Riemann Hypothesis
An Original Approach: A Ratio Method

Abstract

The simplest solution is usually the best solution---Albert Einstein

A Breath of Fresh Air

Assuming the sum of the original Riemann series is $L$, a ratio method was used to split-up the series equation into sub-equations and each sub-equation was solved in terms of $L$, and ratio terms. It is to be noted that unquestionably, each term of the series equation contributes to the sum, $L$, of the series. There are infinitely many sub-equations and solutions corresponding to the infinitely many terms of the series equation. After the sum, $L$, and the ratio terms have been determined and substituted in the corresponding equations, the Riemann hypothesis would surely be either proved or disproved, since the original equation is being solved. Solving the original series equation eliminates possible hidden flaws in derived equations and consequent solutions.
Preliminaries
Here, one covers examples to illustrate the mathematical validity of how one splits up the series equation to form sub-equations.

Let one think like a child - Albert Einstein. Actually, one can think like an eighth or a ninth grader. Suppose one performs the following operations:

Example 1: \(10 + 20 + 25 = 55\) \hspace{1cm} (1)
\[
10 = 55 \times \frac{10}{55} = 55 \times \frac{2}{11} \hspace{1cm} (2)
\]
\[
20 = 55 \times \frac{20}{55} = 55 \times \frac{4}{11} \hspace{1cm} (3)
\]
\[
25 = 55 \times \frac{25}{55} = 55 \times \frac{5}{11} \hspace{1cm} (4)
\]
Equations (2), (3), and (4) can be written as follows:
\[
10 = 55a \hspace{1cm} (5)
\]
\[
20 = 55b \hspace{1cm} (6)
\]
\[
25 = 55c \hspace{1cm} (7)
\]
One will call \(a, b\) and \(c\) ratio terms.

One is dividing 55 between 10, 20, and 25 in the ratio \(a:b:c\).

Above, \(a = \frac{2}{11}, b = \frac{4}{11}, c = \frac{5}{11}\). Observe also that \(a + b + c = 1\) \(\left(\frac{2}{11} + \frac{4}{11} + \frac{5}{11} = \frac{11}{11} = 1\right)\)

One can conclude that the sum of the ratio terms is always 1.

Example 2: Solve the quadratic equation; \(6x^2 + 11x - 10 = 0\).

Method 1 (a common and straightforward method)
By factoring, \(6x^2 + 11x - 10 = 0\) and solving,
\[
3x - 2)(2x + 5) = 0 \hspace{1cm} (3x - 2) = 0 \hspace{1cm} or \hspace{1cm} (2x + 5) = 0
\]
\[
x = \frac{2}{3}, x = -\frac{5}{2}. \hspace{1cm} Solution \set: \{-\frac{5}{2}, \frac{2}{3}\}
\]

Method 2: One applies a ratio method.

Step 1: From \(6x^2 + 11x - 10 = 0\) \hspace{1cm} (1)
\[
6x^2 + 11x = 10 \hspace{1cm} (6x^2 + 11x) = 10
\]
\[
3x^2 = 5a \hspace{1cm} (2)
\]
\[
11x = 10b \hspace{1cm} (Here, \hspace{1cm} b \hspace{1cm} is \hspace{1cm} a \hspace{1cm} ratio \hspace{1cm} term)
\]
\[
11x = 10(1 - a) \hspace{1cm} \hspace{1cm} (a + b) = 1
\]
\[
11x = 10 - 10a
\]
\[
x = \frac{10 - 10a}{11}
\]
\[
3(\frac{10 - 10a}{11})^2 = 5a \hspace{1cm} (Substituting \hspace{1cm} for \hspace{1cm} x \hspace{1cm} in \hspace{1cm} (2)
\]
\[
3(\frac{100 - 200a + 100a^2}{121}) = 5a
\]

Step 2: \(300a^2 - 1205a + 300 = 0\)
\[
60a^2 - 241a + 60 = 0
\]
\[
a = \frac{241 \pm \sqrt{241^2 - 4(60)(60)}}{120}
\]
\[
a = \frac{241 \pm \sqrt{43681}}{120}
\]
\[
a = \frac{241 \pm 209}{120}
\]
\[
a = \frac{241 + 209}{120} = \frac{241}{120} + \frac{209}{120} \hspace{1cm} or \hspace{1cm} \frac{241 - 209}{120}
\]
\[
= \frac{450}{120} \hspace{1cm} or \hspace{1cm} \frac{32}{120}
\]
\[
= \frac{15}{4} \hspace{1cm} or \hspace{1cm} \frac{4}{15}
\]
Step 3: Since \(a + b = 1\), when \(a = \frac{15}{4}\) or \(3 \frac{3}{4}\). When \(a = \frac{4}{15}\), \(b = 1 - \frac{4}{15} = \frac{11}{15}\).

Step 4: When \(b = -\frac{11}{15}\), \(11x = 10(\frac{11}{15})\) \(x = -\frac{5}{2}\);

When \(b = 1\), \(11x = 10\) \(x = \frac{10}{11}\); \(x = \frac{2}{3}\).

Again, one obtains the same solution set \(\{-\frac{5}{2}, \frac{2}{3}\}\) as by the factoring method.

In the above problem, one could say that if \(6x^2\) and \(11x\) are in the ratio \(a : b\) and the sum of \(6x^2\) and \(11x\) is 10, then \(6x^2 = 10a\) and \(11x = 10b\). (Divide 10 between \(6x^2\) and \(11x\) in the ratio \(a : b\)).

Also, finding the zeros of \(f(x) = 6x^2 + 11x - 10\) is equivalent to solving \(6x^2 + 11x = 10\) for \(x\).

Example 3: A grandmother left $45,000 in her will to be divided between eight grandchildren, Betsy, Comfort, Elaine, Ingrid, Elizabeth, Maureen, Ramona, Marilyn, in the ratio \(\frac{1}{36} : \frac{1}{18} : \frac{1}{12} : \frac{1}{9} : \frac{1}{7} : \frac{5}{36} : \frac{1}{6} : \frac{7}{36} : \frac{2}{9}\). (Note: \(\frac{1}{36} + \frac{1}{18} + \frac{1}{12} + \frac{1}{9} + \frac{1}{7} + \frac{5}{36} + \frac{1}{6} + \frac{7}{36} + \frac{2}{9} = 1\))

How much does each receive?

Solution:

Betsy's share of $45,000 \(= \frac{1}{36} \times 45,000 = $1,250\)

Comfort's share of $45,000 \(= \frac{1}{18} \times 45,000 = $2,500\)

Elaine's share of $45,000 \(= \frac{1}{12} \times 45,000 = $3,750\)

Ingrid's share of $45,000 \(= \frac{1}{9} \times 45,000 = $5,000\)

Elizabeth's share of $45,000 \(= \frac{5}{36} \times 45,000 = $6,250\)

Maureen's share of $45,000 \(= \frac{1}{6} \times 45,000 = $7,500\)

Ramona's share of $45,000 \(= \frac{7}{36} \times 45,000 = $8,750\)

Marilyn's share of $45,000 \(= \frac{2}{9} \times 45,000 = $10,000\)

Check: Sum of shares \(= $45,000\)
Sum of the fractions \(= 1\)

Example 4: The returns on investments A, B, C, D are in the ratio \(a : b : c : d\). If the total return on these four investments is \(P\) dollars, what is the return on each of these investments?

\((a + b + c + d = 1)\)

Solution Return on investment \(A = aP\) dollars
Return on investment \(B = bP\) dollars
Return on investment \(C = cP\) dollars
Return on investment \(D = dP\) dollars

Check: \(aP + bP + cP + dP = P\)
\(P(a + b + c + d) = P\)
\(a + b + c + d = 1\) \((\text{dividing both sides by } P)\)
Example 5: The returns on investments \( \frac{1}{2z}, \frac{1}{3z}, \frac{1}{4z}, \frac{1}{5z} \), are in the ratio \( \lambda_2 : \lambda_3 : \lambda_4 : \lambda_5 \).

If the total return on these four investments is \( L \), what is the return on each of these investments? \( (\lambda_2 + \lambda_3 + \lambda_4 + \lambda_5 = 1) \).

Solution

Return on investment \( \frac{1}{2z} = \lambda_2 L \)

Return on investment \( \frac{1}{3z} = \lambda_3 L \)

Return on investment \( \frac{1}{4z} = \lambda_4 L \)

Return on investment \( \frac{1}{5z} = \lambda_5 L \)

Check:

\[ \lambda_2 L + \lambda_3 L + \lambda_4 L + \lambda_5 L = L \]

\[ L(\lambda_2 + \lambda_3 + \lambda_4 + \lambda_5) = L \]

\[ (\lambda_2 + \lambda_3 + \lambda_4 + \lambda_5 = 1) \] (dividing both sides by \( L \))

Example 6: Sir Isaac Newton left \( \rho g_s \) units in his will to be divided between \( -\mu \frac{\partial^2 V_x}{\partial x^2}, -\mu \frac{\partial^2 V_x}{\partial y^2}, -\mu \frac{\partial^2 V_x}{\partial z^2}, \rho \frac{\partial V_x}{\partial x}, \rho V_x \frac{\partial V_x}{\partial x}, \rho V_x \frac{\partial V_x}{\partial y}, \rho V_x \frac{\partial V_x}{\partial z} \) in the ratio \( a : b : c : d : f : h : m : n \).

where \( a + b + c + d + f + h + m + n = 1 \). How much does each receive?

Solution

\( -\mu \frac{\partial^2 V_x}{\partial x^2} \)'s share of \( \rho g_s \) units = \( a\rho g_s \) units

\( -\mu \frac{\partial^2 V_x}{\partial y^2} \)'s share of \( \rho g_s \) units = \( b\rho g_s \) units

\( -\mu \frac{\partial^2 V_x}{\partial z^2} \)'s share of \( \rho g_s \) units = \( c\rho g_s \) units

\( \rho \frac{\partial V_x}{\partial x} \)'s share of \( \rho g_s \) units = \( d\rho g_s \) units

\( \rho V_x \frac{\partial V_x}{\partial x} \)'s share of \( \rho g_s \) units = \( f\rho g_s \) units

\( \rho V_x \frac{\partial V_x}{\partial y} \)'s share of \( \rho g_s \) units = \( h\rho g_s \) units

\( \rho V_x \frac{\partial V_x}{\partial z} \)'s share of \( \rho g_s \) units = \( m\rho g_s \) units

\( \rho V_z \frac{\partial V_x}{\partial z} \)'s share of \( \rho g_s \) units = \( n\rho g_s \) units

Sum of shares = \( \rho g_s \) units  Note: \( a + b + c + d + f + h + m + n = 1 \)
Example 7: Professor Bernhard Riemann left the sum, $L$, of the convergent series,
$$\sum_{n=1}^{\infty} \frac{1}{n^z}$$
in his will to be divided between the terms, $\frac{1}{2^z}, \frac{1}{3^z}, \frac{1}{4^z}, \frac{1}{5^z}, \ldots$ of the series in the ratio $\lambda_2 : \lambda_3 : \lambda_4 : \lambda_5 : \ldots$ where the sum of the $\lambda$’s equals 1.

How much does each term receive?

Solution
- $\frac{1}{2^z}$’s share of $L = \lambda_2 L$
- $\frac{1}{3^z}$’s share of $L = \lambda_3 L$
- $\frac{1}{4^z}$’s share of $L = \lambda_4 L$
- $\frac{1}{5^z}$’s share of $L = \lambda_5 L$

........................................

Sum of the terms = $L$  Note: The sum of the $\lambda$’s equals 1.

The objective of presenting examples 1, 2, 3, 4, 5, and 6 was to convince the reader that the principles to be used in splitting the terms of the convergent Riemann series, are valid.

In Example 2, one could have used the quadratic formula directly to solve for $x$, without finding $a$ and $b$ first. The objective was to convince the reader that the introduction of $a$ and $b$ did not change the solution set of the original equation.

Nota bene
1. Finding the zeros of $f(x) = 6x^2 + 11x - 10$ is equivalent to solving $6x^2 + 11x = 10$ for $x$.
   
   (Note: $f(x) = 6x^2 + 11x - 10 = 0$)

2. Similarly, finding the zeros of $f(z) = \sum_{n=1}^{\infty} \frac{1}{n^z} = \frac{1}{1^z} + \frac{1}{2^z} + \frac{1}{3^z} + \ldots$ is equivalent to solving $\sum_{n=1}^{\infty} \frac{1}{n^z} = \frac{1}{1^z} + \frac{1}{2^z} + \frac{1}{3^z} + \ldots = L$ for $z$, where $L$ is the sum of the series.

   (Note: $\sum_{n=1}^{\infty} \frac{1}{n^z} - L = \frac{1}{1^z} + \frac{1}{2^z} + \frac{1}{3^z} + \ldots - L = 0$)
**Riemann Hypothesis**

**An Original Approach: A Ratio Method**

**Given:**
\[ f(z) = \sum_{n=1}^{\infty} \frac{1}{n^z} = \frac{1}{1^z} + \frac{1}{2^z} + \frac{1}{3^z} + \ldots \quad \text{Re}(z) = x > 1 \]
\[ z = x + iy \]

**Required:** To find the zeros of \( f(z) \).

**Plan:** One will assume the sum of the above series is \( L \), and equivalently solve \[ \sum_{n=1}^{\infty} \frac{1}{n^z} = \frac{1}{1^z} + \frac{1}{2^z} + \frac{1}{3^z} + \ldots = L \] for \( z \), where \( L \) is the sum of the series.

One will split-up the series equation to form sub-equations using ratio terms and then solve for \( z \).

Let the sum, \( L \), of the convergent series be divided between the terms, \( \frac{1}{2^z}, \frac{1}{3^z}, \frac{1}{4^z}, \frac{1}{5^z}, \ldots \) of the series in the ratio \( \lambda_2 : \lambda_3 : \lambda_4 : \lambda_5, \ldots \) where the sum of the \( \lambda \)'s equals 1.

Two types of ratio terms will be used, namely, primary ratio terms and secondary ratio terms. The primary ratio terms will be symbolized by \( \lambda \)'s, and the secondary ratio terms will be symbolized by \( \beta \)'s.

(Note that unquestionably, each term of the series contributes to the sum, \( L \), of the series.) Each sub-equation from the series yields a relation, and the relations for which \( \text{Re}(z) = x > 1 \) will be accepted as solutions. From the terms of the series and the ratio terms, one obtains the following sub-equations which are for the first four terms, skipping \( n = 1 \). There are infinitely many sub-equations and solutions corresponding to the infinitely many terms of the series.

1. \( \frac{1}{2^z} = \lambda_2 L \)
2. \( \frac{1}{3^z} = \lambda_3 L \)
3. \( \frac{1}{4^z} = \lambda_4 L \)
4. \( \frac{1}{5^z} = \lambda_5 L \)  (\( \lambda_2, \lambda_3, \lambda_4 \) and \( \lambda_5 \) are ratio terms)

### Solutions of the Sub-equations

**Case 1:** For \( n = 2 \), \( \frac{1}{2^z} = \lambda_2 L \)

**Step 1:**
Let \( \sum_{n=1}^{\infty} \frac{1}{n^z} \) converge to the limit \( L \).

Then \[ \frac{1}{2^z} = \lambda_2 L \ (\lambda_2 \text{ is a ratio term}) \]
\[ 2^{-z} = \lambda_2 L \]
\[ \log 2^{-z} = \log \lambda_2 L \]
\[ -z \log 2 = \log \lambda_2 L \]
\[ z \log 2 = -\log \lambda_2 L \]
\[ z = -\frac{\log \lambda_2 L}{\log 2} \]

**Step 2:**
\[ z = x + iy = -\frac{\log \lambda_2 L}{\log 2} \]
\[ x = -\beta_2 \frac{\log \lambda_2 L}{\log 2} \ (\beta_2 \text{ is a secondary ratio term}) \]
\[ iy = -\beta_3 \frac{\log \lambda_2 L}{\log 2} \ (\beta_3 \text{ is a secondary ratio term}) \]
\[ (\beta_2 + \beta_3 = 1) \]
\[ y = i\beta_3 \frac{\log \lambda_2 L}{\log 2} \]

**Step 3:** Determine the sum \( L \) of the series; determine \( \lambda_2, \beta_2, \beta_3 \) and substitute.

To be continued.
Case 2: For $n = 3, \frac{1}{3^{z}} = \lambda_{3}L$

**Step 1:**

Let $\sum_{n=1}^{\infty} \frac{1}{n^{z}}$ converge to the limit $L$.

Then $\frac{1}{3^{z}} = \lambda_{3}L$ ($\lambda_{3}$ is a ratio term)

$3^{-z} = \lambda_{3}L$

$\log 3^{-z} = \log \lambda_{3}L$

$-z \log 3 = \log \lambda_{3}L$

$z \log 3 = -\log \lambda_{3}L$

$z = -\frac{\log \lambda_{3}L}{\log 3}$

**Step 2:**

$z = x + iy = -\frac{\log \lambda_{3}L}{\log 3}$

$x = -\beta_{4} \frac{\log \lambda_{3}L}{\log 3}$ ($\beta_{4}$ is a secondary ratio term)

$iy = -\beta_{5} \frac{\log \lambda_{3}L}{\log 3}$ ($\beta_{5}$ is a secondary ratio term)

($\beta_{4} + \beta_{5} = 1$)

$y = i\beta_{5} \frac{\log \lambda_{3}L}{\log 3}$

**Step 3**

Determine $\lambda_{3}, \beta_{4}, \beta_{5}$ and substitute. (Also substitute for $L$ from Case 1)

To be continued.

---

Case 3: For $n = 4, \frac{1}{4^{z}} = \lambda_{4}L$

**Step 1:**

Let $\sum_{n=1}^{\infty} \frac{1}{n^{z}}$ converge to the limit $L$.

Then $\frac{1}{4^{z}} = \lambda_{4}L$ ($\lambda_{4}$ is a ratio term)

$4^{-z} = \lambda_{4}L$

$\log 4^{-z} = \log \lambda_{4}L$

$-z \log 4 = \log \lambda_{4}L$

$z \log 4 = -\log \lambda_{4}L$

$z = -\frac{\log \lambda_{4}L}{\log 4}$

**Step 2:**

$z = x + iy = -\frac{\log \lambda_{4}L}{\log 4}$

$x = -\beta_{6} \frac{\log \lambda_{4}L}{\log 4}$ ($\beta_{6}$ is a secondary ratio term)

$iy = -\beta_{7} \frac{\log \lambda_{4}L}{\log 4}$ ($\beta_{7}$ is a secondary ratio term)

($\beta_{6} + \beta_{7} = 1$)

$y = i\beta_{7} \frac{\log \lambda_{4}L}{\log 4}$

**Step 3**

Determine $\lambda_{4}, \beta_{6}, \beta_{7}$ and substitute. (Also substitute for $L$ from Case 1)

To be continued.
**Case 4:** For \( n = 5 \), \( \frac{1}{5^z} = \lambda_5 L \)

**Step 1:**
Let \( \sum_{n=1}^{\infty} \frac{1}{n^z} \) converge to the limit \( L \).
Then \( \frac{1}{5^z} = \lambda_5 L \) (\( \lambda_5 \) is a ratio term)
\[
5^{-z} = \lambda_5 L \\
\log 5^{-z} = \log \lambda_5 L \\
-\log 5 = \log \lambda_5 L \\
z = -\frac{\log \lambda_5 L}{\log 5}
\]

**Step 2:**
\[
z = x + iy = -\frac{\log \lambda_5 L}{\log 5} \\
x = -\beta_8 \frac{\log \lambda_5 L}{\log 5} \quad (\beta_8 \text{ is a secondary ratio term}) \\
iy = -\beta_9 \frac{\log \lambda_5 L}{\log 5} \quad (\beta_9 \text{ is a secondary ratio term}) \\
(\beta_8 + \beta_9 = 1) \\
y = i\beta_9 \frac{\log \lambda_5 L}{\log 5}
\]

**Step 3**
Determine \( \lambda_5, \beta_8, \beta_9 \) and substitute. (Also substitute for \( L \) from Case 1)
To be continued.

**Other solutions**
Similarly, as in cases 1-4, one can continue solving the sub-equations from the series for \( n = 6 \), and so on. There will be infinitely many solutions.

**General Case:** \( \frac{1}{n^z} = \lambda_n L \)

**Step 1:**
Let \( \sum_{n=1}^{\infty} \frac{1}{n^z} \) converge to the limit \( L \).
Then \( \frac{1}{n^z} = \lambda_n L \) (\( \lambda_n \) is a ratio term)
\[
n^{-z} = \lambda_n L \\
\log n^{-z} = \log \lambda_n L \\
-\log n = \log \lambda_n L \\
z = -\frac{\log \lambda_n L}{\log n}
\]

**Step 2:**
\[
z = x + iy = -\frac{\log \lambda_n L}{\log n} \\
x = -\beta_{2n-2} \frac{\log \lambda_n L}{\log n} \quad (\beta_{2n-2} \text{ is a secondary ratio term}) \\
iy = -\beta_{2n-1} \frac{\log \lambda_n L}{\log n} \quad (\beta_{2n-1} \text{ is a secondary ratio term}) \\
(\beta_{2n-2} + \beta_{2n-1} = 1) \\
y = i\beta_{2n-1} \frac{\log \lambda_n L}{\log n}
\]

**Step 3**
Determine \( \lambda_n, \beta_{2n-2}, \beta_{2n-1} \) and substitute. (Also substitute for \( L \) from Case 1)
To be continued.
Case Extra: For \( n = 10^{12} \), \( \frac{1}{10^{12}} = \lambda_{10^{12}} L \)

**Step 1:**
Let \( \sum_{n=1}^{\infty} \frac{1}{n^z} \) converge to the limit \( L \).

Then \( \frac{1}{10^{12}} = \lambda_{10^{12}} L \) (\( \lambda_{10^{12}} \) is a ratio term)
- \( 10^{-12}z = \lambda_{10^{12}} L \)
- \( \log 10^{-12}z = \log \lambda_{10^{12}} L \)
- \( -12z \log 10 = \log \lambda_{10^{12}} L \)
- \( z = -\frac{\log \lambda_{10^{12}} L}{12 \log 10} \)

**Step 2:**
\( z = x + iy = -\frac{\log \lambda_{10^{12}} L}{12 \log 10} \)

\( x = -\beta_{2(10^{12})-2} \frac{\log \lambda_{10^{12}} L}{12 \log 10} \) (\( \beta_{2(10^{12})-2} \) is a ratio term)
- \( iy = -\beta_{2(10^{12})-1} \frac{\log \lambda_{10^{12}} L}{12 \log 10} \) (\( \beta_{2(10^{12})-1} \) is a ratio term)
- \( (\beta_{2(10^{12})-2} + \beta_{2(10^{12})-1} = 1) \)
- \( y = i\beta_{2(10^{12})-1} \frac{\log \lambda_{10^{12}} L}{12 \log 10} \)

**Step 3**
Determine \( \lambda_{10^{12}}, \beta_{10^{12}}, \beta_{10^{12}+1} \) and substitute. (Also substitute for \( L \) from Case 1)
To be continued.

**Summary for the First Four Solutions** \((n = 2, 3, 4, 5)\)

\[
\begin{bmatrix}
  x = -\beta_2 \frac{\log \lambda_2 L}{\log 2} \\
  y = i\beta_3 \frac{\log \lambda_2 L}{\log 2}
\end{bmatrix}
\]

(\( \beta_2 \) is a secondary ratio term)

\[
\begin{bmatrix}
  x = -\beta_4 \frac{\log \lambda_3 L}{\log 3} \\
  y = i\beta_5 \frac{\log \lambda_3 L}{\log 3}
\end{bmatrix}
\]

(\( \beta_4 \) is a secondary ratio term)

\[
\begin{bmatrix}
  x = -\beta_6 \frac{\log \lambda_4 L}{\log 4} \\
  y = i\beta_7 \frac{\log \lambda_4 L}{\log 4}
\end{bmatrix}
\]

(\( \beta_6 \) is a secondary ratio term)

\[
\begin{bmatrix}
  x = -\beta_8 \frac{\log \lambda_5 L}{\log 5} \\
  y = i\beta_9 \frac{\log \lambda_5 L}{\log 5}
\end{bmatrix}
\]

(\( \beta_8 \) is a secondary ratio term)

Observation of the above solutions shows that for the real parts to be equal,

\( \beta_2 (\log \lambda_2 L)(\log 3) = \beta_4 (\log \lambda_3 L)(\log 2) \) \( (\text{for } n = 2, 3) \)
To be continued.
