What is a Fair Salary?

Abstract
Pay satisfaction and pay fairness are of vital concern to the employee, the employer, and hence the entire economic structure. Although the importance of fairness to compensation decisions is widely acknowledged, the research examining how fairness perception relates to components of pay is relatively scarce. Here I model a dyadic employer-employee interaction as a "minimal" two-person game, in which an allocator (e.g., an employer) divides a monetary amount (e.g., a workplace net profit), between herself and a recipient (e.g., an employee). Assuming rational, self-interested players, I propose a level of aspiration model, according to which players' pay satisfaction is proportional to their actual payoffs, relative to their aspired payoffs. Solving for the points of equality between the players' levels of pay satisfaction, yields two possible "harmony" points, depending on the assumption made about the recipient's aspiration. Under the assumption that recipients aspire to receive 50% of the total amount, the predicted harmony allocation is \((\frac{2}{3}, \frac{1}{3})\), for the allocator and recipient, respectively. On the other hand, assuming that the recipient aspires to be treated equally, i.e., to receive the same amount as the allocator, the predicted harmony allocation is \((\phi, 1-\phi)\), where \(\phi \approx 0.62\) is the famous Golden Ratio, known for its important role in human aesthetics, and in many fields of science and technology.

For a dyadic employer-employee interaction, the above solution prescribes that a fair salary is any percentage of the net profit between \(\approx 33\%\) to \(\approx 38\%\), with strong preference for the upper limit, which in addition to yielding higher pay and pay satisfaction, is also aesthetically pleasing.

Tests of the proposed model using field data on attitudinal pay fairness, actual pay, and allocation behavior in experimental ultimatum bargaining, lend strong support to the validity of proposed solution.

Keywords: Pay satisfaction, Pay fairness, Salary, Aspiration level, Distributive justice, Resource allocation, Ultimatum game.
1. Introduction

Job satisfaction and pay satisfaction are of vital concern to the individual employee, the individual employer, and, in turn, the entire economic structure (Shapiro, 1976; Porter et al., 1974; Heneman & Schwab, 1985; Wallace & Fay, 1988). Job satisfaction, is related to employee motivation and performance (Ostroff, 1992), employee absenteeism and turnover rates (Hackett & Guion, 1985; Griffeth, Hom, & Gaertner, 2000), organizational citizenship behavior (Organ & Ryan, 1995), and more. Pay satisfaction, which I discuss in the present paper, is a much narrower construct than job satisfaction. However, it is also an important variable, linked to significant organizational outcomes. As examples, empirical evidence suggests that dissatisfaction with pay and work conditions may lead to decreased job satisfaction (Lumi et al., 1998), decreased motivation and performance (Lumi et al., 1998; Ostroff, 1992), increased absenteeism and turnover rates (Hackett & Guion, 1985, Griffeth, Hom, & Gaertner, 2000; Vandenberghe & Tremblay, 2008), more pay-related grievances and lawsuits (Cable & Judge, 1994; Gerhart & Milkovich, 1990), attitudes toward militancy and willingness to vote for going on strikes (Feuille & Blandin, 1976; Donnenwerth & Cox, 1978; Ng, 1991), and psycho-social problems (Butterworth et al., 2011).

Pay satisfaction is intimately related to the concept of perceived pay fairness. While the perception of fairness is important to all human resource decisions and processes (Cohen-Charash & Spector, 2001; Jawahar, 2007; Thurston & McNall, 2010, Jawahar & Stone, 2011), it is particularly important to compensation decisions. Perceived compensation fairness, the procedures used to make compensation-related decisions, and the manner in which compensation-related information is communicated, play an integral role in shaping reactions to critical elements of the compensation system (Milkovich and Newman, 2008; Nelson et al., 2008, Jawahar & Stone, 2011).

Despite the obvious relationship between pay satisfaction and pay fairness, the literatures on pay satisfaction and compensation, have evolved independently (Williams et al., 2006). Moreover, even though most researches would readily acknowledge that fairness is important to compensation decisions, the research examining the relationship between pay satisfaction and perceived pay fairness is relatively scarce (Jawahar & Stone, 2011).
Two major theoretical frameworks - equity theory (Adams, 1965) and discrepancy theory (Lawler, 1971, 1981) have been proposed to explain the relationship between pay satisfaction and perceived fairness in the workplace. Both theories posit that perceptions of fairness and equity in payment are central to explaining employee pay satisfaction or dissatisfaction (Ruiz-Palomino et al., 2013). Equity theory assumes that employees seek to maintain an equitable ratio between the inputs they bring to the relationship and the outcomes they receive from it (Adams, 1965). Equity theory in business, however, introduces the concept of social comparison, whereby employees evaluate their own input/output ratios based on their comparison with the input/outcome ratios of other employees (Carrell & Dittrich, 1978; Dittrich & Carell, 1979). Discrepancy theory (Lawler, 1971, Lawler & Porter, 1967) posits that the levels of satisfaction, including pay satisfaction, are negatively correlated with the discrepancy between the actual, and expected, job satisfaction.

Several empirical studies have investigated the main factors that influence the level of employees' pay satisfaction. In a study based on data from two similar companies engaged in the manufacture of aircraft components and systems for the government and private industry, Shapiro (1976) was able to delineate four important antecedents of pay satisfaction: (1) Actual pay - how much actual money the individual receives, (2) Social comparisons - how the individual's pay compares with his or her perceptions of what others receive, (3) Scale of living — satisfactory pay must cover a worker's basic needs, and (4) Wage history - How much the individual was paid in the past. Shapiro and Wahba, (1978) found that actual pay, social comparison, wage history, status, performance and job difficulty, were the best predictors of pay satisfaction. A more recent study on the antecedents and consequences of pay level satisfaction, (Williams et al., 2006) reported results from a meta-analysis of 28 correlates of pay level satisfaction, involving 240 samples from 203 studies conducted over 35 years. The analysis main findings indicate that the strongest predictor of pay satisfaction is the discrepancy between perceived amount of pay that should be received, and the perceived amount of pay received. Yet in another comprehensive study it was found that the three types of psychological determinants which contributed most to predicting pay satisfaction were: equity considerations, actual pay, and living standards (Berkowitz et al., 1987).
2. The proposed model

The proposed model could be viewed as a conceptualization, in strategic formal terms, of ideas drawn from both equity and discrepancy theories (Adams, 1965; Lawler, 1971, 1981). With respect to the role of aspiration levels, despite different formalization, the proposed model, although interactive, holds resemblance to classical studies on aspiration levels in individual choice behavior (Hilgard et al., 1940; Lewin et al., 1944; Siegel, 1957; Simon, 1959), and to recent theories of level of aspiration in individual decision-making under risk (e.g., Lopes, 1987, Lopes, 1995; Lopes & Oden, 1999; Rieger, 2010).

In the context of allocation of profits between employers and employees, the present study asks: what is a fair salary? The strategy taken in the present study is to model a dyadic employer-employee interaction by a "minimal", two-person game, in which an allocator (e.g., an employer) must allocate a monetary amount (e.g., a workplace net profit), between himself or herself and a recipient (e.g., an employee). Assuming rational, self-interested players, the model posits that the players' payoff satisfaction levels are proportional to their actual payoffs, relative to their aspired payoffs. In formal terms, the level of satisfaction (LS) of an individual i, who is allocated \( x_i \) monetary units, when he or she had aspired for receiving \( A_i \) monetary units, is assumed to be a function of \( x_i/A_i \), or \( LS = F(x_i/A_i) \). For the "minimal" dyadic interaction described above, assume that the allocator keeps \( x_a \) units, out of \( S \) monetary units, and transfers \( x_r = S - x_a \) to the recipient. The levels of payoff satisfaction of the two players, as prescribed by the model will be \( LS_a = F_a(x_a/A_a) \) and \( LS_r = F_r(x_r/A_r) = F_r((S - x_a)/A_r) \), for the allocator and recipient, respectively, where \( A_a \) and \( A_r \) are the maximal aspired payoffs of the allocator and the recipient, respectively. For simplicity, assume linear relationships, such that \( LS_a = x_a/A_a \) and \( LS_r = x_r/A_r \).

The two players will be equally satisfied with their payoffs if \( LS_a = LS_r \), or:

\[
\frac{x_a}{A_a} = \frac{x_r}{A_r} = \frac{(S-x_a)}{A_r} \quad \text{...... (1)}
\]

Yielding:

\[
x_a = \frac{A_a}{A_a+A_r} S \quad \text{...... (2)}
\]
And

\[ x_r = S - \frac{A_a}{A_a + A_r} S = \frac{A_r}{A_a + A_r} S \] \hspace{1cm} \ldots \ldots (3)

Determining the allocation \((x_a, x_r)\), which guarantees a fair allocation - in the sense of equal levels of satisfaction - requires the assessment or measurement of the players' maximal aspirations. In the absence of any constraints put on the allocator's decision, the maximal aspired payoff by a rational allocator is the entire sum \(S\) (i.e., \(A_a = S\)). Hypothesizing about the recipient's maximal aspired payoff is trickier. We consider two plausible possibilities: 1. that the recipient might aspire to receive half of the net profit, or \(A_r = \frac{1}{2} S\), 2. that he or she might aspire to receive a sum that equals the sum that the allocator keeps for himself or herself. Although from first sight the two conjectures seem identical, they are not.

Under the first assumption we have \(A_a = S\) and \(A_r = \frac{1}{2} S\). Substitution in Equations 2 and 3 yields:

\[ x_a = \frac{A_a}{A_a + A_r} S = \frac{S}{S + \frac{1}{2} S} S = \frac{2}{3} S \] \hspace{1cm} \ldots \ldots (4)

And

\[ x_r = S - \frac{2}{3} S = \frac{1}{3} S \] \hspace{1cm} \ldots \ldots (5)

On the other hand, under the second assumption, we have \(A_a = S\) and \(A_r = x_a\). Substitution in Equations 2 and 3 yields:

\[ x_a = \frac{S}{S + x_a} S \] \hspace{1cm} \ldots \ldots (6)

Solving for \(x_a\) we get:

\[ x_a^2 + S x_a - S^2 = 0 \] \hspace{1cm} \ldots \ldots (7)

Whish solves for:

\[ x_a = \frac{-S \pm \sqrt{S^2 + 4S^2}}{2} = \frac{-1 \pm \sqrt{5}}{2} S \] \hspace{1cm} \ldots \ldots (8)

For positive \(x_a\) values we get:
\[ x_a = \frac{\sqrt{5} - 1}{2} S = \phi S \approx 0.62 S \] …… (9)

Where \( \phi \) is the famous Golden ratio (see e.g., Livio, 2002; Posamentier & Lehmann, 2007). The corresponding portion for the recipient is:

\[ x_r = (1 - \phi) S \approx 0.38 S \] …… (10)

In summary, the proposed model predicts that if the recipient aspires to receive 50% out of the total amount; the point of equal levels of payoff satisfaction is achieved by him or her receiving on third of the total amount. On the other hand, if the recipient aspires to be treated equally (i.e., \( A_r = x_a \)), then the point of equal levels of payoff satisfaction is achieved by him or her receiving a portion of \( 1 - \phi \approx 0.38 \) of the total amount. Since rational allocators will not allocate to recipients more than they allocate to themselves, the difference between the above two predictions falls within the ±5% error range. With the absence of any information about the fairness principle adhered by individuals, in accounting for empirical reports of mean pay satisfaction, the model predicts a mean allocation for the recipient in the range between \( \approx 0.33 \) and \( \approx 0.38 \) of the entire amount.

The solution prescribing a Golden Ratio division is quite striking, given the appearances of this algebraic number in many fields of science and the arts. I shall say more on the appearance of the golden ratio in the concluding section. It is also worth noting that none of the model's predictions of what constitutes fair allocations is a stable outcome. In the absence of binding rules (e.g., a minimum wage), or sanctions for allocating unfairly, rational allocators will strive to maximize their personal payoff. In game theoretical terms, the points of harmony, predicted by the model, are not in equilibrium. For a point of harmony to be stable, it must be supported by an external mechanism, such as an institutional or social sanctioning mechanism (see e.g. Fehr & Fischbacher, 2004; Samid & Suleiman, 2008; O’Gorman et al. 2009).

3. Comparison with empirical findings
Tests of the model, whether in the workplace or in experimental settings, requires a reliable assessment of the interacting parties aspiration levels. In the present papers I tested the model's predictions using data from studies in which measurements of aspiration levels were not conducted. Consequently, the model was tested under the rationality assumption, prescribing that the levels of aspired payoffs by the allocator
and the recipient are $A_a = S$ and $A_r = \frac{1}{2} S$, or $x_a$. The following subsections detail tests of the model's predictions using data from field and experimental studies.

3.1 Field Study 1: Perceptions of pay fairness by executives and secretaries

In a classical questionnaire-based field study, Zedek & Cain Smith (1968) investigated the pay satisfaction of male junior executives (Group I), female secretaries in the maintenance department (Group II), and in the executive department (Group III), in a large academic institution in the United State. To determine the upper and lower thresholds of the perceived equitable payment, and the "just meaningful difference" (jmd) of payment (analogous to the jnd in psychophysical measurement), the study used an adaptation of the Method of Limits (Woodworth & Schlosberg, 1954) for determining the points of subjective equity (PSE) and the jmd. The main results of the study are depicted in Table 1.

| Table 1 |

| Mean perceived fair salaries by executives and secretaries |
| (adopted from Zedek & Cain Smith, 1977) |

<table>
<thead>
<tr>
<th>Group</th>
<th>&lt; Fair (PSE ± jmd)</th>
<th>Equitable (PSE ± jmd)</th>
<th>&gt; Fair</th>
</tr>
</thead>
<tbody>
<tr>
<td>Junior executives</td>
<td>7008.00</td>
<td>7008.00 - 8832.00</td>
<td>8832.00</td>
</tr>
<tr>
<td>Secretaries</td>
<td>3578.58</td>
<td>3576.58 - 4050.00</td>
<td>4050.00</td>
</tr>
<tr>
<td>Group II</td>
<td>3278.58</td>
<td>3278.58 - 3870.00</td>
<td>3870.00</td>
</tr>
<tr>
<td>Group III</td>
<td>3722.73</td>
<td>3722.73 - 4115.45</td>
<td>4115.45</td>
</tr>
</tbody>
</table>

Calculation of the average perceived fair salary by the executives group, and the secretaries group, yields $\frac{1}{2} (7008+ 8832) \approx 7920$ for the executives, and $\frac{1}{2} (3676+ 4050) \approx 3813$ for the secretaries. Given the type of relationship between executives and secretaries, it makes sense to view the executives as "employers" and the secretaries as "employee". Calculating the secretaries' perceived fair pay, relative to the total pay gives: $\frac{3813}{(3813 + 7920)} \approx 0.33$, which is identical to the lower limit of the predicted range of fair pay.
3.2 Field Study 2: Salaries of senior and junior employee

I looked at actual mean salaries of senior and junior employee in two high-tech professions and two non-high-tech professions, from ten "developed" countries with high Gross National Income (GNI), and ten "developing" countries with low GNI, representing different cultures around the world. The high-tech professions were computer programmer and electrical engineer, and two non-high-tech (hereafter "low-tech") professions were: accountant and school teacher. The "developed" countries were: USA, England, Canada, Israel, Spain, New Zealand, Australia, Italy, Austria, and Japan, and the "developing" countries were: Pakistan, Jordan, Lebanon, Oman, India, Bahrain, Egypt, Saudi Arabia, Brazil, and Thailand. Table 2 depicts the average salaries and the ratios of the junior salary to the total salaries (junior salary/(junior salary + senior salary) ) in the sampled countries, by levels of country development (developed vs. developing), and profession type (high-tech vs. low-tech). Table 3 depicts the mean ratios (and standard deviations) for the tested categories, across the sampled countries (see also Figure 1). As could be seen from the tables and the figure, for developed countries, the average ratios of the juniors' salaries to the total salaries are almost the same for the high and low-tech professions (0.37), and are only slightly below the Golden Ratio prediction of 0.38. On the other hand, for the low-tech professions, the mean ratio of juniors' salaries is about 28% lower than the mean ratio of senior salaries, with both ratios falling below the predicted 0.33-0.38 fairness range.

Among the developing countries, Egypt is an outlier with a ratio of 0.19 for low-tech professions (which equals the mean ratio of developing countries), but with a more than fair ratio of 0.46 for the high-tech professions. Dropping Egypt from the sample yields means of 0.24 and 0.19, for the high and low-tech professions, respectively, with difference of 21% between the two. To compare the actual ratios in the various categories with the golden ratio prediction (≈ 0.38), I used a two One-Sided Test (TOST). A rule of thumb for testing equivalence using TOST is to set a confidence level at ±10%. For the developed countries, the equivalence between the observed and predicted proportions was statistically significant, t(19) = -2.65, p < .01, and t(19) = -1.95, p < .05, for the high- and low-tech professions, respectively. For developing countries the statistical test of equivalence were non- significant, t(19) = 2.71, and t(19) = 11.67, for the high- and low-tech professions, respectively.

3.3 Allocation decisions in ultimatum game experiments

As noted in the section 2, for a point of harmony to be stable, it must be supported by an external mechanism, such as an institutional or social sanctioning mechanism. In experimental economics, the effect of sanctions, whether by a second-party, third-party, or an institution, has been subjected to extensive investigation (e.g., Boyd & Richerson, 1992; Fehr, & Gächter, 2002; Fehr & Fischbacher, 2004; Henrich, et al. 2005; Samid & Suleiman, 2008; O’Gorman et al., 2009; Servátka, 2009; Baldassarria & Grossman, 2011). This line of research has shown, unequivocally, that the option of punishment, even though when it is costly and altruistic, is highly effective in enhancing cooperation and fairness in resource allocation games.

I tested the model's predictions using two large set of data on the ultimatum game: 1. A meta-analysis on 75 ultimatum game experiments conducted in twenty six
countries, with different cultural backgrounds (Oosterbeek, Sloof & Van de Kuilen, 2004). 2. A large cross-cultural study conducted in fifteen small-scale societies, including three groups of foragers, six groups of slash-and burn horticulturalists, four groups of nomadic herders, and two groups of small-scale agriculturalists (Henrich et al., 2005). In the ultimatum game (Güth, Schmittberger & Schwartze, 1982; Camerer & Thaler, 1995) one player, designated the role of allocator, receives an amount of monetary units and must decide how much to keep for herself and how much to transfer to another player (the recipient). The recipient replies either by accepting the proposed allocation, in which case both players receive their shares, or by rejecting the proposal, in which case the two players receive nothing. Thus, while the allocator has complete entitlement to make an allocation decision, the recipient can inflict a harsh, although costly, punishment on an unfair allocator. The ultimatum game has proven to be a potent workhorse for studying selfishness, fairness, cooperation, competition, and punishment (Kahneman, Knetsch & Thaler, 1986; Prasnikar & Roth, 1992; Suleiman, 1996; Camerer, 2003). Experimental findings of numerous UG ultimatum game studies show that the mean offers are about 40% and that offers of 20% or less are rejected with high probability (Camerer & Thaler, 1995; Suleiman, 1996; Camerer, 2003). The mean offer in the Oosterbeek et al. was ≈ 0.41 of the entire amount, and in the Henrich et al. study it was ≈ 0.39. Clearly, the two results are quite close to the Golden Ratio prediction (≈ 0.38). A two One-Sided Test (TOST) validates this conjecture. For the Oosterbeek, et al. study the analysis yielded significant results for the upper and lower bounds of the equivalence range (upper bound=42.016, p<0.0001; lower bound=34.377, p= 0.0425; overall significance= 0.0425). For the Henrich et al. study the results were also significant (upper bound= 42.016, p= 0.012; lower bound = 34.377, p = 0.0255; overall significance= 0.0255). Similar tests for the adequacies of the second prediction (2/3, 1/3) and of an equality model (1/2, 1/2) yielded insignificant results.

4. Summary and concluding remarks
Under assumptions of rationality and linearity of level of satisfaction functions, the present paper proposed a model for the division of net the profit between an employer and an employee. The model is based on the assumption that the parties' payoff satisfactions are proportional to their actual payoffs, relative to their aspired payoffs.
Depending on the assumption made about the recipient's aspiration, the model yields two numerical solutions, termed "harmony" points, at which the levels of pay satisfaction of the two parties are equal. Under the assumption that recipients aspire to receive 50% of the total amount, the predicted "harmony" pay for the employee is one third of the total amount to be allocated. On the other hand, assuming that the employee aspires to be treated equally, i.e., to receive the same amount as the employer, the predicted harmony pay is 1-φ ≈ 0.38 of the total amount, where φ ≈ 0.62 is the famous Golden Ratio.

Worth stressing that on the behavioral level, a point of harmony in pay satisfaction is not in equilibrium, unless it is supported by a social or institutional mechanism, like social and institutional sanctions. Such mechanisms has been proven effective in experimental studies on altruistic and non-altruistic punishment in public goods games (Fehr Gächter, 2002; Fehr & Fischbacher, 2004; O’Gorman et al., 2009), and in second and third party punishment in two-person ultimatum and dictator games (e.g., Henrich et al., 2005). Another effective mechanism for enhancing fairness and cooperation in similar games is reputation (Milinski et al., 2002; Servátka, 2009).

Further development of the model should account for the non-linearity in the individuals' perception of outcome fairness, reflected, among other things, in more sensitivity to underpayment than overpayment (Adams, 1963; Greenberg, 1988). Also, generalization of the model to account for perceptions and behaviors in multi-person interactions involving resource allocation, is yet another direction for future investigation.

The present analysis leaves out several individual and organizational, non-pay-related factors, such as the employee "voice", i.e., the opportunity to present an opinion in the decision making process (e.g., Lind et al., 1990; Tyler & Lind, 1992), and the employee level of engagement (e.g., Saks, 2006; Bakker & Demerouti, 2008; Shuck et al. 2011).

**The Golden Ratio as a point of harmony**

The appearance of the Golden Ratio as a point of harmony between the player's pay satisfaction levels, adds to several appearances of this algebraic number in the social sciences, including in human aesthetics (Green, 1995; Pittard et al., 2007), ethical judgment (Lefebvre, 1985), market behavior (Nikolic et al., 2011), and brain functioning (Weiss & Weiss, 2003; Roopun et al., 2008). A review of the role played
by the Golden Ratio in all fields of science and the arts is beyond the scope of this paper. A very short list includes biology (e.g., Klar, 2002), chemistry (e.g., Shechtman et al, 1984), physics (e.g., Coldea et al., 2010; Suleiman, 2013), brain science (e.g., Weiss & Weiss, 2003; Conte et al., 2009; Roopun et al., 2008), aesthetics and the arts (Pittard et al., 2007; Hammel & Vaughan, 1995, Livio, 2002; Olsen, 2006). It is not implausible to conjecture that the role of the Golden Ratio in human cognition and behavior has deep evolutionary roots, in earlier times in the evolution of our universe, even before the evolution of life. Aside from its contributing to the demystification and secularization of the Golden Ratio, such perspective could generate some interesting testable hypotheses. As example, one might hypothesize that humans' psychophysiological responses to receiving fair offers in a resource allocation game, will be similar to responses aroused by visual or auditory stimuli, characterized by Golden Ratio symmetries. In fact, a similar, although opposite hypotheses, was recently confirmed by Chapman et al. (2009). In a study published in Science, the authors demonstrating that photographs of disgusting contaminates, and receiving unfair offers, evoked similar activation of muscle region of the face characteristic of an oral-nasal rejection response.

Going back to the opening question: What is a fair salary?, the present paper suggests that it is any percentage out of the entire resource, in the range 33% to 38%, but with high preference to the upper limit, since it is not only fair and yields higher pay satisfaction to the employee, but also more aesthetically pleasing.
