An algorithm for general solution of Monkey and Coconut problem

Prem Kumar
mynamesprem@gmail.com

Abstract: In this paper I discuss an algorithm which will solve a very famous puzzle involving a monkey, few men and some coconuts. The puzzle involves a group of \( n \) men who have an unknown amount of coconuts among them. At night, while the others are asleep, one of the men divides the coconuts in \( n \) parts and hides his share. While dividing, he discovers that there is one extra coconut, which he gives away to a monkey. Exactly the same thing happens with the rest of the men, one by one. They all hide their share, are left with one extra coconut that cannot be divided, which they give to the monkey. The next morning they again divide the coconuts together equally among themselves, with no extra coconut remaining this time. The puzzle is to find out the initial number of coconuts.

Index Terms— Algorithm, Puzzle, Number Theory

I. INTRODUCTION

The difficulty of this puzzle is computational in nature. This question can be reduced to finding the solution of a simple equation, which is,

\[
\frac{an + b}{c} = x \quad \text{... (1)}
\]

Here \( a, b, c, n \) and \( x \) are integers. Also, the values of \( a, b \) and \( c \) are known. Here \( x \) denotes the initial number of coconuts. The problem is to find an integral value of \( n \) for which \( x \) is also an integer. The calculative difficulty in this problem is caused by large values of \( a, b \) and \( c \).

Please note that infinitely many solutions of the equation (1) are possible.

II. THE ALGORITHM

Here is the algorithm:

Let \( a = (g_1.c) - h_1 \),

Here \( g_1 \in N \) and \( 0 < h_1 < c \)

Similarly, let \( a = (g_2.h_1) - h_2 \)

Here \( g_2 \in N \) and \( 0 < h_2 \leq h_1 \)

\[ \vdots \]

Let, \( a = (g_i.h_{i-1}) - h_i \)

Here \( g_i \in N \) and \( h_i = 0 \)

Now, let,

\[
b = p_0.c + p_1.h_1 + p_2.h_2 + \cdots + p_{i-1}.h_{i-1} \quad \text{... (2)}
\]
Here $A = \{p_0, p_1, \ldots, p_{i-1}\} \subseteq Z$. Note that there exist infinitely many sets $A$ satisfying the above equation since there exist infinitely many solution to our question, but it is a simple procedure to find the simpler ones.

Now,

$$x = p_0 + p_1 \cdot g_1 + p_1 \cdot g_1 \cdot g_2 + \cdots + p_{i-1} \cdot g_1 \cdot g_2 \ldots g_{i-1}$$

$$\ldots (3)$$

Hence, we have arrived at an expression for the number of coconuts in our puzzle.

Now, I will like to prove that there exists at least one set $A$ satisfying equation (2). We can do this in following manner:

Theorem 1: Given two distinct integers $x$ and $y$, where both $x$ and $y$ are not simultaneously even, then all other integers $n \in Z$ can be expressed as $n = ax + by$, where $a, b \in Z$.

Theorem 2: Given two distinct even integers $x$ and $y$, all other even integers $n$ can be expressed as $n = ax + by$, where $a, b \in Z$.

Now, there can be total 4 cases in our situation:

1. $a$ is odd
   1.1. $c$ is even $\Rightarrow h_1$ is odd.
   1.2. $c$ is odd $\Rightarrow h_1$ is even.

2. $a$ is even
   2.1. $c$ is even $\Rightarrow b$ is even $\Rightarrow h_1$ is even $\ldots (4)$
       Reason: If $a$ and $c$ are even and $b$ is odd then $\frac{an+b}{c}$ cannot be integer.
   2.2. $c$ is odd $\Rightarrow h_1$ is odd.

Now, $b$ can be expressed as,

$$b = p_0 \cdot c + p_1 \cdot h_1$$

$$\ldots (5)$$

According to theorem 1 and 2, if $c$ and $h_1$ are both even then they cannot satisfy equation (5) for all integral values of $b$. But from consideration (4), we know that for every even values of $c$ and $h_1$, the value of $b$ is also even.

Hence, we deduce that we can always find a set $A = \{p_0, p_1, \ldots, p_{i-1}\}$ such that $A$ satisfies equation (2). Hence, it is proved.

III. VERIFICATION

Let us assume, for simplicity, a situation in which there are just three men in our original question. Let us assume that initially there exist $x$ coconuts. Also, let the number of coconuts hidden by the first, the second and the third man be $j, k$ and $l$ respectively. Let the number of coconuts they finally receive after sharing it equally the next morning be $m$. Then:

$$x = 3j + 1$$

$$2j = 3k + 1$$

$$2k = 3l + 1$$

$$2l = 3m$$

After expressing $x$ in terms of $m$, we get:

$$x = \frac{81m + 38}{8} \ldots (6)$$

Equation (6) is of the same form as equation (1), as I have mentioned earlier.

Now, applying the algorithm to this situation:

Here, $a = 81$, $b = 38$ and $c = 8$.

Now,

1. $81 = 8 \times 11 - 7$
2. $81 = 7 \times 12 - 3$
3. $81 = 3 \times 27 - 0$

Hence, $g_1 = 11, g_2 = 12, g_3 = 27, h_1 = 7, h_2 = 3$ and $h_3 = 0$

Now, $b$ can be expressed as:

$$b = 38 = 5 \times h_1 + 1 \times h_2$$

Hence, $p_1 = 5$ and $p_2 = 1$.

Now, solving for $x$ using equation (3),

$$x = p_0 + p_1 \cdot g_1 + p_1 \cdot g_1 \cdot g_2 + \cdots + p_{i-1} \cdot g_1 \cdot g_2 \ldots g_{i-1}$$

$$= 5 \times 11 + 1 \times 11 \times 12$$

$$= 187$$

Putting the value of $x = 187$ in equation...(6), we find that it indeed gives an integral value for $m = 18$. Hence, our algorithm is verified!

Note that in this situation, $b$ can also be expressed as:

$$b = 4 \times c + 2 \times h_2$$

Which will give $x = 268$. This value is slightly larger than the previous one, yet correct. In fact, one has to creatively think of ways to express $b$ in different manners and one will get infinitely many values of $x$.

ACKNOWLEDGMENT

The Author thanks the readers for going through this paper.
