#### Abstract

In a $p$-sequence, every term is the sum of $p$ previous terms given $p$ initial values called seeds. It is an extension of the Fibonacci sequence. In this article, we investigate the $p$-golden ratio of $p$-sequences. We express a positive integer power of the $p$-golden ratio as a polynomial of degree $p-1$, and obtain values of golden angles for different $p$-golden ratios. We also consider further generalizations of the golden ratio.

## 1 Introduction

The Fibonacci sequence is a series of numbers, starting from 0 and 1 , where every number is the sum of two previous numbers. It is named after the Italian mathematician Fibonacci who introduced it to the Western world in his book Liber Abaci in 1202. The ratio of two consecutive Fibonacci numbers approaches the golden ratio $\Phi=1.618$. The Fibonacci numbers and the golden ratio are central concepts in modern mathematics. The golden ratio together with the Fibonacci numbers is often called the nature's code because it is observed in several natural phenomena. See, e.g., [1-13], and the references given therein for the theory of Fibonacci numbers and the golden ratio.

In this article, we present golden ratio $\left(\Phi_{p}\right)$ and golden angle $\left(\theta_{g}(p)\right)$ associated with $p$-sequences, and consider other generalizations of golden ratio.

## $2 p$-golden ratio

The golden ratio is one of the most famous numbers. Given $a$ and $b(<a)$ two positive numbers, the golden ratio is defined as [1]

$$
\begin{equation*}
\frac{a}{b}=\frac{a+b}{a} \tag{1}
\end{equation*}
$$

Figure 1: Division of a line into $p$ segments.

Taking $\frac{a}{b}=\Phi$, Eq. (1) reduces to the quadratic equation $\Phi^{2}=\Phi+1$ whose positive solution is $\Phi=\frac{\sqrt{5}+1}{2}=1.61803$. This value corresponds to the limiting ratio value of the Fibonacci sequence.

For the golden ratios associated with $p$-sequences, we first ask a couple of questions: (i) Does there exist a ratio, like golden ratio [Eq. (1)], for given $p \geq 3$ positive real numbers? (ii) What is the value of this ratio? Is this value unique? (ii) Is this value of ratio equal to the limiting ratio value of p-sequences? Surprisingly enough, the answer is in affirmative.

Suppose $a_{1}<a_{2}<\cdots<a_{p}$ are $p \geq 2$ positive real numbers (see Fig. 1). We define the $p$-golden ratio as ${ }^{1}$

$$
\begin{equation*}
\frac{a_{2}}{a_{1}}=\frac{a_{3}}{a_{2}}=\cdots=\frac{\sum_{k=1}^{p} a_{k}}{a_{p}}\left(=\Phi_{p}\right) . \tag{2}
\end{equation*}
$$

Note that Eq. (1) is a special case of Eq. (2) for $p=2$.

### 2.1 Characteristic equation for $\Phi_{p}$

We find that from Eq. (2) follows naturally the $p$-degree algebraic equation whose positive solution gives the value of $\Phi_{p}$ :

$$
\begin{equation*}
X_{p}(x) \equiv x^{p}-\sum_{k=0}^{p-1} x^{k}=0 . \tag{3}
\end{equation*}
$$

We call this golden equation. Note that $X_{p}(0)=-1$ for all $p$ and $X_{p}(1)=-(p-1)$. This equation has been obtained recently in an interesting physical problem concerning center of masses in two and higher dimensions [14].

[^0]

Figure 2: Schematic representation of roots of the golden equation: $x^{p}=\sum_{k=0}^{p-1} x^{k}$.

### 2.2 Less radical characteristic equations

For fixed $p$ and positive integers $\left\{k_{i}\right\}$, one can choose recurrence relations with $m$ terms ( $2 \leq m, k_{i}<p$ ) to obtain the following less radical characteristic equations,

$$
\begin{aligned}
x^{p} & =1+x^{k_{1}} \\
x^{p} & =1+x^{k_{1}}+x^{k_{2}}, \\
x^{p} & =1+x^{k_{1}}+x^{k_{2}}+x^{k_{3}},
\end{aligned}
$$

and so on, each with its own convergence. Wilson's Meru 1 through Meru 9 are particular examples of the above 2 -term characteristic equation for $p=2,3,4,5$.

### 2.3 Roots of the golden equation

Here we look at the nature of roots of Eq. (3). Roots can be positive, negative and complex. Complex roots obviously occur in pairs and lie within a unit circle and approaches towards the boundary of the circle with increasing $p$. The only negative root approaches -1 for large $p$. The only positive root lies between 1 and 2 , and tends to 2 for large $p$. See Figs. 2 and 3.

Figure 3: Roots of the golden equation for different values of $p$.

Figure 4: Schematic representation of roots of the near cousins of the golden equation.

### 2.4 Near cousins of the golden equation

The equations $(a) x^{p}=x^{p-1}-x^{p-2}+\cdots \pm 1$ and $(b) x^{p}=-\sum_{k=0}^{p-1} x^{k}$ are two immediate near cousins of the golden equation $x^{p}=\sum_{k=0}^{p-1} x^{k}$. Roots of both $(a)$ and $(b)$ are complex and real. Complex roots obviously occur in pairs and lie within a unit circle and approaches towards the boundary of the circle with increasing $p$. The only real positive root of $(a)$ is +1 , and the only real negative root of $(b)$ is -1 . See Fig. 4.

## 3 Recursion relation for $\Phi_{p}$

Because $\Phi_{p}$ is a solution of Eq. (3), we have

$$
\begin{align*}
\Phi_{p}^{p} & =\Phi_{p}^{p-1}+\Phi_{p}^{p-2}+\cdots+\Phi_{p}+1=\sum_{k=0}^{p-1} \Phi_{p}^{k},  \tag{4}\\
\Phi_{p}^{p+1} & =\Phi_{p}^{p}+\Phi_{p}^{p-1}+\cdots+\Phi_{p}^{2}+\Phi_{p}, \\
& =2 \Phi_{p}^{p}-1 . \tag{5}
\end{align*}
$$

Eq. (4) can be equivalently rewritten as

$$
\begin{align*}
\Phi_{p} & =1+\frac{\sum_{k=0}^{p-2} \Phi_{p}^{k}}{\Phi_{p}^{p-1}}  \tag{6}\\
& =1+\frac{1}{\Phi_{p}-1+\frac{1}{\sum_{k=0}^{p-2} \Phi_{p}^{k}}} . \tag{7}
\end{align*}
$$

Also, Eq. (4) implies a recursion relation

$$
\begin{equation*}
\Phi_{p}^{n}=\Phi_{p}^{n-1}+\Phi_{p}^{n-2}+\cdots+\Phi_{p}^{n-p}=\sum_{k=n-p}^{n-1} \Phi_{p}^{k} . \tag{8}
\end{equation*}
$$

## $4 \Phi_{1}$ of 1-sequence

We have seen above that Eq. (4) is the basic equation for $\Phi_{p \geq 2}$. If we consider this sacred golden equation for $p=1$, we have

$$
\begin{equation*}
\Phi_{1}=\Phi_{1}^{0}=1 . \tag{9}
\end{equation*}
$$

We remark that $\Phi_{1}$ is related with the limiting ratio value of 1 -sequences. We construct a 1 -sequence by choosing a seed $s_{0} \geq 0$ and a constant $a \geq 0$ such that $t_{0}=s_{0}$, and for $n \geq 1$

$$
\begin{equation*}
t_{n}=t_{n-1}+a=s_{0}+n a \tag{10}
\end{equation*}
$$

The limiting ratio value for this 1 -sequence is then

$$
\begin{equation*}
\lim _{n \rightarrow \infty} \frac{t_{n+1}(1)}{t_{n}(1)}=\lim _{n \rightarrow \infty} \frac{s_{0}+(n+1) a}{s_{0}+n a}=\lim _{n \rightarrow \infty}\left(1+\frac{1}{n+\frac{s_{0}}{a}}\right)=1=\Phi_{1} . \tag{11}
\end{equation*}
$$

We note that Eq. (9) provides the lower limit on $\Phi_{p}$ 's. That is,

$$
\begin{equation*}
\Phi_{p \geq 1} \geq 1 \tag{12}
\end{equation*}
$$

| $p$ | $\Phi_{p}$ | $\theta=\arcsin \left[\frac{\Phi_{p}-1}{2}\right]$ | $\theta=\arcsin \left[\Phi_{p} / 2\right]$ |

## $5 \quad \Phi_{p}^{n}$ as a polynomial of degree $p-1$

We have seen earlier the following relations:

$$
\Phi_{p}^{p}=\Phi_{p}^{p-1}+\Phi_{p}^{p-2}+\cdots+\Phi_{p}+1,
$$

and

$$
\Phi_{p}^{n}=\Phi_{p}^{n-1}+\Phi_{p}^{n-2}+\cdots+\Phi_{p}^{n-p} .
$$

Here the question we want to address is: is it possible to reduce $\Phi_{p}^{n}$ to a polynomial of degree $p-1$ ? Put differently, can we express $\Phi_{p}^{n}$ in terms of $\left\{\Phi_{p}^{k}\right\}_{k=0}^{p-1}$. It is very illuminating to see that it is possible to express $\Phi_{p}^{n}(n \geq 0)$ in terms of $\left\{\Phi_{p}^{k}\right\}_{k=0}^{p-1}$ as follows:

$$
\begin{align*}
\Phi_{p}^{n} & =t_{n}\left[S_{p-1}(p)\right] \Phi_{p}^{p-1}+\cdots+t_{n}\left[S_{1}(p)\right] \Phi_{p}+t_{n}\left[S_{0}(p)\right] \\
& =\sum_{k=0}^{p-1} t_{n}\left[S_{k}(p)\right] \Phi_{p}^{k}
\end{align*}
$$

Figure 5: Plot of $p$-golden ratios.
where $t_{n}\left[S_{k}(p)\right]=\sum_{j=n-p}^{n-1} t_{j}\left[S_{k}(p)\right]$. Eq. (13) can be easily verified from Tables 2, 3, 4 and 5 [1].

In particular, for $p=2$ and 3 , the explicit expressiosn are

$$
\Phi_{2}^{n}= \begin{cases}t_{n}\left[S_{1}(2)\right] \Phi_{2}+t_{n}\left[S_{0}(2)\right] & (n \geq 0),  \tag{14}\\ t_{n+1}\left[S_{0}(2)\right] \Phi_{2}+t_{n}\left[S_{0}(2)\right] & (n \geq 2), \\ t_{n}\left[S_{X}(2)\right] \Phi_{2}+t_{n-1}\left[S_{X}(2)\right] & (n \geq 2),\end{cases}
$$

and

$$
\Phi_{3}^{n}= \begin{cases}t_{n}\left[S_{2}(3)\right] \Phi_{3}^{2}+t_{n}\left[S_{1}(3)\right] \Phi_{3}+t_{n}\left[S_{0}(3)\right] & (n \geq 0)  \tag{15}\\ t_{n-3}\left[S_{S}(3)\right] \Phi_{3}^{2}+t_{n-2}\left[S_{X}(3)\right] \Phi_{3}+t_{n-4}\left[S_{S}(3)\right] & (n \geq 4)\end{cases}
$$

## 6 Applications of $p$-golden ratios

We have seen earlier that the golden ratio and the related Fibonacci sequence are present in abundance in our everyday life. We also learnt the skeptical view on this, and that not all objects exhibit the golden ratio in the sense that convergent limits do not settle down to the numerical value 1.618. This is now evident with the introduction of $p$-sequences and the associated $p$-golden ratios why it is not the case. In fact, $\Phi_{2}=1.618$ is only one member of several families of golden ratios (such as those of Stakhov, Spinadel, Krcadinac, etc. including the present work). Therefore, it is natural to expect that $\Phi_{p>2}$ will have many interesting applications as well.

| $n$ | $S_{1}(2)$ | $S_{0}(2)$ | $S_{C}(2)$ | $S_{S}(2)$ | $S_{G}(2)$ |

Table 5: 5-sequences. (i) $S_{C} \equiv S_{4}+S_{3}+S_{2}+S_{1}+S_{0}$. (ii) $S_{4} \sim S_{0} \sim S_{S}$. (iii) For each of these 5 -sequences, $\lim _{n \rightarrow \infty} \frac{t_{n+1}}{t_{n}}=1.96595$.

Figure 6: The golden angle $\theta_{g}$ is determined by using $a / b=\Phi_{p}$.

| $p$ | 1 | 2 | 3 | 18 |
| :--- | :--- | :--- | :--- | :--- |
| $\Phi_{p}$ | 1.0 | 1.61803 | 1.83929 | 2.0 |
| $\theta_{g}(p)$ | $180^{\circ}$ | $137.5^{\circ}$ | $126.8^{\circ}$ | $120^{\circ}$ |

Table 6: The golden angles for $p$-sequences, $p=1,2,3,18$.

## 7 Golden geometry

### 7.1 Golden angles

The golden angle is defined as the acute angle $\theta_{g}$ that divides the circumference of a circle into two arcs $A B D$ and $A C D$ with lengths in the golden ratio. See Fig. 6(a). The golden ratio here satisfies $\Phi_{p}=\frac{a}{b}$. We then determine the golden angle by $\frac{\theta_{g}(p)}{2 \pi}=$ $\frac{b}{a+b}=\frac{1}{1+\frac{a}{b}}=\frac{1}{1+\Phi_{p}}$. Hence,

$$
\begin{equation*}
\theta_{g}(p)=\frac{2 \pi}{1+\Phi_{p}} \tag{16}
\end{equation*}
$$

From Table 6 we see that $\frac{2 \pi}{3} \leq \theta_{g}(p) \leq \pi$.

### 7.2 Golden shapes

We can construct geometrical objects such as polygons (rectangle, pentagon, etc.) and spirals which have properties characterizing the golden $p$-ratio or certain $p$-sequences. Note that a square is a golden rectangle with golden ratio $\Phi_{1}=1$.

## 8 Further generalizations of golden ratio

The trouble with the notion of golden ratio is that it can be extended in many ways such that the original golden ratio $\Phi_{2}$ is a particular case. In an earlier section, we have seen that the recurrence relation $t_{n}(p)=\sum_{k=1}^{p} t_{n-k}(p)$ and the golden ratio $\frac{a_{2}}{a_{1}}=\frac{a_{3}}{a_{2}}=\cdots=$ $\frac{\sum_{k=1}^{p} a_{k}}{a_{p}}$ correspond to the characteristic equation $x^{p}=\sum_{k=0}^{p-1} x^{k}$. A straight-forward generalization of these yield

$$
\begin{align*}
t_{n}(p) & =\sum_{k=1}^{p} c_{k} t_{n-k}(p),  \tag{17}\\
\frac{a_{2}}{a_{1}} & =\frac{a_{3}}{a_{2}}=\cdots=\frac{\sum_{k=1}^{p} c_{k} a_{k}}{a_{p}},  \tag{18}\\
x^{p} & =\sum_{k=0}^{p-1} c_{k} x^{k} . \tag{19}
\end{align*}
$$

That is, for a sequence of numbers whose terms are given by the (weighted) sum of its consecutive p-previous terms, the characteristic polynomial equation can be obtained by using the golden ratio. However, how do we obtain the characteristic polynomial equation for an arbitrary recurrence relation ${ }^{2}$,

$$
\begin{equation*}
t_{n}=c_{1} t_{n-m_{1}}+c_{2} t_{n-m_{2}}+\cdots+c_{p} t_{n-m_{p}} \tag{20}
\end{equation*}
$$

otherwise? In this case also, we can project a ratio like the golden one, Eq. (18), as given below

$$
\begin{equation*}
x=\frac{t_{n-m+1}}{t_{n-m}}=\frac{t_{n-m+2}}{t_{n-m+1}}=\cdots=\frac{t_{n}}{t_{n-1}}, \tag{21}
\end{equation*}
$$

where $m=\max \left\{m_{1}, m_{2}, \cdots, m_{p}\right\}$ so that

$$
\begin{align*}
t_{n-m_{k}} & =x^{m-m_{k}} t_{n-m}, \quad(1 \leq k \leq p) \\
t_{n-1} & =x^{m-1} t_{n-m} \tag{22}
\end{align*}
$$

Then, the characteristic polynomial equation is ${ }^{3}$

$$
\begin{equation*}
x^{m}=c_{1} x^{m-m_{1}}+c_{2} x^{m-m_{2}}+\cdots+c_{p} x^{m-m_{p}} . \tag{23}
\end{equation*}
$$

[^1]We state a proposition below which gives us a straightforward general rule to obtain the characteristic polynomial equation for an arbitrary recurrence relation.
Proposition. The polynomial equation characteristic to a given recurrence relation is obtained by requiring $x^{u-v}:=\lim _{n \rightarrow \infty} \frac{t_{n+u}}{t_{n+v}}$, where $u$ and $v$ are integers. The characteristic equation is the minimal polynomial which gives the value of the limiting ratio of the sequence, and from which all its algebraic properties follow. For the generalized recurrence relation, $t_{n}=c_{1} t_{n-m_{1}}+c_{2} t_{n-m_{2}}+\cdots+c_{p} t_{n-m_{p}}$, the characteristic polynomial equation is given by $x^{m}=c_{1} x^{m-m_{1}}+c_{2} x^{m-m_{2}}+\cdots+c_{p} x^{m-m_{p}}$, where $m=\max \left\{m_{1}, m_{2}, \cdots, m_{p}\right\}^{4}$.

Moving a step further, we consider the relation

$$
\begin{equation*}
\left(u_{1} \frac{a_{2}}{a_{1}}\right)^{v_{1}}=\left(u_{2} \frac{a_{3}}{a_{2}}\right)^{v_{2}}=\cdots=\left(u_{p-1} \frac{a_{p}}{a_{p-1}}\right)^{v_{p-1}}=\left(u_{p} \frac{\sum_{k=1}^{p} c_{k} a_{k}}{a_{p}}\right)^{v_{p}}, \tag{24}
\end{equation*}
$$

where $\left\{\left(u_{i}, v_{i}\right)\right\}$ and $\left\{c_{k}\right\}$ are given. Goal is to find values of the ratios $\left\{\frac{a_{k+1}}{a_{k}}\right\}$ and $\frac{\sum_{k=1}^{p} c_{k} a_{k}}{a_{p}}$ such that Eq. (24) holds. Does a solution exist? This problem is rather hard to solve in general.

Next, one can choose any pair of ratios at a time. Say, $\left(u_{1} \frac{a_{2}}{a_{1}}\right)^{v_{1}}=\left(u_{2} \frac{a_{3}}{a_{2}}\right)^{v_{2}}$. There are two cases here. (i) Assume that $\frac{a_{2}}{a_{1}}=x$ and $\frac{a_{3}}{a_{2}}=f_{23}(x)$. Then the characteristic equation is $\left(u_{1} x\right)^{v_{1}}=\left(u_{2} f_{23}(x)\right)^{v_{2}}$ and the positive solution is $x=\frac{1}{u_{1}}\left(u_{2} f_{23}(x)\right)^{\frac{v_{2}}{v_{1}}}$. (ii) For $\frac{a_{3}}{a_{2}}=x$ and $\frac{a_{2}}{a_{1}}=f_{12}(x)$, the characteristic equation is $\left(u_{1} f_{12}(x)\right)^{v_{1}}=\left(u_{2} x\right)^{v_{2}}$ and the positive solution is $x=\frac{1}{u_{2}}\left(u_{1} f_{12}(x)\right)^{\frac{v_{1}}{v_{2}}}$. Thus, equating two ratios at a time, we will have $2(p-1)$ ! characteristic polynomial equations and consequently as many roots of them for given $\left\{\left(u_{i}, v_{i}\right)\right\}$ and $\left\{c_{k}\right\}$. To the best of our knowledge, most generalizations of the Fibonacci sequence and the golden ratio (see [1] and the references therein) can be seen as special cases of Eqs. (20), (23) and (24).

$$
\begin{aligned}
& { }^{4} \text { Another proof of Eq. (23). } \\
& \qquad \begin{aligned}
x & =\lim _{n \rightarrow \infty} \frac{t_{n+1}}{t_{n}}, \\
& =\lim _{n \rightarrow \infty} \frac{c_{1} t_{n-\left(m_{1}-1\right)}+c_{2} t_{n-\left(m_{2}-1\right)}+\cdots+c_{p} t_{n-\left(m_{p}-1\right)}}{t_{n}}, \\
& =c_{1} \lim _{n \rightarrow \infty} \frac{t_{n-\left(m_{1}-1\right)}}{t_{n}}+c_{2} \lim _{n \rightarrow \infty} \frac{t_{n-\left(m_{2}-1\right)}}{t_{n}}+\cdots+c_{p} \lim _{n \rightarrow \infty} \frac{t_{n-\left(m_{p}-1\right)}}{t_{n}}, \\
& =c_{1} x^{-\left(m_{1}-1\right)}+c_{2} x^{-\left(m_{2}-1\right)}+\cdots+c_{p} x^{-\left(m_{p}-1\right)}, \\
& =\frac{c_{1} x^{m-m_{1}}+c_{2} x^{m-m_{2}}+\cdots+c_{p} x^{m-m_{p}}}{x^{m-1}} \\
\Rightarrow x^{m} & =c_{1} x^{m-m_{1}}+c_{2} x^{m-m_{2}}+\cdots+c_{p} x^{m-m_{p}}
\end{aligned}
\end{aligned}
$$

Thus, $\lim _{n \rightarrow \infty} \frac{t_{n+1}}{t_{n}}$ is the golden ratio in general.
