the energies of subatomic particles are thought to be concentrated. FPs store the energy in longitudinal and transversal rotations which define corresponding angular momenta. Forces between subatomic particles are the product of the interactions of their FPs. The laws of interactions between fundamental particles are postulated in that way, that the linear momenta for all the basic laws of physics can subsequently be derived from them, linear momenta that are generated out of opposed pairs of angular momenta of fundamental particles.

The flattening of Galaxies’ Rotation Curve is derived without the need of the definition of Dark Matter, and the repulsion between galaxies is shown without the need of Dark Energy.

The mechanism of the dragging between neutral moving masses is explained (Thirring-Lense-effect) and how gravitation affects the precision of atomic clocks is presented (Hafele-Keating experiment).

Finally, the quantification of the gravitation force is derived.

1 Introduction.

Our ”Standard Model” describes a particle as a point-like entity with the energy concentrated on one point in space. The mechanism how forces between charged particles are generated is not explained. This limitation of our Standard Model results from the introduction of a series of artificial particles and constructions like Gluons, Gravitons, particle’s wave, dark matter, dark energy, etc., to explain the mechanism of interaction between particles.
The proposed approach postulates that a particle is formed by rays of Fundamental Particles (FPs) that move through a focal point in space. The relativistic energy of the particle is stored by the FPs as longitudinal and transversal rotations. Interactions between two particles are now the result of the interactions between FPs of the two particles.

The steps followed to describe mathematically the new model are:

1. Definition of a distribution function \( d\kappa \) that assigns to each volume \( dV \) in space a differential energy \( dE \) of the total relativistic energy of the particle.

2. Definition of a field magnitude \( d\vec{H} \) associated with the angular momenta of FPs.

3. Definition of interaction laws between \( d\vec{H} \) fields of FPs in that way, that all forces between particles can be mathematically derived.

In what follows electrons and positrons are called "Basic Subatomic Particles" (BSPs).

The total relativistic energy of a BSP is

\[
E_e = \sqrt{E_o^2 + E_p^2} = E_s + E_n \quad \text{with} \quad E_s = \frac{E_o^2}{\sqrt{E_o^2 + E_p^2}} \quad E_n = \frac{E_p^2}{\sqrt{E_o^2 + E_p^2}} \tag{1}
\]

The differential energies for each differential volume are:

\[
dE_e = E_e \, d\kappa = \nu \, J_e \quad dE_s = E_s \, d\kappa = \nu \, J_s \quad dE_n = E_n \, d\kappa = \nu \, J_n \tag{2}
\]

with \( d\kappa \) the distribution function, \( \nu \) the angular frequency and \( J \) the angular momenta.

\[
d\kappa = \frac{1}{2} \frac{r_o}{r^2} \, dr \, \sin \varphi \, d\varphi \, \frac{d\gamma}{2\pi} \quad dV = dr \, d\varphi \, r \, \sin \varphi \, d\gamma \tag{3}
\]

\( d\kappa \) is inverse proportional to the square distance to the focal point and gives the fraction of the relativistic energy for the volume \( dV \) of the FP.

FPs leaving the focal point (emitted FPs) have only longitudinal angular momenta \( J_e \) and associated to it a longitudinal emitted field \( d\vec{H}_e \) defined as

\[
d\vec{H}_e = H_e \, d\kappa \, \vec{s}_e = \sqrt{\nu \, J_e \, d\kappa \, \vec{s}_e} \quad \text{with} \quad H_e^2 = E_e \tag{4}
\]

FPs moving to the focal point (regenerating FPs) have longitudinal \( J_s \) and transversal \( J_n \) angular momenta and associated to them respectively a longitudinal emitted field

The differential energies for each differential volume are:

\[
dE_e = E_e \, d\kappa = \nu \, J_e \quad dE_s = E_s \, d\kappa = \nu \, J_s \quad dE_n = E_n \, d\kappa = \nu \, J_n \tag{2}
\]
$d\vec{H}_s$ defined as

$$d\vec{H}_s = H_s \, d\kappa \, \vec{s} = \sqrt{\nu \, J_s} \, d\kappa \, \vec{s} \quad \text{with} \quad H_s^2 = E_s \quad (5)$$

and a transversal emitted field $d\vec{H}_n$ defined as

$$d\vec{H}_n = H_n \, d\kappa \, \vec{n} = \sqrt{\nu \, J_n} \, d\kappa \, \vec{n} \quad \text{with} \quad H_n^2 = E_n \quad (6)$$

For the total field magnitude $H_e$ it is $H_e^2 = H_s^2 + H_n^2$.

![Figure 1: Unit vector $\vec{s}_e$ for an emitted FP and unit vectors $\vec{s}$ and $\vec{n}$ for a regenerating FP of a BSP moving with $v \neq c$](image)

Fig. 1 shows at the origin of the Cartesian coordinates the focus of a BSP moving with speed $\vec{v}$. The vector $\vec{s}_e$ is an unit vector in the moving direction of the emitted fundamental particle (FP). The vector $\vec{s}$ is an unit vector in the moving direction of the regenerating FP. The vector $\vec{n}$ is an unit vector transversal to the moving direction of the regenerating FP and oriented according the right screw rule relative to the velocity $\vec{v}$ of the BSP.

The differential linear momentum $dp$ of a moving BSP is generated out of pairs of opposed transversal fields $d\vec{H}_n$ at the regenerating FPs of the BSP. Opposed pairs of transversal fields $d\vec{H}_n$ are generated because of the axial symmetry relative to the velocity $\vec{v}$ of the BSP as shown in Fig. 1.

**Conclusion:** Basic subatomic particles (BSPs) are structured particles with longitudinal and transversal angular momenta. The sign of the angular momenta of emitted FPs define the sign of the BSP (electron or positron). The transversal field $d\vec{H}_n$ gives the kinetic linear moment.
Interaction laws between FPs of two BSPs are defined as products between their $d\vec{H}$ fields.

- **Coulomb law**: The close path integration of the cross product between longitudinal $d\vec{H}_s$ fields gives the Coulomb equation.
- **Ampere law**: The close path integration of the cross product between transversal $d\vec{H}_n$ fields gives the Lorentz, Ampere and Bragg equations.
- **Induction law**: The close path integration of the product between the transversal field $d\vec{H}_n$ and the absolute value of the longitudinal $d\vec{H}_s$ field of a static BSP gives the Maxwell equations and the gravitation equations.

The fundamental equation to calculate the differential force between two BSPs is

$$dF = \frac{dp}{\Delta t} = \frac{1}{c\Delta t} dE_p = \frac{1}{c\Delta t} |d\vec{H}_1 \times d\vec{H}_2| \quad (7)$$

## 2 Mechanism of Gravitation.

To explain the mechanism of gravitation, the concept of reintegration of BSPs that have migrated out of their nuclei is required.

Because of $d\vec{H}_s = d\vec{H}_s\vec{s}$ and $\vec{J}_s = J_s\vec{s}$ the interaction law between FPs of static BSPs (Coulomb) follows the cross product between longitudinal angular momenta $|\vec{J}_{e_1} \times \vec{J}_{s_2}| = J_{e_1} J_{s_2} \sin \beta = J_n$ of the FPs, cross product which is zero for the distance $d = 0$ between BSPs because of $\beta = \pi/2$.

In Fig. 2 the differential linear momentum $dp$ at BSP 2 is generated by pairs of opposed angular momentum $\vec{J}_{n_2}$ of regenerating FPs.

Fig. 3 gives the linear momentum between two BSPs as a function of the distance $d$. The variable $r_o$ represents the radii of the focus of the BSPs, which are constant for non relativistic speeds.

Nucleons are composed of electrons and positrons which are concentrated in the range of $0 \leq \gamma \leq 0.1$ of the curve of Fig. 3 where the attractions and repulsions between them are zero.
Figure 2: Generation of angular momentum $J_n$ at regenerating fundamental particles of two static basic subatomic particles at the distance $d$

\end{align*}
\]

Figure 3: Linear momentum $p_{\text{stat}}$ as function of $\gamma = d/r_0$ between two static BSPs with equal radii $r_{o1} = r_{o2}$
Electrons and positrons of a nucleon migrate slowly into the range of \(0.1 \leq \gamma \leq 1.8\) polarizing the nucleon, and are subsequently reintegrated with high speed when their FPs cross with FPs of the remaining electrons and positrons of the nucleon because of \(\beta < \pi/2\) (Neutron 1 at Fig. 4). Opposed linear momenta \(d\bar{p}_a\) and \(d\bar{p}_b\) are generated at BSPs \(a\) and \(b\).

![Figure 4: Transmission of momentum \(dp_b\) from neutron 1 to neutron 2](image_url)

The movement of BSP \(b\) generates the \(dH_n\) field shown in Fig. 4, field that is passed to the static BSP \(p\) of neutron 2 according the induction law of sec. 1. The final result is that neutron 1 moves with the linear momentum \(-d\bar{p}_a\) and neutron 2 with the opposed linear momentum \(d\bar{p}_p\). The mechanism is independent of the sign of the interacting BSPs explaining the attracting force of gravitation. It is important to note that as BSPs \(a\) and \(b\) generate opposed \(dH_n\) fields that are passed to BSP \(p\) of neutron 2, the field of BSP \(b\) is closer to BSP \(p\) and has a higher probability to be passed to BSP \(p\).

### 3  Newton gravitation force.

To calculate the gravitation force induced by the reintegration of migrated BSPs, we need to know the number of migrated BSPs in the time \(\Delta t\) for a neutral body with mass \(M\).

The following equation was derived in [6] for the induced gravitation force gen-
erated by one reintegrated electron or positron

\[ F_i = \frac{dp}{\Delta t} = \frac{k c \sqrt{m} \sqrt{m_p}}{4K d^2} \int \int \text{Induction} \quad \text{with} \quad \int \int \text{Induction} = 2.4662 \quad (8) \]

with \( m \) the mass of the reintegrating BSP, \( m_p \) the mass of the resting BSP, \( k = 7.4315 \cdot 10^{-2} \). It is also

\[ \Delta t = K r_o^2 \quad r_o = 3.8590 \cdot 10^{-13} m \quad \text{and} \quad K = 5.4274 \cdot 10^4 \text{ s/m}^2 \quad (9) \]

The direction of the force \( F_i \) on BSP \( p \) of neutron 2 in Fig. 4 is independent of the sign of the BSPs and is always oriented in the direction of the reintegrating BSP \( b \) of neutron 1.

Fig. 5 shows reintegrating BSPs \( a \) and \( d \) at Neutron 1 that transmit respectively opposed momenta \( p_g \) and \( p_e \) to neutron 2. Because of the greater distance from neutron 2 of BSP \( a \) compared with BSP \( d \), the probability for BSP \( d \) to transmit his momentum is greater than the probability for BSP \( a \). Momenta are quantized and have all equal absolute value independent if transmitted or not. The result computed over a mass \( M \) gives a net number of transmitted momentum to neutron 2 in the direction of neutron 1, what explains the attraction between neutral masses.
For two bodies with masses $M_1$ and $M_2$ and where the number of reintegrated BSPs in the time $\Delta t$ is respectively $\Delta G_1$ and $\Delta G_2$ it must be

$$F_i \Delta G_1 \Delta G_2 = G \frac{M_1 M_2}{d^2} \quad \text{with} \quad G = 6.6726 \cdot 10^{-11} \frac{m^3}{kg \ s^2} \quad (10)$$

As the direction of the force $F_i$ is the same for reintegrating electrons $\Delta^- G$ and positrons $\Delta^+ G$ it is

$$\Delta G = |\Delta^- G| + |\Delta^+ G| \quad (11)$$

We get that

$$\Delta G_1 \Delta G_2 = G \frac{4 K M_1 M_2}{m k c \int \int_{\text{Induction}}} \quad (12)$$

or

$$\Delta G_1 \Delta G_2 = 2.8922 \cdot 10^{17} M_1 M_2 = \gamma^2_G M_1 M_2 \quad (13)$$

The number of migrated BSPs in the time $\Delta t$ for a neutral body with mass $M$ is thus

$$\Delta G = \gamma_G M \quad \text{with} \quad \gamma_G = 5.3779 \cdot 10^8 \ kg^{-1} \quad (14)$$

**Calculation example:** The number of migrated BSPs that are reintegrated at the sun and the earth in the time $\Delta t$ are respectively, with $M_\odot = 1.9891 \cdot 10^{30} \ kg$ and $M_\oplus = 5.9736 \cdot 10^{24} \ kg$

$$\Delta G_\odot = 1.0697 \cdot 10^{39} \quad \text{and} \quad \Delta G_\oplus = 3.2125 \cdot 10^{33} \quad (15)$$

The power exchanged between two masses due to gravitation is

$$P_G = F_i c = \frac{E_p}{\Delta t} = \frac{k m c^2}{4 K d^2} \Delta G_1 \Delta G_2 \int \int_{\text{Induktion}} \quad (16)$$

The power exchanged between the sun and the earth is, with $d_{\odot \oplus} = 1.49476 \cdot 10^{11} \ m$

$$P_G = F_G c = G \frac{M_\odot M_\oplus}{d_{\odot \oplus}^2} c = 1.0646 \cdot 10^{31} \ J/s \quad (17)$$

4 Ampere gravitation force.

In the previous sections we have seen that the induced gravitation force is due to the reintegration of migrated BSPs in the direction $d$ of the two gravitating bodies
When a BSP is reintegrated to a neutron, the two BSPs of different signs that interact produce an equivalent current $i_m$ in the direction of the positive BSP as shown in Fig. 6.

![Diagram of neutrons and migrated BSPs](image)

Figure 6: Resulting current $i_m$ due to reintegration of migrated BSPs

As the numbers of positive and negative BSPs that migrate during the time $\Delta t$ in one direction at one neutron are equal, it is

$$\Delta R = \Delta R^+ + \Delta R^- = 0 \quad (18)$$

where $\Delta R$ represents the number of migrated BSPs in the time $\Delta t$.

No average current $I_m$ should exist in that direction in the time $\Delta t$ to generate a force between parallel currents of the two neutrons according to the Ampere law

$$\frac{F}{\Delta l} \propto \frac{I_{m_1} I_{m_2}}{d} \quad (19)$$

Fig. 7 shows a mass $M_2$ moving with $v_2$ in an orbit relative to mass $M_1$. Longitudinal reintegrating electrons and positrons at $M_2$ generate currents $i_m$ relative to $M_2$. Because of the speed $v_2$ the longitudinal currents $i_m$ of $M_2$ have transversal components $i_2$ relative to $M_1$ which interact with the transversal reintegrating electrons and positrons at $M_1$ in that way that $\Delta R \neq 0$ at $M_1$ and $M_2$.

We conclude that because of the power exchange (16) between the two neutral
Figure 7: Ampere gravitation due to orbital speed.

bodies $M_1$ and $M_2$ a synchronization between the reintegration of BSPs of equal sign in the direction orthogonal to the axis defined by the two bodies is generated, resulting in parallel currents of equal sign that generate an attracting force between the bodies. The synchronization is generated by the relative movement between the gravitating bodies and is zero between static bodies. Thus the total attracting force between the two neutral bodies is produced first by the induced (Newton) force and second by the force due to parallel currents of reintegrating BSPs (Ampere), which like the Newton force is proportional to the masses of the bodies.

$$F_T = F_G + F_R \quad \text{with} \quad F_G = G \frac{M_1 M_2}{d^2} \quad \text{and} \quad F_R = R \frac{M_1 M_2}{d} \quad (20)$$

To derive an equation we start with the following equation from [6] derived for the total force density due to Ampere interaction.

$$\frac{F}{\Delta l} = \frac{b}{c \Delta_0 t} \frac{r_o^2}{64 m} \frac{I_{m1} I_{m2}}{d} \int_{\gamma_{2\text{max}}}^{\gamma_{2\text{min}}} \int_{\gamma_{1\text{min}}}^{\gamma_{1\text{max}}} \frac{\sin^2(\gamma_1 - \gamma_2)}{\sin \gamma_1 \sin \gamma_2} d\gamma_1 d\gamma_2 \quad (21)$$

with $\int \int_{\text{Ampere}} = 5.8731$.

It is also for $v \ll c$

$$\rho_x = \frac{N_x}{\Delta x} = \frac{1}{2 r_o} \quad I_m = \rho m v \quad \Delta_0 t = K r_o^2 \quad I_m = \frac{m}{q} I_q \quad (22)$$

We have defined a density $\rho_x$ of BSPs for the current so that one BSP follows
immediately the next without space between them. As we want the force between one pair of BSPs of the two parallel currents we take $\Delta l = 2r_o$.

For one reintegrating BSP it is $\rho = 1$. The current generated by one reintegrating BSP is

$$I_{m_1} = i_m = \rho m v_m = \rho m k c \quad \text{with} \quad v_m = k c \quad k = 7.4315 \cdot 10^{-2} \quad (23)$$

We get for the force between one transversal reintegrating BSP at the body with mass $M_1$ and one longitudinal reintegrating BSP at $M_2$ moving parallel with the speed $v_2$

$$dF_R = 5.8731 \frac{b}{\Delta_o l} \frac{2r_o^3}{64} \rho^2 m k \frac{v_2}{d} \frac{\gamma^2}{d} = 2.2086 \cdot 10^{-50} \frac{v_2}{d} N \quad (24)$$

with $I_{m_2} = i_2 = \rho m v_2$.

The concept is shown in Fig. 7.

**Note:** The currents $i_m$ and $i_2$ of the bodies respectively $M_1$ and $M_2$ may synchronize with equal or opposed signs resulting in an attraction or repulsion force $F_R$.

In sec. 3 we have derived the mass density $\gamma_G$ of reintegrating BSPs. At Fig. 5 we have seen that half of the longitudinal reintegrating BSPs of a neutron 1 induce momenta on neutron 2 in one direction while the other half of longitudinal reintegrating BSPs induce momenta in the opposed direction on neutron 2. In Fig. 7 we see, that all longitudinal reintegrating BSPs at $M_2$ generate a current component $i_2$ in the direction of the speed $v_2$. This means that we have to take for the density $\gamma_A$ of reintegrating BSPs for the Ampere gravitation force approximately twice the value of the density $\gamma_G$ of the Newton gravitation force

$$\gamma_A \approx 2 \gamma_G = 2 \cdot 5.3779 \cdot 10^8 = 1.07558 \cdot 10^9 \text{ kg}^{-1} \quad (25)$$

resulting for the total Ampere gravitation force between $M_1$ and $M_2$

$$F_R = 5.8731 \frac{b}{\Delta_o l} \frac{2r_o^3}{64} \rho^2 m k \frac{v_2}{d} \gamma_A \frac{M_1 M_2}{d^2} = 2.5551 \cdot 10^{-32} \frac{M_1 M_2}{d^2} N \quad (26)$$

where

$$F_R = R \frac{M_1 M_2}{d} \quad \text{with} \quad R = 2.5551 \cdot 10^{-32} \frac{v_2}{d} = R(v_2) \quad (27)$$
The total gravitation force gives

\[ F_T = F_G + F_R = \left[ \frac{G}{d^2} + \frac{R}{d} \right] M_1 M_2 \]  \hspace{1cm} (28)

The concept is shown in Fig. 8.

The equation for the centrifugal force of a body with mass \( M_2 \) is

\[ F_c = M_2 \frac{v_{orb}^2}{d} \]  \hspace{1cm} (30)

For steady state mode the centrifugal force \( F_c \) must equal the gravitation force \( F_T \).

For our case it is

\[ F_c = M_2 \frac{v_{orb}^2}{d} = F_T \approx F_R = \frac{R}{d} M_1 M_2 \]  \hspace{1cm} (31)

We get for the tangential speed

\[ v_{orb} \approx \sqrt{\frac{R}{M_1}} \text{ constant} \]  \hspace{1cm} (32)

---

**4.1 Flattening of galaxies’ rotation curve.**

For galactic distances the Ampere gravitation force \( F_R \) predominates over the induced gravitation force \( F_G \) and we can write eq. (28) as

\[ F_T \approx F_R = \frac{R}{d} M_1 M_2 \]  \hspace{1cm} (29)

Figure 8: Gravitation forces at sub-galactic and galactic distances.

\[ G = 6.672 \cdot 10^{-11} \frac{m^3}{kg \cdot s^2} \]

\[ R \left( v_2 \right) = 2.5551 \cdot 10^{-3} v_2 \frac{Nm}{kg \cdot s^2} \]

\[ d_{gal} = 2.6154 \cdot 10^{21} \frac{1}{v_2} m \]
The tangential speed $v_{\text{orb}}$ is independent of the distance $d$ what explains the flattening of galaxies’ rotation curves.

**Calculation example**

In the following calculation example we assume that the transition distance $d_{\text{gal}}$ is much smaller than the distance between the gravitating bodies and that the Newton force can be neglected compared with the Ampere force.

For the Sun with $v_2 = v_{\text{orb}} = 220 \ km/s$ and $M_2 = M_\odot = 2 \cdot 10^{30} \ kg$ and a distance to the core of the Milky Way of $d = 25 \cdot 10^{19} \ m$ we get a centrifugal force of

$$F_c = M_2 \frac{v_{\text{orb}}^2}{d} = 3.872 \cdot 10^{20} \ N \quad (33)$$

With

$$R(v_2) = 2.5551 \cdot 10^{-32} \ v_2 = 5.6212 \cdot 10^{-27} \ Nm/kg^2 \quad (34)$$

and

$$F_c \approx R \frac{M_1 M_2}{d} \quad (35)$$

we get a Mass for the Milky Way of

$$M_1 = F_c d \frac{1}{R M_\odot} = 4.3 \cdot 10^6 \ M_\odot \quad (36)$$

and with

$$F_G = F_R \quad \text{we get} \quad d_{\text{gal}} = \frac{G}{R} = 1.1870 \cdot 10^{16} \ m \quad (37)$$

justifying our assumption for $F_T \approx F_R$ because the distance between the Sun and the core of the Milky Way is $d \gg d_{\text{gal}}$.

**Note:** The mass of the Milky Way calculated with the Newton gravitation law gives $M_1 \approx 1.5 \cdot 10^{12} \ M_\odot$ which is huge more than the bright matter and therefore called dark matter. The mass calculated with the present approach corresponds to the bright matter and there is no need to introduce virtual masses in space.

For sub-galactic distances the induced force $F_G$ is predominant, while for galactic distances the Ampere force $F_R$ predominates, as shown in Fig. 8.

$$d_{\text{gal}} = \frac{G}{R} \quad (38)$$

**Note:** The flattening of galaxies’ rotation curve was derived based on the assumption that the gravitation force is composed of an induced component and a component due to parallel currents generated by reintegrating BSPs and, that for galactic distances...
the induced component can be neglected.

4.2 Current induced on a rotating body.

In sec. 4 we have analysed the interactions between reintegrating BSPs of two bodies that move relative with the speed $v_2$. Now we analyse the case of two bodies where one of them rotates relative to the other.

The concept is shown in Fig. 9

Comparing with Fig. 7 all BSPs at the distance $d_1$ move with $-v_2$ and all BSPs at the distance $d_2$ move with $v_2$. Reintegrating BSPs at $M_2$ that are at the distance $d_1$ from $M_1$ define the direction of the currents $i_m$ at $M_1$ because they are closer than reintegrating BSPs of $M_2$ at the distance $d_2$. The net result is a closed loop of currents $i_2$ at $M_2$ giving the current $I_M$ which generates the transversal field $dH_n$. Please see also subsection Permanent magnetism at §6.
5 Precession of the perihelion.

The total gravitation force is

\[ F_T = F_G + F_R = \left[ \frac{G}{d^2} + \frac{R}{d} \right] M_1 M_2 \quad \text{with} \quad G = G = 6.6726 \cdot 10^{-11} \frac{m^3}{kg \ s^2} \] (39)

and

\[ R(v_2) = 2.5551 \cdot 10^{-32} v_2 \ Nm/kg^2 \] (40)

The first term \( F_G \) gives the elliptic shape of the planet orbit while the second term \( F_R \) gives the precession of the orbit.

6 Quantification of gravitation forces.

In sec. 8.1 from [6] “Induction between an accelerated and a probe BSP expressed as closed path integration over the whole space” the elementary linear momentum \( p_{elem} \) is derived which with

\[ \Delta t(v = 0) = \Delta_o t = 8.082110^{-21} \ s \quad \text{and} \quad k = 7.4315 \cdot 10^{-2} < 1 \] (41)

gives

\[ p_{elem} = m c k = \frac{h}{c \Delta_o t} k = 2.0309 \cdot 10^{-23} \ kg \ m \ s^{-1} \] (42)

The elementary linear momentum \( p_{elem} \) is now used to quantize the two components of the gravitation force.

6.1 Quantification of the induced gravitation force.

From sec. 2 eq. (8) we have that the gravitation force for one aligned reintegrating BSPs is

\[ F_i = \frac{k m c}{4 K d^2} \int \int_{Induction} \quad \text{with} \quad \int \int_{Induction} = 2.4662 \] (43)

which we can write with \( \Delta_o t = K \ r_o^2 \) and \( p_{elem} = k \ m \ c \) as

\[ F_i = N_i \ \nu_o \ p_{elem} \quad \text{with} \quad N_i = \frac{r_o^2}{4 \ d^2} \int \int_{Induction} \] (44)
Considering that $\Delta G_1 \Delta G_2 = \gamma_2 \frac{M_1 M_2}{r_0^2}$ we can write for the total force between two masses $M_1$ and $M_2$

$$F_G = F_1 \Delta G_1 \Delta G_2 = N_G \nu_o p_{elem} \quad \text{with} \quad N_G = N_i \Delta G_1 \Delta G_2$$ \hspace{1cm} (45)

where $N_G$ represents the probability of elementary forces $f_{elem} = \nu_o p_{elem}$ in the time $\Delta_o t = K r_o^2$.

Finally we get

$$F_G = N_G(M_1, M_2, d) \nu_o p_{elem} \quad \text{with} \quad N_G = 2.6555 \cdot 10^{-8} \frac{M_1 M_2}{d^2}$$ \hspace{1cm} (46)

The frequency with which elementary momenta are generated is

$$\nu_G = N_G(M_1, M_2, d) \nu_o = 3.2856 \cdot 10^{15} \frac{M_1 M_2}{d^2}$$ \hspace{1cm} (47)

For the earth with a mass of $M_\oplus = 5.974 \cdot 10^{24}$ kg and the sun with a mass of $M_\odot = 1.9889 \cdot 10^{30}$ kg and a distance of $d = 147.1 \cdot 10^9$ m we get a frequency of $\nu_G = 1.8041 \cdot 10^{45}$ s$^{-1}$ for aligned reintegrating BSPs.

### 6.2 Quantification of Ampere force between parallel reintegrating BSPs.

From sec. 4 eq. (24) we have for a pair of parallel reintegrating BSPs that

$$dF_R = 5.8731 \frac{b}{\Delta_o t} \frac{2 r_o^3}{64} \rho^2 m k \frac{v_2}{d} = 2.2086 \cdot 10^{-50} \frac{v_2}{d} N$$ \hspace{1cm} (48)

which we can write as

$$dF_R = N \nu_o p_{elem} \quad \text{with} \quad N = 8.7893 \cdot 10^{-48} \frac{v_2}{d}$$ \hspace{1cm} (49)

where

$$p_{elem} = k m c \quad \text{and} \quad k = 7.4315 \cdot 10^{-2}$$ \hspace{1cm} (50)

The total Ampere force between masses $M_1$ and $m_2$ is given with eq. (26)

$$F_R = 2.5551 \cdot 10^{-32} v_2 \frac{M_1 M_2}{d} N$$ \hspace{1cm} (51)

We now write the equation in the form

$$F_R = N_R(M_1, M_2, d) \nu_o p_{elem} \quad \text{with} \quad N_R = 1.01682 \cdot 10^{-29} \frac{v_2}{d} \frac{M_1 M_2}{d}$$ \hspace{1cm} (52)
The frequency with which pairs of FPs cross in space is

\[ \nu_R = N_R(M_1, M_2, d) \nu_o = 1.25811 \cdot 10^{-9} v_2 \frac{M_1 M_2}{d} s^{-1} \quad (53) \]

For the earth with a mass of \( M_\oplus = 5.974 \cdot 10^{24} \text{ kg} \) and the sun with a mass of \( M_\odot = 1.9889 \cdot 10^{30} \text{ kg} \) and a distance of \( d = 1.5 \cdot 10^8 \text{ m} \) and a tangential speed of the earth around the sun of \( v_2 = 30 \text{ m/s} \) we get a frequency of \( \nu_R = 2.9896 \cdot 10^{39} \text{ s}^{-1} \) for parallel reintegrating BSPs. The frequency \( \nu_G \) for aligned BSPs is nearly \( 10^6 \) times grater than the frequency for parallel reintegrating BSPs and so the corresponding forces.

### 6.3 Quantification of the total gravitation force.

The total gravitation force is given by the sum of the induced force between aligned reintegrating BSPs and the force between parallel reintegrating BSPs.

\[ F_T = F_G + F_R = [N_G(M_1, M_2, d) + N_R(M_1, M_2, d)] p_{elem} \nu_o \quad (54) \]

or

\[ F_T = F_G + F_R = p_{elem} \nu_o \left[ \frac{2.6555 \cdot 10^{-8}}{d^2} + \frac{1.01682 \cdot 10^{-29}}{d} v_2 \right] M_1 M_2 \quad (55) \]

We define the distance \( d_{gal} \) as the distance for which \( F_G = F_R \) and get

\[ d_{gal} = \frac{2.6555 \cdot 10^{-8}}{1.01682 \cdot 10^{-29} v_2} = 2.6116 \cdot 10^{21} \frac{1}{v_2} \text{ m} \quad (56) \]

### 7 Precession of a gyroscope due to the Ampere gravitation force.

To derive the precession of a gyroscope in the presence of a massive body we start with the following equation from [6], derived for the total force density due to Ampere interaction.

\[ \frac{F}{\Delta l} = \frac{b}{c \Delta \gamma} \frac{r_0^2}{64 m} \frac{I_{m_1} I_{m_2}}{d} \int_{\gamma_{2\text{min}}}^{\gamma_{2\text{max}}} \int_{\gamma_{1\text{min}}}^{\gamma_{1\text{max}}} \sin^2(\gamma_1 - \gamma_2) \frac{\sin \gamma_1}{\sin \gamma_2} \frac{d\gamma_1}{d\gamma_2} d\gamma_1 d\gamma_2 \quad (57) \]
with \( \int \int \text{Ampere} = 5.8731 \).

It is also for \( v \ll c \)

\[
\rho_x = \frac{N_x}{\Delta x} = \frac{1}{2 r_o} \quad I_m = \rho m v \quad \Delta_x t = K r_o^2 \quad I_m = \frac{m}{q} I_q \quad (58)
\]

We have defined a density \( \rho_x \) of BSPs for the current so that one BSP follows immediately the next without space between them. As we want the force between one pair of BSPs of the two parallel currents we take \( \Delta l = 2 r_o \).

The concept is shown in Fig. 10

![Gyroscopic precession](image)

**Figure 10: Gyroscopic precession.**

For one reintegrating BSP it is \( \rho = 1 \). The current generated by one reintegrating BSP is

\[
i_m = \rho m v_m = \rho m k c \quad \text{with} \quad v_m = k c \quad k = 7.4315 \cdot 10^{-2} \quad (59)
\]

The currents at the rotating gyroscope that are parallel to the current \( i_m \) of \( M_1 \) are

\[
i_\omega = \pm \rho m v_\omega \quad \text{with} \quad v_\omega = \omega R_2 \quad (60)
\]

For the two opposed forces that give the momentum at the gyroscope and which generate the precession we get

\[
F_{\omega_1} \propto + \frac{v_m v_\omega}{d - R_\omega} \quad F_{\omega_2} \propto - \frac{v_m v_\omega}{d + R_\omega} \quad (61)
\]
From eq. (57) with \( v_1 = v_m = k c \) we get for a pair of moving BSPs

\[
dF_R = 5.8731 \frac{b}{c} \frac{2 r_o^3}{c} \frac{\rho^2}{64} m \frac{v_1 v_2}{d} N
\]

(62)

and \( d >> R_2 \) we get the total force

\[
F_R = 5.8731 \frac{b}{c} \frac{2 r_o^3}{c} \frac{\rho^2}{64} m v_m v_\omega \gamma_A^2 \frac{M_1 M_2}{d} N
\]

(63)

\[
F_R = 2.551 \cdot 10^{-32} v_\omega \frac{M_1 M_2}{d} N
\]

(64)

with \( M_1 \) and \( M_2 \) the masses of the bodies.

**Note:** For distances \( d \) between gravitating masses smaller than \( d_{gal} \) the precession due to the Ampere force is neglectable compared with the precession due to the Newton gravitation force.

## 8 Thirring-Lense-Effect.

The Thirring-Lense-Effect is an effect that is based on the induction law and on the Doppler effect.

In [6] about induction bending the following equation was deduced for the force induced on a probe BSP by a BSP moving with speed \( v \).

The concept is shown in Fig. 11

![Figure 11: Force induced on a BSP at a bending edge by a BSP moving with speed \( v \).](image)

\[
d'F_{in} = \frac{1}{8 \pi} \sqrt{m_p \rho_p} \rho \varepsilon \cdot C_n
\]

(65)
with
\[ \text{rot } \vec{C}_n' = \frac{1}{2\pi} \sqrt{mv^2 \frac{r_o}{r_r^3}} \left[ 2 \cos^2 \theta - \sin^2 \theta \right] \bar{e}_r + 0 \cdot \bar{e}_\gamma \] (66)

\[ \frac{1}{2\pi} \sqrt{mv^2 \frac{r_o}{r_r^3}} \sin \theta \cos \theta \bar{e}_\theta \]

For the analysis of the dragging produced by a rotating mass on a probe mass placed in the equatorial plane, the components of the induced force in the direction \( \bar{e}_r \) and the direction \( \bar{e}_\theta \) are required.

\[ d' F_{in} \bar{e}_r = \frac{1}{16 \pi^2} m \frac{r_o^2}{r_r^3} \left[ 2 \cos^2 \theta - \sin^2 \theta \right] \bar{e}_r \] (67)

\[ d'' F_{in} \bar{e}_\theta = \frac{1}{16 \pi^2} m \frac{r_o^2}{r_r^3} \sin \theta \cos \theta \bar{e}_\theta \] (68)

Figure 12: Plotting of the trigonometric relation for the analysis of Dragging.

For equal speed \( v \) and distance \( r_r \), the components of the forces in the direction of the speed \( v \) are equal but opposed for the angles \( \theta \) and \( 2\pi - \theta \). This means that two BSPs located at \( \theta \) and \( 2\pi - \theta \) induce on the probe BSP forces in the direction of \( v \) that compensate each other.

Fig. 13 shows two BSPs from the surface of the earth that moves with the speed \( v \) relative to a probe \( BSP_p \) located at the distance \( d \). Each moving BSP emittes rays of FPs with light speed \( c \) relative to the BSP, with a constant interval \( \lambda \) between them. The speed of the FPs relative to a probe \( BSP_p \) located at the ray is

\[ c + v \cos \theta = \lambda \nu \] (69)

FPs located at the proximity of the probe \( BSP_p \) have a higher probability to contribute to the generation of the force on the probe \( BSP_p \). The angle \( \theta = \arcsin(d/r) \) of the probe \( BSP_p \) is therefore used to calculate the force.

For the two BSPs located at the angles \( \theta_1 = \theta \) and \( \theta_2 = 2\pi - \theta \) we get the frequencies
of FPs at the probe $BSP_p$

$$\nu_1 = \frac{c + v \cos \theta_1}{\lambda} \quad \nu_2 = \frac{c + v \cos \theta_2}{\lambda} \quad \nu_o = \frac{c}{\lambda} \quad (70)$$

With eqs. (67) and (68) we get for the components of the forces in the direction of the speed $v$ taking into consideration the Doppler effect

$$d' \bar{F}_v = \nu \frac{v}{\nu_o} d' \bar{F}_{in} \cos \theta \bar{e}_r \quad \theta = \arcsin(d/r) \quad (71)$$

$$d'' \bar{F}_v = \nu \frac{v}{\nu_o} d'' \bar{F}_{in} \sin \theta \bar{e}_\theta \quad \theta = \arcsin(d/r) \quad (72)$$

The dragging forces in the direction of the speed $v$ on the probe $BSP_p$ are

$$d' \bar{F}_{drag} = (d' \bar{F}_{v1} - d' \bar{F}_{v2}) = \nu_1 - \nu_2 \nu_o \frac{v}{\nu_o} d' \bar{F}_{in} \cos \theta e_r \quad (73)$$

$$d'' \bar{F}_{drag} = (d'' \bar{F}_{v1} - d'' \bar{F}_{v2}) = \nu_1 - \nu_2 \nu_o \frac{v}{\nu_o} d'' \bar{F}_{in} \sin \theta e_\theta \quad (74)$$

The total dragging force is

$$\bar{F}_{drag} = \frac{2}{\pi} \int_{\theta=0}^{\pi/2} (d' \bar{F}_{drag} + d'' \bar{F}_{drag}) \, d\theta \quad (75)$$
9 Atomic clocks and gravitation.

Oscillations of mechanical instruments like a pendulum have been used in the past to define the time units. Big efforts were made to minimise the influence of factors like temperature, vibrations, humidity, gravitation, etc. on the precision, stability and reliability of the instruments. Modern clocks make use of the quantized change of states of atoms which takes place at a much higher frequency leading to better precisions. When comparing the precision of clocks it is very important to compare them under the same conditions of temperature, vibrations, humidity, gravitation, etc. If this is not possible, corrections for each deviation must be made. The origin of the variation of the precision of atomic clocks due to gravitation is unknown and can be attributed to changes in the energy levels of the atoms itself what would produce changes in the frequencies of the emitted photons.

The present section shows a possible mechanism for the variation of the precision of atomic clocks based on the approach that gravitation is generated by the reintegration of migrated BSP to their nuclei. According to the approach, the energies of level electrons are given by stable dynamic configurations of BSPs in their nuclei, which is different for each atom and its ions. The number of regenerating FPs with opposed angular momenta that arrive to a nucleus is a function of the distance to the other gravitating nucleus. They influence the stable dynamic configuration of BSPs in the nucleus changing the energy levels of electrons.

The approach is based on the assumption that the transition between two hyperfine levels of the ground state of atoms used in atomic clocks (Caesium-133, Rubidium-87, Thalium-205, etc.) is influenced by the Newton and Ampere gravitation forces. Because of the different mechanism for the generation of these two forces the strength of the influence is different.

The gravitation components are due to:

- Reintegration of BSPs in the direction of the distance between the gravitating bodies (induction, Newton).

\[ F_G = G \frac{M_1 M_2}{r^2} \tag{76} \]

- Reintegration of BSPs perpendicular to the distance between the gravitating bodies (Ampere).

\[ F_R = \pm R(v) \frac{M_1 M_2}{r} \quad \text{with} \quad R(v) = 2.551 \cdot 10^{-32} v \tag{77} \]
9.1 Hafele-Keating Experiment.

We assume that the atomic transition frequencies of the atoms used in atomic clocks change proportional to the gravitation force and so the gains and losses expressed in $ns$. Each Caesium atom $C_{s}^{133}$ of an atomic clock changes its frequency with the gravitation force.

The following measured data were obtained during the Hafele-Keating Experiment: The concept is shown on Fig. 14.

![Diagram of gravitation influence on clocks frequency](image)

Figure 14: Influence of gravitation on clocks frequency.

a) Flying eastwards a total loss of $\Delta t^{E} = -59 \, ns$ was measured during a flight of 41.2 hours at a height of $h^{E} = 8.900 \, m$ and a speed of $v = 950 \, km/h$ relative to the earth surface.

b) Flying westwards a total gain of $\Delta t^{W} = 273 \, ns$ was measured during a flight of 48.6 hours at a height of $h^{W} = 9.400 \, m$ and a speed of $v = 950 \, km/h$ relative to the earth surface.

The gain or loss was measured relative to an equivalent atomic clock based on the earth.

At Fig. 14 we have the earth with mass $M_{1}$ and the mass $M_{2}$ of an Caesium atom $C_{s}^{133}$ moving with the speed $v$ east or westwards relative to the surface of the earth at an altitude $h$. The current $I_{M}$ due to the interaction of reintegrating BSPs of the earth and the sun has the same direction as the rotation $\omega$ of the earth on its axis relative to the sun (see sec.4.2).
The results of the Hafele-Keating Experiment are better expressed in \( ns \) loss or gain per day.

Eastwards the plane was flying during 41, 2 \( h \) which is equivalent to 1, 716 \( days \) and which gives a total loss eastwards of \( \Delta t^E = -59/1.716 = -34, 38 \ ns/day \).

Westwards the plane was flying during 48, 6 \( h \) which is equivalent to 2, 025 \( days \) and which gives a total loss westwards of \( \Delta t^W = 273/2, 025 = 134, 81 \ ns/day \).

We get for the losses and gains in \( ns/day \)

\[
\Delta t^E = -34, 38 \ ns/day \quad \text{and} \quad \Delta t^W = 134, 81 \ ns/day
\]  

(78)

The total gain or loss eastwards and westwards is

\[
\Delta t^E = \Delta t^E_E + \Delta t^E_R \quad \text{and} \quad \Delta t^W = \Delta t^W_W + \Delta t^W_R
\]  

(79)

The proportionality factors are not the same for the Newton and Ampere gravitation
forces because of the different generation mechanism of the gravitation forces.

The proportionality factors are defined as

\[
K_G = \frac{\Delta t}{\Delta F_G} \quad \text{and} \quad K_R = \frac{\Delta t}{\Delta F_R}
\]  

(80)

where \( \Delta t_G \) are the \( ns/day \) due to the Newton gravitation and \( \Delta t_R \) are the \( ns/day \) due to the Ampere gravitation.

The difference between the Newton gravitation forces between the distances \( d_1 \) and \( d_2 \) from the centre of the earth is given by

\[
\Delta F_G = F_{G_2} - F_{G_1} = G \ M_1 \ M_2 \ \left[ \frac{1}{d_2^2} - \frac{1}{d_1^2} \right] \quad \text{where} \quad d_2 < d_1
\]  

(81)

The difference between the Ampere gravitation forces of a body moving with \( v_{tot} \) at the hight \( d_1 \) and \( d_2 \) from the centre of the earth is given by

\[
\Delta F_R = R(v_{tot}) \ M_1 \ M_2 \ \left[ \frac{1}{d_2^2} - \frac{1}{d_1^2} \right] \quad \text{where} \quad d_2 < d_1
\]  

(82)

where \( v_{tot} \) is a velocity still to be deduced.

As the Hafele-Keating experiment doesn’t give measured values of \( \Delta t_G \), we calculate the proportionality factor \( K_G \) with measured values of an experiment made by Briatore and Leschiutto in 1976. The experiment concentrates exclusively on the influence of the Newton gravitation on the frequency of clocks. The measured data are:

a) Turin \( h_2 = 250 \ m \) and Plateau Rosa \( h_1 = 3.500 \ m \)
\[ \Delta t_G = 33,8 - 36,5 \ \text{ns/day} \]

For the calculation of \( \Delta F_G \) we use

a) The mass of \( C_s^{133} \) with \( M_2 = 2,2061 \cdot 10^{-25} \text{ kg} \)

b) The mass of the earth \( M_1 = 5,972 \cdot 10^{24} \text{ kg} \)

c) For Plateau Rosa \( d_1 = R_\oplus + h_1 = 6.378,0 \text{ km} + 3,5 \text{ km} = 6.381,5 \text{ km} \)

d) For Turin \( d_2 = R_\oplus + h_2 = 6.378,0 \text{ km} + 0,25 \text{ km} = 6.378,25 \text{ km} \)

We get \( \Delta F_G = 2,2201 \cdot 10^{-27} \text{ N} \) and for the proportionality factor

\[
K_G = \frac{\Delta t_G}{\Delta F_G} = \frac{33,8}{2,2201 \cdot 10^{-27}} = 1,5362 \cdot 10^{28} \frac{\text{ns}}{\text{N day}} \quad (83)
\]

Now we can calculate for the Hafele-Keating Experiment the clock variations that correspond to the Newton gravitation for the east flight with \( d_E^2 = 8,9 \text{ km} \) and the west flight with \( d_W^2 = 9,4 \text{ km} \). We get

\[
\Delta t_G^E = 92,45 \frac{\text{ns}}{\text{day}} \quad \text{and} \quad \Delta t_G^W = 97,63 \frac{\text{ns}}{\text{day}} \quad (84)
\]

With

\[
\Delta t_E = \Delta t_G^E + \Delta t_R^E \quad \text{and} \quad \Delta t_W = \Delta t_G^W + \Delta t_R^W \quad (85)
\]

we get

\[
\Delta t_R^E = -126,83 \quad \text{and} \quad \Delta t_R^W = 37,18 \quad (86)
\]

With

\[
\Delta t_R = K_R \ R(v_{tot}) \ M_1 \ M_2 \left[ \frac{1}{d_2} - \frac{1}{d_1} \right] \quad R(v_{tot}) = 2.551 \cdot 10^{-32} \ v_{tot} \quad (87)
\]

we get with \( v_{tot} = v_E \) in the east direction and \( v_{tot} = v_W \) in the west direction

\[
\frac{\Delta t_R^E}{\Delta t_R^W} = - \frac{v_E}{v_W} \left[ \frac{1}{d_2^E} - \frac{1}{d_1^E} \right] \div \left[ \frac{1}{d_2^W} - \frac{1}{d_1^W} \right] \quad (88)
\]

and

\[
\frac{\Delta t_R^E}{\Delta t_R^W} = - 0,9468 \frac{v_E}{v_W} \quad \text{or} \quad \frac{v_E}{v_W} = k = 3,6029 \quad (89)
\]
We define that

\[ v_E = v_S + v \quad \text{and} \quad v_w = v_S - v \quad (90) \]

where \( v \) is the velocity of the plane relative to the surface of the earth and \( v_S \) a velocity still to be determined. We get that

\[ v_S = \frac{k + 1}{k - 1} v = 1,7683 \, v \quad (91) \]

If we assume that the velocity of the commercial plane used was \( v = 750 \, \text{km/h} \) we get for \( v_S = 1.326 \, \text{km/h} \) or \( v_S = 368 \, \text{m/s} \). The speed of the surface of the earth at the equator in a frame with centre at the sun and the earth placed at an axis of the frame is \( v_{\text{center}} = 463 \, \text{m/s} \), which is not far from \( v_S = 368 \, \text{m/s} \). The difference could come from the not very reliable data of the Hafele-Keating experiment.

The conclusion is, that the speed \( v_S = 368 \, \text{m/s} \) calculated on the basis of the variations of the frequencies of atomic clocks due to the influences of the Newton and Ampere gravitation forces based on the mass of the \( C_{133} \) atom, is not far from the speed \( v_{\text{center}} = 463 \, \text{m/s} \) of the surface of the earth at the equator for a frame placed at the centre of the earth. This can be seen as a confirmation of the proposed approach for the gravitation mechanism as the result of the reintegration of migrated electrons and positrons to their nuclei.

Finally we calculate also the proportionality factor \( K_R \) for the Ampere gravitation.

\[
K_R = \frac{\Delta t_R}{\Delta F_R} E = \frac{\Delta t_R}{\Delta F_R} W \quad (92)
\]

\[
\Delta F_R = R(v_{\text{tot}}) M_1 M_2 \left[ \frac{1}{d_2} - \frac{1}{d_1} \right] \quad \text{where} \quad d_2 < d_1 \quad (93)
\]

with \( v_{\text{tot}} = v_E \) for the east direction and \( v_{\text{tot}} = v_W \) for the west direction. We get

\[
K_R = \frac{\Delta t_R}{\Delta F_R} E = \frac{\Delta t_R}{\Delta F_R} W = 2,9965 \cdot 10^{40} \frac{\text{ns}}{\text{N day}} \quad (94)
\]

For \( K_G \) we had

\[
K_G = \frac{\Delta t_G}{\Delta F_G} = \frac{33.8}{2.2201 \cdot 10^{-27}} = 1.5362 \cdot 10^{28} \frac{\text{ns}}{\text{N day}} \quad (95)
\]

Now we calculate the current \( I_M \) generated by the speed \( v_S \) of BSPs. From sec.4
we have with \( v_S \) that \( i_S = \rho_x m v_S \) and for the earth we get \( I_M = i_S \gamma_A M_\oplus \).

We defined a density \( \rho_x \) of BSPs for the current \( I_M \) so that one BSP follows immediately the next without space between them and get

\[
\rho_x = \frac{N_x}{\Delta x} = \frac{1}{2 r_o} \quad \text{with} \quad r_o = 3,8590 \cdot 10^{-13} \text{ m}
\]  

(96)

With \( \rho_x = 1,2957 \cdot 10^{12} \text{ m}^{-1}, m = 9,1094 \cdot 10^{-31} \text{ kg}, v_S = 368 \text{ m/s}, \gamma_A = 1,07558 \cdot 10^9 \text{ kg}^{-1} \), and \( M_\oplus = 5,972 \cdot 10^{24} \text{ kg} \) we get for the current \( I_M \) at the equator that generates the transversal field \( dH_n \) of the earth.

\[
I_M = \rho_x m v_S \gamma_A M_\oplus = 2,7900 \cdot 10^{18} \text{ kg/s}
\]  

(97)

10 Interpretation of Data in a theoretical frame.

A theory like our Standard Model was improved over time to match with experimental data introducing fictious entities (particle wave, gluons, gravitons, dark matter, dark energy, time dilation, length contraction, Higgs particle, Quarks, Axions, etc.) and helpmates (duality principle, equivalent principle, uncertainty principle, violation of energy conservation, etc.) taking care that the theory is as consistent and free of paradoxes as possible. The concept is shown in Fig. 15. These improvements were integrated to the existing model trying to modify it as less as possible what led, with the time, to a model that resembles a monumental patchwork. To return to a mathematical consistent theory without paradoxes (contradictions) a completely new approach is required that starts from the basic picture we have from a particle. “E & R” UFT is such an approach representing particles as focal points in space of rays of FPs. This representation contains from the start the possibility to describe interactions between particles through their FPs, interactions that the SM with its particle representation attempts to explain with fictious entities.

Fig. 15 is an organigram where the main steps of the integration of fictious entities to the SM are shown. All experiments where the previously defined fictious entities are indirectly detected (point 7. of Fig. 15) are not a confirmation of the existence of the fictious entities (point 8. of Fig. 15), they are simply the confirmation that the model was made consistent with the fictious entities (point 3. of Fig. 15).
Fallacy used to conclude that the existence of fictitious entities is experimentally proven

1. Detection of experimental data that don’t fit with the SM
2. Definition of fictitious entities based on the experimental data that don’t fit.
3. Making the SM consistent with new fictitious entities as good as possible
4. Inventing justifications for remaining paradoxes and contradictions
5. Becoming used over the years to the fictitious entities and contradictions
6. Glorifying and idolizing the fictitious entities and their creators
7. Indirect detection of experimental data that led to the definition of the fictitious entities

Wrong

Right

8. Prove that fictitious entities really exist

Fictitious entities of the SM
- Particle wave
- Gravitons
- Dark energy
- Length contraction
- Quarks

Gluons
Dark matter
Time dilation
Higgs
Axions

Figure 15: Fallacy used to conclude that fictitious entities really exist
All experiments where time dilation or length contraction are apparently measured are indirect measurements and where the experimental results are explained with time dilation or length contraction, which stand for the interactions between light and the measuring instruments, interactions that were omitted.

In the case of the increase of the life time of moving muons the increase is because of the interactions between the FPs of the muons with the FPs of the matter that constitute the real frame relative to which the muons move. To explain it with time dilation only avoids that scientists search for the real physical origin of the increase of the life time.

11 Resume.

The work is based on particles represented as structured dynamic entities with the relativistic energy distributed over the whole space on FPs, contrary to the representation used in standard theory where particles are point-like entities with the energy concentrated on one point in space.

Fundamental parts of the mechanism of gravitation are the reintegration of migrated electrons and positrons to their nuclei, and the Induction and Ampere laws between FPs of BSPs.

The gravitation force has two components, one component due to the reintegration in the direction of the two gravitating bodies and one component due to the reintegration in the direction perpendicular to it.

For sub-galactic distances the first component, which is inverse proportional to the square distance, predominates, while for galactic distances the second component, which is inverse proportional to the distance is predominant.

The second component explains the flattening of galaxies’ rotation curves without the need of additional virtual matter (dark matter).

The second component also explains the repulsive forces between galaxies without the need of additional virtual energies (dark energy).

The two components of the gravitation force are quantized with the help of the elementary linear momentum deduced for the reintegration of migrated electrons and positrons to their nuclei.

The present approach is based on a more physical description of nature when postulating that light is emitted with light speed relative to the emission source (Emission Theory). There are no incompatibilities with “Galilean Relativity with virtual speeds” deduced in [6].

The dragging between two parallel moving neutral masses (Thirring-Lense-Effect) is the result of the induction law and the Doppler effect of FPs.
The time gain or loss of atomic clock due to the interaction with gravitation (Hafele-Keating-Experiment) is explained with the two components (Newton and Ampere) of the gravitation force.
